ADSP-SC596/ADSP-SC598 SHARC+ Processor

Hardware Reference

Revision 0.3, July 2023

Part Number
82-100149-01

,

Contents

Arm Cortex-A55 Subsystem

Cortex-A55 Features 1–2
Functional Description 1–2
Cortex-A55 Block Diagram 1–2
Instruction Fetch Unit (IFU) 1–3
Data Processing Unit (DPU) 1–3
Performance Monitor Unit (PMU) 1–3
Advanced SIMD and Floating-point support 1–3
Cryptographic Extension 1–4
Memory Management Unit (MMU) 1–4
L1 Memory System 1–6
L2 Memory System 1–7
Reliability, Availability, and Serviceability (RAS) 1–7
Generic Interrupt Controller (GIC) 1–7
A55 Core in DynamIQ Shared Unit (DSU) 1–8
System Control 1–8
Generic Timer 1–8
ADSP-SC59x GIC Interrupt List 1–9
A55 Configurations 1–9
DynamIQ Shared Unit Interfaces 1–10
Performance Monitor Unit (PMU) 1–13

Clock Generation Unit (CGU)

CGU Features 2–1
CGU Functional Description 2–1
ADSP-SC59x CGU Register List 2–2
ADSP-SC59x CGU Interrupt List 2–3

ADSP-SC59x CGU Trigger List 2–3
CGU Definitions 2–3
CGU PLL Block Diagram 2–4
CLKOUT Selections 2–5
CGU Operating Modes 2–6
CGU Power-up Sequence 2–7
CGU Event Control 2–7
Oscillator Watchdog 2–8
CGU Programming Model 2–9
Configuring CGU Modes 2–9
Changing the Clock Frequencies 2–10
Changing the PLL Clock Frequency 2–10
Changing the CCLKn or SYSCLK Frequency Without Modifying the PLLCLK Frequency 2–11
Changing the OCLK Frequency 2–11
Selecting SCLK1_X and SCLK0_X Source 2–12
Changing SCLK1_X or SCLK0_X Frequencies 2–12
Aligning All Clocks 2–12
Shutting Off CCLKn from Another Controller 2–13
Valid Clock Multiplier Settings 2–14
PLL Bypass and PLL Disable 2–14
ADSP-SC59x CGU Register Descriptions 2–15
Core Clock Buffer Disable Register 2–16
Core Clock Buffer Status Register 2–17
CLKOUT Select Register 2–18
Control Register 2–20
Clocks Divisor Register 2–22
DIV Register Extension 2–25
Oscillator Watchdog Register 2–26
PLL Control Register 2–28
Revision ID Register 2–30

System Clock Buffer Disable Register 2–31
System Clock Buffer Status Register 2–33
Status Register 2–35
Time Stamp Counter 32 LSB Register 2–38
Time Stamp Counter 32 MSB Register 2–39
Time Stamp Control Register 2–40
Time Stamp Counter Initial 32 LSB Value Register 2–41
Time Stamp Counter Initial MSB Value Register 2–42
ADSP-SC59x MISCREG Register Descriptions 2–42
CANFD Low Power Selection Mode 2–43
Error Register 2–45
PLL2 Control Register 2–48
SH0 Prefetch Range Selection Register 2–50
SH1 Prefetch Range Selection Register 2–51
SPORT Direct Interrupt Enable for SH0 and SH1 2–52

Clock Distribution Unit (CDU)

CDU Features 3–1
CDU Functional Description 3–1
CDU Block Diagram 3–1
CDU Definitions 3–3
ADSP-SC59x CDU Register List 3–3
CDU Clock Configuration Options 3–4
CDU Programming Model 3–4
Changing the PLL and Clock Frequency 3–4
Changing the Clock Frequency 3–5
ADSP-SC59x CDU Register Descriptions 3–6
CDU Configuration 3–7
CLKIN Select 3–8
CDU Revision ID 3–9

CDU Status 3–10

Dynamic Power Management (DPM)

DPM Features 4–1
DPM Functional Description 4–1
ADSP-SC59x DPM Register List 4–1
DPM Definitions 4–2
DPM Operating Modes 4–2
Reset State 4–2
Full-on Mode 4–2
DPM Event Control 4–3
DPM Programming Model 4–3
ADSP-SC59x DPM Register Descriptions 4–4
Control Register 4–6
Peripherals Disable Register 0 4–7
Peripherals Disable Register 1 4–9
Revision ID 4–11
Status Register 4–12

Reset Control Unit (RCU)

RCU Features 5–1
RCU Functional Description 5–2
ADSP-SC59x RCU Register List 5–2
ADSP-SC59x RCU Trigger List 5–2
RCU Definitions 5–3
RCU Architectural Concepts 5–3
RCU Status and Error Signals 5–4
Resetting the Arm Core through Another Core/System Requester 5–4
Resetting a SHARC+ Core Through Another Core 5–5
ADSP-SC59x RCU Register Descriptions 5–6
Boot Code Register 5–8

Core Reset Outputs Control Register 5–11
Core Reset Outputs Status Register 5–12
Control Register 5–13
Message Register 5–15
Message Clear Bits Register 5–18
Message Set Bits Register 5–19
System Interface Disable Register 5–20
System Interface Status Register 5–21
System Reset Request Status Register 5–22
Status Register 5–23
Software Vector Register 0 5–25
Software Vector Register 1 5–26
Software Vector Register 2 5–27
SVECT Lock Register 5–28

System Event Controller (SEC) and Generic Interrupt Controller (GIC)

SEC Features 6–1
SEC Functional Description 6–2
ADSP-SC59x SEC Register List 6–2
ADSP-SC59x SEC Interrupt List 6–3
ADSP-SC59x SEC Trigger List 6–3
Combined SEC and GIC Interrupt List 6–4
SEC Definitions 6–18
SEC System Event Aggregator (SEA) 6–19
SEC Block Diagram 6–19
SEC Fault Interface (SFI) 6–20
SEC Core Interface (SCI) 6–21
SEC Source Interface (SSI) 6–22
SEC Architectural Concepts 6–22
System Interrupt Acknowledge 6–22
System Interrupt Groups 6–23

System Interrupt Flow 6–23
System Interrupt Priorities 6–24
SEC Error 6–24
SEC Programming Model 6–24
Programming Concepts 6–25
Programming Examples 6–25
Fault Management Interface Programming Model 6–25
Configuring a System Source to Interrupt a Core 6–26
Core/SEC Handshake Requirements to Ensure Proper Interrupt Handling 6–27
Configuring a System Source as a Fault 6–28
Configuring the WDOG Expiry Event to Issue a System Reset 6–28
SEC Programming Restrictions 6–28
ADSP-SC59x SEC Register Descriptions 6–29
SCI Active Register n 6–31
SCI Control Register n 6–32
SCI Group Mask Register n 6–34
SCI Priority Level Register n 6–36
SCI Priority Mask Register n 6–38
Core Pending Register n 6–39
SCI Source ID Register n 6–40
SCI Status Register n 6–41
Global End Register 6–43
Fault COP Period Register 6–44
Fault COP Period Current Register 6–45
Fault Control Register 6–46
Fault Delay Register 6–49
Fault Delay Current Register 6–50
Fault End Register 6–51
Fault Source ID Register 6–52
Fault System Reset Delay Register 6–53

Fault System Reset Delay Current Register 6–54
Fault Status Register 6–55
Global Control Register 6–57
Global Status Register 6–58
Global Raise Register 6–60
Source Control Register n 6–61
Source Status Register n 6–64
GIC Overview 6–65
GIC Functional Description 6–66
GIC Block Diagram 6–67
GIC Performance Monitoring Unit (GIC PMU) 6–67
ADSP-SC59x GIC Interrupt List 6–68

Trigger Routing Unit (TRU)

TRU Features 7–1
TRU Functional Description 7–1
ADSP-SC59x TRU Register List 7–2
ADSP-SC59x TRU Interrupt List 7–2
ADSP-SC59x Trigger List 7–3
TRU Definitions 7–17
TRU Block Diagram 7–18
TRU Architectural Concepts 7–18
TRU Programming Model 7–19
Programming Concepts 7–19
Programming Examples 7–19
Configuring a Simple Trigger Sequence 7–19
TRU Event Control 7–20
TRU Status and Error Signals 7–20
ADSP-SC59x TRU Register Descriptions 7–20
Error Address Register 7–21

Global Control Register 7–22
Generator Trigger Register 7–24
Receiver Select Register 7–25
Status Information Register 7–26

L2 System Memory

L2 System Memory Features 8–1
L2 System Memory Functional Description 8–1
ADSP-SC59x L2CTL Register List 8–1
ADSP-SC59x L2CTL Interrupt List 8–3
ADSP-SC59x L2CTL Trigger List 8–3
L2 System Memory Block Diagram 8–3
L2 System Memory Architectural Concepts 8–4
Access Characteristics 8–4
Read/Write Latency and Throughput 8–4
L2 Memory Controller Block Diagram (Instance) 8–4
Arbitration and Priority 8–5
Data Integrity 8–7
ECC Algorithm 8–7
ECC Hardware Control 8–9
ECC Error Management 8–9
Memory Refresh 8–10
Power Modes 8–10
L2 System Memory Event Control 8–11
ECC Error Interrupt 8–11
ADSP-SC59x L2CTL Register Descriptions 8–11
Control Register 8–13
Error Type 0 Address Register 8–16
Error Type 1 Address Register 8–17
Error Type 2 Address Register 8–18
Error Type 3 Address Register 8–19

Error Type 4 Address Register **8–20**
ECC Error Address 0 Register **8–21**
ECC Error Address 1 Register **8–22**
ECC Error Address 2 Register **8–23**
ECC Error Address 3 Register **8–24**
ECC Error Address 4 Register **8–25**
ECC Error Address 5 Register **8–26**
ECC Error Address 6 Register **8–27**
ECC Error Address 7 Register **8–28**
ECC Error Address 8 Register **8–29**
Error Type 0 Register **8–30**
Error Type 1 Register **8–32**
Error Type 2 Register **8–33**
Error Type 3 Register **8–34**
Error Type 4 Register **8–35**
Initialization Register **8–36**
Initialization Status Register **8–38**
Power Control Register **8–40**
Revision ID Register **8–42**
Read Priority Count Register **8–43**
Read Priority Count Register **8–44**
Scrub Start Address Register **8–45**
Scrub Count Register **8–46**
Scrub Control Register **8–47**
Status Register **8–49**
L2 Port Error Status Register **8–52**
Write Priority Count Register **8–53**
Write Priority Count Register **8–54**

Dynamic Memory Controller (DMC)

DMC Features 9–1
Feature Exclusions 9–2
DMC Functional Description 9–2
ADSP-SC59x DMC Register List 9–3
ADSP-SC59x DMC Register List 9–4
Protocol Controller 9–5
Efficiency Controller 9–5
Page-Based Scheduling 9–5
Same Controller Transaction Scheduling 9–5
DMC Read Data Buffer 9–5
Closed Page Per Bank 9–6
SCB ID-Based Priority 9–6
Delaying up to Eight Auto-Refresh Commands 9–7
Page and Bank Interleaving 9–7
System Crossbar Completer Interface 9–7
Read/Write Command and Data Buffers 9–8
Peripheral Bus Completer Interface 9–8
Architectural Concepts 9–8
Controller On Die Termination (ODT) 9–8
Mode Register Set and Extended Mode Register Set Command 9–8
DDR3 Reset Functionality 9–9
DDR3 SDRAM Organization 9–9
DMC Clocking 9–10
DMC DMA 9–10
DMC Operating Modes 9–10
Self-Refresh Mode 9–10
DMC Event Control 9–11
DMC Programming Model 9–11
PHY DLL Calibration 9–11
DDR3 ZQ Calibration Short CMD 9–11
DDR3 ZQ Calibration Long CMD 9–12

On Die Termination (DDR3) 9–12
Leveling Techniques 9–12
Initializing the DMC 9–13
Resetting the DMC Lane 9–14
Performing ZQ Calibration 9–14
Programming Duty Cycles 9–15
Programming the DMC Controller 9–15
Programming DQ Delay Trim 9–16
DMC Performance Monitor (DMCPM) 9–17
ADSP-SC59x DMC Register Descriptions 9–17
Configuration Register 9–20
Control Register 9–22
DLL Control Register 9–26
Data Calibration Address Register 9–27
Data Calibration Data 0 Register 9–28
Data Calibration Data 1 Register 9–29
Efficiency Control Register 9–30
Shadow EMR3 Register 9–34
Shadow MR0 Register (DDR3) 9–35
Shadow MR1 Register (DDR3) 9–37
Shadow MR2 Register (DDR3) 9–40
Mask (Mode Register Shadow) Register 9–42
DMC Performance Control Register 9–44
Performance Monitor Idle Cycle DQ Count Register 9–47
Performance Monitor Idle Page Count Register 9–48
Performance Monitor Page Hit Count 9–49
Performance Monitor Page Miss Count 9–50
Performance Monitor Read to Write Turn Around Count Register 9–51
Performance Monitor Refresh Count Register 9–52
Performance Monitor Write to Read Turn Around Count Register 9–53

Priority ID Register 1 9–54
Priority ID Register 2 9–55
Priority ID Mask Register 1 9–56
Priority ID Mask Register 2 9–57
DMC Read Data Buffer ID Register 1 9–58
DMC Read Data Buffer ID Register 2 9–59
DMC Read Data Buffer Mask Register 1 9–60
DMC Read Data Buffer Mask Register 2 9–61
Performance Monitor Buffer Hit Count Register 9–62
SCB Performance AXI Transfer Count Register 9–63
SCB Performance AXI Transfer Count Register 9–64
SCB Performance Monitor Idle Cycle Count Register 9–65
SCB Performance Monitor Idle Cycle Count Register 9–66
Status Register 9–67
Timing 0 Register 9–70
Timing 1 Register 9–72
Timing 2 Register 9–73
ADSP-SC59x DMC Register Descriptions 9–74
DDR CA Lane Control Register 9–75
Data Lane 0 Control Register 0 9–77
Data Lane 0 Control Register 1 9–79
Data Lane 1 Control Register 0 9–80
Data Lane 1 Control Register 1 9–82
DDR ROOT Module Control Register 9–83
Scratch Register 2 9–85
Scratch Register 3 9–86
Scratch Register 4 9–87
Scratch Register 5 9–88
Scratch Register 6 9–89
Scratch Register 7 9–90

DDR Calibration Control Register 0 9–91
DDR Calibration Control Register 1 9–92
DDR Calibration Control Register 2 9–93

DDR Pre-fetch Buffer (DDRPFB)

DDRPFB Features 10–2
Smart Pre-fetch 10–2
Data Invalidation 10–2
Direct Access 10–2
Return Zero 10–2
Controller ID Based Direct Access 10–2
Range Based Pre-fetch 10–4
ADSP-SC59x DDRPFB Register List 10–5
DDRPFB Programming Model 10–6
Enabling the Pre-fetch Buffer and PFB Idle State 10–6
General Programming Guidelines 10–6
Guidelines For Achieving Maximum Performance 10–6
ADSP-SC59x DDRPFB Register Descriptions 10–7
Control Register 0 10–8
Control Register 1 10–10
Range Select Register 10–11
Requester ID 0 Register 10–12
Requester ID 0 Mask Register 10–13
Requester ID 1 Register 10–14
Requester ID 1 Mask Register 10–15
Requester ID 2 Register 10–16
Requester ID 2 Mask Register 10–17
Requester ID 3 Register 10–18
Requester ID 3 Mask Register 10–19
Requester ID Enable Register 10–20

Prefetch Buffer First Status Register 10–21
Return Zero End Address Register 10–22
Return Zero Start Address Register 10–23

One-Time Programmable Memory Controller (OTPC)

OTPC Features 11–1
OTPC Functional Description 11–1
ADSP-SC59x OTPC Register List 11–1
ADSP-SC59x OTPC Interrupt List 11–2
OTPC Memory Layout 11–2
Error Correction 11–5
OTPC Event Control 11–5
OTPC Interrupt Signals 11–6
OTPC Status and Error Signals 11–6
OTPC Programming Model 11–6
ADSP-SC59x OTPC Register Descriptions 11–6
OTP Security State Register 11–7
OTP Status Register 11–8

System Memory Protection Unit (SMPU)

SMPU Features 12–1
SMPU Functional Description 12–2
ADSP-SC59x SMPU Register List 12–3
SMPU Interrupts 12–4
Memory Writes 12–4
Memory Reads 12–4
ID Comparison 12–4
Memory Region 12–8
SMPU Definitions 12–9
SMPU Block Diagram 12–10
SMPU Architectural Concepts 12–10

SMPU Operating Modes 12–11
SMPU Interrupt Signals 12–11
SMPU Status and Error Signals 12–12
ADSP-SC59x SMPU Register Descriptions 12–12
Bus Error Address Register 12–14
Bus Error Details Register 12–15
SMPU Control Register 12–16
Exclusive Access IDn Address 12–18
Exclusive Access Status 12–19
Interrupt Address Register 12–20
Interrupt Details Register 12–21
Region n Address Register 12–22
Region n Control Register 12–23
SMPU Revision ID Register 12–26
Region n ID A Register 12–27
Region n ID B Register 12–28
Region n ID Mask A Register 12–29
Region n ID Mask B Register 12–30
SMPU Control Secure Accesses Register 12–31
Region n Control Secure Accesses Register 12–33
SMPU Status Register 12–34

General-Purpose Ports (PORT)

PORT Features 13–2
PORT Functional Description 13–2
ADSP-SC59x PORT Register List 13–3
ADSP-SC59x PORT Trigger List 13–3
ADSP-SC59x PINT Register List 13–4
ADSP-SC59x PINT Interrupt List 13–4
ADSP-SC59x PINT Trigger List 13–5

ADSP-SC59x PADS Register List 13–5
PORT Architectural Concepts 13–7
Internal Interfaces 13–7
External Interfaces 13–7
GPIO Pin Function 13–7
Input Mode 13–7
Output Mode 13–7
Trigger Toggle Mode 13–8
Open-Drain Mode 13–8
Port Multiplexing Control 13–8
PORT Event Control 13–9
PORT Interrupt Signals 13–9
PORT Programming Model 13–11
Programmable Pull-up Resistors for PORT and DAI 13–14
ADSP-SC59x PORT Register Descriptions 13–15
Port x GPIO Data Register 13–17
Port x GPIO Data Clear Register 13–21
Port x GPIO Data Set Register 13–25
Port x GPIO Output Toggle Register 13–28
Port x GPIO Direction Register 13–31
Port x GPIO Direction Clear Register 13–35
Port x GPIO Direction Set Register 13–39
Port x Function Enable Register 13–42
Port x Function Enable Clear Register 13–45
Port x Function Enable Set Register 13–48
Port x GPIO Input Enable Register 13–51
Port x GPIO Input Enable Clear Register 13–54
Port x GPIO Input Enable Set Register 13–57
Port x GPIO Lock Register 13–60
Port x Multiplexer Control Register 13–62

Port x GPIO Polarity Invert Register 13–64
Port x GPIO Polarity Invert Clear Register 13–68
Port x GPIO Polarity Invert Set Register 13–71
Port x GPIO Trigger Toggle Register 13–74
ADSP-SC59x PINT Register Descriptions 13–75
PINT Assign Register 13–77
PINT Edge Clear Register 13–79
PINT Edge Set Register 13–82
PINT Invert Clear Register 13–85
PINT Invert Set Register 13–88
PINT Latch Register 13–91
PINT Mask Clear Register 13–95
PINT Mask Set Register 13–98
PINT Pin State Register 13–101
PINT Request Register 13–105
ADSP-SC59x PADS Register Descriptions 13–109
DAI0 1 to 10 pins DS control 13–111
DAI0 11 to 20 pins DS control 13–114
DAI0 Port Input Enable Control Register 13–117
DAI1 1 to 10 pins DS control 13–118
DAI1 11 to 20 pins DS control 13–121
DAI1 Port Input Enable Control Register 13–124
DAI[n] Pull-Down Enable 13–125
DAI[n] Pull-Up Enable 13–126
Non-GPIO Drive Strength Register 13–127
Peripheral PAD Configuration0 Register 13–130
Peripheral Configuration1 Register 13–133
PORTA 0 to 7 pins DS control 13–136
PORTA 8 - 15 pins DS control 13–139
PORTB 0 to 7 pins DS control 13–142

PORTB 8 - 15 pins DS control 13–145
PORTC 0 to 7 pins DS control 13–148
PORTC 8 - 15 pins DS control 13–151
PORTD 0 to 7 pins DS control 13–152
PORTD 8 to 15 pins DS control 13–153
PORTE 0 to 7 pins DS control 13–154
PORTE 8 to 15 pins DS control 13–155
PORTF 0 to 7 pins DS control 13–156
PORTF 8 to 15 pins DS control 13–157
PORTG 0 to 7 pins DS control 13–158
PORTG 8 to 15 pins DS control 13–159
PORTH 0 to 7 pins DS control 13–160
PORTH 8 to 15 pins DS control 13–161
PORTI 0 to 7 pins DS control 13–162
PORT[n] Pull-Down Enable 13–163
PORT[n] Pull-Up Enable 13–164

Thermal Monitoring Unit (TMU)

TMU Features 14–1
TMU Functional Description 14–1
ADSP-SC59x TMU Register List 14–1
ADSP-SC59x TMU Interrupt List 14–2
ADSP-SC59x TMU Trigger List 14–2
TMU Definitions 14–2
TMU Block Diagram 14–3
TMU Architectural Concepts 14–3
TMU and HADC 14–4
TMU Event Control 14–5
Status and Error Signals 14–5
TMU Programming Guidelines 14–5

TMU Calibration 14–6
ADSP-SC59x TMU Register Descriptions 14–6
Alert High Limit Register 14–8
Alert Low Limit Register 14–9
Averaging Register 14–10
Temperature Conversion Blank Register 14–11
TMU Control Register 14–12
Fault High Limit Register 14–13
Fault Low Limit Register 14–14
Gain Value Register 14–15
Interrupt Mask Register 14–16
Offset Register 14–17
Temperature Refresh Counter 14–18
Status Register 14–19
Temperature Value Register 14–20

Housekeeping ADC (HADC)

HADC Features 15–1
HADC Functional Description 15–1
ADSP-SC59x HADC Register List 15–2
ADSP-SC59x HADC Interrupt List 15–2
ADSP-SC59x HADC Trigger List 15–3
HADC Definitions 15–3
HADC Block Diagram 15–4
HADC Signal Descriptions 15–5
HADC Architectural Concepts 15–5
Converter Operation 15–5
Auto-Scan 15–6
Channel Sequence Programming 15–6
ADC Transfer Function 15–7
Results 15–7

HADC Operating Modes 15–7
HADC Event Control 15–8
HADC Programming Model 15–8
ADSP-SC59x HADC Register Descriptions 15–8
Channel Mask Register 15–10
Control Register 15–11
Channel Data Registers 15–13
Interrupt Mask Register 15–14
Status Register 15–15

Controller Area Network Flexible Data Rate (CANFD)

CANFD Features 16–1
CANFD Functional Description 16–2
ADSP-SC59x CANFD Register List 16–3
ADSP-SC59x CANFD Interrupt List 16–4
ADSP-SC59x CANFD Trigger List 16–5
CANFD Architectural Concepts 16–5
Block Diagram 16–5
Message Buffer (MB) 16–6
Message Buffer Memory Map 16–12
Memory Partition 16–17
Rx FIFO Structure 16–18
CANFD Processes 16–21
Transmit Process 16–21
Arbitration Process 16–22
Lowest Number Mailbox First 16–22
Highest-Priority Mailbox First 16–22
Arbitration Completion 16–23
Arbitration Start and Stop Conditions 16–24
Receive Process 16–25
Matching Process 16–26

Receive Process Pretending Network Mode 16–31
Move Process 16–34
Move-In 16–34
Move-Out 16–36
Data Coherence 16–36
Transmission Abort Mechanism 16–36
Mailbox Inactivation 16–37
Mailbox Lock Mechanism 16–38
Rx FIFO 16–39
Rx FIFO Under DMA Operation 16–40
Clear FIFO Operation 16–40
CAN Protocol Features 16–41
CAN FD Frames 16–41
Transceiver Delay Compensation 16–45
Remote Frames 16–46
Overload Frames 16–47
Time Stamp 16–47
Protocol Timing 16–48
Arbitration and Matching Timing 16–51
Tx Arbitration Start Delay 16–52
CANFD Clock Domains and Restrictions 16–55
CANFD Operating Modes 16–58
Normal Mode 16–58
Freeze Mode 16–59
Loop-Back Mode 16–59
Listen-Only Mode 16–60
CAN FD Active Mode 16–60
Module Disable Mode 16–60
Doze Mode 16–61
Stop Mode 16–62
Pretended Network Mode 16–63

CANFD Event Control 16–64
Interrupts 16–64
Bus Interface 16–65
Detection and Correction of Memory Errors 16–66
Sources of Memory Access 16–68
Error Indication 16–68
Error Reporting 16–69
Response to Errors 16–69
Error Injection 16–70
CANFD Programming Model 16–71
Initialization 16–72
Pretended Network - Doze Mode 16–75
Pretended Network - Stop Mode 16–75
ADSP-SC59x CANFD Register Descriptions 16–75
Can Bit Timing Register 16–78
CRC Register 16–81
Control 1 Register 16–82
Pretended Networking Control1 Register 16–88
Control 2 Register 16–91
Pretended Networking Control2 Register 16–96
Error Counter Register 16–97
Error Injection Address Register 16–100
Error Injection Data Pattern Register 16–101
Error Injection Parity Pattern Register 16–102
Error Status Register 16–103
Error and Status 1 Register 16–106
Error and Status 2 Register 16–117
CANFD Bit Timing Register 16–119
CANFD CRC Register 16–121
CANFD Control Register 16–123

Pretended Networking DLC Filter Register 16–127
Pretended Networking ID Filter1 Register 16–128
Pretended Networking ID Filter2 / IDMask Register 16–129
Mailbox Interrupt Flag 1 Register 16–131
Mailbox Interrupt Flag 2 Register 16–142
Mailbox Interrupt Mask 1 Register 16–150
Mailbox Interrupt Mask 2 Register 16–158
Module Configuration Register 16–166
Memory Error Control Register 16–175
Pretended Networking Payload Low Filter2 Register 16–178
Pretended Networking Payload Low Filter1 Register 16–179
Pretended Networking Payload High Filter2 High Order Bits / Payload High Mask Register 16–180
Pretended Networking Payload Low Filter2 / Payload Low Mask Register 16–181
Error Report Address Register 16–182
Error Report Data Register 16–184
Error Report Syndrome Register 16–185
Receive Mailbox14 Mask Register 16–187
Receive Mailbox15 Mask Register 16–188
Receive FIFO Global Mask Register 16–189
Receive FIFO Information Register 16–190
Receive Individual Mask Register 16–191
Receive Mailbox Global Mask Register 16–192
Free Running Timer Register 16–193
Wakeup Message Buffer Data 4-7 Register 16–194
Wakeup Message Buffer Data 0-3 Register 16–195
Wakeup Message ID Buffer Register 16–196
Wakeup Message Buffer Control/Status Register 16–197
Pretended Networking Wakeup Match Register 16–198
ADSP-SC59x MISCREG Register Descriptions 16–199
CANFD Low Power Selection Mode 16–200

Error Register 16–202
PLL2 Control Register 16–205
SH0 Prefetch Range Selection Register 16–207
SH1 Prefetch Range Selection Register 16–208
SPORT Direct Interrupt Enable for SH0 and SH1 16–209

Watchdog Timer (WDOG)

WDOG Features 17–1
WDOG Functional Description 17–2
ADSP-SC59x WDOG Register List 17–3
ADSP-SC59x WDOG Interrupt List 17–3
ADSP-SC59x WDOG Trigger List 17–3
WDOG Block Diagram 17–3
Internal Interface 17–4
External Interface 17–4
ADSP-SC59x WDOG Register Descriptions 17–4
Count Register 17–5
Control Register 17–6
Watchdog Timer Status Register 17–7
Watchdog Timer Window Register 17–9

Enhanced Mobile Storage Interface (eMSI)

eMSI Features 18–1
eMSI Functional Description 18–2
ADSP-SC59x EMSI Register List 18–2
ADSP-SC59x EMSI Interrupt List 18–4
ADSP-SC59x EMSI Trigger List 18–5
eMSI Block Diagram 18–5
eMSI Architectural Concepts 18–5
Generating SD/eMMC Commands 18–7
Block Count 18–7

Preset Value Registers 18–8
Automatic Command Generation (Auto CMD) 18–8
Data Transfer Modes 18–9
Direct Memory Access (DMA) 18–9
Non Descriptor (Single Operation) DMA 18–9
Descriptor (Advanced) DMA 18–10
Advanced DMA 2 (ADMA2) 18–10
Advanced DMA 3 (ADMA3) 18–14
Command Queueing Engine 18–17
Task Processing 18–18
Task Selection and Execution 18–19
Task Completion: Interrupts and Interrupt Coalescing 18–19
Direct Command (DCMD) Submission 18–19
Queue-Barrier (QBR) Tasks 18–20
eMMC Command Queuing Data Structures 18–20
Task Descriptor Structure 18–21
Transfer Descriptor Structure 18–22
Task Descriptor for Direct-Command (DCMD) Tasks 18–23
eMMC Boot Operation 18–24
Mandatory Boot Operation 18–24
Alternate Boot Operation 18–25
eMSI Event Control and Interrupts 18–26
Error Detection 18–26
Response Error Check 18–26
eMSI Programming Model 18–27
Initial Programming Sequence 18–27
Card Detection 18–28
eMSI Controller Setup Sequence 18–29
eMMC Device Setup 18–29
SD Interface Setup 18–30
Clock Control 18–31

eMSI Controller Clock Setup Sequence 18–31
eMSI Bus Clock Supply and Stop Sequence 18–32
eMSI Bus Clock Frequency Change Sequence 18–32
Card Interface Setup Sequence 18–34
SD Card Setup Sequence 18–34
eMMC Card Interface Setup 18–35
Setting Timeout on the eMSI Bus 18–35
Abort Transaction 18–36
Abort Command Sequence 18–36
Asynchronous Abort 18–38
eMMC Transaction Mode 18–38
Initializing and Identifying an eMMC Device 18–38
Switching to Various Speed Modes in an eMMC Device 18–40
Changing the Data Bus Width for an eMMC Device 18–40
Error Recovery in eMMC Mode 18–41
Issuing CMD With or Without Data Transfers for an eMMC Device 18–45
Issuing CMD Without Data Transfer 18–45
Issuing CMD With Data Transfer 18–48
Command Queueing 18–56
Initializing the Command Queuing Engine 18–56
Submitting and Completing a Task in the Command Queuing Engine 18–58
CQE Error Recovery 18–60
eMMC Device Boot Programming Sequences 18–61
Preparing for a Boot 18–61
Initiating a Mandatory Boot in SDMA Mode 18–62
Initiating a Mandatory Boot in ADMA2 Mode 18–64
Initiating Alternate Boot 18–66
SD Transaction Mode 18–66
SD Card Initialization and Identification 18–66
Changing Bus Width for an SD Card 18–67
Changing Bus Speed Mode for an SD Card 18–68

Issuing CMD With or Without Data Transfers for an SD Card 18–68
ADSP-SC59x EMSI Register Descriptions 18–69
ADMA System Address Register - Low 18–72
ADMA3 Integrated Descriptor Address Register - Low 18–73
ADMA Error Status Register 18–74
Argument Register 18–75
Auto CMD Status Register 18–76
Base Address 0 Register 18–78
Base Address 1 Register 18–79
16-bit Block Count Register 18–80
Block Size Register 18–81
eMMC Boot Control Register 18–83
Capabilities 1 Register - 0 to 31 18–85
Capabilities Register - 32 to 63 18–91
Clock Control Register 18–94
Command Register 18–96
Command Queuing Version Register 18–98
Command Queuing Capabilities Register 18–99
Command Queuing Configuration Register 18–100
CQ Command Response Argument Register 18–102
Command Response for Direct Command Register 18–103
CQ Command Response Index 18–104
Command Queuing Control Register 18–105
Device Pending Tasks Register 18–106
Device Queue Status Register 18–107
Command Queuing Interrupt Coalescing Register 18–108
Command Queuing Interrupt Status Register 18–111
Command Queuing Interrupt Status Enable Register 18–113
Command Queuing Interrupt Signal Enable Register 18–115
Command Response Mode Error Mask Register 18–116

CQ Send Status Configuration 1 Register 18–117
CQ Send Status Configuration 2 Register 18–119
Command Queuing Task Clear Register 18–120
Command Queuing Task Completion Notification Register 18–121
Command Queuing DoorBell Register 18–122
Command Queuing Task Descriptor List Base Address Register 18–123
CQ Task Error Information Register 18–124
EMSI Control 1 Register 18–126
EMSI Control 2 Register 18–128
SD Host Controller Specification Version 18–130
eMMC Control Register 18–131
Error Interrupt Status Register 18–133
Error Interrupt Status Enable Register 18–137
Error Interrupt Signal Enable Register 18–140
Force Event Register for Auto CMD Error Status Register 18–143
Force Event Register for Error Interrupt Status 18–145
Interrupt Status Register 18–148
Interrupt Status Enable Register 18–150
Interrupt Signal Enable Register 18–152
Preset Value for Default Speed 18–154
Preset Value for HSDDR 18–155
Preset Value for HSSDR 18–156
Preset Value for Initialization 18–157
Preset Value for Legacy Mode 18–158
Present State Register 18–159
Response Register 0 18–163
Response Register 1 18–164
Response Register 2 18–165
Response Register 3 18–166
SDMA System Address Register 18–167

Software Reset Register 18–169
Timeout Control Register 18–171
Transfer Mode Register 18–172
EMSI Version 18–175
EMSI Version Type 18–176
Wakeup Control Register 18–177

Link Port (LP)

LP Features 19–1
LP Functional Description 19–1
ADSP-SC59x LP Register List 19–2
ADSP-SC59x LP Interrupt List 19–2

ADSP-SC59x Register List

Preface

Thank you for purchasing and developing systems using a ADSP-SC59x SHARC+® processor from Analog Devices, Inc.

Purpose of This Manual

The ***ADSP-SC596/SC598 SHARC+ Processor Hardware Reference*** provides architectural information about the ADSP-SC59x processors. This hardware reference provides the main architectural information about these processors. The architectural descriptions cover functional blocks, buses, and ports, including all features and processes that they support.

For timing, electrical, and package specifications, refer to the ***SHARC+ Dual-Core DSP with Arm Cortex-A55 ADSP-SC596/SC598 Data Sheet***.

Intended Audience

The primary audience for this manual is a programmer who is familiar with Analog Devices processors. The manual assumes the audience has a working knowledge of the appropriate processor architecture and instruction set. Programmers who are unfamiliar with Analog Devices processors can use this manual, but should supplement it with other texts, such as programming reference books and data sheets, that describe their target architecture.

What's New in This Manual

This manual is the third preliminary revision (0.3) of the *ADSP-SC596/SC598 SHARC+ Processor Hardware Reference*. The following changes are included in this edition:

- Added the programming model topics in the USB chapter
- Updated the SCB Controlled DMA Channel Peripherals and Bus Requester ID tables.
- Fixed typo in Secure Boot Header table, Keyless Format BLx value.
- Added Loopback Pin Buffers topic in the DAI chapter
- Added Default Booting Peripheral Pin-Mux section in Boot Chapter
- Updated eMSI chapter
- Updated the title of the book to reflect correct product offering.

NOTE: Analog Devices is in the process of updating documentation to provide terminology and language that is culturally appropriate. This is a process with a wide scope and will be phased in as quickly as possible. Thank you for your patience.

Technical or Customer Support

You can reach customer and technical support for processors and peripherals from Analog Devices using the following resources:

- Post your questions in the processors and DSP support community at ***EngineerZone***®:

  http://ez.analog.com/community/dsp

- Submit your questions to technical support at ***Connect with ADI Specialists***:

  http://www.analog.com/support

- Contact your Analog Devices sales office or authorized distributor. Locate one at:

  http://www.analog.com/adi-sales

Product Information

Product information can be obtained from the Analog Devices Internet site and the CrossCore Embedded Studio® (CCES) online Help system.

Analog Devices Web Site

The Analog Devices Web site, http://www.analog.com, provides information about a broad range of products—analog integrated circuits, amplifiers, converters, and digital signal processors.

To access a complete technical library for each processor family, go to: http://www.analog.com/processors/technical_library The manuals selection opens a list of current manuals related to the product as well as a link to the previous revisions of the manuals. When locating your manual title, note a possible errata check mark next to the title that leads to the current correction report against the manual.

Also note, MyAnalog.com is a free feature of the Analog Devices Web site that allows customization of a Web page to display only the latest information about products you are interested in. You can choose to receive weekly e-mail notifications containing updates to the Web pages that meet your interests, including documentation errata against all manuals. MyAnalog.com provides access to books, application notes, data sheets, code examples, and more.

Visit MyAnalog.com to sign up. If you are a registered user, just log on. Your user name is your e-mail address.

EngineerZone

EngineerZone is a technical support forum from Analog Devices. It allows you direct access to ADI technical support engineers. You can search FAQs and technical information to get quick answers to your embedded processing and DSP design questions.

Use EngineerZone to connect with other DSP developers who face similar design challenges. You can also use this open forum to share knowledge and collaborate with the ADI support team and your peers. Visit http://ez.analog.com to sign up.

Supported Processors

The following is the list of Analog Devices, Inc. processors.

Blackfin+® (ADSP-BF7xx) Processors

The name *Blackfin+* refers to the enhanced fixed-point Blackfin core architecture featured by the ADSP-BF70x processor product line, which is a family of 16-bit embedded processors.

Blackfin® (ADSP-BF6xx/BF5xx) Processors

The name *Blackfin* refers to the fixed-point core architecture featured on the following processors: ADSP-BF5xx and ADSP-BF6xx.

SHARC® (ADSP-21xxx) Processors

The name *SHARC* refers to the high-performance, 32-bit, floating-point core architecture featured on the following processors: ADSP-2116x, ADSP-2126x, ADSP-213xx, and ADSP-214xx. These processors can be used in speech, sound, graphics, and imaging applications.

SHARC+® (ADSP-SC5xx, ADSP-215xx) Processors

The name *SHARC+* refers to the enhanced high-performance, 32-bit, floating-point core architecture featured on the following processors: ADSP-215xx/ADSP-SC5xx. The connected SHARC+ ADSP-SC5xx processors also contain an Arm® Cortex®-A5 core. These products can be used in speech, sound, graphics, and imaging applications.

The following is the list of Analog Devices, Inc. processors supported by the IAR Embedded WorkBench® development tools. For information about the IAR Embedded WorkBench product and software download, go to http://www.iar.com/en/Products/IAR-Embedded-Workbench .

Notation Conventions

Text conventions used in this manual are identified and described as follows. Additional conventions, which apply only to specific chapters, may appear throughout this document.

Example	Description
File > ***Close***	Titles in reference sections indicate the location of an item within the CrossCore Embedded Studio IDE's menu system (for example, the ***Close*** command appears on the ***File*** menu).
`{this | that}`	Alternative required items in syntax descriptions appear within curly brackets and separated by vertical bars; read the example as `this` or `that`. One or the other is required.

Example	Description
`[this | that]`	Optional items in syntax descriptions appear within brackets and separated by vertical bars; read the example as an optional `this` or `that`.
`[this, …]`	Optional item lists in syntax descriptions appear within brackets delimited by commas and terminated with an ellipse; read the example as an optional comma-separated list of `this`.
`.SECTION`	Commands, directives, keywords, and feature names are in text with `Letter Gothic` font.
`filename`	Non-keyword placeholders appear in text with italic style format.
NOTE:	***NOTE:*** For correct operation, ... A note provides supplementary information on a related topic. In the online version of this book, the word ***NOTE:*** appears instead of this symbol.
CAUTION:	***CAUTION:*** Incorrect device operation may result if ... ***CAUTION:*** Device damage may result if ... A caution identifies conditions or inappropriate usage of the product that could lead to undesirable results or product damage. In the online version of this book, the word ***CAUTION:*** appears instead of this symbol.
ATTENTION:	***ATTENTION:*** Injury to device users may result if ... A warning identifies conditions or inappropriate usage of the product that could lead to conditions that are potentially hazardous for devices users. In the online version of this book, the word ***ATTENTION:*** appears instead of this symbol.
Registers/Bits	All registers and bits in this manual are linked (clickable) to their respective descriptions in the "Register Descriptions" of each chapter.
Miscellaneous Conventions	Interrupt and internal signals are shown in all caps with no other formatting. For example the SPDIFn_RX or SCLK signal or the PKTE0_IRQ interrupt. An overbar denotes an active-low signal as in $\overline{\text{SYS_FAULT}}$.

Register Documentation Conventions

Register diagrams use the following conventions:

- The descriptive name of the register appears at the top with the short form of the name.
- If a bit has a short name, the short name appears first in the bit description, followed by the long name.
- The reset value appears in binary in the individual bits and in hexadecimal to the left of the register.
- Bits marked ***X*** have an unknown reset value. Consequently, the reset value of registers that contain such bits is undefined or dependent on pin values at reset.
- Shaded bits are reserved

NOTE: To ensure upward compatibility with future implementations, write back the value that is read for reserved bits in a register, unless otherwise specified.

Register description tables use the following conventions:

- Each bit's or bit field's access type appears beneath the bit number in the table in the form (read-access/write-access). The access types include:
  - R = read, RC = read clear, RS = read set, R0 = read zero, R1 = read one, Rx = read undefined
  - W = write, NW = no write, W1C = write one to clear, W1S = write one to set, W0C = write zero to clear, W0S = write zero to set, WS = write to set, WC = write to clear, W1A = write one action
- Many bit and bit field descriptions include enumerations, identifying bit values and related functionality. Unless otherwise indicated (with a prefix), these enumerations are decimal values.

1 Arm Cortex-A55 Subsystem

The ADSP-596/598 processor includes an Arm® Cortex-A55® core. The Cortex-A55 core is a mid-range, low-power core that implements the Armv8-A architecture with support for the Armv8.1-A extension, the Armv8.2-A extension and the reliability, availability, and serviceability (RAS) extension. The core has a Level 1 (L1) memory system, and private Level 2 (L2) cache. The core is implemented inside the DynamIQ Shared Unit (DSU) as a Little core.

The Cortex-A55 sub-system in the ADSP-596/598 processor includes a Data Engine unit that implements the Advanced SIMD and floating-point architecture support, Cryptographic Extension, Generic Interrupt Controller, Performance Monitoring Unit, and a Generic Timer. The Cortex-A55 also includes support for a L1-Cache sub-system and a full-fledged Memory Management Unit. The Cortex-A55 implements the Armv8 architecture and runs 64-bit Arm instructions in AArch64 execution state and 32-bit Arm and 32-bit Thumb instructions in AArch32 execution state.

This document describes the Arm Cortex-A55 core and memory architecture used on the ADSP-596/598 processor but does not provide detailed programming information for the Arm processor. For more information about programming the Arm processor, visit the Arm Information Center:

- ARM Documentation

The applicable documentation for programming the Arm Cortex-A5 processor include:

- Arm Cortex-A55 Core Technical Reference Manual, Revision: r2p0
- Arm Cortex-A Series Programmer's Guide for ARMv8-A, Version: 1.0
- ARM CoreLink NIC-400 Network Interconnect Technical Reference Manual
- Arm Architecture Reference Manual Armv8, for Armv8-A architecture profile
- Arm DynamIQ™ Shared Unit Technical Reference Manual, Revision: r4p1
- ARM NEON™ Programmer’s Guide
- Arm Cortex®-A55 Core Advanced SIMD and Floating-point Support Technical Reference Manual
- Arm Generic Interrupt Controller Architecture Specification GIC architecture version 3.0 and 4.0

Cortex-A55 Features

The Arm Cortex-A55 subsystem has the following features.

Core Features

- Full implementation of the Arm8.2-A A64, A32, and T32 instruction sets
- Both the AArch32 and AArch64 execution states at all Exception levels (EL0 to EL3)
- In-order pipeline with direct and indirect branch prediction
- Separate L1 data and instruction side memory systems with a Memory Management Unit (MMU)
- Support for Arm TrustZone® technology
- Data Engine unit that implements the Advanced SIMD and floating-point architecture support
- Cryptographic Extension. This architectural extension is only available if the Data Engine is present
- Generic Interrupt Controller (GIC) CPU interface to connect to an external distributor
- Generic Timers interface that support a 64-bit count input from an external system counter

Cache Features

- Unified private L2 cache
- L1 and L2 cache protection in the form of Error Correction Code (ECC) or parity on all RAM instances

Debug Features

- Reliability, Availability, and Serviceability (RAS) extension
- Arm8.2-A debug logic
- Performance Monitoring Unit (PMU)
- Embedded Trace Macrocell (ETM) that supports instruction trace only

Functional Description

The following sections provide information on the function of the subsystem.

Cortex-A55 Block Diagram

The ***A55 Subsystem Block Diagram*** shows the primary blocks of the Cortex-A55 subsystem. The cluster consists of the core and the DynamIQ Shared Unit (DSU), which connects the cores to an external memory system.

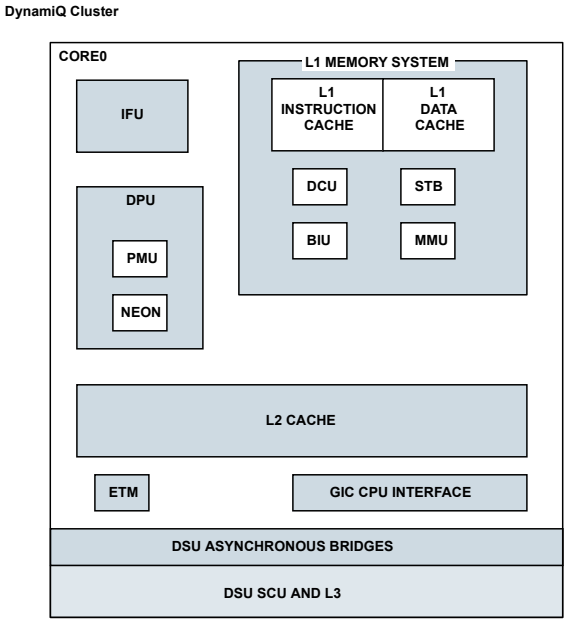

Figure 1-1: A55 Subsystem Block Diagram

Instruction Fetch Unit (IFU)

The IFU fetches instructions from the instruction cache or from external memory and predicts the outcome of branches in the instruction stream. It passes the instructions to the Data Processing Unit (DPU) for processing.

Data Processing Unit (DPU)

The DPU decodes and executes instructions. It executes instructions that require data transfer to or from the memory system by interfacing to the Data Cache Unit (DCU). The DPU includes the PMU, the Advanced SIMD and floating-point support, and the Cryptographic Extension.

Performance Monitor Unit (PMU)

The Cortex-A55 core includes performance monitors that can be configured to gather various statistics on the operation of the core and its memory system during runtime. These provide useful information about the behavior of the code that can be used for debug and code profiling. The PMU provides six counters. Each counter can count any of the events available in the core.

See the Performance Monitor Unit (PMU) section below for details of the PMU register set and events.

Advanced SIMD and Floating-point support

Advanced SIMD is a media and signal processing architecture that adds instructions primarily for audio, video, 3D graphics, image, and speech processing. The floating-point architecture provides support for single-precision and double-precision floating-point operations.

The Cortex-A55 core supports the Advanced SIMD and scalar floating-point instructions in the A64 instruction set and the Advanced SIMD and floating-point instructions in the A32 and T32 instruction sets. The A64 instruction set offers additional Advanced SIMD instructions, including double-precision floating-point vector operations.

The Cortex-A55 floating-point implementation:

- Does not generate floating-point exceptions
- Implements all scalar operations in hardware with support for all combinations of:
    - Rounding modes
    - Flush-to-zero
    - Default Not a Number (NaN) modes

The Advanced SIMD architecture, its associated implementation, and supporting software, are also referred to as NEON™ technology.

See the *Arm® Cortex®-A55 Core Advanced SIMD and Floating-point Support Technical Reference Manual* for details of the instruction and register set.

Cryptographic Extension

The Cortex-A55 core Cryptographic Extension supports the Armv8-A cryptographic extension. The cryptographic extension adds new A64, A32, and T32 instructions to advanced SIMD that accelerate:

- Advanced Encryption Standard (AES) encryption and decryption
- The Secure Hash Algorithm (SHA) functions SHA-1, SHA-224, and SHA-256
- Finite field arithmetic used in algorithms such as Galois/Counter mode and elliptic curve cryptography

See the *Arm® Architecture Reference Manual Armv8*, for Armv8-A architecture profile for details of the instruction and register set.

Memory Management Unit (MMU)

The MMU is responsible for translating addresses of code and data from the virtual view of memory to the physical addresses in the real system. The translation is carried out by the MMU hardware and is transparent to the application. In addition, the MMU controls such things as memory access permissions, memory ordering and cache policies for each region of memory.

The MMU enables tasks or applications to be written in a way that requires them to have no knowledge of the physical memory-map of the system, or about other programs that might be running simultaneously. This enables you to use the same virtual memory address space for each program. It also lets you work with a contiguous virtual memory map, even if the physical memory is fragmented. This virtual address space is separate from the actual physical map of memory in the system. Applications are written, compiled, and linked to run in the virtual memory space. Virtual addresses are those used by you, and the compiler and linker, when placing code in memory. Physical addresses are those used by the actual hardware system.

The three main functions of the MMU are:

Page table entries support:

- Control the translation table walk hardware that accesses translation tables in main memory
- Translate virtual addresses (VAs) to physical addresses (PAs)
- Provide fine-grained memory system control through a set of virtual-to-physical address mappings and memory attributes that are held in translation tables

Each stage of address translation uses a set of address translations and associated memory properties that are held in memory-mapped tables called translation tables. Translation table entries can be cached into a Translation Lookaside Buffer (TLB). The following table describes the components included in the MMU.

Table 1-1: TLBs and TLB Caches in the MMU

Component	Description
Instruction L1 TLB	15 entries, fully associative
Data L1 TLB	16 entries, fully associative
L2 TLB	1024 entries, 4-way set associative
Walk cache RAM	64 entries, 4-way set associative
IPA cache RAM	64 entries, 4-way set associative

The Cortex-A55 core supports a 40-bit physical address range, which allows 1TB of physical memory to be addressed.

The Cortex-A55 core implements a two-level TLB structure.

L1 TLB

The first level of caching for the translation table information is an L1 TLB. It is implemented on both the instruction and data sides. The Cortex-A55 L1 instruction TLB supports 4 KB, 16 KB, 64 KB, and 2 MB pages. The Cortex-A55 L1 data TLB supports 4 KB pages only. Any other page sizes are fractured after the L2 TLB and the appropriate page size are sent to the L1 TLB. All TLB-related maintenance operations result in flushing both the instruction and data L1 TLBs.

L2 TLB

A unified L2 TLB handles the misses from the L1 instruction and data TLBs using a 4-way, set-associative, 1024-entry cache. In implementations with core cache protection, parity bits protect the TLB RAMs by detecting any single-bit error. If an error is detected, the entry is invalidated and fetched again.

IPA Cache RAM

The Intermediate Physical Address (IPA) cache RAM holds mappings between the IPAs and Physical Addresses (PAs). Only non-secure EL1 and EL0 stage 2 translations use the IPA cache. When a stage 2 translation completes,

the cache is updated. The IPA cache is checked whenever a stage 2 translation is required. Like the L2 TLB, the IPA cache RAM can hold entries for different sizes.

Walk Cache RAM

The walk cache RAM holds the result of a stage 1 translation up to, but not including the last level.

NOTE: Virtual memory translation tables are typically created by operating systems and are often dynamically managed by the memory management layer. However, even a bare metal system can enable the MMU. For this, a flat mapping technique is used, where all virtual memory addresses are programmed exactly as the physical memory addresses in the system.

L1 Memory System

The Cortex-A55 processor L1 memory system consists of separate instruction and data caches that run at Arm core clock speed. The L1 instruction cache size is 32 KB and data cache size is 32 KB.

L1 Instruction-side Memory System

The L1 instruction-side memory system provides an instruction stream to the DPU. Its key features are:

- 64-byte instruction side cache line length
- 4-way set associative L1 instruction cache
- 128-bit read interface to the L2 memory system

The Cortex-A55 core uses extensive branch prediction to improve Instructions Per Clock (IPC) and power efficiency.

L1 Data-side Memory System

The L1 data-side memory system responds to load and store requests from the DPU. It also responds to SCU snoop requests from other cores, or external controllers. Its key features are:

- 64-byte data side cache line length
- 4-way set associative L1 data cache
- A read buffer that services both the Data Cache Unit (DCU), and the Instruction Fetch Unit (IFU)
- A 64-bit read path from the data L1 memory system to the data path
- A 128-bit write path from the data path to the L1 memory system
- Merging store buffer capability which writes to all types of memory (device, normal cacheable and normal non-cacheable)
- A data side prefetch engine that detects patterns of strides with multiple streams are allowed in parallel, capable of detecting both constant and patterns of strides

L2 Memory System

The Cortex-A55 L2 memory system is required to interface the Cortex-A55 cores to the L3 memory system. The main features of the L2 memory system are:

- Strictly exclusive with L1 data cache
- Pseudo-inclusive with L1 instruction cache
- Private per-core unified L2 cache
- 40-bit physical address space
- Physically indexed, physically tagged

The L2 memory subsystem consists of:

- A 4-way, set-associative L2 cache with a size of 256 KB. Cache lines have a fixed length of 64 bytes.
- Optional ECC protection for tag, data, and L2 data buffer RAM structures

Reliability, Availability, and Serviceability (RAS)

The Cortex-A55 core implements the RAS extension to the Armv8-A architecture which provides mechanisms for the standardized reporting of errors generated by cache protection mechanisms. When configured with core cache protection, the Cortex-A55 core can detect and correct a 1-bit error in any RAM and detect 2-bit errors in some RAMs.

See the *Arm Cortex-A55 Core Technical Reference Manual* for more information on RAS.

Generic Interrupt Controller (GIC)

The GIC-600 is an Arm architecture compliant System-on-Chip (SoC) peripheral. It is a high-performance, area-optimized interrupt controller. The GIC implements the Arm generic interrupt controller architecture. The GIC takes interrupts asserted at the system level and signals them to each connected processor as appropriate. The GIC has the following features.

- Registers for managing interrupt sources, interrupt behavior, and interrupt routing to one or more processors
- Support for the Arm architecture security extensions
- The ability to enable, disable, and generate processor interrupts from hardware (peripheral) interrupt sources
- The ability to generate software interrupts
- Support for interrupt masking and prioritization

Refer to the GIC Overview section for more information on the processor-specific configuration of the GIC.

The GIC-600 contains a performance monitoring unit (PMU) for counting key GIC events from the distributor.

Refer to the GIC Performance Monitoring Unit (GIC PMU) section for more information.

A55 Core in DynamIQ Shared Unit (DSU)

The ADSP-SC596/SC598 processor implements a single A55 Core (LITTLE core) with L1 and L2 cache inside the DynamIQ. The LITTLE cluster does not contain shared/L3 cache, only the Snoop Control Unit (SCU) with snoop filter. The A55 core is configured to run synchronously with the DSU.

See the *Arm DynamIQ™ Shared Unit Technical Reference Manual* for further details on DSU.

System Control

The system registers control and provide status information for the functions that the core implements. The main functions of the system registers are:

- Overall system control and configuration
- MMU configuration and management
- Cache configuration and management
- System performance monitoring
- GIC configuration and management

The system registers are accessible in the AArch64 and AArch32 execution states.

Generic Timer

The generic timer can schedule events and trigger interrupts that are based on an incrementing counter value. It generates timer events as active-low interrupt outputs and event streams. The timer contains:

- An EL1 non-secure physical timer
- An EL2 hypervisor physical timer
- An EL3 secure physical timer
- A virtual timer
- A hypervisor virtual timer

The Cortex-A55 core does not include the system counter. This resides in the SoC. The system counter value is distributed to the core with a 64-bit bus.

See the *Arm DynamIQ Shared Unit Technical Reference Manual* and the *Arm Architecture Reference Manual Armv8*, for Armv8-A architecture profile for more information on the generic timer.

Generic Timer Interrupts

Timers can be configured to generate an interrupt. The active-low, level sensitive timer interrupt signals are routed to the GIC as a private peripheral interrupt (PPI). The specific interrupts are shown in the *GIC Interrupt* table.

Table 1-2: Generic Timer Interrupts

Interrupt ID	Name	Description	Sensitivity
26	CNTHP_IRQ	Hypervisor physical timer event	Level
27	CNTV_IRQ	Virtual timer event	Level
28	CNTHV_IRQ	Hypervisor virtual timer event	Level
29	CNTPS_IRQ	Secure physical timer event	Level
30	CNTPNS_IRQ	Non-Secure physical timer event	Level

ADSP-SC59x GIC Interrupt List

Table 1-3: ADSP-SC59x GIC Interrupt List

Interrupt ID	Name	Description	Sensitivity	DMA Channel
339	GIC0_SPI_SOFT0_INT	GIC0 GIC Software Interrupt 0		
340	GIC0_SPI_SOFT1_INT	GIC0 GIC Software Interrupt 1		
341	GIC0_SPI_SOFT2_INT	GIC0 GIC Software Interrupt 2		
342	GIC0_SPI_SOFT3_INT	GIC0 GIC Software Interrupt 3		
343	GIC0_SPI_SOFT4_INT	GIC0 GIC Software Interrupt 4		
344	GIC0_SPI_SOFT5_INT	GIC0 GIC Software Interrupt 5		
345	GIC0_SPI_SOFT6_INT	GIC0 GIC Software Interrupt 6		
346	GIC0_SPI_SOFT7_INT	GIC0 GIC Software Interrupt 7		
347	GIC0_SPI_SOFT8_INT	GIC0 GIC Software Interrupt 8		
348	GIC0_SPI_SOFT9_INT	GIC0 GIC Software Interrupt 9		
349	GIC0_SPI_SOFT10_INT	GIC0 GIC Software Interrupt 10		
350	GIC0_SPI_SOFT11_INT	GIC0 GIC Software Interrupt 11		
351	GIC0_SPI_SOFT12_INT	GIC0 GIC Software Interrupt 12		
352	GIC0_SPI_SOFT13_INT	GIC0 GIC Software Interrupt 13		
353	GIC0_SPI_SOFT14_INT	GIC0 GIC Software Interrupt 14		
354	GIC0_SPI_SOFT15_INT	GIC0 GIC Software Interrupt 15		

A55 Configurations

The ***Core Configuration*** and ***DSU Configuration*** tables describe the Cortex A55 and processor configurations.

Table 1-4: Core Configuration

Core Feature	Comment
L1 instruction cache size	32 KB
L1 data cache size	32 KB
L2 cache	Included
L2 cache size	256 KB
ECC or parity core cache protection	Included
Advanced SIMD and floating-point support (including Dot Product instruction support)	Included
Cryptographic Extension	Included
CoreSight Embedded Logic Analyzer (ELA)	False
CoreSight ELA RAM address size	N/A
Page Based Hardware Attributes (PBHA) support	Not included

Table 1-5: DSU Configuration

Core Feature	Comment
NUM_BIG_CORES	0
NUM_LITTLE_CORES	1
NUM_OTHER_CORES	0
BIG_CORE_TYPE	N/A
LITTLE_CORE_TYPE	Ananke
OTHER_CORE_TYPE	N/A
MODULE	N/A
MODULE_DEBUG_BLOCK	N/A
ACE	True
MASTER_DATA_WIDTH	128
ACP	False
PERIPH_PORT	True
SCU_CACHE_PROTECTION	True
L3_CACHE	False

DynamIQ Shared Unit Interfaces

This section describes the DSU interface signals.

Clock and Clock Enable Signals

The ***Clock Signals*** and ***Clock Enable Signals*** tables describe the clock and clock enable signals.

Table 1-6: Clock Signals

Signal Name	Description	Connection
SCLK	Clock for the SCU/L3 and the AMBA interface	CLKO2
PCLK	Clock for the debug peripheral interface and the timers, power management, and other miscellaneous logic	SYSCLK
ATCLK	Clock for the ATB trace interface	SYSCLK
GICCLK	Clock for the GIC interface	SYSCLK

The *Default Configuration* table describe the default configuration of the Cortex-A55.

Table 1-7: Default Configuration

Configuration	Status
Default Execution Mode in EL3	AArch64
Endianness configuration, controls the reset value of the SCTLR_EL3/SCTLR EE bit	Little Endian
Enable Thumb exceptions, controls the reset value of the SCTLR.TE bit	Enabled
Value read in ClusterID Affinity Level-2 field, MPIDR bits [23:16]	8'h0
Value read in ClusterID Affinity Level-3 field, MPIDR bits [39:32]	8'h0
Disables the Cryptographic Extensions	False
Globally disables the CPU interface logic and routes the external interrupt signals directly to the cores	False

GIC Signals

This section describes the GIC default configuration.

Table 1-8: GIC Default Configuration (Interrupts)

Signal Name	Description	Connection
$\overline{\text{FIQ}}$	Active-low, level-sensitive fast interrupt request	Disabled
$\overline{\text{IRQ}}$	Active-low, level-sensitive interrupt request	Disabled
$\overline{\text{VFIQ}}$	Active-low, level-sensitive virtual fast interrupt request	Disabled
$\overline{\text{VIRQ}}$	Active-low, level-sensitive virtual interrupt request	Disabled
IRIT I/F	Distributor to GIC CPU Interface messages	From GIC
ICC I/F	GIC CPU Interface to distributor messages	To GIC

WFE Wakeup Event Signals

This section describes the wakeup event signals

Table 1-9: WFE Wakeup Event Signals

Signal Name	Description	TRU Requester/ Completer ID
EVENTIREQ	Event input request for core wake-up from WFE state. It must remain asserted until EVENTIACK is asserted and must not be re-asserted until EVENTIACK is low.	TRU Completer 2
EVENTIACK	Event input request acknowledge. It is not asserted until EVENTIREQ is high, and then remains asserted until after EVENTIREQ goes low.	TRU Requester 8
EVENTOREQ	Event output request for core wake-up, triggered by SEV instruction. It is only asserted when EVENTOACK is low, and then remains high until after EVENTOACK goes high.	TRU Requester 9
EVENTOACK	Event output request acknowledge. It must not be asserted until EVENTOREQ is high, and then must remain asserted until after EVENTOREQ goes low.	TRU Completer 3

Error Signals

This section describes the error signals

Table 1-10: Error Signals

Signal Name	Description
$\overline{\text{ERRIRQ[0]}}$ A55_SCU_ERR (A55 SCU Error)	Active-low, level-sensitive error indicator for an ECC error that causes potential data corruption or loss of coherency in snoop filter RAMs or ACE write transactions with a write response condition. It is output from the SCLK domain.
$\overline{\text{ERRIRQ[1]}}$ A55_L1L2_ERR (A55 L1,L2 Error)	Active-low, level-sensitive error indicator for an ECC error that causes potential data corruption or loss of coherency for the L1 and L2 caches in the core. The bit is output from the PERIPHCLK domain.

Debug Block APB Interface Signals (Debug)

The interface between the debug block and the DSU consists of a pair of APB interfaces, one in each direction. The following table shows the signals between the cluster APB controller and the debug block APB target.

Table 1-11: Debug Block APB Interface Signals (Debug)

Signal Name	Description
$\overline{\text{COMMIRQ}}$	Active-low, level-sensitive comms channel receive or transmit interrupt request
DBGEN	Invasive debug enable
NIDEN	Non-invasive debug enable
SPIDEN	Secure privilege invasive debug enable
SPNIDEN	Secure privilege non-invasive debug enable

Performance Monitor Unit (PMU)

The Cortex-A55 core includes performance monitors that can be configured to gather various statistics on the operation of the core and its memory system during runtime. These provide useful information about the behavior of the code that can used for debug and code profiling. The PMU provides six counters. Each counter can count any of the events available in the core.

For complete register information refer to the *Arm Cortex-A55 Core Technical Reference Manual* and the *Arm Cortex-A Series Programmer's Guide for ARMv8-A*.

Functional Description

This section describes the functionality of the PMU. The PMU includes the following interfaces and counters:

- Events from all other units from across the design are provided to the PMU
- The PMU registers can be programmed using the system registers or the external peripheral interface
- The PMU has 32-bit counters that increment when they are enabled, based on events, and a 64-bit cycle counter
- The Cortex-A55 core supports access to the performance monitor registers from the internal system register interface and a memory-mapped interface

PMU Events

The PMU event counters can gather various statistics on the operation of the core and its memory system, like cycle count, cache miss/hit, memory read/write, load and prefetch instructions. For the all the PMU events, please refer to *Arm Cortex-A55 Core Technical Reference Manual*.

PMU Interrupts

The Cortex-A55 core asserts the nPMUIRQ signal when the PMU generates an interrupt. The active-low, level sensitive PMU interrupt signal is routed to the GIC as a private peripheral interrupt.

Interrupt ID	Name	Description	Sensitivity
23	PMU_IRQ	PMU interrupt request	Level

2 Clock Generation Unit (CGU)

The Clock Generation Unit (CGU) includes the phase locked loop (PLL) and the PLL control unit (PCU). The PLL generates a requester clock that runs at a frequency that is a multiple of the CLKIN input clock frequency. The PCU divides down the requester clock to generate various system clocks and synchronization signals.

CGU Features

The CGU module supports the following features:

- Provides smooth transitions from the current clock condition to a new condition with PLL logic and executes the changes to clocks due to register programming.
- Provides PLL and clock domain status reporting for event management.
- Supports the capability to bypass the PLL for power savings.
- Software controlled dynamic power management allows control of the core clock frequency (f_{CCLK}).
- Controls clock gating of the core and system clocks.

NOTE: For more information about processor-specific CGU features, see the processor data sheet.

CGU Functional Description

The CGU generates all on-chip clocks and synchronization signals based on the programmed PLL multiplication factor and dividers. The CGU provides the following functionality.

Change the PLL Clock Frequency

The CGU allows programs to change the PLL clock frequency by writing new values to bits in the control register. Any time the PLL relocks, the CGU aligns all core and system clocks.

Change Other Clock Frequencies

The CGU allows programs to change the CCLKn, SYSCLK, SCLKn, DCLK, and OCLK frequencies by writing values to the CGU_DIV register. Any time the clock frequency is changed, the OCLK, CCLKn, SYSCLK, DCLK, and SCLKn clocks exit the frequency change sequence aligned.

Perform Clock Alignment

The CGU can align all clocks by writing to the CGU_DIV register. This function aligns all PLL-based clocks.

For more information on these functions, see the CGU Programming Model section.

ADSP-SC59x CGU Register List

The clock generation unit (CGU) includes the phase locked loop (PLL) and the PLL control unit (PCU). The PLL generates a clock, running at a frequency that is a multiple of the CLKIN input clock's frequency. The CGU also generates all on-chip clocks and synchronization signals. The PCU permits application software control of the PLL's operation. A set of registers govern CGU operations. For more information on CGU functionality, see the CGU register descriptions.

Table 2-1: ADSP-SC59x CGU Register List

Name	Description
CGU_CCBF_DIS	Core Clock Buffer Disable Register
CGU_CCBF_STAT	Core Clock Buffer Status Register
CGU_CLKOUTSEL	CLKOUT Select Register
CGU_CTL	Control Register
CGU_DIV	Clocks Divisor Register
CGU_DIVEX	DIV Register Extension
CGU_OSCWDCTL	Oscillator Watchdog Register
CGU_PLLCTL	PLL Control Register
CGU_REVID	Revision ID Register
CGU_SCBF_DIS	System Clock Buffer Disable Register
CGU_SCBF_STAT	System Clock Buffer Status Register
CGU_STAT	Status Register
CGU_TSCOUNT0	Time Stamp Counter 32 LSB Register
CGU_TSCOUNT1	Time Stamp Counter 32 MSB Register
CGU_TSCTL	Time Stamp Control Register
CGU_TSVALUE0	Time Stamp Counter Initial 32 LSB Value Register
CGU_TSVALUE1	Time Stamp Counter Initial MSB Value Register

ADSP-SC59x CGU Interrupt List

Table 2-2: ADSP-SC59x CGU Interrupt List

Interrupt ID	Name	Description	Sensitivity	DMA Channel
1	CGU0_EVT	CGU0 Event	Edge	
2	CGU1_EVT	CGU1 Event	Edge	

ADSP-SC59x CGU Trigger List

Table 2-3: ADSP-SC59x CGU Trigger List Generators

Trigger ID	Name	Description	Sensitivity
1	`CGU0_EVT`	CGU0 Event	Edge
2	`CGU1_EVT`	CGU1 Event	Edge

Table 2-4: ADSP-SC59x CGU Trigger List Receivers

Trigger ID	Name	Description	Sensitivity
None			

CGU Definitions

DPM

The Dynamic Power Management module (DPM) works with the CGU to provide flexible power dissipation modes for the processor.

PCU

The PLL control unit (PCU) in the CGU controls PLL operations. The MMR registers of the CGU are implemented in the PCU.

PLL

The phase-locked loop (PLL) operates within the CGU.

RCU

The reset control unit (RCU) provides input to the CGU to manage clocks during processor reset.

CDU

The clock distribution unit distributes the clocks from the CGU to different clock domains

CGU

The clock generation unit (CGU) is comprised of the PLL and PCU. The CGU generates the clocks listed in the ***Clock Descriptions*** table.

Table 2-5: Clock Descriptions

Clock	Description
CCLK0_0	CCLK0 derived from CGU0
CCLK1_0	CCLK1 derived from CGU0
CCLK2_0	CCLK2 derived from CGU0 *1
SYSCLK_0	SYSCLK derived from CGU0
SCLK0_0	SCLK0 derived from CGU0
SCLK1_0	SCLK1 derived from CGU0
DCLK_0	DCLK derived from CGU0
OCLK_0	OCLK derived from CGU0
CCLK0_1	CCLK0 derived from CGU1
CCLK2_1	CCLK2 derived from CGU1*1
SYSCLK_1	SYSCLK derived from CGU1
SCLK0_1	SCLK0 derived from CGU1
SCLK1_1	SCLK1 derived from CGU1
DCLK_1	DCLK derived from CGU1
OCLK_1	OCLK derived from CGU1
DCLK_2	DCLK derived from CGU2

*1. CCLK2_x is directly derived from the VCO clock; it is divided by 3. Hence, the frequency of CCLK2 = (PLL clock x 2/3).

CGU PLL Block Diagram

The ***CGU PLL Block Diagram*** provides a top-level block diagram of the phase locked loop (PLL). The main blocks of the PLL are the phase/frequency detector (PFD), the charge pump, the loop filter and the voltage controlled oscillator (VCO). The VCO multiplies the `SYS_CLKIN0` or `SYS_CLKIN1`, input to a higher frequency.

Additional configuration options are configured using the Clock Distribution Unit.

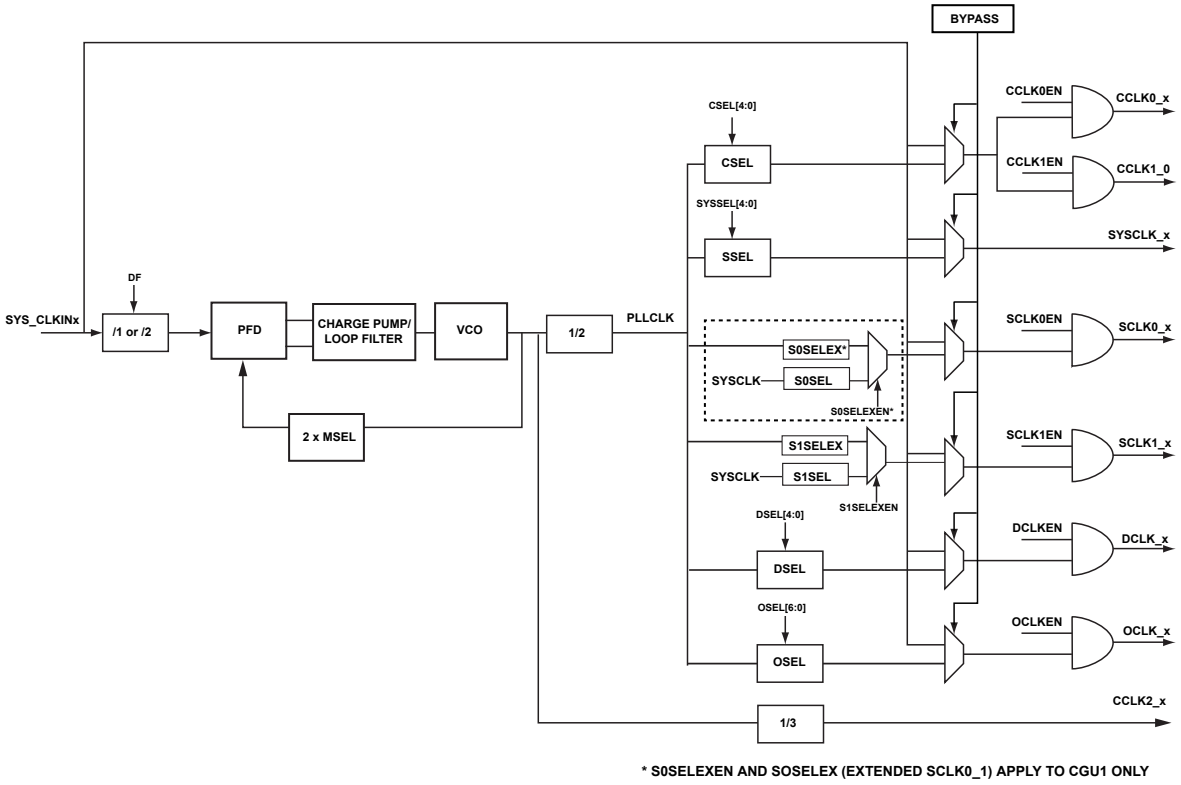

Figure 2-1: CGU1 PLL Block Diagram

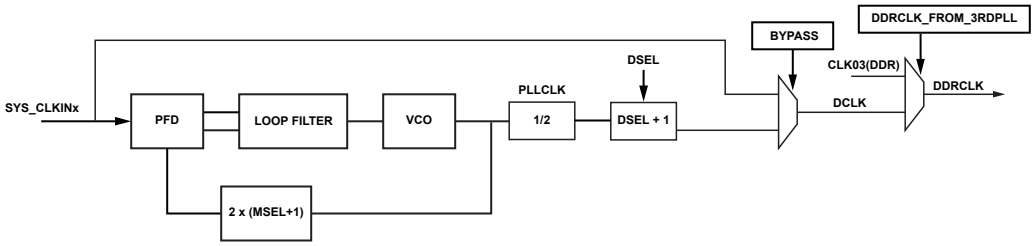

Figure 2-2: CGU2 PLL Block Diagram

CLKOUT Selections

The ***SYS_CLKOUT Generation*** figure is a conceptual representation of the CLKOUT module. Different clocks that originate from the CGU blocks are available on the SYS_CLKOUT output pin. The selection of the clock output on the SYS_CLKOUT pin is controlled by the `CGU_CLKOUTSEL.CLKOUTSEL` bit field. Most of the clock frequencies are divided with a fixed divider value, for example CGU0_SYSCLK0 has a fixed divider of 8 for the CLKOUT pin.

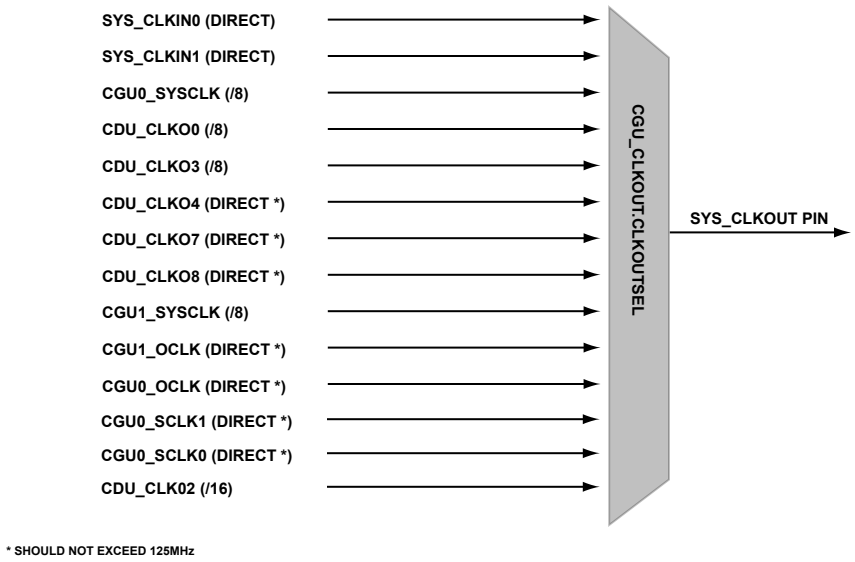

Figure 2-3: SYS_CLKOUT Generation

The BMODE pin affects the CLKOUT pins after a hardware reset is deasserted.

BMODE= 0 — When a hardware reset is deasserted, CGU0_OCLK/PLLCLK0 is selected to come out of the CLKOUT pin. The default value of OSEL and MSEL is the same. This functionality enables the user to verify PLL functionality by checking that the CLKOUT period is identical to CLKIN period. While programming all values of the `CGU_CLKOUTSEL.CLKOUTSEL` bit field is possible, changing it to 0 (SYS_CLKIN) is not possible until and unless a non-zero value is first programmed to the `CGU_CLKOUTSEL.CLKOUTSEL` bit field.

BMODE = (non-zero) — When a hardware reset is deasserted, SYS_CLKIN is selected by default.

CGU Operating Modes

The CGU does not have configurable operating modes, but CGU operations affect the operating modes of other modules. Some CGU operation issues that affect operation of other modules include the following:

- The PLL of the CGU operates in either normal mode (CGU clock divisors applied) or bypass mode (CGU PLL is bypassed and clock divisors ignored).
- The SCB uses the CGU for clock synchronization across clock domains. For more information, see System Crossbars (SCB).
- The DPM uses the CGU for clock management as power state transitions occur. For more information, see the Dynamic Power Management (DPM) chapter.
- The CGU uses clock gating control to obtain flexible low-power modes.

CGU Power-up Sequence

See the product data sheet for exact power-up requirements. The processor is configured to come up in clock bypass mode. The programs is required to configure full speed clocks and safety monitors. SYS_CLKIN0 or SYS_CLKIN1, and all supplies should be stable before the SYS_HWRST signal is deasserted.

CGU Event Control

The CGU generates an event or error for several different reasons. Events and errors are described in the following sections.

Events

After a frequency change, a CGU event indicates that the PLL has locked, and clocks are synchronized. If a core was idled while changing frequencies, the CGU can use an event interrupt to break the core idle. While in active mode, a CGU event indicates that the PLL has locked.

CGU Errors

A CGU error occurs under following conditions:

- A write access to the CGU_DIV/CGU_DIVEX registers trigger an alignment sequence while the PLL is locked and is still aligning the clocks.

  The CGU_STAT.WDIVERR bit state indicates this error. If this error occurs, clear the CGU_STAT.WDIVERR bit and rewrite the desired values to the CGU_DIV/CGU_DIVEX registers.

- A change to the CGU_DIV/CGU_DIVEX registers occur while the PLL is locked and is still aligning the clocks.

  The CGU_STAT.WDIVERR bit state indicates this error. If this error occurs, clear the CGU_STAT.WDIVERR bit and rewrite the desired values to the CGU_DIV/CGU_DIVEX registers.

- A write access to the CGU_CTL.DF bit field occurs or a write access to the CGU_CTL.MSEL bit field occurs while the PLL is locking.

  The CGU_STAT.WDFMSERR bit state indicates this error. If this error occurs, wait until the PLL has finished locking, cleared the error, and rewritten the desired value change.

- A write access to CGU_DIV.S1SEL when CGU_CTL.S1SELEXEN is enabled or a write access to CGU_DIVEX.S1SELEX when CGU_CTL.S1SELEXEN is disabled.

  A write access to CGU_DIV.S0SEL when CGU_CTL.S0SELEXEN is enabled or a write access to CGU_DIVEX.S0SELEX when CGU_CTL.S0SELEXEN is disabled.

  The CGU_STAT.WDIVERR bit state indicates this error. If this error occurs, clear the CGU_STAT.WDIVERR bit and rewrite the desired values to the CGU_DIV and CGU_DIVEX registers.

The CGU monitors changes to the following fields:

- SYSCLK Divisor – CGU_DIV.SYSSEL

CGU Generated Bus Errors

The CGU generates a bus error when a read or write transaction to an unused address within the CGU address range is attempted. It also generates a bus error when a misaligned access is made to a CGU register. In addition to the bus error, the CGU_STAT.ADDRERR bit is set. If a write to a write-protected CGU register is attempted, the CGU generates a bus error. In addition, the CGU_STAT.LWERR bit is set.

Oscillator Watchdog

The oscillator watchdog detects the absence of input clock transitions and provides a fault warning through the SYS_FAULT pin. To detect harmonic or subharmonic crystal oscillator behavior, the watchdog (under programmable control) also detects and reports input oscillator frequencies above and below the specified limits. Use an internal asynchronous, local 1 MHz oscillator combined with a series of programmable counters for this detection. Set the CGU_OSCWDCTL.MONDIS bit and clear the CGU_OSCWDCTL.FAULTEN bit to optionally disable all the input clock monitor and fault detection functions.

Set the CGU_OSCWDCTL.HODEN bit to enable harmonic oscillation detection. The CGU uses the CGU_OSCWDCTL.HODF bit field to indicate the desired lower fail limit (in MHz) for the harmonic oscillation detection. The upper limit is always twice the lower limit.

The ***HODF Settings for Different Input Clock Frequencies*** table shows the recommended values of the CGU_OSCWDCTL.HODF bit settings for different input clock frequencies.

Table 2-6: HODF Settings for Different Input Clock Frequencies

CGU_OSCWDCTL.HODF[5:0]	**Subharmonic Frequency (MHz)**	**Nom. Lower Fail Limit (MHz)**	**Input Clock Frequency (MHz)**	**Nom. Upper Fail Limit (MHz)**	**Second Harmonic Frequency (MHz)**
16	10	16	20	32	40
16	12.5	16	25	32	50
20	15	20	30	40	60

NOTE: Use a HODF value of 16 for frequency ranges greater than 20 MHz and less than 25 MHz. For frequency ranges greater than 25 MHz and less than 30 MHz, use a HODF value of 20.

The CGU uses the CGU_OSCWDCTL.BOUF (Bad Oscillator Upper Frequency limit) asynchronous control bit field to indicate the desired upper fail limit for the bad oscillation detection. Set the CGU_OSCWDCTL.BOUEN bit to enable upper-limit bad oscillation detection. A bad oscillation detection condition signals a fault before any processor operations occur. This detection occurs (even in bypass mode) whenever a clock frequency exceeds the specifications.

The CGU_OSCWDCTL.BOUF =0 operation starts with a target of 32 MHz and each additional LSB increases the frequency test limit by 2 MHz. For example:

Target Upper Frequency Limit = CGU_OSCWDCTL.BOUF × 2 MHz + 32 MHz

The CGU_STAT.OSCWDSTATFC status bits indicate the nature of the fault.

The ***Fault Map*** table shows the fault values.

Table 2-7: Fault Map

CGU_STAT.OSCWDSTATFC Bitfield Values	**Fault Type**
0	No Fault
1	No Input Clock
2	Subharmonic CLKIN
3	Harmonic CLKIN
4	No AUX_CLK
5	CLKIN > Upper Freq Limit (BOUF)
6	Reserved
7	Multiple Limit Faults

There is a priority to the faults given in the case of multiple fault errors. The highest priority is given to No Input clock followed by No AUX_CLK. The other three fault cases share the lowest priority. Multiple limit faults are asserted if more than one type of subharmonic CLKIN, harmonic CLKIN, or BOUF faults are observed.

NOTE: All the CGU_STAT.OSCWDSTATFC faults other than the absence of AUX_CLK (for example, CGU_STAT.OSCWDSTATFC =4) are not reliable and used for debug only.

Program and enable the OSCWDOG to match the actual crystal, before bringing the PLL out of bypass.

CGU Programming Model

The programming model for the CGU involves the various mode configuration techniques.

Configuring CGU Modes

Use the following procedures to configure the clocks and PLL.

NOTE: The program needs to clear the CGU_STAT.CLKSALGN bit before changing clocks. The following sequence is executed once, inside the application, after coming out of reset.

```
*pREG_CGU0_PLLCTL |= BITM_CGU_PLLCTL_PLLBPCL; // come out of bypass and enter
Full ON
while( (pADI_CGU0 ->STAT & 0xF) != 0x5 ) { } // poll
// now clocks are running with hardware default divisors.
// now program can change frequencies If desired the program can put the PLL
again into bypass.
```

Changing the Clock Frequencies

Applications change clock frequencies in two ways. The first way is modifying the PLL multiplication value by writing to the CGU_CTL register and the second is modifying the clock dividers by writing to the CGU_DIV register. Both actions have different implications even if the frequencies of the final clock are the same. Write accesses to change the CGU_CTL.DF or CGU_CTL.MSEL bit fields while the PLL is locking set the CGU_STAT.WDFMSERR error bit. The CGU_STAT.WDIVERR error bit is set when one of following accesses is attempted while the PLL is locked, but still aligning the clocks:

- A write access to the CGU_DIV/CGU_DIVEX to trigger an alignment sequence.
- A write access to the CGU_DIV/CGU_DIVEX to change the CGU_DIV.CSEL/, CGU_DIV.SYSSEL, CGU_DIV.S0SEL, CGU_DIV.S1SEL, or CGU_DIV.DSEL/CGU_DIVEX.S1SELEX, CGU_DIVEX.S0SELEX bits.

Read-after-write accesses to these registers return the new value, even if the frequency of the clock change is still in-progress.

Modifying the PLL multiplier requires the PLL to relock. Once the PLL locks, the CGU synchronizes the clocks. Changes to the CGU_CTL.DF or CGU_CTL.MSEL bit field result in bypassing the PLL. If necessary, clear the CGU_DIV.UPDT bit to avoid multiple clock alignment sequences. If the CGU_DIV register is not updated, the CGU uses the current values to determine the frequencies of the clock. It is the programs responsibility to guarantee that the new CGU_CTL.DF or CGU_CTL.MSEL and CGU_DIV combinations are legal.

Changing the PLL Clock Frequency

To change the phase-locked loop clock (*PLLCLK*) frequency, write new values to the CGU_CTL.MSEL field or CGU_CTL.DF field. Any time the PLL relocks, all core and system clocks are aligned.

1. Read CGU_STAT register and verify that:
   a. The CGU_STAT.PLLEN bit =1 (PLL enabled)
   b. The CGU_STAT.PLOCK bit =1 (PLL is not locking)
   c. The CGU_STAT.CLKSALGN bit =0 (clocks aligned)
2. Write the desired values to the clock divisor select fields of the CGU_DIV/CGU_DIVEX register with the CGU_DIV.UPDT bit =0.
3. Write the desired values to the CGU_CTL.DF and CGU_CTL.MSEL fields.

This sequence performs these actions:

1. Updates the corresponding CGU registers.
2. Bypasses the PLL.
3. Makes the PLL lock to the new values in the CGU_CTL.MSEL or CGU_CTL.DF fields.
4. Changes the clock frequencies.

5. Exits the PLL bypass with all clocks aligned.

When exiting the PLL bypass state, a CGU event occurs.

The CGU_STAT register exits this sequence with the CGU_STAT.PLLEN bit =1, the CGU_STAT.PLOCK bit =1, the CGU_STAT.PLLBP bit =0, and the CGU_STAT.CLKSALGN bit =0. Poll the CGU_STAT.PLOCK bit, CGU_STAT.PLLBP bit, and CGU_STAT.CLKSALGN bit to discover when the PLL is locked and the clocks are aligned.

Changing the frequency of the PLL is allowed while the PLL is bypassed. In this case the new PLLCLK frequency is not used until the PLL is no longer bypassed.

Changing the CCLKn or SYSCLK Frequency Without Modifying the PLLCLK Frequency

To change the clock frequencies, write new values to CGU_DIV.CSEL or CGU_DIV.SYSSEL bits. The frequency change occurs only when the PLL is not bypassed. Any time the CCLKn or SYSCLK clock frequencies are changed, they exit the frequency change sequence aligned.

1. Read the CGU_STAT register to verify that the CGU_STAT.CLKSALGN bit =0 (clocks aligned).
2. Write the desired CGU_DIV.CSEL, CGU_DIV.SYSSEL, and CGU_DIV.OSEL bitfield values with the CGU_DIV.UPDT bit = 1 and/or, write to the CGU_DIVEX.S1SELEX field. This write updates the CGU_DIV register, changes the SCLKn and SYSCLK frequencies, and aligns the clocks. When the clocks are aligned, a CGU event occurs.

The CGU_STAT register exits this sequence with the CGU_STAT.CLKSALGN bit =0. Poll the CGU_STAT.CLKSALGN bit to discover when the clocks are aligned. Any write attempt to change the CGU_DIV.S0SEL or CGU_DIV.S1SEL bit fields while CGU_STAT.CLKSALGN bit =1 (clocks alignment in progress) triggers an MMR access bus error and the CGU_DIV register is not modified.

Also, any write attempt to change the CGU_DIVEX.S1SELEX field while the CGU_STAT.CLKSALGN bit =1 (clocks alignment in progress) triggers an MMR access bus error and the CGU_DIVEX register is not modified.

Programming the SYSCLK frequency to a higher value than CCLKn also triggers an MMR access bus error and the CGU_DIV/CGU_DIVEX register is not modified.

Writing to the CGU_DIV/CGU_DIVEX register is allowed while the processor is in active (PLL bypassed) mode. In this case the effect of the write is visible only after the transition to full-on (PLL not bypassed) mode.

Accessing the DDR memory while changing the SYSCLK frequency is not supported and can have unpredictable results.

Changing the OCLK Frequency

To change the OCLK clock frequency, write a new CGU_DIV.OSEL bit value. Any time the OCLK clock frequency is changed, the OCLK, CCLKn, SYSCLK, and SCLKn clocks exit the frequency change sequence aligned.

1. Read the CGU_STAT register to verify that the CGU_STAT.CLKSALGN bit =0 (clocks aligned).
2. Write the desired CGU_DIV.OSEL value with the CGU_DIV.UPDT bit =1. This write updates the CGU_DIV register, changes the OCLK frequency, and aligns all clocks except OCLK.

The CGU_STAT register exits this sequence with the CGU_STAT.CLKSALGN bit =0. Poll the CGU_STAT.CLKSALGN bit to discover when the clocks are aligned. Any write attempt to change the CGU_DIV.DSEL field while the CGU_STAT.CLKSALGN bit =1 (clock alignment in progress) triggers an MMR access bus error and the CGU_DIV/CGU_DIVEX is not modified. When the clocks are aligned, a CGU event occurs.

Writing to the CGU_DIV.OSEL bit field is allowed while the processor is in active (PLL bypassed) mode. In this case the effect of the write is visible only after the transition to full-on (PLL not bypassed) mode.

Selecting SCLK1_X and SCLK0_X Source

Programming the CGU_DIVEX enables the PLL clock as a source (bypassing SYSCLK0_0 that continues to source other peripherals). When CGU_DIVEX is enabled, the PLL clock is divided from CGU_DIVEX register value.

Changing SCLK1_X or SCLK0_X Frequencies

Complete the following steps to change the SCLK0 or SCLK1 frequency.

1. Read the CGU_STAT register. Verify that CGU_STAT.CLKSALGN = 0 (Clocks aligned).
2. Read the CGU_CTL register. Verify that the CGU_DIVEX.S1SELEX or CGU_DIVEX.S0SELEX bit is set as needed. (These bits can only be modified when the PLL is bypassed).
3. Read the CGU_STAT register. Verify that the PLL is not bypassed. (If it is bypassed, see PLL Bypass and PLL Disable topic.)
4. Read the CGU_DIV register. Verify that the CGU_DIV.UPDT bit is set.
5. Write the desired CGU_DIVEX.S1SELEX or CGU_DIVEX.S0SELEX value to the CGU_DIVEX registers .

Aligning All Clocks

To align the clocks, write 1 to the CGU_DIV.ALGN bit. The frequency can also be changed, if necessary. The clocks aligned include:

- CCLKn
- SYSCLK
- SCLKn
- DCLK
- OCLK

1. Read the CGU_STAT register to verify that CGU_STAT.CLKSALGN bit =0 (clocks aligned).
2. Write 1 to the CGU_DIV.ALGN bit. All other fields can change.

   ADDITIONAL INFORMATION: This write does not alter the CGU_DIV/CGU_DIVEX register unless one of the clock-select fields is modified. When the clocks are aligned, a CGU event occurs.

The CGU_STAT register exits this sequence with the CGU_STAT.CLKSALGN bit =0. Poll the CGU_STAT.CLKSALGN bit to discover when the clocks are aligned. Any write to the CGU_DIV/CGU_DIVEX register intended to align clocks or to change a clock select field while the CGU_STAT.CLKSALGN bit =1 (clocks alignment in progress) triggers an MMR access bus error. In this case, the CGU_DIV/CGU_DIVEX register is not modified.

Writing 1 to the CGU_DIV.ALGN bit has no effect while the processor is in active (PLL bypassed) mode.

Shutting Off CCLKn from Another Controller

CCLKn can be shut off to save power when it is not in use.

1. Disable interrupts to core n.
2. Set the RCU_SIDIS.SI[n] bit to disable the interfaces of core n to:
   a. Stop DMA accesses to its L1
   b. Stop memory accesses to core 0
   c. Stop accesses to MMRs
3. Test the RCU_SISTAT.SI[n] bit to detect when accesses to core n have been disabled and all the pending transactions have completed.
4. Set the CGU_CCBF_DIS.CCBF0 bit to disable the CCLKn buffer.
5. Check the CGU_CCBF_STAT.CCBF0 bit.

If the CGU_CCBF_STAT.CCBF0 bit is set, continue.

Reenable CCLKn From Another Controller

1. Clear the CGU_CCBF_DIS.CCBF0 to enable CCLKn.
2. Check the CGU_CCBF_STAT.CCBF0 bit.
   a. If the CGU_CCBF_DIS.CCBF0 bit is cleared, continue
3. Clear the RCU_SIDIS.SI[n] bit. The core deasserts its acknowledge signal in response to the RCU_SYSRST0signal. This operation clears the RCU_SISTAT.SI[n] bit.

Valid Clock Multiplier Settings

Processor operations depend on valid settings in the CGU_CTL and CGU_DIV registers. These registers control the clock multiplier and divisor values. Set these registers such that the minimum and maximum clocks specified in the data sheet are not violated. All other clock specifications in the data sheet must also be adhered to for correct operation of the processor.

PLL Bypass and PLL Disable

Writing 1 to the CGU_PLLCTL.PLLBPST bit tells the PLL to apply OSC_CLKIN clock to CCLK, SYSCLK, SCLK0, SCLK1, DCLK (PLL Bypass), and OCLK outputs. Writing 1 to the CGU_PLLCTL.PLLBPCL bit tells the PLL to exit its PLL Bypass state and make all output clocks align and transition to their programmed frequencies.

The PLL can be disabled by clearing the CGU_PLLCTL.PLLEN bit while in the bypass state. If necessary, clock buffers can be disabled.

CCLK0 clock can be disabled or enabled by writing 1 or 0 to the corresponding bit in the CGU_CCBF_DIS register.

To determine which core clock buffers were disabled since the last read, software reads the CGU_CCBF_STAT register. The SCLK0, SCLK1, DCLK and OCLK clocks can be disabled or enabled by writing 1 or 0 to the corresponding bit in the CGU_SCBF_DIS register. Software cannot disable SYSCLK.

DCLK from CGU2

PLL relocking with MSEL update:

1. Clear the MISCREG_PLL2_CONTROL.BYPASSB, MISCREG_PLL2_CONTROL.DSEL_DIV_CHG and MISCREG_PLL2_CONTROL.MSELDF_CHG bits.
2. Wait 20 core clock cycles for the PLL of the third SYSCLK to reflect CLKIN.
3. Update the MISCREG_PLL2_CONTROL.MSEL value and set the MISCREG_PLL2_CONTROL.MSELDF_CHG bit.
4. Wait 768 core clock cycles for the MSELDF_CHG pulse.
5. Wait 2048 CLKIN cycles for the PLL to lock.
6. Set the MISCREG_PLL2_CONTROL.BYPASSB bit.
7. Set the MISCREG_PLL2_CONTROL.BYPASSB bit

DCLK divider update:

1. Clear the MISCREG_PLL2_CONTROL.BYPASSB, MISCREG_PLL2_CONTROL.DSEL_DIV_CHG, and MISCREG_PLL2_CONTROL.MSELDF_CHG bits.
2. Update the MISCREG_PLL2_CONTROL.DSEL value and set the MISCREG_PLL2_CONTROL.DSEL_DIV_CHG bit.

3. Wait 768 core clock cycles for the MSELDF_CHG pulse.
4. Set the MISCREG_PLL2_CONTROL.BYPASSB control bit.
5. Set the MISCREG_PLL2_CONTROL.DDRCLK_FROM_3RDPLL bit to connect the third PLL DCLK to DMC.

   This bit determines whether the DCLK is sourced from the third PLL.

ADSP-SC59x CGU Register Descriptions

Clock Generation Unit (CGU) contains the following registers.

Table 2-8: ADSP-SC59x CGU Register List

Name	Description
CGU_CCBF_DIS	Core Clock Buffer Disable Register
CGU_CCBF_STAT	Core Clock Buffer Status Register
CGU_CLKOUTSEL	CLKOUT Select Register
CGU_CTL	Control Register
CGU_DIV	Clocks Divisor Register
CGU_DIVEX	DIV Register Extension
CGU_OSCWDCTL	Oscillator Watchdog Register
CGU_PLLCTL	PLL Control Register
CGU_REVID	Revision ID Register
CGU_SCBF_DIS	System Clock Buffer Disable Register
CGU_SCBF_STAT	System Clock Buffer Status Register
CGU_STAT	Status Register
CGU_TSCOUNT0	Time Stamp Counter 32 LSB Register
CGU_TSCOUNT1	Time Stamp Counter 32 MSB Register
CGU_TSCTL	Time Stamp Control Register
CGU_TSVALUE0	Time Stamp Counter Initial 32 LSB Value Register
CGU_TSVALUE1	Time Stamp Counter Initial MSB Value Register

Core Clock Buffer Disable Register

The CGU_CCBF_DIS register controls each core's clock buffer to determine if the CCLK is enabled.

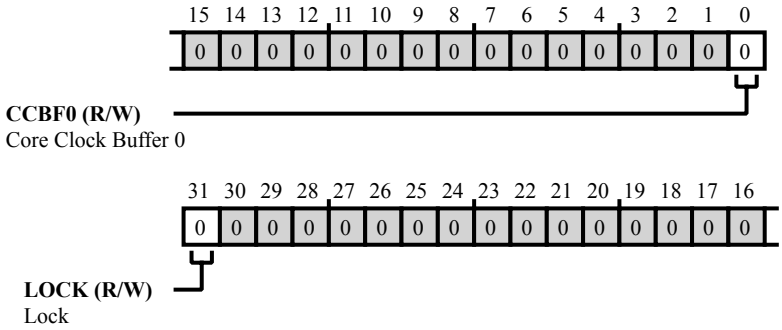

Figure 2-4: CGU_CCBF_DIS Register Diagram

Table 2-9: CGU_CCBF_DIS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If set (=1) the CGU_CCBF_DIS.LOCK bit locks the CGU_CCBF_DIS register.	
		0	Unlock register
		1	Lock register
0 (R/W)	CCBF0	Core Clock Buffer 0. The CGU_CCBF_DIS.CCBF0 bit enables (=0) or disables (=1) CCLK0s buffer.	
		0	Enable buffer
		1	Disable buffer

Core Clock Buffer Status Register

The CGU_CCBF_STAT register shows which core clock buffer(s) are disabled. For example clearing the CGU_CCBF_DIS.CCBF0 bit clears the CGU_CCBF_STAT.CCBF0 bit after a number of cycles. To guarantee that the correct value is read, this register should be read twice and the second result used.

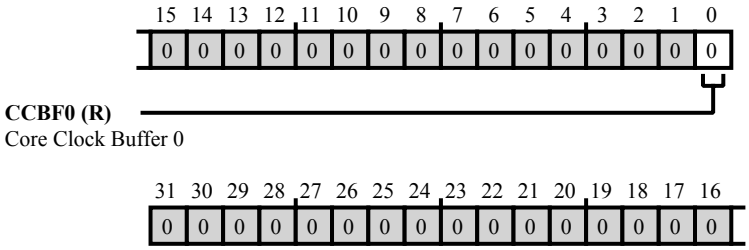

Figure 2-5: CGU_CCBF_STAT Register Diagram

Table 2-10: CGU_CCBF_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/NW)	CCBF0	Core Clock Buffer 0. The CGU_CCBF_STAT.CCBF0 bit reports the status of the CGU_CCBF_DIS.CCBF0 bit where 0 = enabled and 1 = disabled.	
		0	Enabled
		1	Disabled

CLKOUT Select Register

The CGU_CLKOUTSEL selects the signal that the CGU drives through the CLKOUT multiplexer.

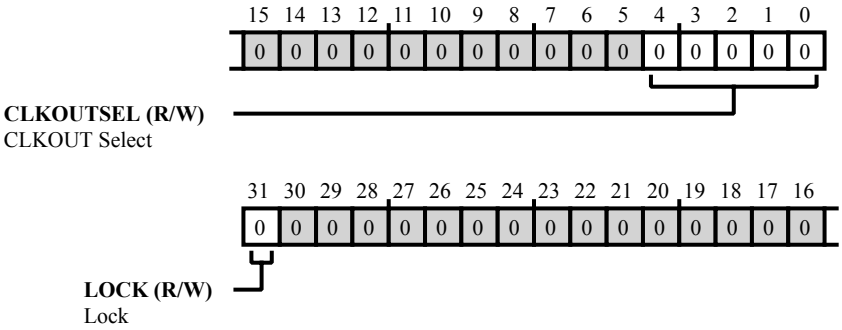

Figure 2-6: CGU_CLKOUTSEL Register Diagram

Table 2-11: CGU_CLKOUTSEL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock bit is set (SPU_CTL.GLCK bit =1) and the CGU_CLKOUTSEL.LOCK bit is set, the CGU_CLKOUTSEL register is read only (locked).	
		0	Unlock
		1	Lock
4:0 (R/W)	CLKOUTSEL	CLKOUT Select. The CGU_CLKOUTSEL.CLKOUTSEL selects the signal that the CGU drives through the CLKOUT pin multiplexer.	
		0	CLKIN0
		1	CLKIN1
		2	PLLTOP0.SYSCLKO
		3	PLLTOP0.CCLK0
		4	CDU.CLKO3 for DDR
		5	CDU.CLKO4 for CAN
		6	CDU.CLKO7 for EMAC
		7	CDU.CLKO8 for LP
		8	PLLTOP1.SYSCLKO
		9	PLLTOP1.OCLK
		10	PLLTOP0.OCLK

Table 2-11: CGU_CLKOUTSEL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		11	Reserved
		12	Reserved
		13	Reserved
		14	PLLTOP0.SCLK1
		15	Reserved
		16	PLLTOP0.SCLK0
		17	Reserved
		18	Reserved
		19	CDU.CLKO2 for ARM Core
		20	GND

Control Register

The CGU_CTL controls the clock generation divisors for SYS_CLKIN and the PLL. Read after write accesses to the CGU_CTL register returns the new value even if the clock's frequency change is still in progress.

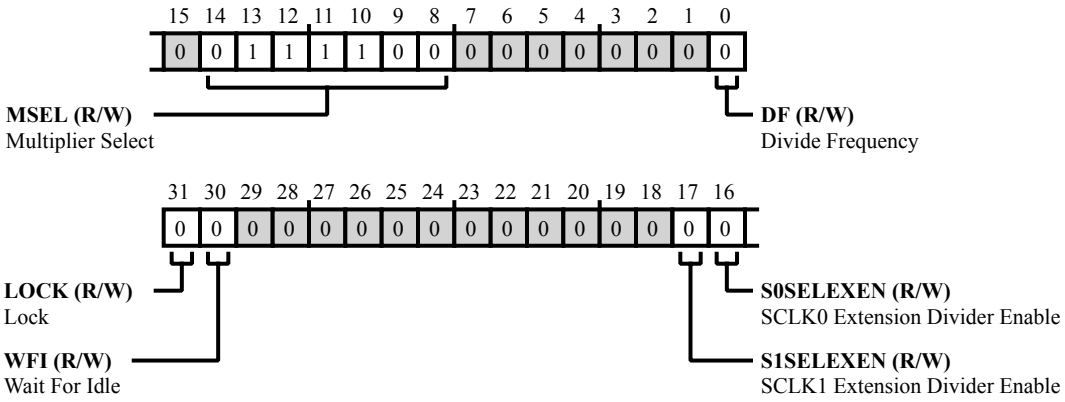

Figure 2-7: CGU_CTL Register Diagram

Table 2-12: CGU_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock bit is set (SPU_CTL.GLCK bit =1) and the CGU_CTL.LOCK bit is set, the CGU_CTL register is read only (locked).	
		0	Unlock
		1	Lock
30 (R/W)	WFI	Wait For Idle. Modifying the PLL multiplier requires the PLL to re-lock and once the PLL locks, clocks have to be synchronized. Changes to the CGU_CTL.MSEL and the CGU_CTL.DF bit values results in bypassing the PLL. The CGU_CTL.WFI bit forces the PLL to wait for all processor cores to be in an idle or reset state before changing frequencies as a result of changes to the CGU_CTL.MSEL or CGU_CTL.DF bits. Write accesses to the CGU_CTL to change the CGU_CTL.DF or CGU_CTL.MSEL bit values while the PLL is locking sets the CGU_STAT.WDFMSERR bit.	
		0	Update Immediately
		1	Wait for Idle

Table 2-12: CGU_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/W)	S1SELEXEN	SCLK1 Extension Divider Enable. The `CGU_CTL.S1SELEXEN` directs the CGU to select S1SELEX instead of S1SEL. This bit can only be updated when the PLL is bypassed.	
		0	Selects SYSCLK to SCLK1 Divider
		1	Selects PLLCLK to SCLK1 Divider
16 (R/W)	S0SELEXEN	SCLK0 Extension Divider Enable. The `CGU_CTL.S0SELEXEN` directs the CGU to select S0SELEX instead of S0SEL. This bit can only be updated when the PLL is bypassed.	
		0	Selects SYSCLK to SCLK0 Divider
		1	Selects PLLCLK to SCLK0 Divider
14:8 (R/W)	MSEL	Multiplier Select. The `CGU_CTL.MSEL` bit field selects the multiplier in the PLLCLK equation: PLLCLK frequency = (SYS_CLKIN frequency / (DF+1)) * MSEL Where the value of MSEL is between 1 and 127.	
		0	MSEL = 128
		1-127	MSEL = 1 to 127
0 (R/W)	DF	Divide Frequency. The `CGU_CTL.DF` bit selects whether or not the CLKIN input is divided by two before being passed to the PLL.	
		0	Pass OSC_CLKIN to PLL
		1	Pass OSC_CLKIN/2 to PLL

Clocks Divisor Register

The CGU_DIV register controls clock divisors for core clocks, system clocks, external (off core) memory clocks, and output clock. Read after write accesses to the CGU_DIV register returns the new value even if the clock's frequency change is still in progress.

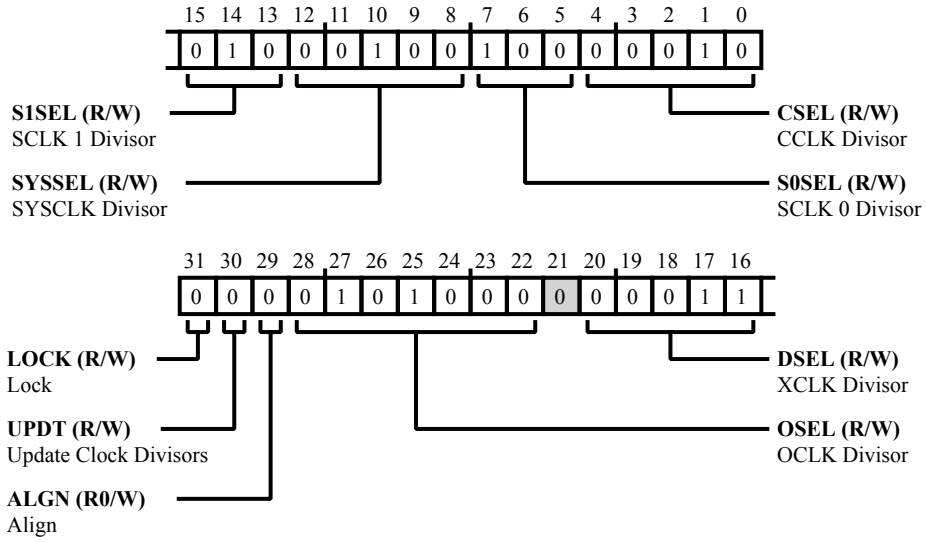

Figure 2-8: CGU_DIV Register Diagram

Table 2-13: CGU_DIV Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock bit is set (SPU_CTL.GLCK bit =1) and the CGU_DIV.LOCK bit is set, the CGU0_DIV and CGU0_DIVEX registers are read only (locked).	
		0	Unlock
		1	Lock
30 (R/W)	UPDT	Update Clock Divisors. The CGU_DIV.UPDT controls whether the CGU drives new CGU_DIV.CSEL, CGU_DIV.SYSSEL, CGU_DIV.S0SEL, CGU_DIV.S1SEL, CGU_DIV.DSEL, and CGU_DIV.OSEL values to PLL after CGU_DIV register update.	
		0	No PLL Update
		1	Drive Updated SEL Values to PLL

Table 2-13: CGU_DIV Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
29 (R0/W)	ALGN	Align. The CGU_DIV.ALGN directs the CGU to align the PLL-based clocks. The divisor selections (CGU_DIV.CSEL, CGU_DIV.SYSSEL, CGU_DIV.S0SEL, CGU_DIV.S1SEL, CGU_DIV.DSEL, and/or CGU_DIV.OSEL) do not have to change.	
		0	No Action
		1	Align PLL Clocks
28:22 (R/W)	OSEL	OCLK Divisor. The CGU_DIV.OSEL selects the divisor in the OCLK equation: OCLK frequency = (SYS_CLKIN frequency / (DF+1)) * MSEL / CGU_DIV.OSEL Where the value of CGU_DIV.OSEL is between 1 and 127.	
		0	OSEL = 128
		1-127	OSEL = 1 to 127
20:16 (R/W)	DSEL	XCLK Divisor. The CGU_DIV.DSEL selects the divisor in the XCLK equation: XCLK frequency = (SYS_CLKIN frequency/(DF+1)) MSEL/CGU_DIV.DSEL Where the value of CGU_DIV.DSEL is between 1 and 31.	
		0	DSEL = 32
		1-31	DSEL = 1 to 31
15:13 (R/W)	S1SEL	SCLK 1 Divisor. The CGU_DIV.S1SEL selects the divisor in the SCLK1 equation: SCLK1 frequency = (SYSCLK frequency) / CGU_DIV.S1SEL Where the value of CGU_DIV.S1SEL is between 1 and 7.	
		0	S1SEL = 8
		1-7	S1SEL = 1 to 7
12:8 (R/W)	SYSSEL	SYSCLK Divisor. The CGU_DIV.SYSSEL selects the divisor in the SYSCLK equation: SYSCLK frequency = (SYS_CLKIN frequency/(DF+1)) MSEL/CGU_DIV.SYSSEL Where the value of CGU_DIV.SYSSEL is between 1 and 31.	
		0	SYSSEL = 32
		1-31	SYSSEL = 1 to 31

Table 2-13: CGU_DIV Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7:5 (R/W)	S0SEL	SCLK 0 Divisor. The CGU_DIV.S0SEL selects the divisor in the SCLK0 equation: SCLK0 frequency = (SYSCLK frequency) / CGU_DIV.S0SEL Where the value of CGU_DIV.S0SEL is between 1 and 7.	
		0	S0SEL = 8
		1-7	S0SEL = 1 to 7
4:0 (R/W)	CSEL	CCLK Divisor. The CGU_DIV.CSEL bit field selects the divisor in the CCLK equation: CCLK frequency = (SYS_CLKIN frequency / (DF+1)) * MSEL / CGU_DIV.CSEL Where the value of CGU_DIV.CSEL is between 1 and 31.	
		0	CSEL = 32
		1-31	CSEL= 1 to 31

DIV Register Extension

The CGU_DIVEX register contains bitfields for programming the divisor values of the system clock [SCLK0 and SCLK1] in extended divisor mode.

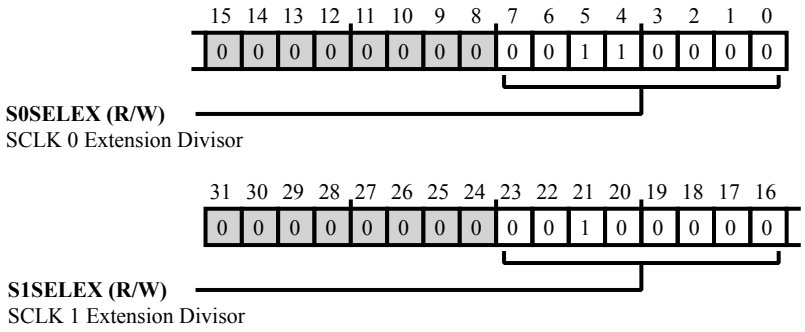

Figure 2-9: CGU_DIVEX Register Diagram

Table 2-14: CGU_DIVEX Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
23:16 (R/W)	S1SELEX	SCLK 1 Extension Divisor. The CGU_DIVEX.S1SELEX selects the divisor in the SCLK1EX equation: SCLK1EX frequency = (PLLCLK frequency) / CGU_DIVEX.S1SELEX Where the value of CGU_DIVEX.S1SELEX is between 1 and 255.	
		0	S1SELEX = 256
		1-255	S1SELEX = 1 to 255
7:0 (R/W)	S0SELEX	SCLK 0 Extension Divisor. The CGU_DIVEX.S0SELEX selects the divisor in the SCLK0EX equation: SCLK0EX frequency = (PLLCLK frequency) / CGU_DIVEX.S0SELEX Where the value of CGU_DIVEX.S0SELEX is between 1 and 255.	
		0	S1SELEX = 256
		1-255	S1SELEX = 1 to 255

Oscillator Watchdog Register

The CGU_OSCWDCTL register configures the CGU to allow the detection of the absence of input clock transitions and provides a fault warning via the SYS_FAULT pin. The CGU_OSCWDCTL register also detects and reports input oscillator frequencies above and below specified limits, in order to specifically detect harmonic or sub-harmonic crystal oscillator behavior. This detection is achieved by using an internal asynchronous, local 1 MHz oscillator combined with a series of programmable counters.

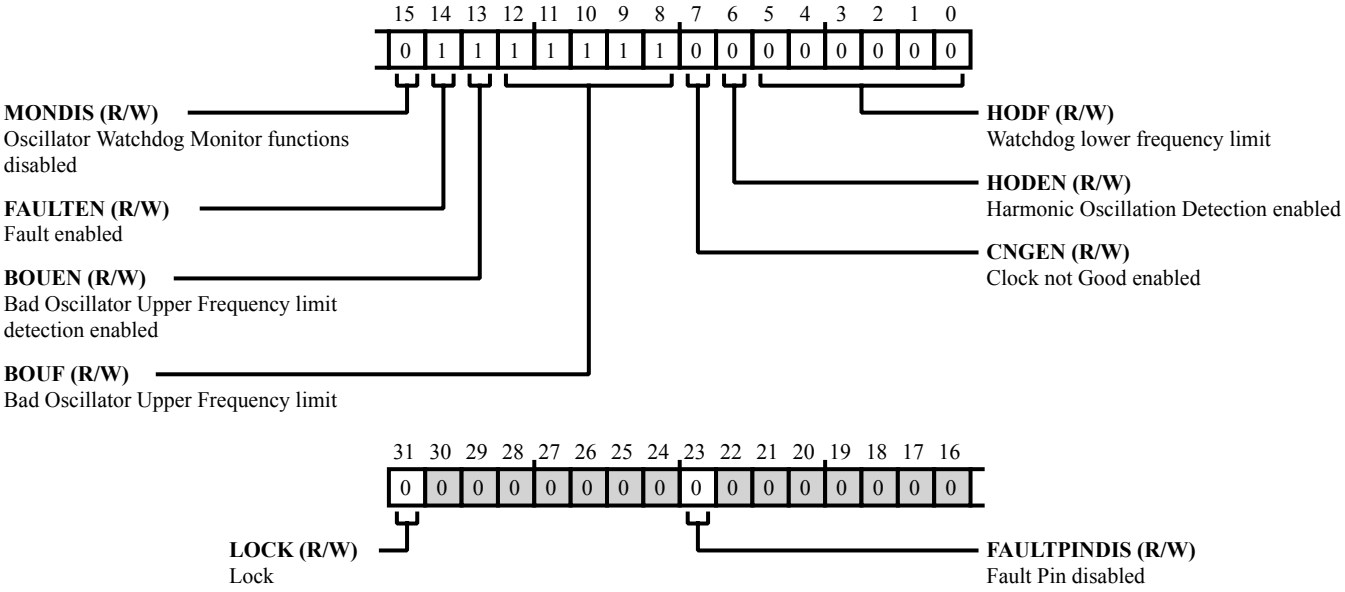

Figure 2-10: CGU_OSCWDCTL Register Diagram

Table 2-15: CGU_OSCWDCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	LOCK	Lock.
23 (R/W)	FAULTPINDIS	Fault Pin disabled. The CGU_OSCWDCTL.FAULTPINDIS bit disables pin fault detection.
15 (R/W)	MONDIS	Oscillator Watchdog Monitor functions disabled. The CGU_OSCWDCTL.MONDIS bit disables all the input clock monitor and fault detection functions.
14 (R/W)	FAULTEN	Fault enabled. The CGU_OSCWDCTL.FAULTEN bit enables fault detection.
13 (R/W)	BOUEN	Bad Oscillator Upper Frequency limit detection enabled. The CGU_OSCWDCTL.BOUEN bit enables upper limit bad oscillation detection.

Table 2-15: CGU_OSCWDCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
12:8 (R/W)	BOUF	Bad Oscillator Upper Frequency limit. The `CGU_OSCWDCTL.BOUF` bits indicate the desired upper fail limit for the bad oscillation detection.
7 (R/W)	CNGEN	Clock not Good enabled. The `CGU_OSCWDCTL.CNGEN` bit enables the detection of an oscillator watchdog clock fault.
6 (R/W)	HODEN	Harmonic Oscillation Detection enabled. The `CGU_OSCWDCTL.HODEN` bit enables harmonic oscillation detection.
5:0 (R/W)	HODF	Watchdog lower frequency limit. The `CGU_OSCWDCTL.HODF` bit field is used to indicate the desired lower fail limit for the harmonic oscillation detection in MHz.

PLL Control Register

The CGU_PLLCTL register contains bits that enable and disable the PLL as well as control its function.

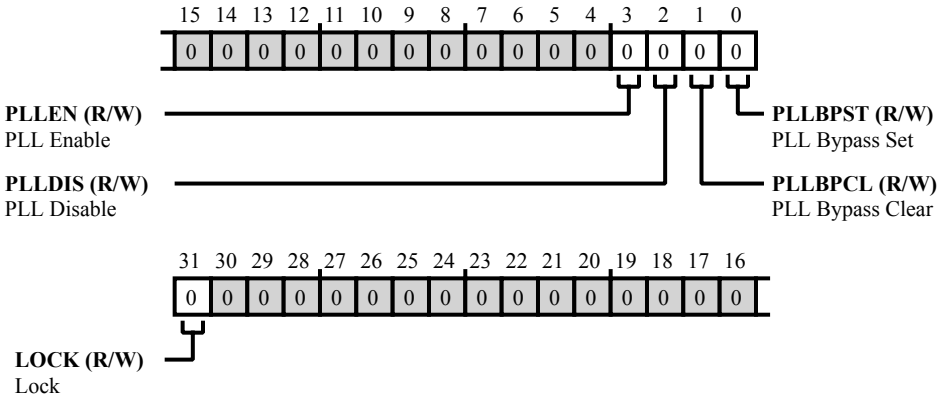

Figure 2-11: CGU_PLLCTL Register Diagram

Table 2-16: CGU_PLLCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. Setting (=1) the CGU_PLLCTL.LOCK bit locks access to the CGU_PLLCTL register.	
		0	Unlock register
		1	Lock register
3 (R/W)	PLLEN	PLL Enable. Setting (=1) the CGU_PLLCTL.PLLEN bit enables the PLL. Check the CGU_STAT.PLLEN bit to verify that the action is complete.	
		0	No action
		1	Enable PLL
2 (R/W)	PLLDIS	PLL Disable. Setting (=1) the CGU_PLLCTL.PLLDIS bit disables the PLL. Check the CGU_STAT.PLLEN bit to verify that the action is complete.	
		0	No action
		1	Disable PLL
1 (R/W)	PLLBPCL	PLL Bypass Clear. Setting (=1) the CGU_PLLCTL.PLLBPCL bit takes the PLL out of bypass mode. Check the CGU_STAT.PLLBP bit to verify that the action is complete.	
		0	No action
		1	Exit bypass mode

Table 2-16: CGU_PLLCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	PLLBPST	PLL Bypass Set. Setting (=1) the `CGU_PLLCTL.PLLBPST` bit bypasses the PLL and all the clocks run on CLKIN. Check the `CGU_STAT.PLLBP` bit to verify that the action is complete.	
		0	Use PLL
		1	Bypass PLL

Revision ID Register

The CGU_REVID register reports the version of the CGU.

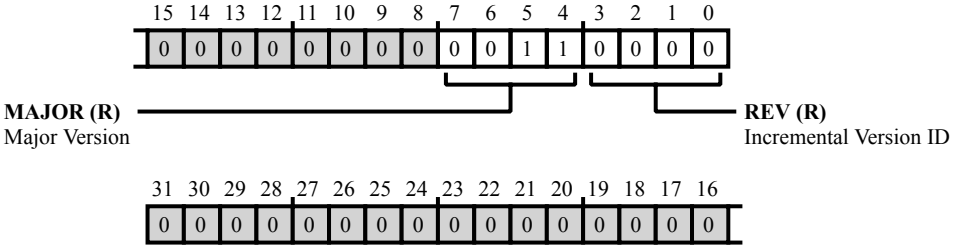

Figure 2-12: CGU_REVID Register Diagram

Table 2-17: CGU_REVID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:4 (R/NW)	MAJOR	Major Version.
3:0 (R/NW)	REV	Incremental Version ID.

System Clock Buffer Disable Register

The CGU_SCBF_DIS register controls each system's clock buffer to determine if the SCLKn buffer is enabled.

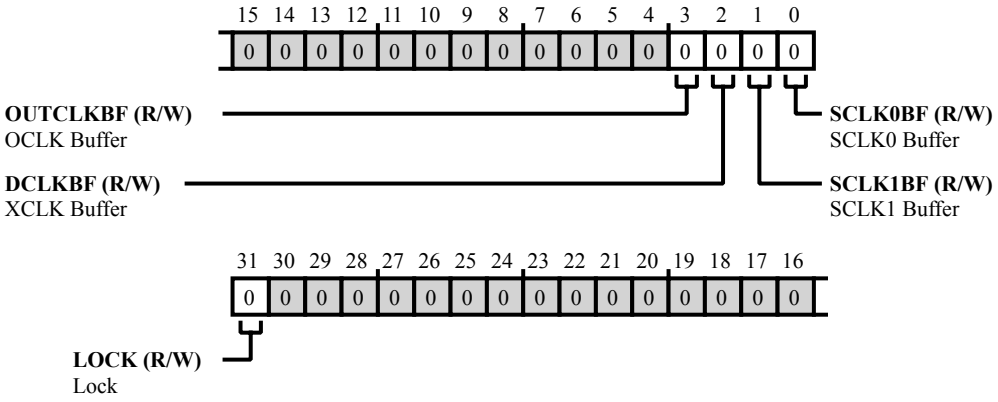

Figure 2-13: CGU_SCBF_DIS Register Diagram

Table 2-18: CGU_SCBF_DIS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. The CGU_SCBF_DIS.LOCK bit allows writes to the CGU_SCBF_DIS register when cleared (=0) or blocks writes if set (=1) and the SPU_CTL.GLCK bit is set.	
		0	Unlock register
		1	Lock register
3 (R/W)	OUTCLKBF	OCLK Buffer. The CGU_SCBF_DIS.OUTCLKBF bit enables (=0, default) or disables (=1) OCLKs buffer.	
		0	Enable buffer
		1	Disable buffer
2 (R/W)	DCLKBF	XCLK Buffer. The CGU_SCBF_DIS.DCLKBF bit enables (=0, default) or disables (=1) XCLKs buffer.	
		0	Enable buffer
		1	Disable buffer

Table 2-18: CGU_SCBF_DIS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W)	SCLK1BF	SCLK1 Buffer. The `CGU_SCBF_DIS.SCLK1BF` bit enables (=0, default) or disables (=1) SCLK1s buffer.	
		0	Enable buffer
		1	Disable buffer
0 (R/W)	SCLK0BF	SCLK0 Buffer. The `CGU_SCBF_DIS.SCLK0BF` bit enables (=0, default) or disables (=1) SCLK0s buffer.	
		0	Enable buffer
		1	Disable buffer

System Clock Buffer Status Register

The CGU_SCBF_STAT register shows which system clock buffer(s) are disabled. For example clearing the CGU_CCBF_DIS.CCBF0 bit clears the CGU_SCBF_STAT.SCLK0BF bit after a number of cycles. To guarantee that the correct value is read, this register should be read twice and the second result used.

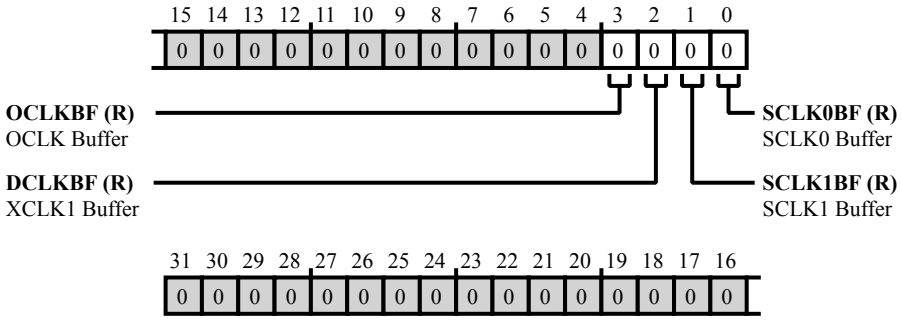

Figure 2-14: CGU_SCBF_STAT Register Diagram

Table 2-19: CGU_SCBF_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/NW)	OCLKBF	OCLK Buffer. The CGU_SCBF_STAT.OCLKBF bit reports the status of the CGU_SCBF_DIS.OUTCLKBF bit where 0 = enabled and 1 = disabled.	
		0	Enabled
		1	Disabled
2 (R/NW)	DCLKBF	XCLK1 Buffer. The CGU_SCBF_STAT.DCLKBF bit reports the status of the CGU_SCBF_DIS.DCLKBF bit where 0 = enabled and 1 = disabled.	
		0	Enabled
		1	Disabled
1 (R/NW)	SCLK1BF	SCLK1 Buffer. The CGU_SCBF_STAT.SCLK1BF bit reports the status of the CGU_SCBF_DIS.SCLK1BF bit where 0 = enabled and 1 = disabled.	
		0	Enabled
		1	Disabled

Table 2-19: CGU_SCBF_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/NW)	SCLK0BF	SCLK0 Buffer. The `CGU_SCBF_STAT.SCLK0BF` bit reports the status of the `CGU_SCBF_DIS.SCLK0BF` bit where 0 = enabled and 1 = disabled.	
		0	Enabled
		1	Disabled

Status Register

The CGU_STAT register reflects the PLL status and errors detected during the PLL configuration. This register may be cleared asynchronously by a reset signal from the RCU module. All bits---except those defined as W1C (write-1-to-clear)---are read only.

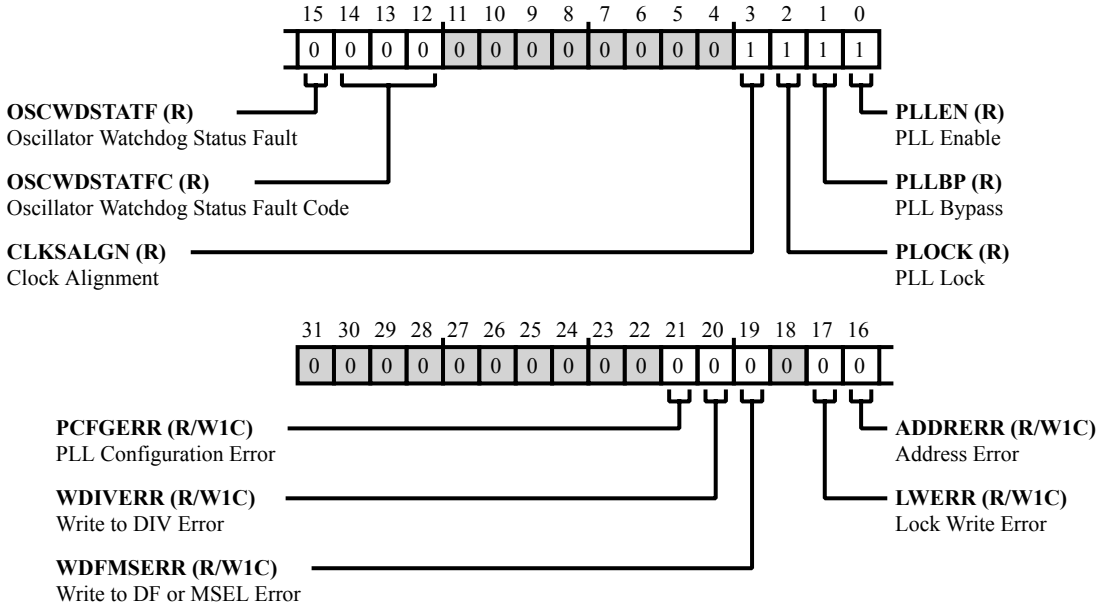

Figure 2-15: CGU_STAT Register Diagram

Table 2-20: CGU_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
21 (R/W1C)	PCFGERR	PLL Configuration Error. If the CGU_PLLCTL.PLLBPST and the CGU_PLLCTL.PLLBPCL bits are set (=1) simultaneously or the CGU_PLLCTL.PLLDIS bit was set (=1) in full-on mode or while trying to enter full-on mode (CGU_PLLCTL.PLLBPCL =1), the CGU_STAT.PCFGERR bit triggers the bus error.	
		0	No Error
		1	Configuration Error

Table 2-20: CGU_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
20 (R/W1C)	WDIVERR	Write to DIV Error. The CGU_STAT.WDIVERR bit indicates a write access to the CGU_DIV register (to trigger an alignment sequence or to change the CGU_DIV.CSEL, CGU_DIV.SYSSEL, CGU_DIV.S0SEL, CGU_DIV.S1SEL, or CGU_DIV.DSEL bit values) while the PLL is locked, but still aligning the clocks. Read after write accesses to the CGU_STAT and CGU_DIV registers return the new value even if the clock frequency change is still in progress.	
		0	No Error
		1	Write DIV Error
19 (R/W1C)	WDFMSERR	Write to DF or MSEL Error. The CGU_STAT.WDFMSERR bit indicates a write access to the CGU_CTL register to change the CGU_CTL.DF or CGU_CTL.MSEL bit values while the PLL is locking.	
		0	No Error
		1	Write DF/MSEL Error
17 (R/W1C)	LWERR	Lock Write Error. The CGU_STAT.LWERR bit indicates an attempt to write to write-protected (locked) CGU registers. The CGU issues a bus error for this condition.	
		0	No Error
		1	Lock Write Error
16 (R/W1C)	ADDRERR	Address Error. The CGU_STAT.ADDRERR bit indicates an attempt to make a read or write access to unimplemented addresses or accesses are non-aligned. The CGU issues a bus error for this condition.	
		0	No Error
		1	Address Error
15 (R/NW)	OSCWDSTATF	Oscillator Watchdog Status Fault. The CGU_STAT.OSCWDSTATF bit indicates a fault in the oscillator watchdog (CGU's OSC_WDSTAT[1:0]) input pins.	
		0	No Fault
		1	Fault
14:12 (R/NW)	OSCWDSTATFC	Oscillator Watchdog Status Fault Code. The CGU_STAT.OSCWDSTATFC bit field indicates the nature of the fault in the oscillator watchdog (CGU's OSC_WDSTAT[1:0]) input pins.	
		0	No Fault
		1	No Input Clock

Table 2-20: CGU_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		2	Subharmonic CLKIN
		3	Harmonic CLKIN
		4	No AUX_CLK
		5	CLKIN > Upper Frequency Limit (BOUF)
		6	Reserved
		7	Multiple Limit Faults
3 (R/NW)	CLKSALGN	Clock Alignment. The CGU_STAT.CLKSALGN bit indicates whether a clock alignment sequence is in progress. This bit is set when clocks alignment is required by changes to CGU_DIV.CSEL, CGU_DIV.S0SEL, CGU_DIV.S1SEL, CGU_DIV.DSEL, or CGU_DIV.OSEL. The CGU_STAT.CLKSALGN bit is cleared when clocks are aligned. Note that (after a PLL frequency change in active state) the CGU_STAT.CLKSALGN bit may indicate that clocks are not aligned even though the clocks are aligned (all clocks are aligned and running at CLKIN frequency).	
		0	Clocks are Aligned
		1	Clocks not Aligned (alignment in progress)
2 (R/NW)	PLOCK	PLL Lock. The CGU_STAT.PLOCK bit indicates whether the PLL is locked. This bit is set when the PLL locks (PLL lock counter end-of-count). The CGU_STAT.PLOCK bit is cleared when requested PLL frequency change (for PLL reset, PLL disable-to-enable transition, or a change to the CGU_CTL.MSEL or CGU_CTL.DF values) is in progress.	
		0	PLL not Locked (PLL frequency change in progress)
		1	PLL Locked
1 (R/NW)	PLLBP	PLL Bypass. The CGU_STAT.PLLBP bit indicates whether the PLL is bypassed. The default value for the CGU_STAT.PLLBP bit is determined by the bypass strap pin.	
		0	PLL not Bypassed
		1	PLL Bypassed
0 (R/NW)	PLLEN	PLL Enable. The CGU_STAT.PLLEN bit indicates whether the PLL is enabled.	
		0	Disabled
		1	Enabled

Time Stamp Counter 32 LSB Register

The CGU_TSCOUNT0 register address is used to read the CoreSight time stamp counter LSB 32-bit (bits [31:0]) value.

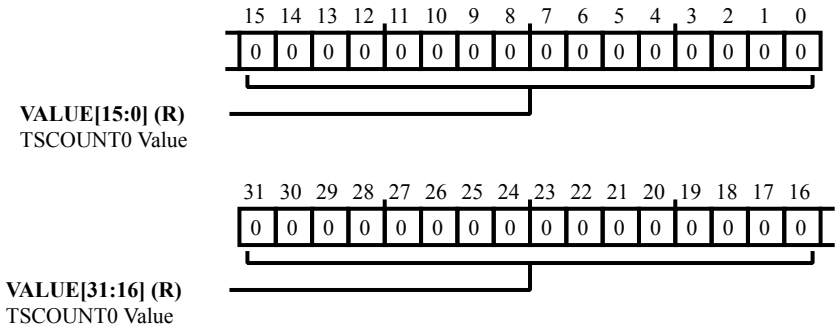

Figure 2-16: CGU_TSCOUNT0 Register Diagram

Table 2-21: CGU_TSCOUNT0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	TSCOUNT0 Value. The CGU_TSCOUNT0.VALUE bit field holds the time stamp counter 32 LSBs.

Time Stamp Counter 32 MSB Register

The CGU_TSCOUNT1 register address is used to read the CoreSight time stamp counter MSB 32-bit (bits [63:32]) value.

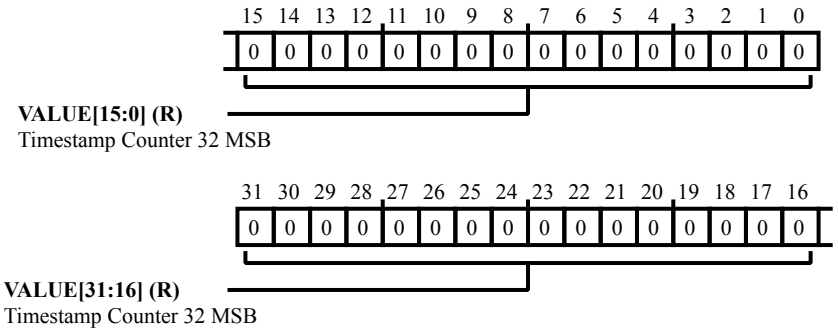

Figure 2-17: CGU_TSCOUNT1 Register Diagram

Table 2-22: CGU_TSCOUNT1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Timestamp Counter 32 MSB. The CGU_TSCOUNT1.VALUE bit field holds the time stamp counter 32 MSBs.

Time Stamp Control Register

The CGU_TSCTL register controls the operation of the CoreSight time stamp counter.

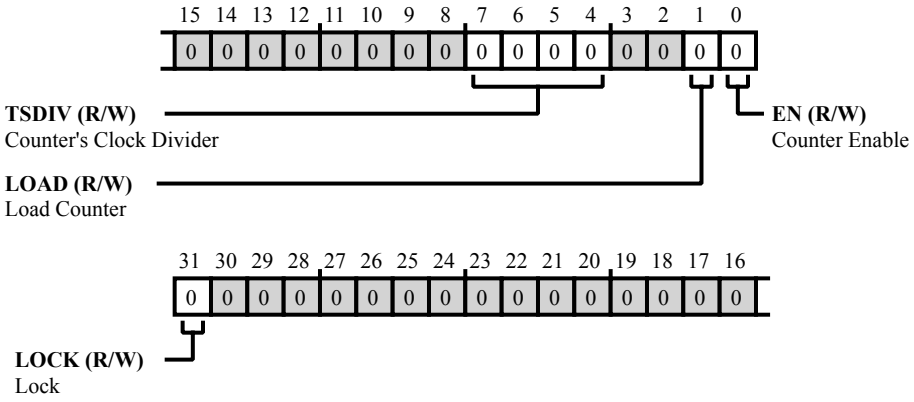

Figure 2-18: CGU_TSCTL Register Diagram

Table 2-23: CGU_TSCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. Setting the CGU_TSCTL.LOCK bit locks this register.	
		0	Unlock
		1	Lock
7:4 (R/W)	TSDIV	Counter's Clock Divider. The CGU_TSCTL.TSDIV bit field divides SYSCLK by 2^{TSDIV}.	
		0-15	Divides SYSCLK by 2^{TSDIV}
1 (R/W)	LOAD	Load Counter. Writing one to the CGU_TSCTL.LOAD bit causes CoreSight time stamp counter to be loaded from the CGU_TSVALUE0 and CGU_TSVALUE1 registers.	
		0	Always read as "0"
0 (R/W)	EN	Counter Enable. The CGU_TSCTL.EN bit enables or disables the CoreSight time stamp counter.	
		0	Counter Disabled
		1	Counter Enabled

Time Stamp Counter Initial 32 LSB Value Register

The CGU_TSVALUE0 register holds the least significant bits (bits [31:0]) value that is initially loaded to the Core-Sight time stamp counter.

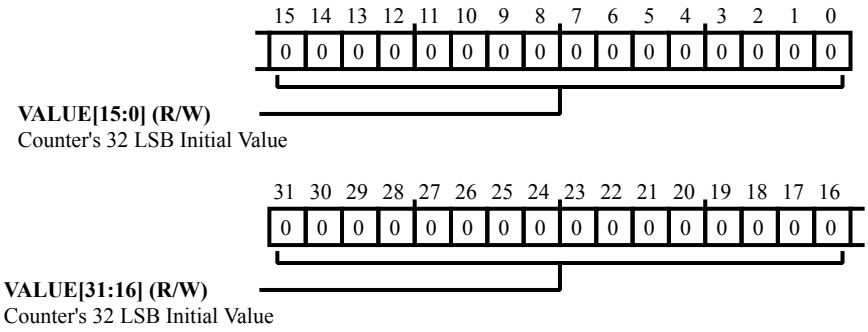

Figure 2-19: CGU_TSVALUE0 Register Diagram

Table 2-24: CGU_TSVALUE0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Counter's 32 LSB Initial Value. The CGU_TSVALUE0.VALUE bit field holds the LSBs value that is initially loaded to the CoreSight time stamp counter.

Time Stamp Counter Initial MSB Value Register

The CGU_TSVALUE1 register holds the most significant bits (bits [63:32]) value that is initially loaded to the CoreSight time stamp counter.

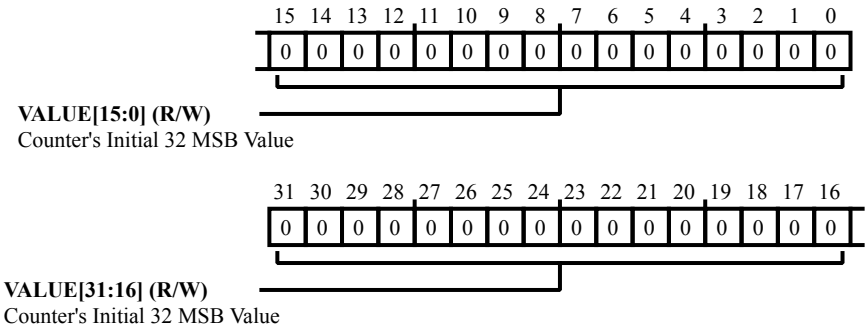

Figure 2-20: CGU_TSVALUE1 Register Diagram

Table 2-25: CGU_TSVALUE1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Counter's Initial 32 MSB Value. The CGU_TSVALUE1.VALUE bit field holds the MSBs value that is initially loaded to the CoreSight time stamp counter.

ADSP-SC59x MISCREG Register Descriptions

Misc registers for module are for integration purpose (MISCREG) contains the following registers.

Table 2-26: ADSP-SC59x MISCREG Register List

Name	Description
MISCREG_CAN_SYSCTL	CANFD Low Power Selection Mode
MISCREG_ECO_REG9	Error Register
MISCREG_PLL2_CONTROL	PLL2 Control Register
MISCREG_SH0_PFB_RANGE_SELECT	SH0 Prefetch Range Selection Register
MISCREG_SH1_PFB_RANGE_SELECT	SH1 Prefetch Range Selection Register
MISCREG_SHARC_BRIDGE_REMAP	SPORT Direct Interrupt Enable for SH0 and SH1

CANFD Low Power Selection Mode

The MISCREG_CAN_SYSCTL register contains the control bits for the different low power modes supported in the CANFD module.

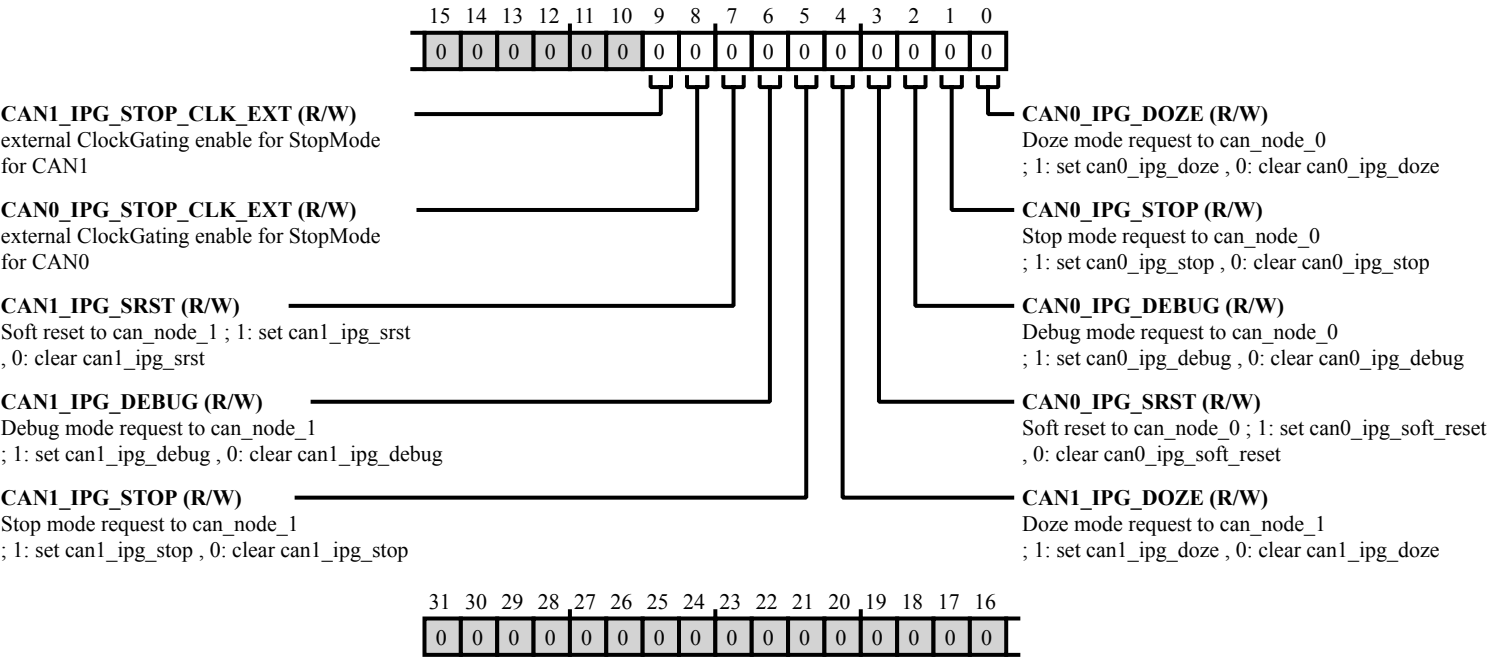

Figure 2-21: MISCREG_CAN_SYSCTL Register Diagram

Table 2-27: MISCREG_CAN_SYSCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
9 (R/W)	CAN1_IPG_STOP_CLK_EXT	external ClockGating enable for StopMode for CAN1.
8 (R/W)	CAN0_IPG_STOP_CLK_EXT	external ClockGating enable for StopMode for CAN0.
7 (R/W)	CAN1_IPG_SRST	Soft reset to can_node_1 ; 1: set can1_ipg_srst , 0: clear can1_ipg_srst.
6 (R/W)	CAN1_IPG_DEBUG	Debug mode request to can_node_1 ; 1: set can1_ipg_debug , 0: clear can1_ipg_debug.
5 (R/W)	CAN1_IPG_STOP	Stop mode request to can_node_1 ; 1: set can1_ipg_stop , 0: clear can1_ipg_stop.
4 (R/W)	CAN1_IPG_DOZE	Doze mode request to can_node_1 ; 1: set can1_ipg_doze , 0: clear can1_ipg_doze.

Table 2-27: MISCREG_CAN_SYSCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
3 (R/W)	CAN0_IPG_SRST	Soft reset to can_node_0 ; 1: set can0_ipg_soft_reset , 0: clear can0_ipg_soft_reset.
2 (R/W)	CAN0_IPG_DEBUG	Debug mode request to can_node_0 ; 1: set can0_ipg_debug , 0: clear can0_ipg_debug.
1 (R/W)	CAN0_IPG_STOP	Stop mode request to can_node_0 ; 1: set can0_ipg_stop , 0: clear can0_ipg_stop.
0 (R/W)	CAN0_IPG_DOZE	Doze mode request to can_node_0 ; 1: set can0_ipg_doze , 0: clear can0_ipg_doze.

Error Register

The MISCREG_ECO_REG9 register contains eight Tx channels, eight Rx channels, and DMA errors for both EMAC0 and EMAC1.

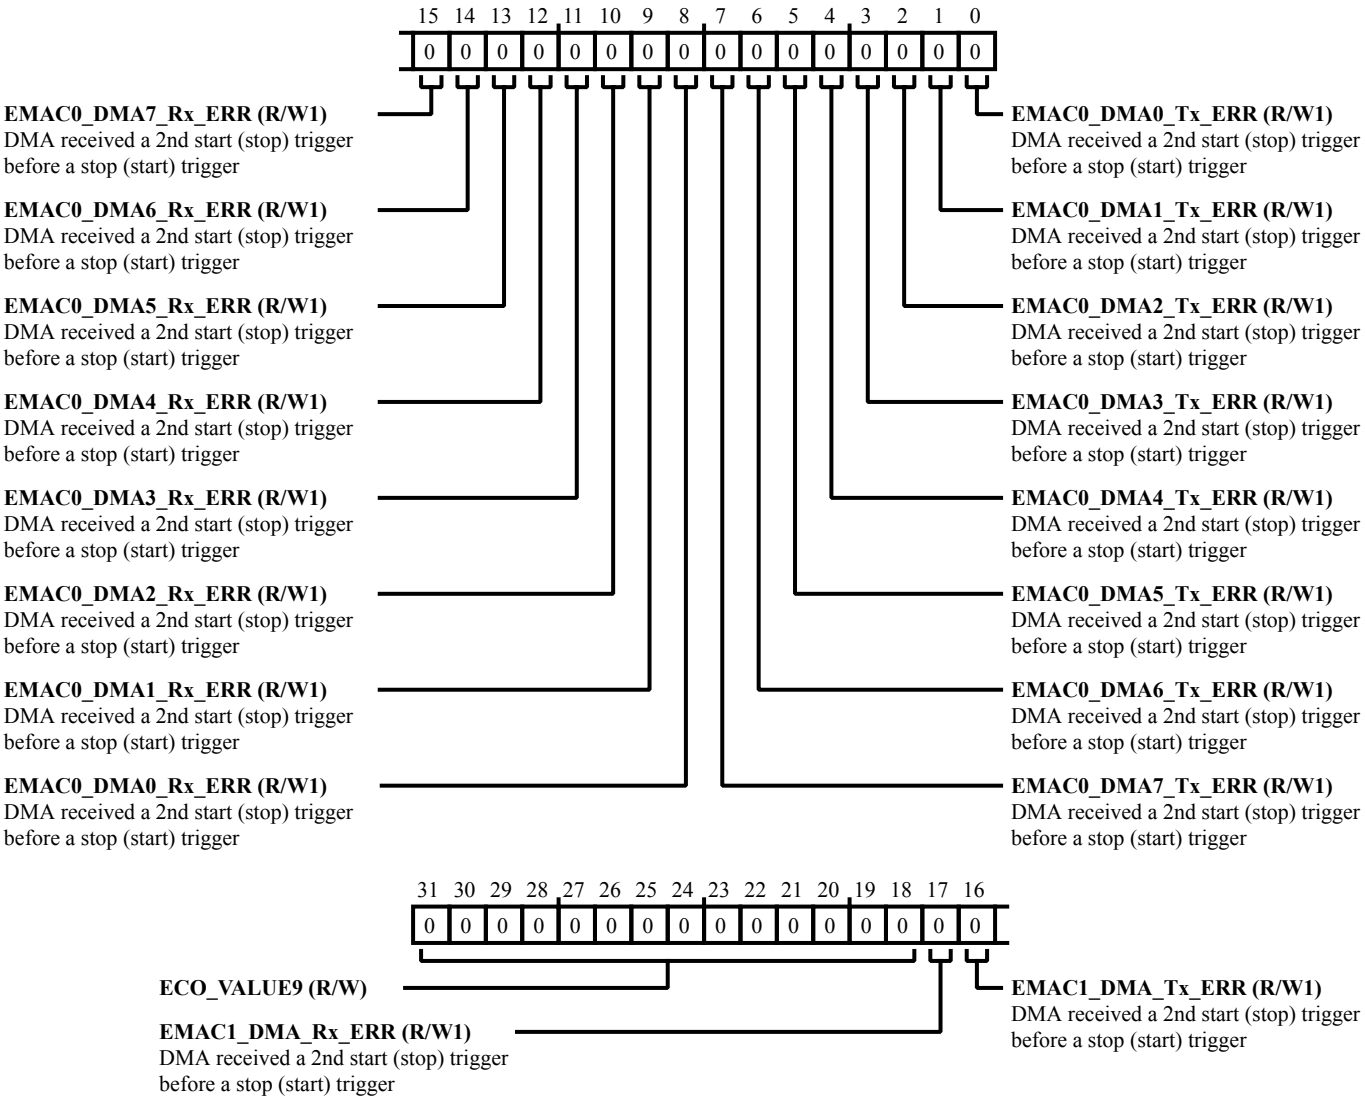

Figure 2-22: MISCREG_ECO_REG9 Register Diagram

Table 2-28: MISCREG_ECO_REG9 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:18 (R/W)	ECO_VALUE9	.

Table 2-28: MISCREG_ECO_REG9 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
17 (R/W1)	EMAC1_DMA_RX_ERR	DMA received a 2nd start (stop) trigger before a stop (start) trigger.
16 (R/W1)	EMAC1_DMA_TX_ERR	DMA received a 2nd start (stop) trigger before a stop (start) trigger.
15 (R/W1)	EMAC0_DMA7_RX_ERR	DMA received a 2nd start (stop) trigger before a stop (start) trigger.
14 (R/W1)	EMAC0_DMA6_RX_ERR	DMA received a 2nd start (stop) trigger before a stop (start) trigger.
13 (R/W1)	EMAC0_DMA5_RX_ERR	DMA received a 2nd start (stop) trigger before a stop (start) trigger.
12 (R/W1)	EMAC0_DMA4_RX_ERR	DMA received a 2nd start (stop) trigger before a stop (start) trigger.
11 (R/W1)	EMAC0_DMA3_RX_ERR	DMA received a 2nd start (stop) trigger before a stop (start) trigger.
10 (R/W1)	EMAC0_DMA2_RX_ERR	DMA received a 2nd start (stop) trigger before a stop (start) trigger.
9 (R/W1)	EMAC0_DMA1_RX_ERR	DMA received a 2nd start (stop) trigger before a stop (start) trigger.
8 (R/W1)	EMAC0_DMA0_RX_ERR	DMA received a 2nd start (stop) trigger before a stop (start) trigger.
7 (R/W1)	EMAC0_DMA7_TX_ERR	DMA received a 2nd start (stop) trigger before a stop (start) trigger.
6 (R/W1)	EMAC0_DMA6_TX_ERR	DMA received a 2nd start (stop) trigger before a stop (start) trigger.
5 (R/W1)	EMAC0_DMA5_TX_ERR	DMA received a 2nd start (stop) trigger before a stop (start) trigger.
4 (R/W1)	EMAC0_DMA4_TX_ERR	DMA received a 2nd start (stop) trigger before a stop (start) trigger.
3 (R/W1)	EMAC0_DMA3_TX_ERR	DMA received a 2nd start (stop) trigger before a stop (start) trigger.
2 (R/W1)	EMAC0_DMA2_TX_ERR	DMA received a 2nd start (stop) trigger before a stop (start) trigger.

Table 2-28: MISCREG_ECO_REG9 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
1 (R/W1)	EMAC0_DMA1_TX_ERR	DMA received a 2nd start (stop) trigger before a stop (start) trigger.
0 (R/W1)	EMAC0_DMA0_TX_ERR	DMA received a 2nd start (stop) trigger before a stop (start) trigger.

PLL2 Control Register

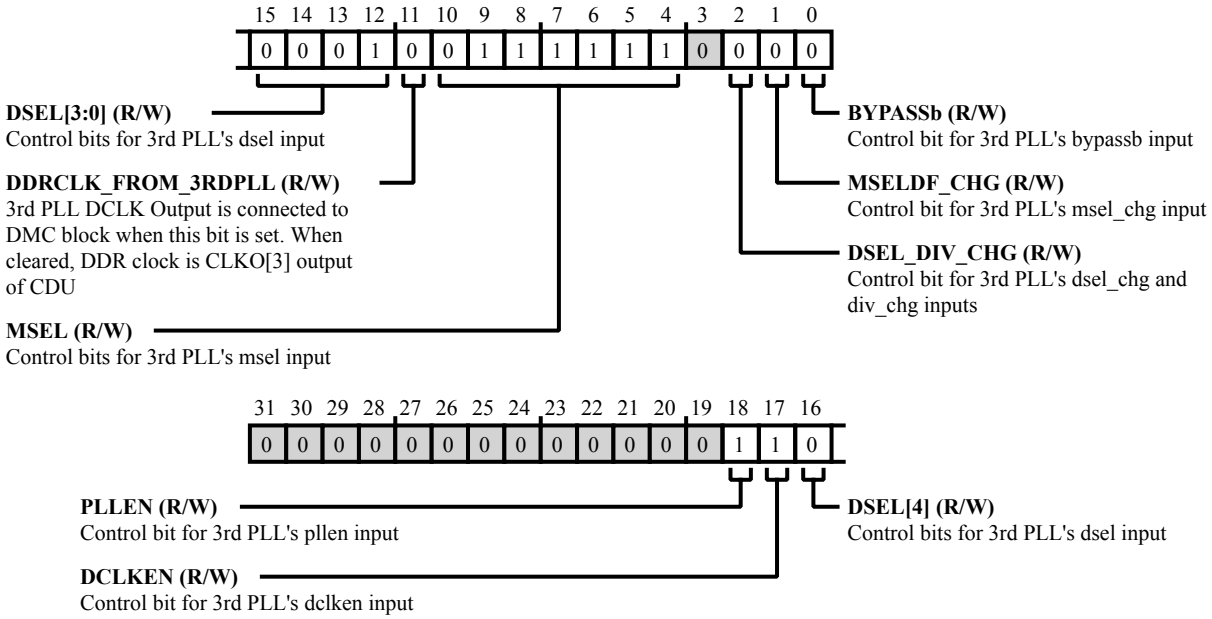

Figure 2-23: MISCREG_PLL2_CONTROL Register Diagram

Table 2-29: MISCREG_PLL2_CONTROL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
18 (R/W)	PLLEN	Control bit for 3rd PLL's pllen input. Internal signal from Dynamic Power Management Unit (DPM) which enables/disables the PLL system (e.g. in Active mode, during BYPASS.)
17 (R/W)	DCLKEN	Control bit for 3rd PLL's dclken input. Enables DCLK clock buffer
16:12 (R/W)	DSEL	Control bits for 3rd PLL's dsel input. Selects DCLK divide ratio
11 (R/W)	DDRCLK_FROM_3RDPLL	3rd PLL DCLK Output is connected to DMC block when this bit is set. When cleared, DDR clock is CLKO[3] output of CDU. 3rd PLL DCLK Output is connected to DMC block when this bit is set. When cleared, DDR clock is CLKO[3] output of CDU
10:4 (R/W)	MSEL	Control bits for 3rd PLL's msel input. The `MISCREG_PLL2_CONTROL.MSEL` selects the multiplier in the PLLCLK equation: PLLCLK frequency = (SYS_CLKIN frequency / (DF+1)) * MSEL * 2 Where the value of MSEL is between 1 and 127.

Table 2-29: MISCREG_PLL2_CONTROL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
2 (R/W)	DSEL_DIV_CHG	Control bit for 3rd PLL's dsel_chg and div_chg inputs. Signal from PCU indicating a DDR clock frequency change
1 (R/W)	MSELDF_CHG	Control bit for 3rd PLL's msel_chg input. Signal from PLL Control Unit indicating a frequency change resulting from a change in either the DF or MSEL bits.
0 (R/W)	BYPASSB	Control bit for 3rd PLL's bypassb input. Active-low control bit to bypass the PLL which forces CLKIN on all output clocks

SH0 Prefetch Range Selection Register

In the MISCREG_SH0_PFB_RANGE_SELECT register, each bit field controls if the corresponding address range will be prefetched. When an address range is set it is prefetched and when it is zero there is no prefetch.

The MISCREG_SH0_PFB_RANGE_SELECT[31:16] bits control the range selection for the instruction cache, and MISCREG_SH0_PFB_RANGE_SELECT[15:0] bits control the range selection for the data cache.

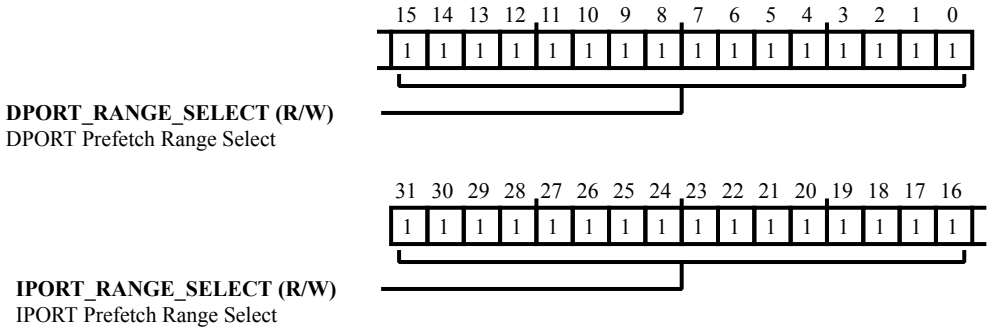

Figure 2-24: MISCREG_SH0_PFB_RANGE_SELECT Register Diagram

Table 2-30: MISCREG_SH0_PFB_RANGE_SELECT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/W)	IPORT_RANGE_SELECT	IPORT Prefetch Range Select. Prefetch Range Selection for IPORT
15:0 (R/W)	DPORT_RANGE_SELECT	DPORT Prefetch Range Select. Prefetch Range Selection for DPORT

SH1 Prefetch Range Selection Register

Each bit field controls if the corresponding address range will be prefetched. When an address range is set it is prefetched an when it is zero there is no prefetch.

The MISCREG_SH1_PFB_RANGE_SELECT[31:16] bits control the range selection for the instruction cache, and MISCREG_SH1_PFB_RANGE_SELECT[15:0] bits control the range selection for the data cache.

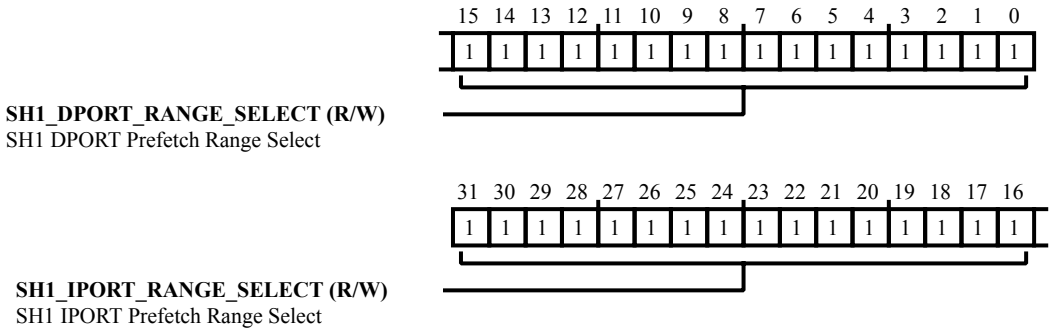

Figure 2-25: MISCREG_SH1_PFB_RANGE_SELECT Register Diagram

Table 2-31: MISCREG_SH1_PFB_RANGE_SELECT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/W)	SH1_IPORT_RANGE_SELECT	SH1 IPORT Prefetch Range Select. Prefetch Range Selection for IPORT
15:0 (R/W)	SH1_DPORT_RANGE_SELECT	SH1 DPORT Prefetch Range Select. Prefetch Range Selection for DPORT

SPORT Direct Interrupt Enable for SH0 and SH1

The bits in the MISCREG_SHARC_BRIDGE_REMAP register control the direct connection of SPORT interrupts to the SHARC core.

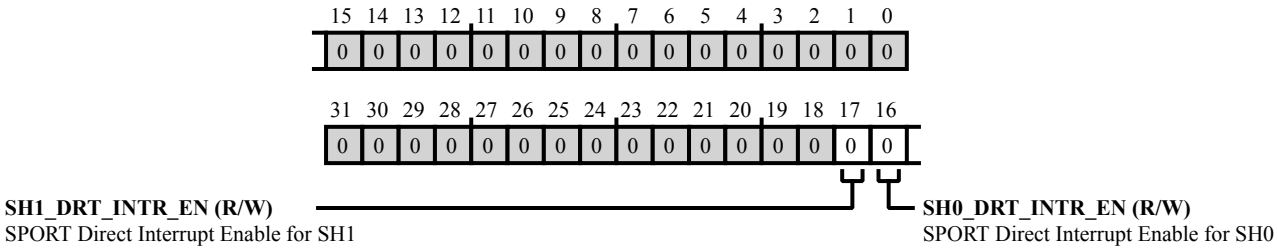

Figure 2-26: MISCREG_SHARC_BRIDGE_REMAP Register Diagram

Table 2-32: MISCREG_SHARC_BRIDGE_REMAP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
17 (R/W)	SH1_DRT_INTR_EN	SPORT Direct Interrupt Enable for SH1. If the MISCREG_SHARC_BRIDGE_REMAP.SH1_DRT_INTR_EN bit is set a direct connection is enabled for SH1. Do not set the MISCREG_SHARC_BRIDGE_REMAP.SH1_DRT_INTR_EN bit when IIR1 of the SH1 is in use. If this bit is zero the direct connection is disabled.
16 (R/W)	SH0_DRT_INTR_EN	SPORT Direct Interrupt Enable for SH0. If the MISCREG_SHARC_BRIDGE_REMAP.SH0_DRT_INTR_EN bit is set a direct connection is enabled for SH0. Do not set the MISCREG_SHARC_BRIDGE_REMAP.SH0_DRT_INTR_EN bit when IIR1 of the SH0 is in use. If this bit is zero the direct connection is disabled.

3 Clock Distribution Unit (CDU)

The Clock Distribution Unit (CDU) consists of an array of multiplexors that select clocks originated from up to four different clock sources. These sources are different clocks that are generated from the Clock Generation Units (CGUs). The multiplexors are configured by software. All clocks multiplexors have up to four different sources. Unused input clocks are grounded internally and never selected. The output clock signal for each multiplexor is assigned to one or more destinations within the processor.

CDU Features

The CDU modules supports the following features:

- Generation of up to 14 output clocks
- Output clock buffers that can be disabled by software
- Multiplexors that are configured by writing to configuration registers (`CDU_CFG[n]`)
- Clocks originated in CGU0 that are selected by default
- A CDU status register (`CDU_STAT`) that indicates a configuration change is in-progress

CDU Functional Description

The CDU functions as a set of software-configurable multiplexors that select clocks from different sources.

CDU Block Diagram

The ***CGU/CDU Block Diagram*** figure shows the functional blocks within the CDU. As shown in the figure, the CDU takes different clocks generated by the CGU blocks and provides flexibility to route any clock from possible options to the output CDU clocks. The output clocks from the CDU are connected to specific targets such as the DDR module. All of the targets are clocked through the CDU output clocks rather than being directly clocked by CGU clocks.

This configuration provides the flexibility to meet the specific clock requirements of the different modules in the system (such as the core, DDR, or SPI module) without compromising the clocking of other modules. Such a flexibility is not possible with a single CGU in the system. With two CGUs:

- Each CGU has its own set of clock multipliers and dividers, providing a greater number of orthogonal clocks than possible with a single CGU.
- The `CDU_CLKINSEL.CGU1` bit determines the input for CGU1.

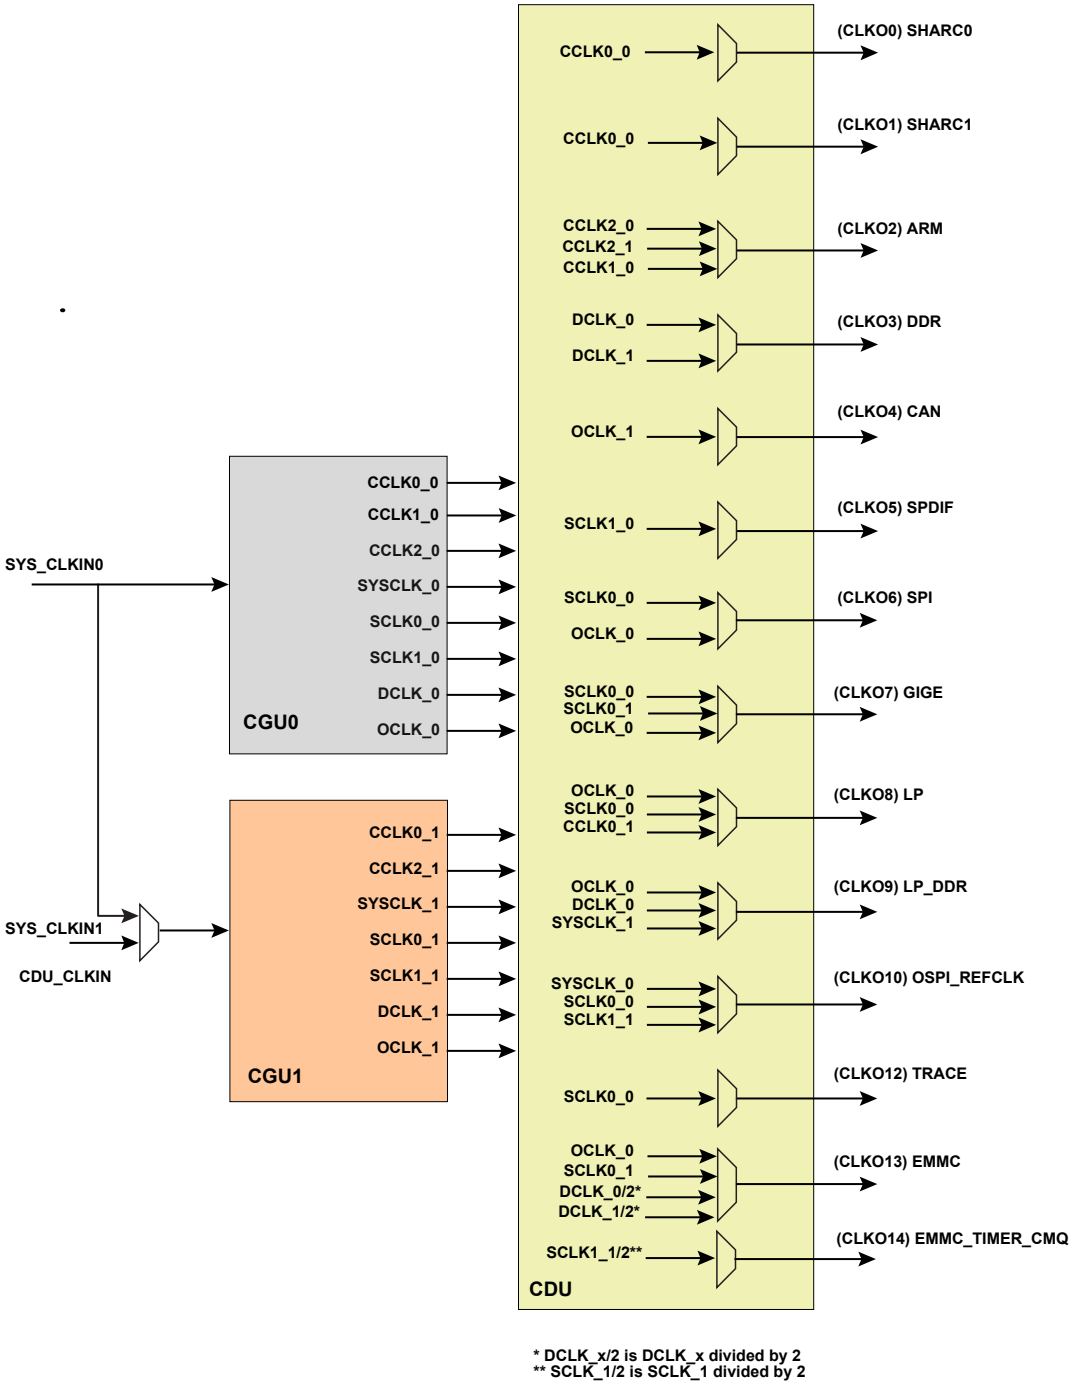

Figure 3-1: CGU/CDU Block Diagram

CDU Definitions

The ***Clock Descriptions*** table provides a brief description of the clocks supported by the processor.

Table 3-1: Clock Descriptions

Clock	Description
CCLK0_0	CCLK0 derived from CGU0
CCLK1_0	CCLK1 derived from CGU0
CCLK2_0	CCLK2 derived from CGU0*1
SYSCLK_0	SYSCLK derived from CGU0
SCLK0_0	SCLK0 derived from CGU0
SCLK1_0	SCLK1 derived from CGU0
DCLK_0	DCLK derived from CGU0
OCLK_0	OCLK derived from CGU0
CCLK0_1	CCLK0 derived from CGU1
CCLK2_1	CCLK2 derived from CGU1*1
SYSCLK_1	SYSCLK derived from CGU1
SCLK0_1	SCLK0 derived from CGU1
SCLK1_1	SCLK1 derived from CGU1
DCLK_1	DCLK derived from CGU1
OCLK_1	OCLK derived from CGU1
CDU_CLKOn	Clocks that come out of the CDU module and go to different blocks
DCLK_2	DCLK derived from CGU2

*1 CCLK2_x is directly derived from the VCO clock; it is divided by 3. Hence, the frequency of CCLK2 = (PLL clock x 2/3).

ADSP-SC59x CDU Register List

Clock Distribution Unit

Table 3-2: ADSP-SC59x CDU Register List

Name	Description
CDU_CFG[n]	CDU Configuration
CDU_CLKINSEL	CLKIN Select
CDU_REVID	CDU Revision ID
CDU_STAT	CDU Status

CDU Clock Configuration Options

The *CDU Targets* table provides information about clock source and destination options.

Table 3-3: CDU Targets

CDU0 Input				CDU0 Output	Target
IN0_CLKOn	IN1_CLKOn	IN2_CLKOn	IN3_CLKOn		
CCLK0_0	N/A	N/A	N/A	CLKO0	SHARC0 and corresponding accelerators
CCLK0_0	N/A	N/A	N/A	CLKO1	SHARC1 and corresponding accelerators
CCLK1_0	N/A	CCLK2_0	CCLK2_1	CLKO2	ARM
DCLK_0	DCLK_1	N/A	N/A	CLKO3	DDR
N/A	OCLK_1	N/A	N/A	CLKO4	CAN
SCLK1_0	N/A	N/A	N/A	CLKO5	SPDIF
SCLK0_0	OCLK_0	N/A	N/A	CLKO6	SPI
SCLK0_0	SCLK0_1	OCLK_0	N/A	CLKO7	GIGE
OCLK_0	SCLK0_0	CCLK0_1	N/A	CLKO8	LP
OCLK_0	DCLK_0	SYSCLK_1	N/A	CLKO9	LP_DDR
SYSCLK_0	SCLK0_0	SCLK1_1	N/A	CLKO10	OSPI_REFCLK
SCLK0_0	N/A	N/A	N/A	CLKO12	TRACE
OCLK_0	SCLK0_1	DCLK_0/2	DCLK_1/2	CLKO13	EMMC
N/A	SCLK1_1/2	N/A	N/A	CLKO14	EMMC_TIMER_CMQ

NOTE: CLKO11 is used internally by the processor and is not user configurable.

CDU Programming Model

The `CDU_CFG[n]` registers are a system configuration resource. These registers are accessed by a system configuration routine that also handles the configuration of other system modules. Writes to a `CDU_CFG[n]` register must occur when there is not a CDU_CLKOn configuration change in progress. If a CGUn inputs are selected, that CGUn configuration must be completed first.

Changing the PLL and Clock Frequency

1. Read the `CGU_STAT` register. Verify that:
   - `CGU_STAT.PLLEN` =1 (enabled)
   - `CGU_STAT.PLOCK` =1 (PLL is not locking)
   - `CGU_STAT.CLKSALGN` =0 (clocks aligned)

2. Write the desired values into the CGU_DIV.CSEL, CGU_DIV.S0SEL, CGU_DIV.SYSSEL, CGU_DIV.S1SEL, CGU_DIV.DSEL and CGU_DIV.OSEL bits with the CGU_DIV.UPDT bit cleared (= 0).
3. Write the desired values to the CGU_CTL.DF and CGU_CTL.MSEL bits.
4. Read the CGU_STAT register. Verify that:
   - CGU_STAT.PLLEN = 1 (enabled)
   - CGU_STAT.PLOCK = 1 (not locking)
   - CGU_STAT.CLKSALGN = 0 (clocks aligned)
5. Read the CDU_STAT register. Verify that the CDU_STAT.CLKO0 = 0 (no CLKOn configuration change in progress).
6. Write to the CDU_CLKINSEL register to select the CGU's CLKIN input clock.
7. Write to the CDU_CFG[n].SEL bit to select the clock source (the CDU_CFG[n].EN bit should =1.)
8. Read the CDU_CFG[n] register. Verify that the CDU_CLKINSEL has the programmed value.

CLKOn is reconfigured.

Changing the Clock Frequency

Use the following procedure to change a clock frequency.

1. Read the CGU_STAT register to verify that the CGU_STAT.CLKSALGN bit =0 (clocks aligned).
2. Write the desired values into the CGU_DIV.CSEL, CGU_DIV.S0SEL, CGU_DIV.SYSSEL, CGU_DIV.S1SEL, CGU_DIV.DSEL and CGU_DIV.OSEL bits with the CGU_DIV.UPDT bit = 1.
3. Read the CGU_DIV registers to verify that the CGU_DIV.CSEL, CGU_DIV.S0SEL, CGU_DIV.SYSSEL, CGU_DIV.S1SEL, CGU_DIV.DSEL and CGU_DIV.OSEL bit values are correct.
4. Read the CGU_STAT register to verify that the CGU_STAT.CLKSALGN = 0 (clocks aligned).
5. If clocks switch from CGUm clocks to CGUn input clocks, read the CGU_SCBF_STAT and CGU_CCBF_STAT registers. The CGU_CCBF_STAT[1:0] bit field corresponds to the CCLK1 and CCLK0 clock buffers, respectively. The CGU_SCBF_STAT[3:0] bit field corresponds to the OUTCLK, DCLK, SCLK1, and SCLK0 clock buffers, respectively.
6. Read the CDU_STAT register.
7. Write to the CDU_CFG[n].SEL bit to select the clock source (CDU_CFG[n].EN = 1).
8. Read the CDU_CFG[n] register. Verify that the CDU_CLKINSEL has the programmed value.
9. Verify that the CDU_STAT.CLKO0 = 0.

ADSP-SC59x CDU Register Descriptions

Clock Distribution Unit (CDU) contains the following registers.

Table 3-4: ADSP-SC59x CDU Register List

Name	Description
CDU_CFG[n]	CDU Configuration
CDU_CLKINSEL	CLKIN Select
CDU_REVID	CDU Revision ID
CDU_STAT	CDU Status

CDU Configuration

The CDU_CFG[n] registers control the configuration of the clock multiplexors. CDU0_CFG[n] corresponds to output clock CDU_CLKO[n].

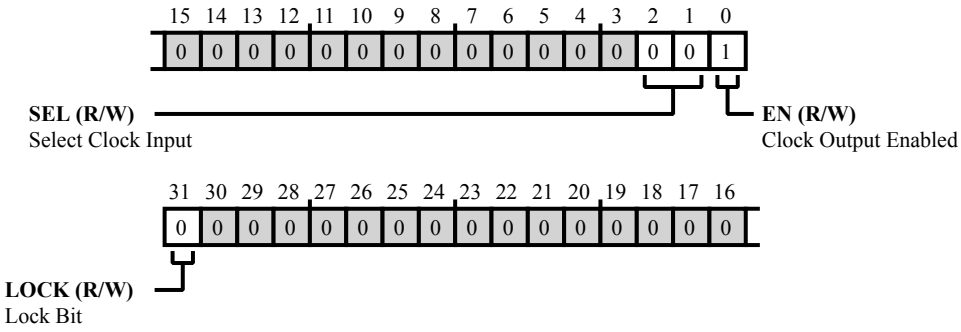

Figure 3-2: CDU_CFG[n] Register Diagram

Table 3-5: CDU_CFG[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock Bit.	
2:1 (R/W)	SEL	Select Clock Input.	
		0	IN0_CLKOn Selected
		1	IN1_CLKOn Selected
		2	IN2_CLKOn Selected
		3	IN3_CLKOn Selected
0 (R/W)	EN	Clock Output Enabled. The CDU_CFG[n].EN bit enables clock output.	

CLKIN Select

The CDU_CLKINSEL register controls the configuration of the CLKIN multiplexors. One bit is assigned to each CGU in the system. This bit selects either CLKIN0 or CLKINn CGUn inputs.

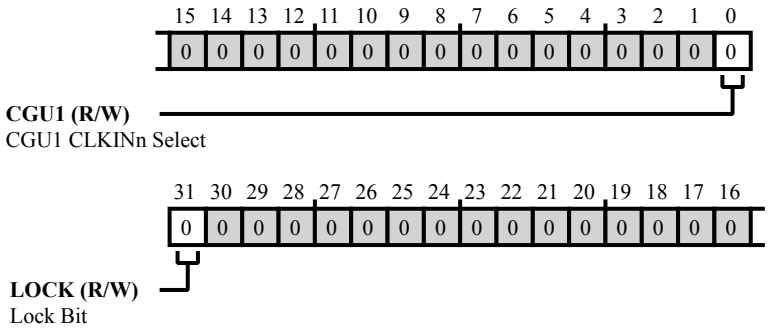

Figure 3-3: CDU_CLKINSEL Register Diagram

Table 3-6: CDU_CLKINSEL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock Bit.	
0 (R/W)	CGU1	CGU1 CLKINn Select. The CDU_CLKINSEL.CGU1 bit drives CDU_CLKIN_SEL[0] to CGU1.	
		0	Selects CLKIN0
		1	Selects CLKIN1

CDU Revision ID

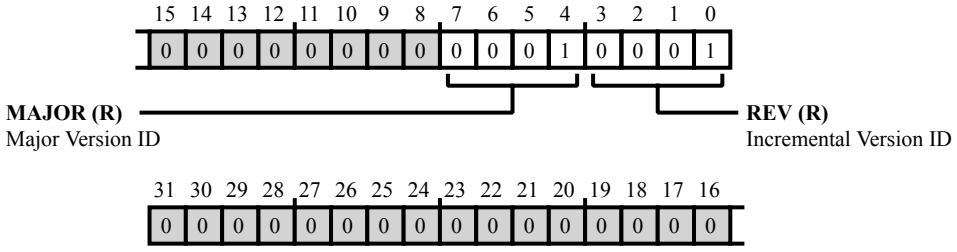

Figure 3-4: CDU_REVID Register Diagram

Table 3-7: CDU_REVID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:4 (R/NW)	MAJOR	Major Version ID.
3:0 (R/NW)	REV	Incremental Version ID.

CDU Status

The CDU_STAT register reflects the status a change in the configuration of the clock muxes.

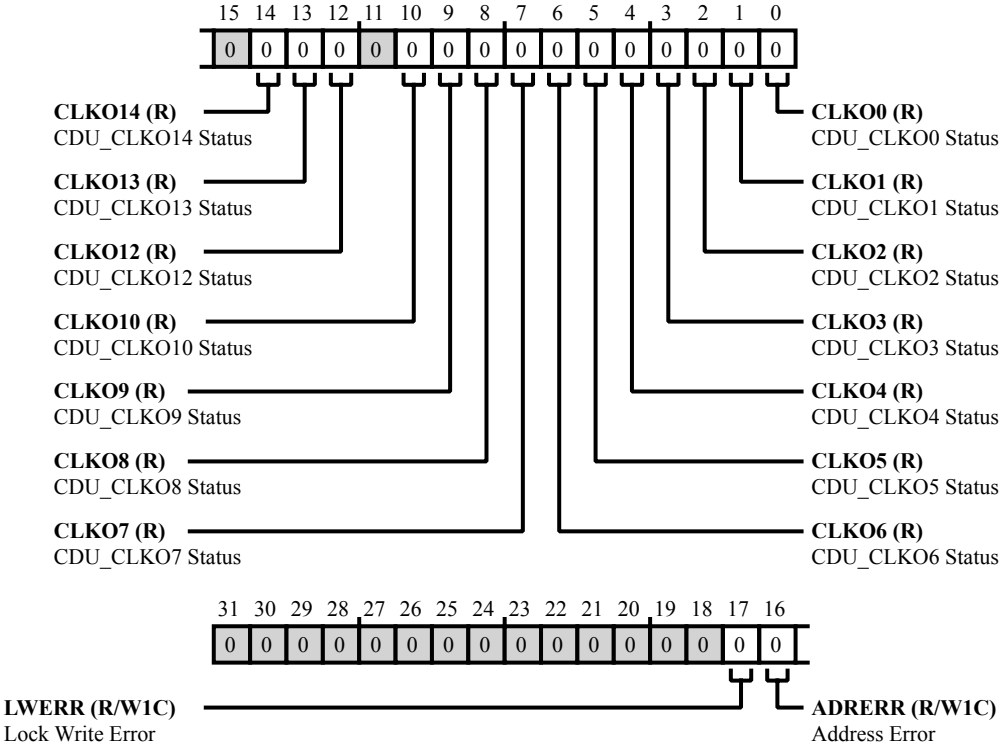

Figure 3-5: CDU_STAT Register Diagram

Table 3-8: CDU_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/W1C)	LWERR	Lock Write Error. The CDU_STAT.LWERR bit indicates a lock error where write transactions try to access write protected registers.	
		0	No Lock Write Error
		1	Lock Write Error
16 (R/W1C)	ADRERR	Address Error. The CDU_STAT.ADRERR bit indicates an address error where read or write transactions try to access unimplemented addresses or accesses are non-aligned.	
		0	No Address Error
		1	Address Error

Table 3-8: CDU_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
14 (R/NW)	CLKO14	CDU_CLKO14 Status.	
		0	No Configuration Change in Progress
		1	Configuration Change in Progress
13 (R/NW)	CLKO13	CDU_CLKO13 Status.	
		0	No Configuration Change in Progress
		1	Configuration Change in Progress
12 (R/NW)	CLKO12	CDU_CLKO12 Status.	
		0	No Configuration Change in Progress

4 Dynamic Power Management (DPM)

The dynamic power management (DPM) unit of the processor controls transitions between different power-saving modes.

DPM provides facility for shutting down clocks for various peripherals. Shutting down peripheral's clocks is considered a power saving feature. To support peripheral clock gating functionality, DPM_PER_DIS0 and DPM_PER_DIS1 are available in the DPM module. The bits in these registers need to be programmed to shut off the clocks to peripherals that are not used in an application to save clock switching power.

DPM Features

The DPM allows programs to control the power mode of the processor as follows.

- Permits operation of multiple, external wake-up sources

DPM Functional Description

The DPM can be programmed to transition between power modes.

ADSP-SC59x DPM Register List

A set of registers govern DPM operations. For more information on DPM functionality, see the DPM register descriptions.

Table 4-1: ADSP-SC59x DPM Register List

Name	Description
DPM_CTL	Control Register
DPM_PER_DIS0	Peripherals Disable Register 0
DPM_PER_DIS1	Peripherals Disable Register 1
DPM_REVID	Revision ID
DPM_STAT	Status Register

DPM Definitions

To make the best use of the DPM, it is useful to understand the following terms.

CGU

Acronym for the clock generation unit (CGU), which is comprised of the PLL and PCU

DPM

Acronym for the dynamic power management (DPM) controller.

Full-on mode

The normal operating mode in which all clock domains are derived from the PLL.

PCU

Acronym for the PLL control unit (PCU).

PLL

Acronym for the phase-locked loop (PLL).

RCU

Acronym for the reset control unit (RCU).

DPM Operating Modes

The DPM includes several operating modes. The modes are:

- Reset
- Full-on

Reset State

Reset is the initial state of the processor and is the result of a hardware or software triggered event. The DPM itself does not trigger entering reset. The external SYS_HWRST pin or the RCU triggers entering reset. The DPM responds to reset by transitioning to its default state.

From Reset, the DPM always transitions to PLL Bypassed state.

Full-on Mode

Full-on mode is the default state of the DPM after Reset.

In full-on mode, the processor can reach its maximum clock rate and power dissipation can be at its highest.

DPM Event Control

The DPM event is triggered when an enabled wake-up is asserted. The DPM generates bus errors when a misaligned access to a register occurs. It also generates errors when an attempt is made to access unused DPM address space or a write-protected register.

DPM Events

The DPM event interrupt is triggered when any bit in the DPM_STAT register is set, indicating that an enabled wake-up was asserted. The DPM event interrupt stays active until the user clears any bits that are set in the DPM_STAT register.

DPM Errors

The DPM generates a bus error when a read or write transaction is attempted to an unused address within the DPM address range. It also generates a bus error when a misaligned access is made to a DPM register. In addition to the bus error, the DPM sets the DPM_STAT.ADDRERR bit.

If a write to a write-protected DPM register is attempted, the DPM generates a bus error. In addition, the DPM sets the DPM_STAT.LWERR bit.

DPM Programming Model

The ***DPM_PER_DIS0 Register Mapping*** and ***DPM_PER_DIS1Register Mapping*** tables show the module clocks and the corresponding peripheral. The DPM_PER_DIS0 and DPM_PER_DIS1 registers are used to shut off the clock to each peripheral if it is not required by the application.

Table 4-2: DPM0_PER_DIS0 Register Mapping

Peripheral Name	Gated Module Clocks	Type of sync on PER-DIS bit	Effect latency (In cycles of module clocks)	DPM0_PER_DISn bit
FIR0/FFT	cclk	Not Required	1	0
IIR0	cclk	Not Required	1	1
DAI0	sclk0 sclk1 sysclk	Single Flop Single Flop Not Required	2 2 1	5
DAI1	sclk0 sclk1 sysclk	Single Flop Single Flop Not Required	2 2 1	6

3:0 (R/NW)	CURMODE	Current Mode. The `DPM_STAT.CURMODE` bit field indicates the current mode of the module.	
		0	Reserved
		1	Full-On
		2	Reserved
		3	Reserved
		4-15	Reserved

5 Reset Control Unit (RCU)

Reset is the initial state of the processor at power-on or the run-time state of any core, as controlled by another core in the device using the RCU or as a result of a hardware or software triggered event. In this state, all control registers are set to their default values and functional units are idle. Exiting a full system hardware reset results with only the host core being released from reset and ready to boot (Core 0 on the devices ADSP-SC5x, Core 1 on the ADSP-215xx devices).

The following table shows the cores that are released from reset. Exiting a Core n only reset starts with this Core n being ready to execute the code from the software vector registers (RCU_SVECT0 , RCU_SVECT2).

Additional information on reset and booting can be found in the *Boot ROM and Booting the Processor* chapter.

Product	Core Released from Reset by RCU
ADSP-SC59x	Core 0
ADSP-2159x	Core 1

The Reset Control Unit (RCU) controls how all the functional units enter and exit reset. Differences in functional requirements and clocking constraints define how reset signals are generated. Programs must guarantee that none of the reset functions puts the system into an undefined state or causes resources to stall. This functionality is important when only one of the cores is reset (programs must ensure that there is no pending system activity involving the core that is being reset). While core resets and software system resets are controlled directly in the RCU, hardware resets can come from the TRU, SEC, or CGU Oscillator Watchdog.

RCU Features

The RCU module supports the following features:

- Hardware reset through the $\overline{\text{SYS_HWRST}}$ pin
- Software system reset through the RCU control (RCU_CTL) register
- Hardware system reset through:
  - TRU module
  - SEC module (System Fault Unit)

- A clock not good reset state (safe state of chip under reset) from the Oscillator Watchdog.
- Core reset through RCU Core Reset Output (RCU_CRCTL) register

RCU Functional Description

This section provides information on the function of RCU module.

ADSP-SC59x RCU Register List

The Reset Control Unit (RCU) controls how all the functional units in the processor enter and exit Reset. Differences in functional requirements and clocking constraints exist (units in different clock domains have to enter reset asynchronously, but units exit reset in a deterministic way), and these differences define how reset signals are generated. Reset signals propagate through all functional units asynchronously. For more information on RCU functionality, see the RCU register descriptions.

Table 5-1: ADSP-SC59x RCU Register List

Name	Description
RCU_BCODE	Boot Code Register
RCU_CRCTL	Core Reset Outputs Control Register
RCU_CRSTAT	Core Reset Outputs Status Register
RCU_CTL	Control Register
RCU_MSG	Message Register
RCU_MSG_CLR	Message Clear Bits Register
RCU_MSG_SET	Message Set Bits Register
RCU_SIDIS	System Interface Disable Register
RCU_SISTAT	System Interface Status Register
RCU_SRRQSTAT	System Reset Request Status Register
RCU_STAT	Status Register
RCU_SVECT0	Software Vector Register 0
RCU_SVECT1	Software Vector Register 1
RCU_SVECT2	Software Vector Register 2
RCU_SVECT_LCK	SVECT Lock Register

ADSP-SC59x RCU Trigger List

Table 5-2: ADSP-SC59x RCU Trigger List Generators

Trigger ID	Name	Description	Sensitivity
None			

Table 5-3: ADSP-SC59x RCU Trigger List Receivers

Trigger ID	Name	Description	Sensitivity
50	RCU0_SYSRST0	RCU0 System Reset Slave 0	Pulse
51	RCU0_SYSRST1	RCU0 System Reset Slave 1	Pulse

RCU Definitions

To make the best use of the RCU, it is useful to understand the terms in this section.

The target or source defines the following are types of resets.

Hardware Reset (by target)

All functional units except a small subsection of debug interfaces are set to their default states. State is lost in all non-volatile storage.

System Reset (by target)

All functional units except the RCU, flash interface, and debug are set to their default states.

Core n Only Reset (by target)

Affects Core n only. The system software must guarantee that a bus requester cannot access the core in reset state.

Hardware Reset (by source)

The $\overline{\text{SYS_HWRST}}$ input signal is asserted active (pulled low).

System Reset (by source)

Software can trigger the reset by writing to the RCU_CTL register or by another functional unit such as the TRU or any of the generic reset inputs.

RCU Architectural Concepts

To understand the architecture of the RCU, it is important to consider the reset sources and how differing resets affect the functional units of the processor.

The RCU provides the hardware that controls how all the functional units enter and exit reset. Differences in functional requirements and clocking constraints define how reset signals are generated. For example, units in different clock domains must enter reset asynchronously but exit reset in a deterministic way.

The ***RCU Reset Sources*** table defines how reset sources affect the different functional units.

Table 5-4: RCU Reset Sources

Reset Source	Reset Type	Affected Functional Units
SYSCLK clock domain system reset by the Fault Unit (FMU) or	System Reset	All functional units, except: • RTC (if present) • RCU_STAT • RCU_BCODE • the units on the VDDEXT power domain
RCU_CTL.SYSRST bit set (software triggered reset)	System Reset	All functional units, except: • RTC (if present) • RCU_STAT • RCU_BCODE • the units on the VDDEXT power domain
RCU_CRCTL.CR[n] bit set (software triggered reset)	Core Only Reset	Core n only

RCU Status and Error Signals

The RCU_STAT register reflects status and error information. There are three kinds of errors that can occur in the RCU. The reset out error is triggered when RSTOUT is both asserted and deasserted at the same time. The lock write error occurs if an attempt is made to write a lock RCU register. The address error occurs if a read-only register is written to or if an attempt is made to a reserved address within the RCU MMR address range.

Resetting the Arm Core through Another Core/System Requester

The RCU allows reset of a given core n using another core or system requester. Core 0 can be individually reset by software, either setting any of CR0 bit in the RCU_CRCTL register. Cores that reset themselves cannot guarantee that all the system transactions to or from it have completed. Although a core n reset can be triggered by core n itself, it is recommended that another core or system requester trigger it. Core n can be reset to restore its functionality when it cannot execute software.

The following steps show the suggested programming sequence to reset core n only.

1. Clear the RCU_CRSTAT.CR[n] bit.
2. Disable interrupts to core n.
3. Set the RCU_CRCTL.CR[n] bit to reset core n.
4. Poll the RCU_CRSTAT.CR[n] bit until core n is in reset.
5. Clear the RCU_CRCTL.CR[n] bit to take core n out of reset.

6. Poll the RCU_CRSTAT.CR[n] bit until core n is out of reset.

Resetting a SHARC+ Core Through Another Core

Resetting a SHARC+ core involves a software handshake between the requester core which issues a reset to the SHARC+ core. The handshake is done using a core interrupt along with message passing through a variable in shared L2 memory RAM. Each SHARC+ core needs two bits for handshaking.

- Core Reset Request bit (CRR). This bit is set by the requesting core to indicate to the SHARC+ core that a core reset needs to be done. When the CRR bit is set the SHARC+ core should disable all interrupts, stop all system and memory accesses, and enter the IDLE state.
- IDLE acknowledgement (IDLE). Once the SHARC+ core is ready for reset, it sets this bit before entering the IDLE state to inform the requesting core that it is ready for reset.

Two bits are needed for SHARC0 core, and two bits are needed for SHARC1 core. These bits are:

- CCR0–SHARC0 core reset request bit in shared variable
- IDLE0–SHARC0 IDLE acknowledgement bit in shared variable
- CCR1–SHARC1 core reset request bit in shared variable
- IDLE1–SHARC1 IDLE acknowledgement bit in shared variable

Use the following programming to reset the SHARC+ core.

1. The requesting core checks the IDLE status bits in shared variable for the corresponding SHARC+ core (RCU_MSG.C1IDLE and RCU_MSG.C0IDLE).
2. When one of the core idle bits is set, then the program jumps to step 10. Otherwise the process continues to step 3.
3. The requesting core sets the CCRx bit in message register and raises the SOFT0 software interrupt through the SEC to the SHARC+ core (see Programming Examples for more information).
4. The SHARC+ core goes to into the ISR and checks the “CCRx” status bit in RCU_MSG register to ensure that software interrupt is for a core reset.

   ADDITIONAL INFORMATION: The SOFT0 software interrupt handler can be used for other non-reset/ general purposes as well.

   ADDITIONAL INFORMATION: The ISR should be in L1 memory.
5. The core should disable all interrupts before entering IDLE for reset.
6. The core sets the appropriate idle status bit (RCU_MSG.C1IDLE and RCU_MSG.C0IDLE).
7. Core enters IDLE.

8. The requester polls for the IDLEx status bit
9. The requester keeps a timeout option where if within N number of cycles the SHARC core doesn't respond then a system reset is initiated.

   ADDITIONAL INFORMATION: N can be decided by the user depending on timing criticality of the application.
10. Once the IDLEx status bit is found set, the requesting core initiates a core reset though the RCU.
11. Clear the `RCU_CRSTAT.CR[n]` bit.
12. Set the `RCU_SIDIS.SI[n]` bit to disable the interfaces for core n, to stop DMA accesses to its L1, to stop accesses to memory for core n, and stop accesses to MMRs.
13. Test the `RCU_SISTAT.SI[n]` bit to detect when accesses to core n have been disabled and all the pending transactions have completed.
14. Set the `RCU_CRCTL.CR[n]` bit to reset core n.
15. Poll the `RCU_CRSTAT.CR[n]` bit until core n is in reset.
16. Once the core is in reset, clear the `RCU_SIDIS.SI[n]` bit to re-enable the core interfaces.
17. Clear the `RCU_CRCTL.CR[n]` bit to take core n out of reset.
18. Poll the `RCU_CRSTAT.CR[n]` bit until core n is out of reset.

When a core is servicing a higher priority interrupt and gets stuck, it may not respond to the SEC.

ADSP-SC59x RCU Register Descriptions

Reset Control Unit (RCU) contains the following registers.

Table 5-5: ADSP-SC59x RCU Register List

Name	Description
RCU_BCODE	Boot Code Register
RCU_CRCTL	Core Reset Outputs Control Register
RCU_CRSTAT	Core Reset Outputs Status Register
RCU_CTL	Control Register
RCU_MSG	Message Register
RCU_MSG_CLR	Message Clear Bits Register
RCU_MSG_SET	Message Set Bits Register
RCU_SIDIS	System Interface Disable Register
RCU_SISTAT	System Interface Status Register

Table 5-5: ADSP-SC59x RCU Register List (Continued)

Name	Description
RCU_SRRQSTAT	System Reset Request Status Register
RCU_STAT	Status Register
RCU_SVECT0	Software Vector Register 0
RCU_SVECT1	Software Vector Register 1
RCU_SVECT2	Software Vector Register 2
RCU_SVECT_LCK	SVECT Lock Register

Boot Code Register

The RCU_BCODE register can be used to determine if and how core boots. This register is set to its default values by RESET.

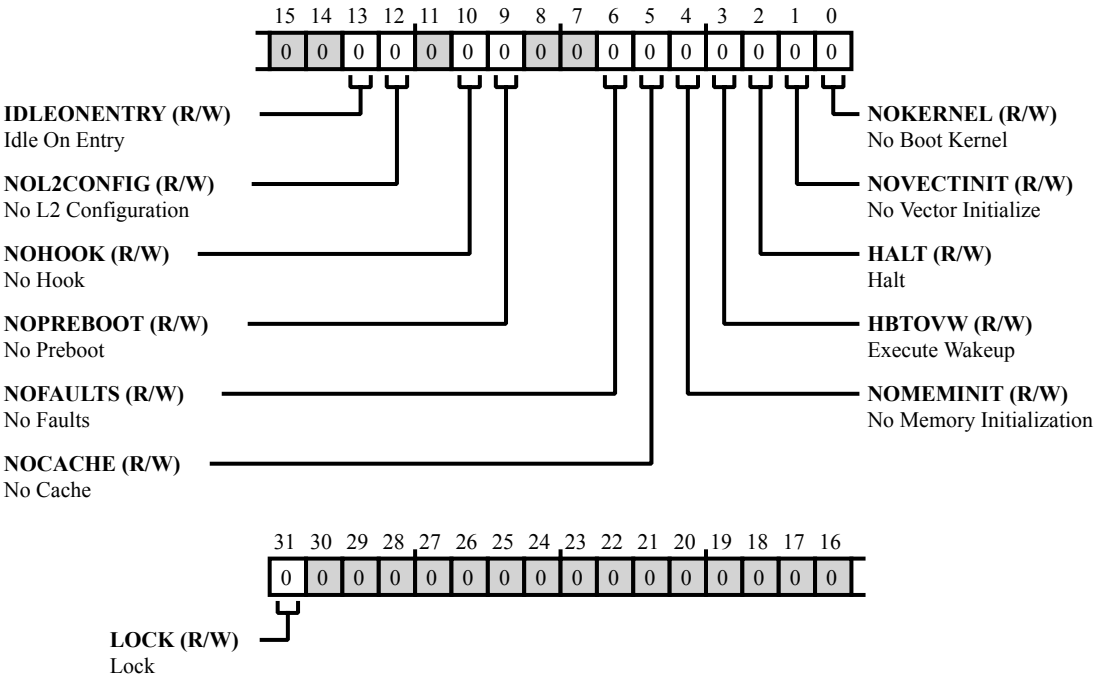

Figure 5-1: RCU_BCODE Register Diagram

Table 5-6: RCU_BCODE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock bit is set (SPU_CTL.GLCK bit =1) and the RCU_BCODE.LOCK bit is set, the RCU_BCODE register is read only (locked).	
		0	Unlock
		1	Lock
13 (R/W)	IDLEONENTRY	Idle On Entry. The RCU_BCODE.IDLEONENTRY bit configures the RCU to enter the idle state at startup.	
		0	Do not enter idle state
		1	Enter idle state

Table 5-6: RCU_BCODE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W)	NOL2CONFIG	No L2 Configuration. The `RCU_BCODE.NOL2CONFIG` bit configures the RCU to not perform the L2 memory configuration.	
		0	Configure L2 memory
		1	Do not configure L2 memory
10 (R/W)	NOHOOK	No Hook. The `RCU_BCODE.NOHOOK` bit configures the RCU to not perform the hook routine.	
		0	Perform hook routine
		1	Do not perform hook routine
9 (R/W)	NOPREBOOT	No Preboot. The `RCU_BCODE.NOPREBOOT` bit configures the RCU to not perform the customer preboot routine.	
		0	Perform preboot
		1	Do not perform preboot
6 (R/W)	NOFAULTS	No Faults. The `RCU_BCODE.NOFAULTS` bit configures the RCU to not perform fault initialization.	
		0	Perform fault initialization
		1	Do not perform fault initialization
5 (R/W)	NOCACHE	No Cache. The `RCU_BCODE.NOCACHE` bit configures the RCU to not perform a cache initialization and to not enable the cache.	
		0	Enable and initialize cache
		1	Do not initialize or enable cache
4 (R/W)	NOMEMINIT	No Memory Initialization. The `RCU_BCODE.NOMEMINIT` bit configures the RCU to not perform a memory initialization.	
		0	Perform memory initialization
		1	Do not perform memory initialization

Table 5-6: RCU_BCODE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	HBTOVW	Execute Wakeup. The `RCU_BCODE.HBTOVW` bit configures the RCU to execute a wakeup.	
		0	Do not wakeup
		1	Execute wakeup
2 (R/W)	HALT	Halt. The `RCU_BCODE.HALT` bit configures the RCU to execute the no boot routine.	
		0	Do not execute routine
		1	Execute routine
1 (R/W)	NOVECTINIT	No Vector Initialize. The `RCU_BCODE.NOVECTINIT` bit configures the RCU to not vector to the application.	
		0	Vector
		1	Do not vector
0 (R/W)	NOKERNEL	No Boot Kernel. The `RCU_BCODE.NOKERNEL` bit configures the RCU to not execute the boot kernel.	
		0	Execute boot kernel
		1	Do not execute boot kernel

Core Reset Outputs Control Register

The RCU core reset control n registers (RCU_CRCTL) include a lock bit (RCU_CRCTL.LOCK) and a core reset bit (RCU_CRCTL.CR[n]) for each core reset signal on the product.

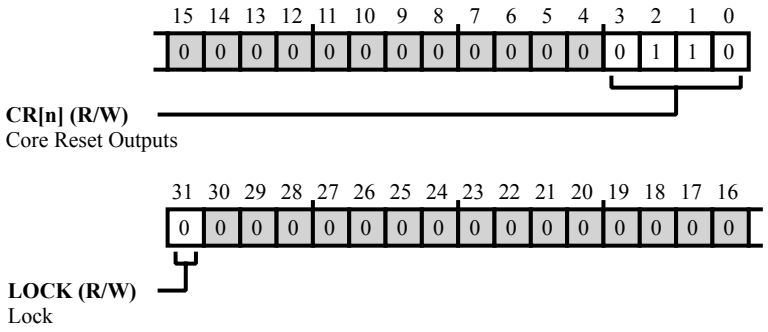

Figure 5-2: RCU_CRCTL Register Diagram

Table 5-7: RCU_CRCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock bit is set (SPU_CTL.GLCK bit =1) and the RCU_CRCTL.LOCK bit is set, the RCU_CRCTL register is read only (locked).	
		0	Unlock
		1	Lock
3:0 (R/W)	CR[n]	Core Reset Outputs. The RCU_CRCTL.CR[n] bits control CRES[1:0] core reset signals. The RCU_CRES[n] signals can be individually controlled. They are reset to their default value by a hard reset or a system reset. For each RCU_CRES[n], the selected RCU0_CRMSKi[n] bit is cleared.	
		0	RCU_CRES[3:0] Deasserted
		1	Reserved
		2	RCU_CRES[1] SHARC0 reset control bit asserted
		4	RCU_CRES[2] SHARC1 reset control bit asserted
		8	RCU_CRES[3] DEBUG reset control bit asserted
		15	RCU_CRES[3:0] Asserted

Core Reset Outputs Status Register

The RCU core reset status register (RCU_CRSTAT) contains status bits, indicating which core reset signals have been asserted.

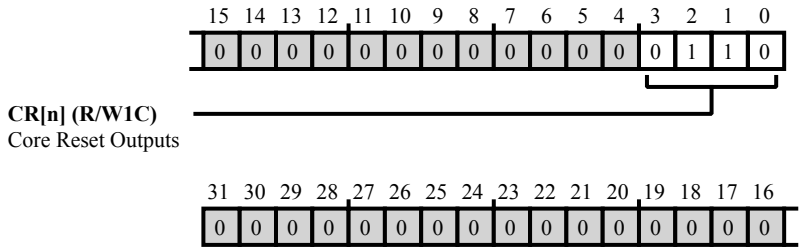

Figure 5-3: RCU_CRSTAT Register Diagram

Table 5-8: RCU_CRSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
3:0 (R/W1C)	CR[n]	Core Reset Outputs. The RCU_CRSTAT.CR[n] bits indicate which cores have been reset since the last time the bit was cleared. Bits masked by CORE_DISABLE_MASK[15:0] are permanently disabled and the corresponding CR bits set. CR bits are sticky, they need to be cleared by software.	
		0	RCU_CRES[1:0] deasserted. CR[n] corresponds to RCU_CRES[n].
		1	RCU_CRES[0] ARM A5 reset control bit asserted
		2	RCU_CRES[1] SHARC0 reset control bit asserted
		4	RCU_CRES[2] SHARC1 reset control bit asserted
		8	RCU_CRES[3] DEBUG reset control bit asserted
		15	RCU_CRES[3:0] were asserted since the last time bits were cleared. CR[n] corresponds to RCU_CRES[n].

Control Register

The RCU control register (RCU_CTL) provides a register lock, enables for the core and system reset requests inputs and control for the Reset Output pin.

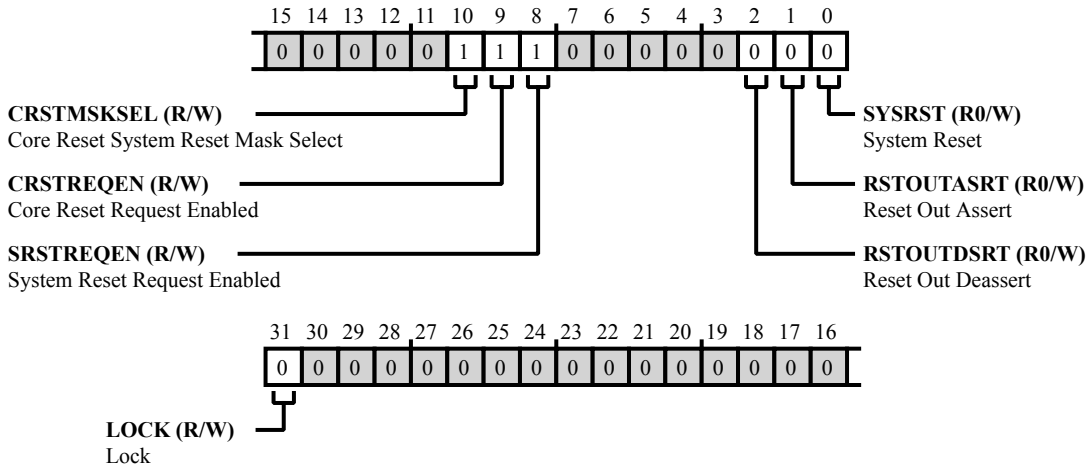

Figure 5-4: RCU_CTL Register Diagram

Table 5-9: RCU_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock bit is set (SPU_CTL.GLCK bit =1) and the RCU_CTL.LOCK bit is set, the RCU_CTL register is read only (locked). This bit is cleared by a hard reset or any system reset event.	
		0	Unlock
		1	Lock
10 (R/W)	CRSTMSKSEL	Core Reset System Reset Mask Select. The RCU_CTL.CRSTMSKSEL bit selects the core reset system reset mask. This bit is cleared by a hard reset.	
9 (R/W)	CRSTREQEN	Core Reset Request Enabled. The RCU_CTL.CRSTREQEN bit controls whether the SYSCLK domain source(s) of reset is/are enabled to reset the core(s) when asserted. This bit is cleared by hard reset or any system reset event.	
		0	Disabled
		1	Enabled

Table 5-9: RCU_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W)	SRSTREQEN	System Reset Request Enabled. The RCU_CTL.SRSTREQEN bit controls whether the SYSCLK domain sources of reset are enabled to do a system reset when asserted. This bit is cleared by a hard reset.	
		0	Disabled
		1	Enabled
2 (R0/W)	RSTOUTDSRT	Reset Out Deassert. The RCU_CTL.RSTOUTDSRT bit controls the deassertion of the system reset pin.	
		0	No Action
		1	Deassert RSTOUT
1 (R0/W)	RSTOUTASRT	Reset Out Assert. The RCU_CTL.RSTOUTASRT bit controls assertion of the system reset pin.	
		0	No Action
		1	Assert RSTOUT
0 (R0/W)	SYSRST	System Reset. The RCU_CTL.SYSRST bit provides reset for all system units.	
		0	No Action
		1	System Reset

Message Register

The RCU_MSG is a general-purpose register. It is intended to provide flexibility for Boot ROM code and to pass predefined variables to the debugger. Please see the Booting chapter for product-specific details.

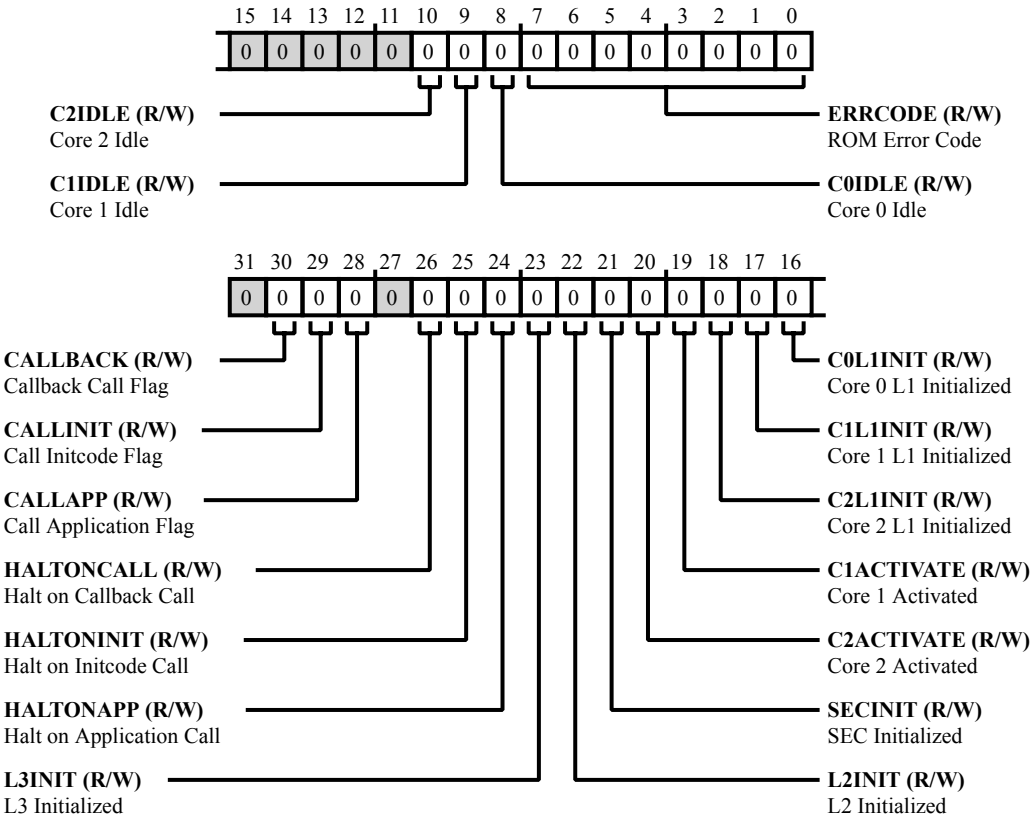

Figure 5-5: RCU_MSG Register Diagram

Table 5-10: RCU_MSG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
30 (R/W)	CALLBACK	Callback Call Flag. The RCU_MSG.CALLBACK bit indicates that a flag has been set by the boot code prior to a callback call.	
		0	Flag not set
		1	Flag set

Table 5-10: RCU_MSG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
29 (R/W)	CALLINIT	Call Initcode Flag. The RCU_MSG.CALLINIT bit indicates that a flag has been set by the boot code prior to an initcode call.	
		0	Flag not set
		1	Flag set
28 (R/W)	CALLAPP	Call Application Flag. The RCU_MSG.CALLAPP bit indicates that a flag has been set by the boot code prior to an application call.	
		0	Flag not set
		1	Flag set
26 (R/W)	HALTONCALL	Halt on Callback Call. The RCU_MSG.HALTONCALL bit generates an emulation exception prior to a callback call.	
		0	Do not generate exception
		1	Generate exception
25 (R/W)	HALTONINIT	Halt on Initcode Call. The RCU_MSG.HALTONINIT bit generates an emulation exception prior to an initcode call.	
		0	Do not generate exception
		1	Generate exception
24 (R/W)	HALTONAPP	Halt on Application Call. The RCU_MSG.HALTONAPP bit generates an emulation exception prior to an application call.	
		0	Do not generate exception
		1	Generate exception
23 (R/W)	L3INIT	L3 Initialized. The RCU_MSG.L3INIT bit indicates that the L3 resource is initialized.	
		0	Resource not initialized
		1	Resource initialized
22 (R/W)	L2INIT	L2 Initialized. The RCU_MSG.L2INIT bit indicates that the L2 resource is initialized.	
		0	Resource not initialized
		1	Resource initialized

Table 5-10: RCU_MSG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
21 (R/W)	SECINIT	SEC Initialized. The RCU_MSG.SECINIT bit is used by tools for initialization of the SEC.	
20 (R/W)	C2ACTIVATE	Core 2 Activated. The RCU_MSG.C2ACTIVATE bit is used by tools for activation of Core 2.	
19 (R/W)	C1ACTIVATE	Core 1 Activated. The RCU_MSG.C1ACTIVATE bit is used by tools for activation of Core 1.	
18 (R/W)	C2L1INIT	Core 2 L1 Initialized. The RCU_MSG.C2L1INIT bit indicates that the core 2 L1 resource is initialized.	
17 (R/W)	C1L1INIT	Core 1 L1 Initialized. The RCU_MSG.C1L1INIT bit indicates that the core 1 L1 resource is initialized.	
		0	Resource not initialized
		1	Resource initialized
16 (R/W)	C0L1INIT	Core 0 L1 Initialized. The RCU_MSG.C0L1INIT bit indicates that the core 0 L1 resource is initialized.	
		0	Resource not initialized
		1	Resource initialized
10 (R/W)	C2IDLE	Core 2 Idle. The RCU_MSG.C2IDLE bit indicates that core 2 is in a safe idle state in ROM.	
9 (R/W)	C1IDLE	Core 1 Idle. The RCU_MSG.C1IDLE bit indicates that core 1 is in a safe idle state in ROM.	
8 (R/W)	C0IDLE	Core 0 Idle. The RCU_MSG.C0IDLE bit indicates that core 0 is in a safe idle state in ROM.	
7:0 (R/W)	ERRCODE	ROM Error Code. The RCU_MSG.ERRCODE bit indicates the error code of the ROM. It is valid only when in the error handler.	

Message Clear Bits Register

The RCU_MSG_CLR register is used to clear bits in RCU_MSG register. Reading this register returns 0x00000000.

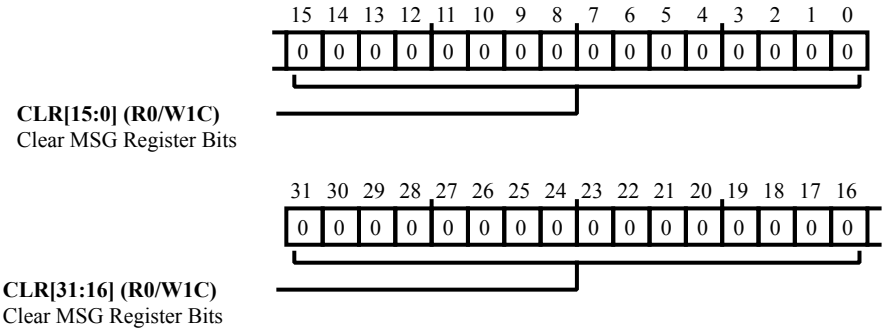

Figure 5-6: RCU_MSG_CLR Register Diagram

Table 5-11: RCU_MSG_CLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R0/W1C)	CLR	Clear MSG Register Bits. The RCU_MSG_CLR.CLR bit resets MSG bit n.

Message Set Bits Register

The RCU_MSG_SET register is used to set bits in RCU_MSG register. Reading this register returns 0x00000000.

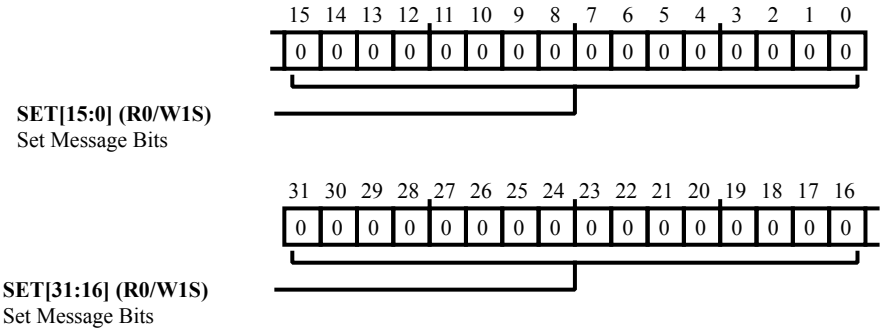

Figure 5-7: RCU_MSG_SET Register Diagram

Table 5-12: RCU_MSG_SET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R0/W1S)	SET	Set Message Bits. The RCU_MSG_SET.SET bit sets MSG bit n.

System Interface Disable Register

The RCU system interface disable register (RCU_SIDIS) lets the RCU assert a system interface disable request to functional units in the processor. This register is set to its default values by a hard reset or any system reset event. For information on mapping between RCU_SIDIS bits and functional units, see the RCU functional description.

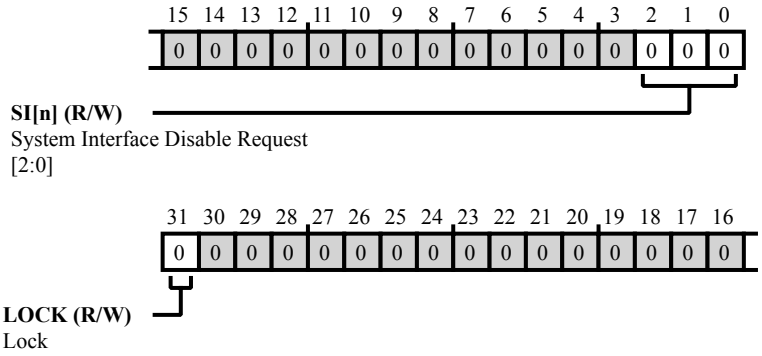

Figure 5-8: RCU_SIDIS Register Diagram

Table 5-13: RCU_SIDIS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock bit is set (SPU_CTL.GLCK bit =1) and the RCU_SIDIS.LOCK bit is set, the RCU_SIDIS register is read only (locked).	
		0	Unlock
		1	Lock
2:0 (R/W)	SI[n]	System Interface Disable Request [2:0]. Each RCU_SIDIS.SI[n] bit corresponds to a functional unit in the processor that supports the system interface disable request-acknowledge protocol.	
		0	RCU_SI_DISABLE_REQ[2:0] deasserted
		1	RCU_SI_DISABLE_REQ[0] system interface disable request to M33 asserted
		2	RCU_SI_DISABLE_REQ[1] system interface disable request to SHARC1 asserted
		4	Reserved
		7	RCU_SI_DISABLE_REQ[2:0] asserted

System Interface Status Register

The RCU system interface status register (RCU_SISTAT) indicates whether a functional unit has or has not acknowledged an RCU unit disable request.

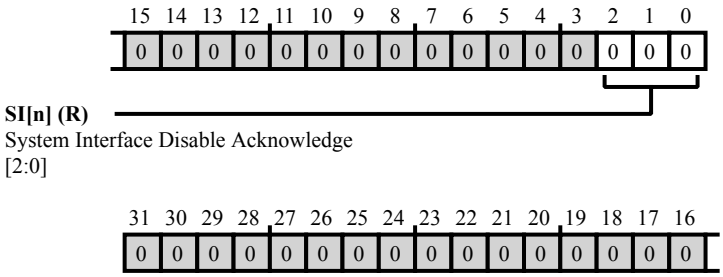

Figure 5-9: RCU_SISTAT Register Diagram

Table 5-14: RCU_SISTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
2:0 (R/NW)	SI[n]	System Interface Disable Acknowledge [2:0]. The RCU_SISTAT.SI[n] bit indicates whether a functional unit has or has not acknowledged an RCU unit disable request.	
		0	No Acknowledge
		1	RCU_SI_DISABLE_ACK[0] system interface disable acknowledge from SHARC0 asserted
		2	RCU_SI_DISABLE_ACK[1] system interface disable acknowledge from SHARC1 asserted
		4	Reserved
		7	SI_DISABLE_ACK[2:0] asserted

System Reset Request Status Register

The RCU system reset request status register (RCU_SRRQSTAT) contains status bits, indicating which system reset request input triggered a system reset. This register is set to its default values by a hard reset.

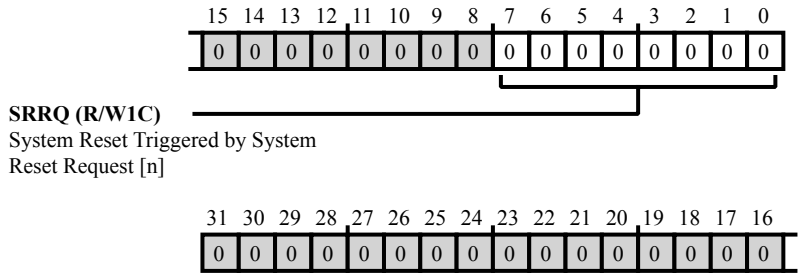

Figure 5-10: RCU_SRRQSTAT Register Diagram

Table 5-15: RCU_SRRQSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
7:0 (R/W1C)	SRRQ	System Reset Triggered by System Reset Request [n]. The RCU_SRRQSTAT.SRRQ bits are set by the assertion of the corresponding system reset request input and deasserted by writing "1" to the bit. The RCU_SRRQSTAT register is cleared by a hard reset.	
		1	RCU_SRRQ[0], System Reset Request from SEC asserted
		2	RCU_SRRQ[1], System Reset Request from TRGS_RCU0_SYSRST0 asserted
		4	RCU_SRRQ[2], System Reset Request from TRGS_RCU0_SYSRST1 asserted
		8	RCU_SRRQ[3], System Reset Request from CTI3 asserted

Status Register

The RCU status register (RCU_STAT) contains status bits for all RCU reset sources, reset status, and boot mode inputs. Status bits for reset sources are sticky and can cleared by software. Error status bits are cleared by any reset event.

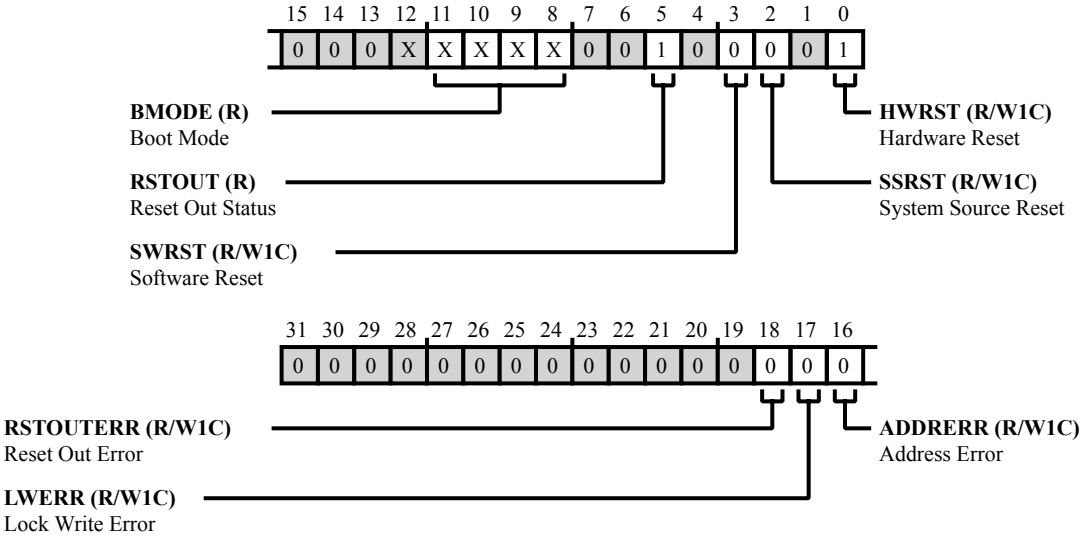

Figure 5-11: RCU_STAT Register Diagram

Table 5-16: RCU_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
18 (R/W1C)	RSTOUTERR	Reset Out Error. The RCU_STAT.RSTOUTERR bit indicates (if set) that a write attempted to set the RCU_CTL.RSTOUTASRT and RCU_CTL.RSTOUTDSRT simultaneously. This condition triggers a bus error.	
		0	No Error
		1	Error Occurred
17 (R/W1C)	LWERR	Lock Write Error. The RCU_STAT.LWERR bit indicates (when set) there was an attempted write to an RCU register while the RCU_CTL.LOCK bit was set and the global lock bit is enabled (SPU_CTL.GLCK bit =1). This status bit is sticky; write-1-to-clear	
		0	No Error
		1	Error Occurred

Table 5-16: RCU_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/W1C)	ADDRERR	Address Error. The RCU_STAT.ADDRERR bit indicates that the RCU generated an address error. This status bit is sticky; write-1-to-clear it.	
		0	No Error
		1	Error Occurred
11:8 (R/NW)	BMODE	Boot Mode. The RCU_STAT.BMODE bits indicate the input on the boot mode pins.	
5 (R/NW)	RSTOUT	Reset Out Status. The RCU_STAT.RSTOUT bit indicates the assertion status of the system reset pin.	
		0	RSTOUT Deasserted
		1	RSTOUT Asserted
3 (R/W1C)	SWRST	Software Reset. The RCU_STAT.SWRST bit indicates that a system reset (which was triggered by software) has occurred since the last time a hardware reset occurred or since the RCU_STAT.SWRST bit was cleared by software.	
		0	Inactive
		1	Reset Occurred
2 (R/W1C)	SSRST	System Source Reset. The RCU_STAT.SSRST bit indicates that a system reset triggered by hardware in the system clock domain, clock A domain, or clock B domain has occurred since the last time a hardware reset occurred or since the RCU_STAT.SSRST bit was cleared by software.	
		0	Inactive
		1	Reset Occurred
0 (R/W1C)	HWRST	Hardware Reset. The RCU_STAT.HWRST bit indicates that a hardware reset has occurred.	
		0	Inactive
		1	Reset Occurred

Software Vector Register 0

The RCU_SVECT0 register contains the default location of the first instruction to execute after a reset.

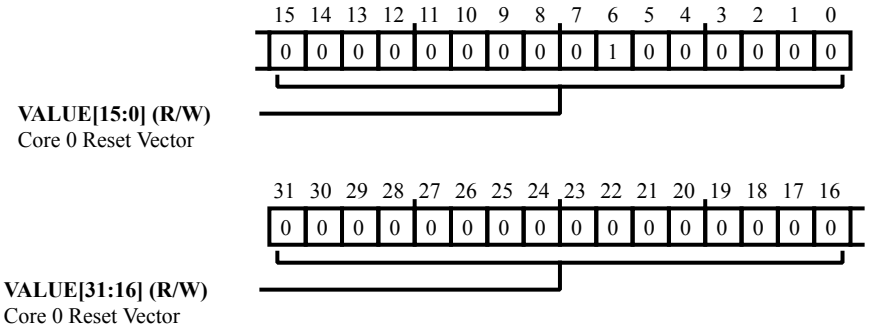

Figure 5-12: RCU_SVECT0 Register Diagram

Table 5-17: RCU_SVECT0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Core 0 Reset Vector. Core0 jumps to the address in the RCU_SVECT0.VALUE bit field after reset.

Software Vector Register 1

The RCU_SVECT1 register contains the default location of the first instruction to execute after a reset.

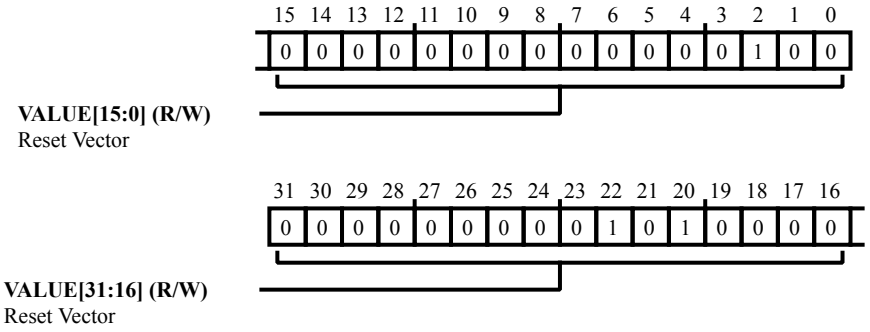

Figure 5-13: RCU_SVECT1 Register Diagram

Table 5-18: RCU_SVECT1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Reset Vector. Core1 jumps to the address in the RCU_SVECT1.VALUE bit field after reset.

Software Vector Register 2

The RCU_SVECT2 register contains the default location of the first instruction to execute after a reset.

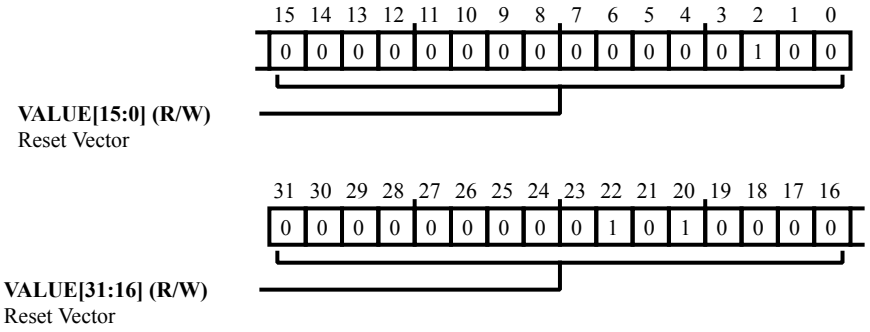

Figure 5-14: RCU_SVECT2 Register Diagram

Table 5-19: RCU_SVECT2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Reset Vector. Core2 jumps to the address in the RCU_SVECT2.VALUE bit field after reset.

SVECT Lock Register

The RCU software vector lock register (RCU_SVECT_LCK) provides a register lock and software vector n enable bits for each processor core on the product. This register is set to its default values by a hard reset or any system reset event.

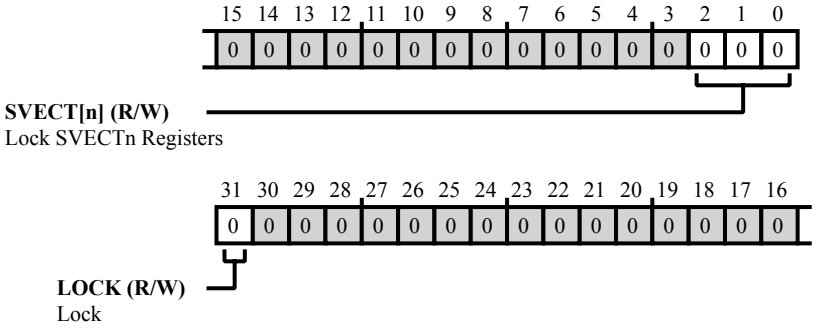

Figure 5-15: RCU_SVECT_LCK Register Diagram

Table 5-20: RCU_SVECT_LCK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock bit is set (SPU_CTL.GLCK bit =1) and the RCU_SVECT_LCK.LOCK bit is set, the RCU_SVECT_LCK register is read only (locked).	
		0	Unlock
		1	Lock
2:0 (R/W)	SVECT[n]	Lock SVECTn Registers. If the global lock bit is set (SPU_CTL.GLCK bit =1) and the RCU_SVECT_LCK.SVECT[n] bit is set, the SVECT registers are read only (locked).	

6 System Event Controller (SEC) and Generic Interrupt Controller (GIC)

There are two interrupt controllers—a generic interrupt controller (GIC) for the Arm core and the system event controller (SEC) for the SHARC cores.

System event management is the responsibility of the system event controller (SEC). The SEC manages the configuration of all system event sources. The SEC also manages the propagation of system events to all connected cores and the system fault interface.

All the peripheral interrupts are routed using a single SEC interrupt to the desired core. The SEC allows programmability of the peripheral interrupt's priority, supporting up to 256 priority levels that are arbitrated within the SEC itself. The SEC also allows these interrupts to be grouped and masked by priority level and provides the flexibility to choose which core(s) the interrupt is routed to.

The SEC also supports self-nesting of interrupts, which is required when sharing a single interrupt request to an individual core, as this allows for a higher-priority peripheral interrupt to be passed to the core while it is currently servicing a lower-priority peripheral interrupt. For more information, refer to "Self-Nesting Mode for System Event Controller Interrupt (SECI)" in the *SHARC+ Core Programming Reference*.

For more information about the Arm GIC, visit the Arm Information Center.

SEC Features

The following list describes the system event controller features.

- Comprehensive system event source management including interrupt enable, fault enable, priority, core mapping, and source grouping.
- Fault management including fault action configuration, timeout, external indication, and system reset.
- Determinism where all system events have the same propagation delay and provide unique identification of a specific system event source.
- Distributed programming model where each system event source control and all status fields are independent of all others.

- Completer control port which provides access to all SEC registers for configuration, status, and interrupt or fault service model.
- Global locking supports a register level protection model to prevent writes to “locked” registers.

SEC Functional Description

The following sections provide a functional description of the SEC.

The *SEC/GIC Interrupt Signal Flow* figure shows an overview of the interrupt systems.

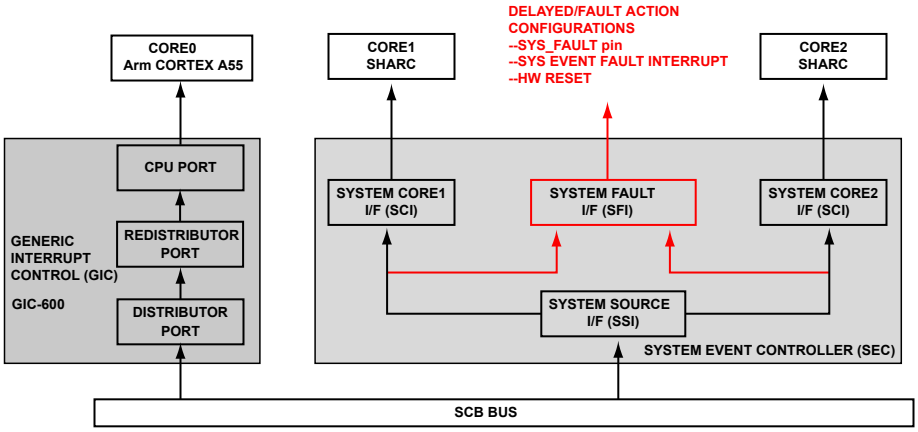

Figure 6-1: SEC/GIC Interrupt Signal Flow

ADSP-SC59x SEC Register List

The System Event Controller (SEC) manages the system fault sources, including control features such as enable/disable and active/pending source status. For more information on SEC functionality, see the SEC register descriptions.

Table 6-1: ADSP-SC59x SEC Register List

Name	Description
SEC_CACT[n]	SCI Active Register n
SEC_CCTL[n]	SCI Control Register n
SEC_CGMSK[n]	SCI Group Mask Register n
SEC_CPLVL[n]	SCI Priority Level Register n
SEC_CPMSK[n]	SCI Priority Mask Register n
SEC_CPND[n]	Core Pending Register n
SEC_CSID[n]	SCI Source ID Register n
SEC_CSTAT[n]	SCI Status Register n
SEC_END	Global End Register

SEC Definitions

The event controller uses the following definitions.

SCI

SEC core interface, core interface subblock of the SEC

SEA

SEC system event aggregator generates an aggregate request to the SEC based on the active events at a given time.

SID (Identification, unique)

Source numeric identifier for each system source connected to the SEC.

SFI

SEC Fault Interface, fault management subblock of the SEC.

SPR

SEC prioritizer determines the highest priority pending interrupt and the highest priority active interrupt. The SPR provides these interrupts in the appropriate registers of the SCI for the priority and nesting model of the SCI.

SSI

SEC source interface, system event source control, and status subblock of the SEC.

System Events

System source indications including interrupts and faults.

System Source

Point of origin of system event.

SEC System Event Aggregator (SEA)

System event sources request event service from the SEC. To reduce the number of required SSI channels in the SEC, the System Event Aggregator (SEA) acts as an intermediate aggregator between the source and the SEC. All unique system events have dedicated inputs to the SEA. The SEA generates an aggregate request to the SEC based on which events are active at a given time.

To determine the active event for a given SEC ID, read the `SEC_SSTAT[n].CHID` bit field. The *Combined SEC and GIC Interrupt List* table shows five SEAs connected to SEC ID 251-255. All the sources grouped over the SEA are error events for a set of peripherals like the FIR-IIR, SPI-UART-LP-EPPI, MDMA, SPORT, and SWU. An error event from a peripheral is only expected when that peripheral is enabled. To mask SEA events from sources, disable the source peripheral conditions. There are no registers to mask events from the SEA, but there is a provision to mask the complete group output at the SEC.

Events are handled with a fixed priority order, on a first-come, first-served basis. If multiple events corresponding to the same SEC ID are active at the same time, the priority level is order dependent with the lower SEA IDs having the higher priority. The SEA events are level-based, so they remain high until the events are cleared at the source ensuring no event is missed. There is no support for nesting in a group since they all have same the SEC ID. An SEA event must be handled completely before addressing the next event.

SEC Block Diagram

The ***SEC Block Diagram*** shows the event management architecture.

System sources connect to the SEC through the SSI. Each core has a dedicated SCI. The SFI provides fault action connections to the rest of the system.

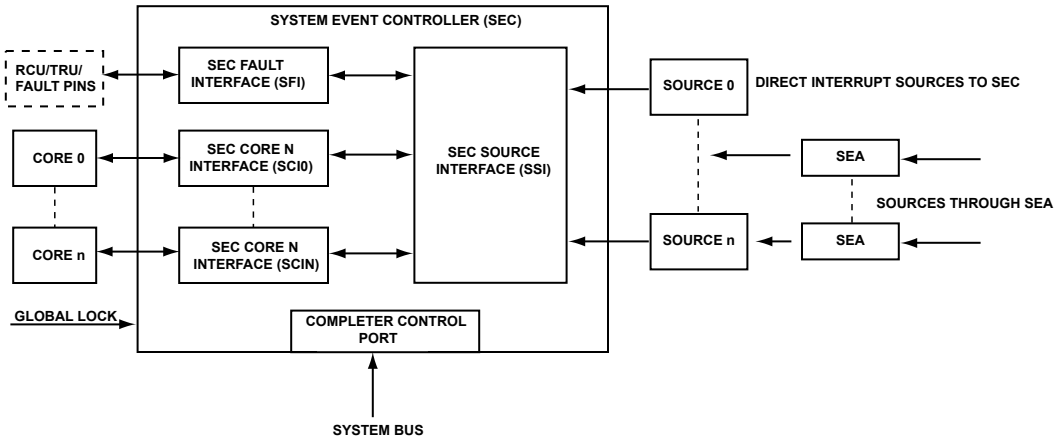

Figure 6-2: SEC Block Diagram

As shown in the figure, the SEC has three blocks for event management. The SFI monitors and manages any fault event triggered from various fault input sources. System interrupt sources are routed to the SFI through SEC source interface (SSI).

SEC Fault Interface (SFI)

The SFI manages fault events and associated actions. The fault management support provided in the SEC helps satisfy the safety requirements of various applications. The SSI provides the highest priority pending source that is enabled as a fault. The SFI captures this value and enables a countdown, and once the countdown expires, takes the prescribed action.

Fault actions which can be configured, as shown in ***SFI Block Diagram***, include

- Trigger Output
- System Reset
- Fault Output
    - Computer Operating Properly (COP) mode
    - Fault Mode

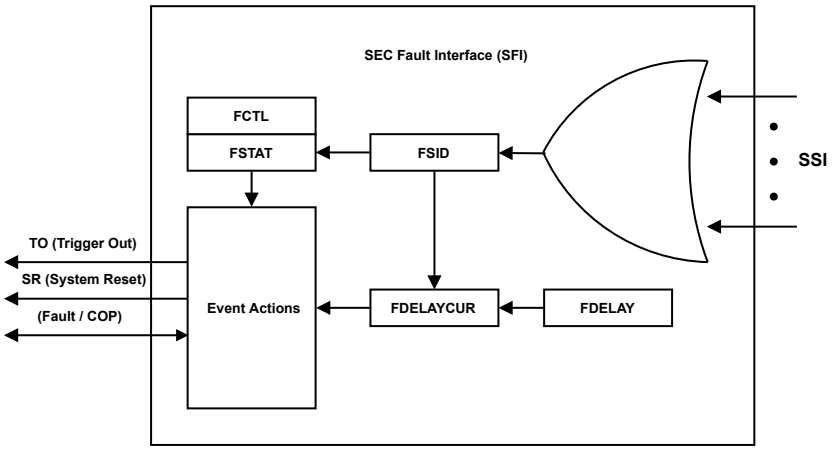

Figure 6-3: SFI Block Diagram

Fault Management

System sources can be enabled as fault sources in the SEC_SCTL[n] register. When a source enabled as a fault moves to pending, it is forwarded to the SFI as a fault indication. The pending bit (SEC_FSTAT.PND) indicates a source has signaled a fault assertion but it has not yet triggered the event actions (if delay is enabled). The SEC fault interface sets the SEC_FSTAT.PND bit when the fault source ID register (SEC_FSID) is updated on assertion of a fault source input. The system source pending triggers a fault pending and after a programmable delay the fault moves to active. Event actions then execute if appropriate action is not taken by the core. The SEC_FSTAT.ACT bit indicates that the SEC has received a fault source input, the delay has expired, and the fault actions are enabled.

The SEC_FSTAT.NPND bit indicates if one or more sources have signaled a fault assertion, but the input has not yet triggered the fault pending detection in the SEC fault interface. The SEC sets the SEC_FSTAT.NPND bit when the fault interface detects assertion of any enabled fault source input, while either the SEC_FSTAT.PND or SEC_FSTAT.ACT bits are set. The SEC clears the SEC_FSTAT.NPND bit when there are no fault sources waiting.

A fault indication from an external device can also be detected on sampling the fault signals. When a fault is detected the SEC_FSTAT.ACT and SEC_FSID.FEXT bits are set. The assertion of either signal results in a fault input detection.

The SEC_FEND register receives a fault end indication from the core. The core writes the SID of the fault to the SEC_FEND register. If the SID matches the value in the SEC_FSID register, the SEC_FSTAT.PND and SEC_FSTAT.ACT bits are cleared.

SEC Core Interface (SCI)

The SCI manages communication between the corresponding core and the SEC. The SEC prioritizer (SPR) of the SCI receives pending, active, and priority information from the SSI for each system event source assigned to this SCI. The SPR determines the highest priority pending system event and the SCI determines whether it propagates to the core. The SCI maintains the coherency for the system event service model implemented on the connected core.

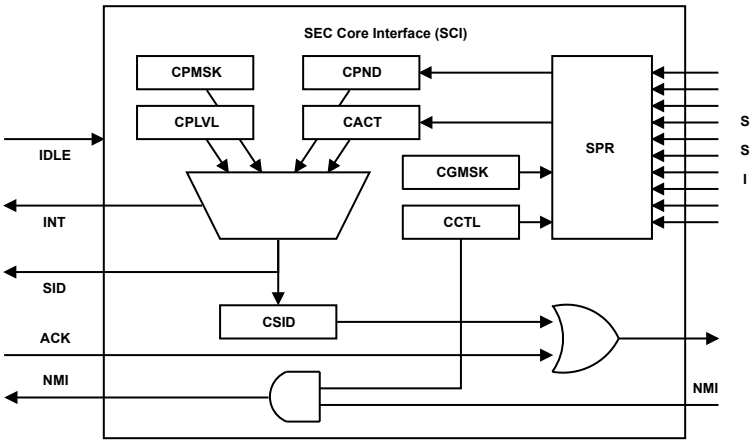

Figure 6-4: SCI Overview Block Diagram

SEC Source Interface (SSI)

The SSI manages all of the system event sources. It maintains the status of each source in the corresponding `SEC_SSTAT[n]` register. The corresponding `SEC_SCTL[n]` register manages the control of each source. A pending and enabled event passes its indication and priority to the SCI to which it is assigned for further processing.

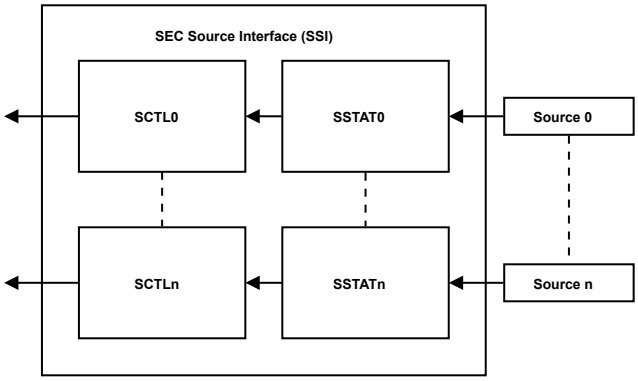

Figure 6-5: SSI Overview Block Diagram

SEC Architectural Concepts

The following sections describe SEC architectural features.

System Interrupt Acknowledge

A system interrupt acknowledge occurs when the core provides an indication that it has acquired the SID of the interrupt last issued by the SEC. The SEC core interface option allows generation by:

- A completer port write to the `SEC_CSID[n]` register.
- The assertion of an input acknowledge signal (the connected core generates the signal).

System Interrupt Groups

System sources can be assigned to groups using the SEC_SCTL[n].GRP bit field. Source groups allow fast context switching for system interrupts at each SCI. The SEC_CGMSK[n] register allows quick masking of interrupt groups of unlimited size with a single write operation.

System Interrupt Flow

An enabled and asserted system interrupt source is latched at the SSI and routed to the appropriate SCI based on the core target select (SEC_SCTL[n].CTG) bit field setting. The SEC priority ordering determines the highest priority pending system interrupt and the SCI updates the SEC_CPND[n].SID and SEC_CACT[n].PRIO bit field values. The SCI compares the SEC_CPND[n] register value against the highest priority active source in the SEC_CACT[n] register).

The priority level register (SEC_CPLVL[n]) determines how many of the MSBs the SEC uses in the comparison. The priority mask register (SEC_CPMSK[n]) and the group mask register (SEC_CGMSK[n]) determines which pending interrupt sources participate. If the SEC_CPND[n] register value is a higher priority (lower value) than the priority of the SEC_CACT[n] register from the comparison based on the SEC_CPLVL[n] register, the system interrupt output is asserted. The source ID register (SEC_CSID[n]) is updated with the SEC_CPND[n].SID bit field value and forwarded to the connected core.

After the core provides an interrupt acknowledgment, the interrupt source is active, until the SEC completes interrupt service with a write to the SEC_END.SID bit field with the same value. Note the following:

- Interrupt acknowledgement occurs with an MMR write of the SEC_CSID[n] register or the core version of the SEC_CSID[n] register.
- Interrupt active status indication is SEC_SSTAT[n].ACT==1.

The following sequence shows the example flow for a single interrupt.

1. The SEC compares the SEC_CPND[n] register value to the SEC_CACT[n] register value. If the interrupt in the SEC_CPND[n] register is higher priority, continue.
2. The SEC copies the SEC_CPND[n] register value to the SEC_CSID[n] register and asserts the interrupt signal.
3. The core reads the SEC_CSID[n] register (or core version).
4. The core writes to the SEC_CSID[n] register (or core version, asserts the acknowledge signal).
5. The SEC deasserts the interrupt signal and clears the SEC_SSTAT[n].PND bit and sets the SEC_SSTAT[n].ACT bit of the source going active.
6. The core writes the SEC_CSID[n] of the active interrupt to the SEC_END register.
7. The SEC clears the SEC_SSTAT[n].ACT bit of the source being ended.

The following sequence shows the example flow for interrupt nesting where interrupt A is a lower priority and occurs earlier than interrupt B.

1. The SEC compares the SEC_CPND[n] (A) register value to the SEC_CACT[n] register and if the interrupt in the SEC_CPND[n] register is a higher priority, continue.
2. The SEC copies SEC_CPND[n] (A) register to the SEC_CSID[n] register and asserts the interrupt signal.
3. The core reads the SEC_CSID[n] (A) register (or core version).
4. The core writes to the SEC_CSID[n] register (or core version, asserts the acknowledge signal).
5. The SEC deasserts the INT signal and clears the SEC_SSTAT[n].PND bit and sets the SEC_SSTAT[n].ACT bit of the source (A) going active.
6. The SEC compares the SEC_CPND[n] (B) register value to the SEC_CACT[n] (A) register value. If the SEC_CACT[n] (B) register value is a higher priority, continue.
7. The SEC copies the SEC_CPND[n] (B) register value to SEC_CSID[n] register and asserts the interrupt signal.
8. The core reads the SEC_CSID[n] (B) register (or core version).
9. The core writes to the SEC_CSID[n] register (or core version, asserts the acknowledge signal).
10. The SEC deasserts the INT signal and clears the SEC_SSTAT[n].PND bit and sets the SEC_SSTAT[n].ACT bit of the source (B) going active.
11. The core writes the SEC_CSID[n] of the active interrupt (B) to the SEC_END register.
12. The SEC clears the SEC_SSTAT[n].ACT bit of the source (B) being ended.
13. The core writes the SEC_CSID[n] of the active interrupt (A) to the SEC_END register.
14. The SEC clears the SEC_SSTAT[n].ACT bit of the source (A) being ended.

System Interrupt Priorities

Each system interrupt source has its own programmable priority level which is configured using the SEC_SCTL[n].PRIO bit field. The SCI evaluates the priority of all pending sources to determine the source of the highest priority pending system interrupt for forwarding to the attached core. If more than one source of the pending system interrupt has the same priority setting, the SCI chooses the one with the lowest SID. For example, if SID 0, SID 1, and SID 2 are all pending and have the same priority setting, the SCI chooses SID 0 as the highest-priority source.

SEC Error

The processor includes an SEC error (SEC_GSTAT.ERR) as a source input to the SEC to allow for handling the error as an interrupt or fault.

SEC Programming Model

Implementing a system interrupt service model using the SEC requires, at a minimum:

- Proper configuration of a system interrupt source (for example a peripheral or DMA)
- A core interrupt or event service model

The core must be configured for response to system interrupts from the SEC. The SEC must be configured to enable and map the system interrupt source to the correct SCI and to forward interrupts to the connected core.

The system interrupt source must be configured to generate interrupt assertions. Alternatively, the processor can use software triggering for interrupt assertion. Software driven interrupts are generated by writing the source ID of the interrupt to be triggered to the SEC_RAISE register.

Programming Concepts

The following list provides the basic programming concepts necessary for configuring the SEC.

- Configuring an SSI as a system interrupt for a specific core.
- Configuring an SCI to provide system interrupts to the connected core (See Configuring a System Source to Interrupt a Core).
- Configuring an SSI as a system fault (See Configuring a System Source as a Fault).
- Configuring the SFI to manage system faults.

Programming Examples

This section provides example programming tasks that are typical for SEC usage.

Fault Management Interface Programming Model

The SFI interface can be programmed to manage fault events from system sources and associated actions such as issuing a system reset when watchdog expiration event occurs.

1. Set the SEC_GCTL.EN bit to enable the SEC.
2. Write to the SEC_FCTL register to configure specific fault actions.
    - Trigger Output. Set the SEC_FCTL.TOEN bit for the SEC to produce trigger outputs when a fault becomes active. The SEC_FCTL.TES bit can be programmed to select the event that directs the SEC to assert trigger output when a fault is pending or active. Configure receivers for SEC fault trigger generator output.

      NOTE: If the SEC_FCTL.TOEN and or the SEC_FCTL.TES bits =1 (Trigger Output Enabled and Trigger on Fault Pending), an external fault (if enabled by the SEC_FCTL.FIEN bit) will not issue a trigger since Fault Pending is bypassed for external faults.
    - System Reset. The Reset Control Unit (RCU) controls how the functional units enter and exit reset. Configure the RCU_CTL.SRSTREQEN bit. This bit controls whether the sources of reset are enabled to perform a system reset. To issue a system reset request when a fault becomes active, set the SEC_FCTL.SREN bit. The SEC fault system reset delay register (SEC_FSRDLY) can be programmed for the delay, if required, from a fault becoming active to system reset request assertion.

- Fault Output. This configuration allows the SEC to indicate the fault status based on the SEC_FCTL.CMS bit configuration.
  - Computer Operating Normally (COP) mode. To configure fault output for COP mode, set the SEC_FCTL.FOEN bit to enable fault output. Set the SEC_FCTL.CMS bit to select COP mode to toggle the fault pin when no fault is active. Program the SEC_FCOPP period register with a desired width value for the COP toggled output pin.
  - Fault mode. Set the SEC_FCTL.FOEN bit to enable fault output. The SEC_FCTL.CMS bit should be set to Fault mode to toggle the fault pin when a fault is active.

3. If required, program the Fault Input to sample fault inputs from external devices on fault pins. Configure the SEC_FCTL.FIEN bit to enable the SEC to sample a fault input from an external device.

   ADDITIONAL INFORMATION: The SEC_FCTL.FIEN bit should be set only while the SEC_FCTL.EN bit is low. If the SEC_FCTL.EN bit is already high and the SEC_FCTL.FIEN bit needs to be set, the SEC_FCTL.EN bit should be cleared first. Fault input can only be enabled when Fault mode is selected by the SEC_FCTL.CMS bit.

4. Program the required fault delay to the SEC_FDLY.COUNT bit field if a delay between fault source assertion and the fault response is required.

5. Configure the SEC_FCTL register to enable the SEC.

   ADDITIONAL INFORMATION: The SEC_FCTL.EN bit should be set only while the SEC_FSTAT.ACT bit is low.

6. Write to the control register of a specific source register using the SEC_SCTL[n] register to enable the source as a fault.

Configuring a System Source to Interrupt a Core

To configure a system source to interrupt a core, the SEC itself must be enabled with the source interface (SSI) and core interface (SCI) properly initialized. Specifically, the SCI must be set up to accept interrupt signaling from the SEC and pass them to the specified core, and the SSI must properly enable each of the peripheral interrupt sources to generate interrupt signals and optionally define a priority scheme that overrides the default priority settings. In summary:

1. Write to the SEC_GCTL register to enable the SEC.
2. Write to the appropriate SCI SEC_CCTL[n] register to enable SEC interrupts to be sent to that core.
3. Write to the appropriate SSI SEC_SCTL[n] register to enable that peripheral as an interrupt source and to set the core target field to map the source to the desired SCI.
4. (Optional) By default, all the SEC interrupts are grouped as a single priority level, so passing of peripheral interrupt requests from the SEC is based solely on the default enumerated source ID. By programming the SEC_CPLVL[n].PLVL register, interrupt sources can be grouped into priority levels within the SEC such that arbitration is first performed by source ID within a grouped priority level before proceeding to the next

priority level, thus providing the flexibility to have lower-priority interrupt sources considered before higher-priority sources.

ADDITIONAL INFORMATION: The SEC_CPMSK[n] and SEC_CGMSK[n] registers must also can be programmed to mask the interrupts based on the customized levels and grouping.

Core/SEC Handshake Requirements to Ensure Proper Interrupt Handling

A specific handshake with the SEC is required to handle interrupts associated with an individual core. The handshake ensures that nested interrupts are properly tracked and that new peripheral interrupts being raised within the SEC are either passed immediately to the core or held off and queued within the SEC for later servicing.

Use the following procedure to write a custom dispatcher inside the Interrupt Service Routine. Note that the core needs to read and acknowledge the SEC_CSID[n] register by writing the same value. The core must also write to the SEC_END register after the ISR execution completes.

1. Read the SEC_CSID[n] register to obtain the source ID of the peripheral interrupt request.
2. Write the read value back to the SEC_CSID[n] register to send the acknowledge signal to the SEC that the core has accepted and begun processing the interrupt request.
3. Execute the actual ISR (typically a call to a specific handler function from a look-up table based on the peripheral source ID). Write to the SEC_GCTL register to enable the SEC.
4. Write the value of the SEC_CSID[n] register of the active interrupt (read in step 1 above) to the SEC_END register to signal to the SEC that the interrupt has now been serviced.
5. Return from interrupt.

This procedure allows a higher-priority interrupt raised by the SEC to be serviced by the core after step 2. The SEC knows what it passed to the core because of the write to the SEC_CSID[n] register. After the core acknowledges that write, the SEC knows whether newly raised peripheral interrupts are a higher priority than the highest-priority interrupt currently being processed by the core.

- When a higher priority, the SEC pushes the current SEC_CSID[n] value to an internal stack, writes the new SEC_CSID[n] value, and asserts a new SEC interrupt request.
- When a lower priority, the SEC queues the interrupt until the core writes to the SEC_END register with the source ID of the higher-priority interrupt, confirming that it was fully processed.

At this point the SEC_CSID[n] value is popped from the internal stack and any pending peripheral interrupt requests are arbitrated before the SEC writes the new SEC_CSID[n] value and asserts a new interrupt request. At the same time the core self-nests the latched SEC interrupt requests as needed. When a higher-priority interrupt is presented to the core the write to the SEC_END register in the SEC handler epilog code guarantees that each nested level has the required handshake to signal to the SEC block that each individual source ID interrupt request is fully serviced. See the *SHARC+ Core Programming Reference* for more details about SEC handler code.

Configuring a System Source as a Fault

Use the following procedure configure a system source as a fault.

1. Write to the SEC_GCTL register to enable the SEC.
2. Write to the SEC_FCTL register to configure specific fault actions.
3. Write to the SEC_FDLY bit field to specify fault delay.
4. Write to the control register of a specific source to enable the source as a fault.

Configuring the WDOG Expiry Event to Issue a System Reset

Use the following procedure to configure the WDOG timer to issue a system reset.

1. Configure the SEC_GCTL register to enable the SEC.

```
*pREG_SEC0_GCTL = BITM_SEC_GCTL_EN;
```

2. Configure the SEC_FCTL register to choose the Fault response mode. In the following code example, the system reset is issued.

```
*pREG_RCU0_CTL |= BITM_RCU_CTL_SRSTREQEN;
*pREG_SEC0_FCTL |= BITM_SEC_FCTL_SREN;
```

3. Configure the SEC_SCTL[n].SEN and SEC_SCTL[n].FEN bits in the registers to determine how the fault source is handled. To configure the WDOG as the fault source, program the register. The program can configure any interrupt as the fault source by programming the corresponding register.

```
 *pREG_SEC0_SCTL3 = BITM_SEC_SCTL_FEN|BITM_SEC_SCTL_SEN;
```

   ADDITIONAL INFORMATION: The SEC ID corresponding to WDOG0 is 3, as indicated in the Combined SEC and GIC Interrupt List .

4. Write to the enable bit.

```
*pREG_SEC0_FCTL |= BITM_SEC_FCTL_EN;
```

SEC Programming Restrictions

Setting the SEC_FCTL.EN bit while the SEC_FSTAT.ACT bit is high can result in unpredictable behavior. To avoid this issue, set the SEC_FCTL.EN bit while the SEC_FSTAT.ACT bit is low. The SEC_FSTAT.ACT bit is only set when the SEC_FCTL.EN bit is high. Therefore, the problem can only occur if the SEC_FCTL.EN bit transitions from 1 to 0 and then to 1 again.

Writing to SEC_FEND to end a fault with both the SEC_FCTL.FOEN bit and the SEC_FCTL.FIEN bit set can result in erroneous external fault detection. If this operation (ending a fault) and configuration (fault input and fault output enabled) are required by the application, clear the SEC_FCTL.FOEN bit prior to writing to SEC_FEND.

The recommended sequence for ending a fault with the SEC_FCTL.FIEN or SEC_FCTL.FOEN==1 is as follows:

1. Clear the SEC_FCTL.FOEN bit.
2. Write to the SEC_FEND register.
3. Set the SEC_FCTL.FOEN bit.

ADSP-SC59x SEC Register Descriptions

System Event Controller (SEC) contains the following registers.

Table 6-6: ADSP-SC59x SEC Register List

Name	Description
SEC_CACT[n]	SCI Active Register n
SEC_CCTL[n]	SCI Control Register n
SEC_CGMSK[n]	SCI Group Mask Register n
SEC_CPLVL[n]	SCI Priority Level Register n
SEC_CPMSK[n]	SCI Priority Mask Register n
SEC_CPND[n]	Core Pending Register n
SEC_CSID[n]	SCI Source ID Register n
SEC_CSTAT[n]	SCI Status Register n
SEC_END	Global End Register
SEC_FCOPP	Fault COP Period Register
SEC_FCOPP_CUR	Fault COP Period Current Register
SEC_FCTL	Fault Control Register
SEC_FDLY	Fault Delay Register
SEC_FDLY_CUR	Fault Delay Current Register
SEC_FEND	Fault End Register
SEC_FSID	Fault Source ID Register
SEC_FSRDLY	Fault System Reset Delay Register
SEC_FSRDLY_CUR	Fault System Reset Delay Current Register
SEC_FSTAT	Fault Status Register
SEC_GCTL	Global Control Register
SEC_GSTAT	Global Status Register
SEC_RAISE	Global Raise Register

Table 6-6: ADSP-SC59x SEC Register List (Continued)

Name	Description
SEC_SCTL[n]	Source Control Register n
SEC_SSTAT[n]	Source Status Register n

SCI Active Register n

The SEC SCI active interrupt register (SEC_CACT[n]) contains the source ID and priority of the highest priority active interrupt detected by the SEC prioritizer.

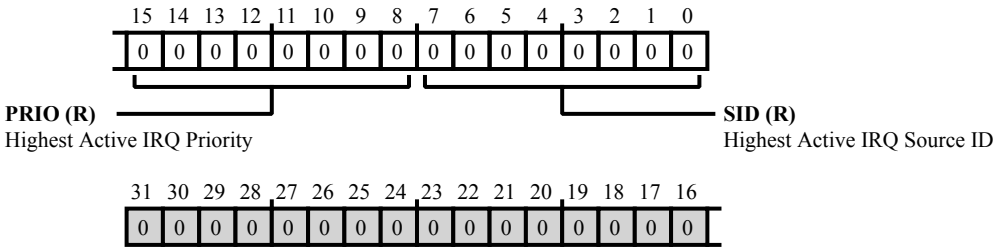

Figure 6-6: SEC_CACT[n] Register Diagram

Table 6-7: SEC_CACT[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:8 (R/NW)	PRIO	Highest Active IRQ Priority. The SEC_CACT[n].PRIO indicates the priority value of the highest priority active interrupt for core n.
7:0 (R/NW)	SID	Highest Active IRQ Source ID. The SEC_CACT[n].SID identifies the source ID value of the highest priority active interrupt for core n.

SCI Control Register n

The SEC control register (SEC_CCTL[n]) contains SCI control bits for all system sources.

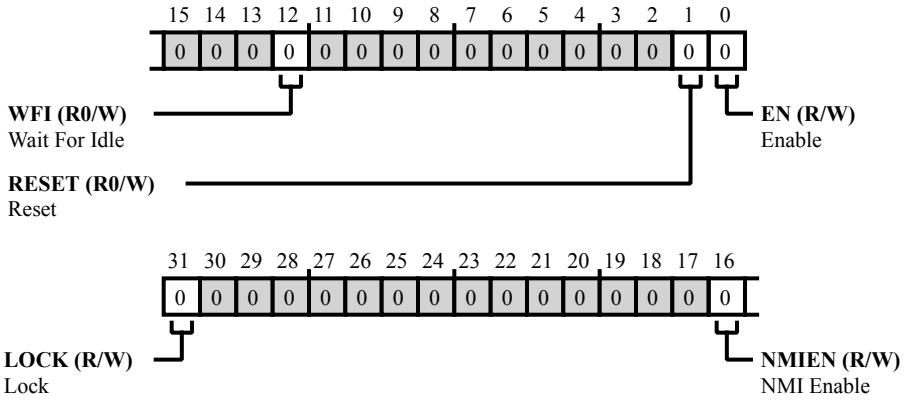

Figure 6-7: SEC_CCTL[n] Register Diagram

Table 6-8: SEC_CCTL[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock is enabled (SPU_CTL.GLCK bit =1) and the SEC_CCTL[n].LOCK bit is enabled, the SEC_CCTL[n] register is read only.	
		0	Unlock
		1	Lock
16 (R/W)	NMIEN	NMI Enable. The SEC_CCTL[n].NMIEN bit controls NMI propagation to the core. When the SEC_CCTL[n].NMIEN bit is enabled, the SCI allows NMIs to propagate to the core for servicing.	
		0	Disable
		1	Enable
12 (R0/W)	WFI	Wait For Idle. When set, the SEC_CCTL[n].WFI bit forces the SCI to wait for indication of core idle before the SCI resumes activity.	
		0	No Action
		1	Wait for Idle

Table 6-8: SEC_CCTL[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R0/W)	RESET	Reset. When set, the `SEC_CCTL[n].RESET` bit resets all SCI registers to their default values.	
		0	No Action
		1	Reset
0 (R/W)	EN	Enable. The `SEC_CCTL[n].EN` bit controls operation of the SCI. Clearing the `SEC_CCTL[n].EN` bit halts the execution of the SCI without resetting status registers. (The INT signal to a core is not affected.) Setting the `SEC_CCTL[n].EN` bit enables the SCI to begin or resume operation with the current configuration and status.	
		0	Disable
		1	Enable

SCI Group Mask Register n

The SEC SCI group mask register (SEC_CGMSK[n]) contains selections for a group mask, an ungroup mask, and a register lock. This register contains the system interrupt group masks for the connected core. The core uses the SEC_CGMSK[n].UGRP and SEC_CGMSK[n].GRP fields to mask (disable) interrupts from the specified groups.

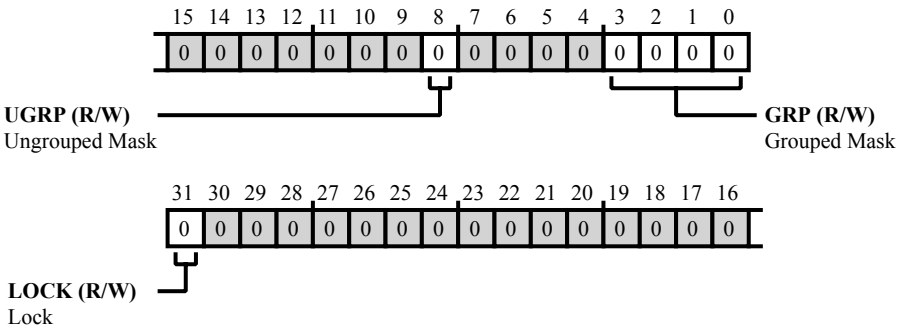

Figure 6-8: SEC_CGMSK[n] Register Diagram

Table 6-9: SEC_CGMSK[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock is enabled (SPU_CTL.GLCK bit =1) and the SEC_CGMSK[n].LOCK bit is enabled, the SEC_CGMSK[n] register is read only.	
		0	Unlock
		1	Lock
8 (R/W)	UGRP	Ungrouped Mask. The SEC_CGMSK[n].UGRP bit masks interrupts (if set) for the ungrouped interrupt sources for core n.	
		0	Unmask Ungrouped Sources
		1	Mask Ungrouped Sources
3:0 (R/W)	GRP	Grouped Mask. The SEC_CGMSK[n].GRP field selects a group of interrupt sources to mask for core n. (For more information about interrupt source groups, see the SEC_SCTL[n] register description.)	
		0	No groups masked
		1	Mask group 0
		2	Mask group 1
		3	Mask groups 0, 1

Table 6-9: SEC_CGMSK[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		4	Mask group 2
		5	Mask groups 0, 2
		6	Mask groups 1, 2
		7	Mask groups 0, 1, 2
		8	Mask group 3
		9	Mask groups 0, 3
		10	Mask groups 1, 3
		11	Mask groups 0, 1, 3
		12	Mask groups 2, 3
		13	Mask groups 0, 2, 3
		14	Mask groups 1, 2, 3
		15	Mask groups 0, 1, 2, 3

SCI Priority Level Register n

The SEC SCI priority level register (SEC_CPLVL[n]) contains selections for priority levels and a register lock. This register is used to divide the total number of priority levels into sub-levels. The sub-level priority resolution provides the tie breaker for simultaneously pending interrupts assigned to the same level.

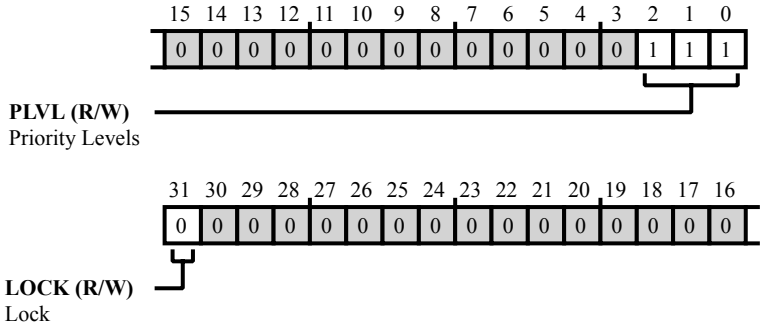

Figure 6-9: SEC_CPLVL[n] Register Diagram

Table 6-10: SEC_CPLVL[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock is enabled (SPU_CTL.GLCK bit =1) and the SEC_CPLVL[n].LOCK bit is enabled, the SEC_CPLVL[n] register is read only.	
		0	Unlock
		1	Lock
2:0 (R/W)	PLVL	Priority Levels. The SEC_CPLVL[n].PLVL field serves to divide the total number of interrupt priority levels into sub-levels. The sub-level priority resolution provides the tie breaker for simultaneously pending interrupts assigned to the same interrupt level. The sub-level priority value specifies the number of MSBs (minus 1) designated to interrupt levels, while the remaining LSBs are designated for sub-level specification. For example, if the SEC_CPLVL[n].PLVL field is set to two, the result is four priority levels are specified, because only the two MSBs are used for preemption evaluation. The remaining bits of the priority setting are used for sub-level prioritization.	
		0	1 MSBs (2 priority levels)
		1	2 MSBs (4 priority levels)
		2	3 MSBs (8 priority levels)
		3	4 MSBs (16 priority levels)
		4	5 MSBs (32 priority levels)
		5	6 MSBs (64 priority levels)

Table 6-10: SEC_CPLVL[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		6	7 MSBs (128 priority levels)
		7	8 MSBs (256 priority levels)

SCI Priority Mask Register n

The SEC SCI priority mask register (SEC_CPMSK[n]) contains the SCI priority mask for core n and includes a register lock.

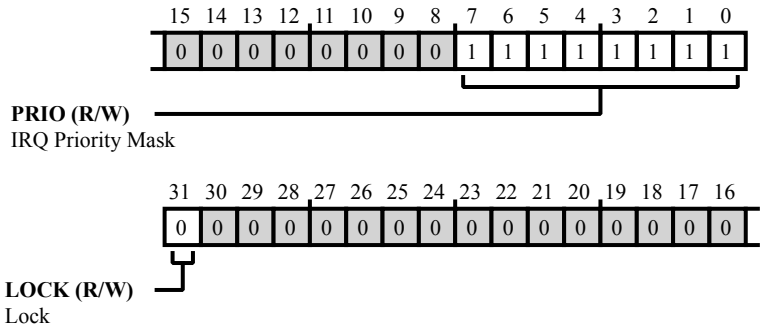

Figure 6-10: SEC_CPMSK[n] Register Diagram

Table 6-11: SEC_CPMSK[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock is enabled (SPU_CTL.GLCK bit =1) and the SEC_CPMSK[n].LOCK bit is enabled, the SEC_CPMSK[n] register is read only.	
		0	Unlock
		1	Lock
7:0 (R/W)	PRIO	IRQ Priority Mask. The SEC_CPMSK[n].PRIO contains the system interrupt priority mask for core n. The core uses the SEC_CPMSK[n].PRIO field to mask (block) interrupts below the specified level.	
		0	Priority level 0 (highest)
		1-254	
		255	Priority level 255 (lowest)

Core Pending Register n

The SCI pending interrupt register (SEC_CPND[n]) contains the source ID and priority of the highest priority pending interrupt detected by the SEC prioritizer.

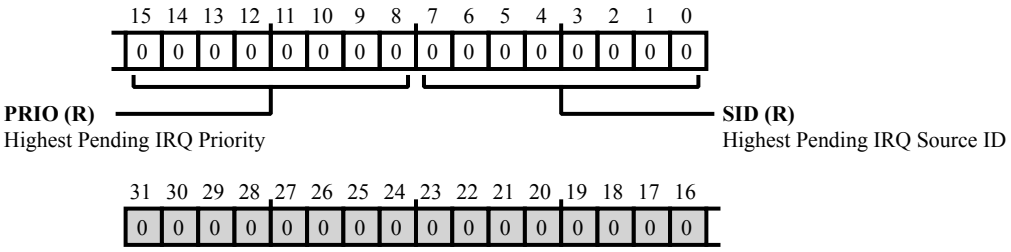

Figure 6-11: SEC_CPND[n] Register Diagram

Table 6-12: SEC_CPND[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:8 (R/NW)	PRIO	Highest Pending IRQ Priority. The SEC_CPND[n].PRIO indicates the priority value of the highest priority pending interrupt for core n.
7:0 (R/NW)	SID	Highest Pending IRQ Source ID. The SEC_CPND[n].SID identifies the source ID value of the highest priority pending interrupt for core n.

SCI Source ID Register n

The SCI source ID register (SEC_CSID[n]) contains the source ID of the interrupt last issued to core n. The SEC_CSID[n] register value is loaded by the SCI when a system interrupt indication is sent to core n. The SCI does not change the SEC_CSID[n] until after the interface receives an interrupt acknowledge from core n. Writing to the SEC_CSID[n] register generates an interrupt acknowledge, but does not update the value in the register.

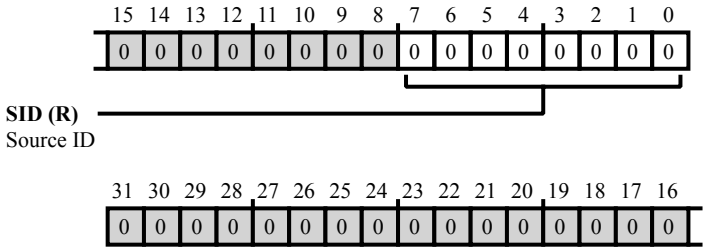

Figure 6-12: SEC_CSID[n] Register Diagram

Table 6-13: SEC_CSID[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/NW)	SID	Source ID. The SEC_CSID[n].SID bit is the source ID of the interrupt last issued to core n.

SCI Status Register n

The SCI status register (SEC_CSTAT[n]) contains status bits, indicating the operational status of the SCI.

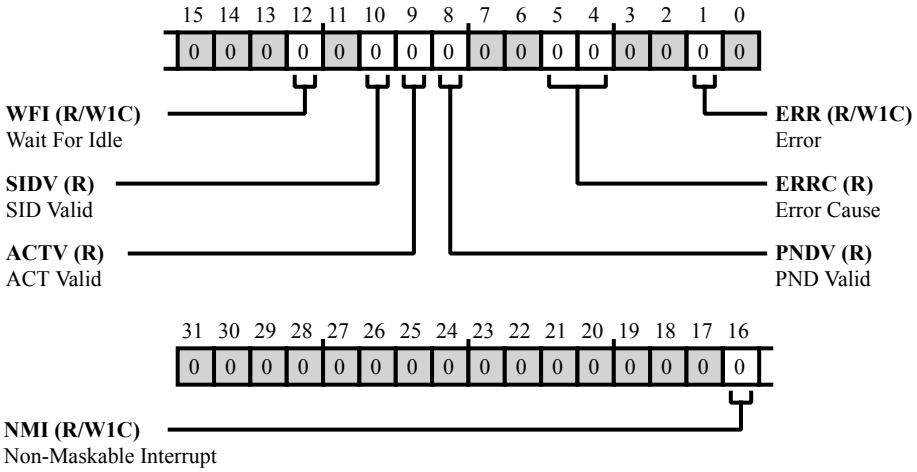

Figure 6-13: SEC_CSTAT[n] Register Diagram

Table 6-14: SEC_CSTAT[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/W1C)	NMI	Non-Maskable Interrupt. The SEC_CSTAT[n].NMI bit indicates whether an NMI has occurred since the bit was last cleared.	
		0	No NMI Occurred
		1	NMI Occurred
12 (R/W1C)	WFI	Wait For Idle. The SEC_CSTAT[n].WFI bit indicates (if set) that the SCI is temporarily disabled, pending a core idle indication. This bit is set when SEC_CCTL[n].WFI is set.	
		0	Not Waiting
		1	Waiting
10 (R/NW)	SIDV	SID Valid. The SEC_CSTAT[n].SIDV bit indicates (if set) that the current value in the SEC_CSID[n] register is valid. The SCI sets the SEC_CSTAT[n].SIDV bit when the updating the SEC_CSID[n] register with a new value. The SEC_CSTAT[n].SIDV bit is cleared when the SEC_CSID[n] register is written. This status indication may be used to extract all pending interrupts in a single interrupt service routine.	
		0	Invalid
		1	Valid

Table 6-14: SEC_CSTAT[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/NW)	ACTV	ACT Valid. The SEC_CSTAT[n].ACTV bit indicates (if set) that the current value in the SEC_CACT[n] register is valid. The SCI sets the SEC_CSTAT[n].ACTV bit when updating the SEC_CACT[n] registers with a new value. The SEC_CSTAT[n].ACTV bit is cleared when the SEC_CSID[n] register is written.	
		0	Invalid
		1	Valid
8 (R/NW)	PNDV	PND Valid. The SEC_CSTAT[n].PNDV bit indicates (if set) that the current value in the SEC_CPND[n] register is valid. The SCI sets the SEC_CSTAT[n].PNDV bit when updating the SEC_CPND[n] register with a new value. The SEC_CSTAT[n].PNDV bit is cleared when the SEC_CSID[n] register is written.	
		0	Invalid
		1	Valid
5:4 (R/NW)	ERRC	Error Cause. The SEC_CSTAT[n].ERRC bits are updated on assertion of the SEC_CSTAT[n].ERR bit to indicate the SCI error type. SEC_CSTAT[n].ERRC is only updated on the assertion of SEC_CSTAT[n].ERR. Subsequent errors while SEC_CSTAT[n].ERR is asserted do not update SEC_CSTAT[n].ERRC.	
		0	Reserved
		1	Acknowledge Error. SCI has received an acknowledge without a pending, unacknowledged interrupt present.
		2	Reserved
		3	Reserved
1 (R/W1C)	ERR	Error. The SEC_CSTAT[n].ERR bit indicates that an error has occurred in the SCI. When SEC_CSTAT[n].ERR is set, the SCI updates the SEC_CSTAT[n].ERRC field to the value of the corresponding error cause.	
		0	No Error
		1	Error Occurred

Global End Register

The SEC global end register (SEC_END) contains a source ID interrupt service end field (SEC_END.SID). When a core has finished servicing an interrupt, the core writes the SEC_END.SID field in the SEC_END register. This write causes the SEC to clear the SEC_SSTAT[n].ACT bit in the SEC_SSTAT[n] register of the corresponding interrupt.

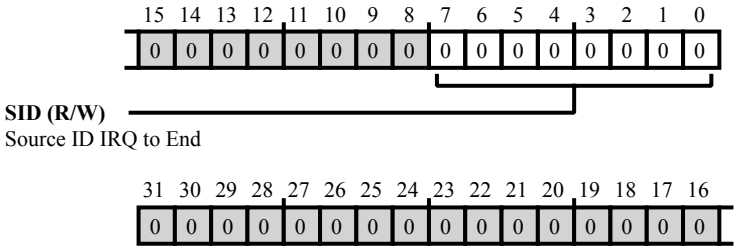

Figure 6-14: SEC_END Register Diagram

Table 6-15: SEC_END Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	SID	Source ID IRQ to End. The SEC_END.SID bit field contains the source ID interrupt service end value.

Fault COP Period Register

The SEC fault COP period register (SEC_FCOPP) contains the width value (count in (SEC) clock cycles) for the high and low phase of the computer operating properly (COP) toggled output on the COP pin. Note that the actual high/low phase value is the SEC_FCOPP.COUNT programmed value plus 1.

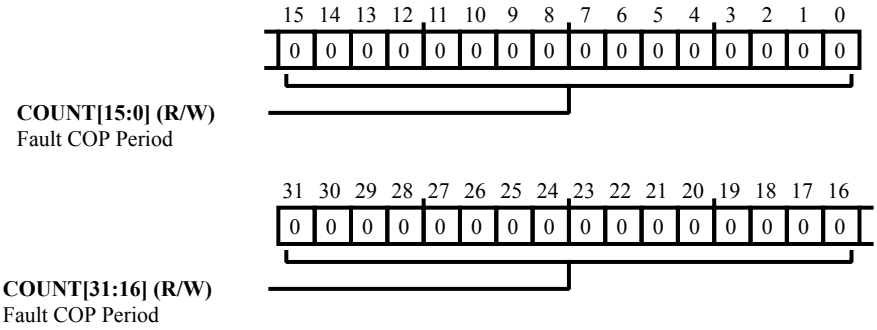

Figure 6-15: SEC_FCOPP Register Diagram

Table 6-16: SEC_FCOPP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	COUNT	Fault COP Period. The SEC_FCOPP.COUNT bit field is the width value for the high and low phase of the computer operating properly (COP) toggled output on the COP pin.

Fault COP Period Current Register

The SEC fault COP period current register (SEC_FCOPP_CUR) contains the active count (in (SEC) clock periods) for the current phase (high or low) of the computer operating properly (COP) toggled output on the COP pin. The SEC loads the SEC_FCOPP_CUR register from the SEC_FCOPP register when the SEC_FCOPP_CUR.COUNT field is cleared and the SEC is in COP mode (SEC_FCTL.CMS bit =1). The SEC decrements the SEC_FCOPP_CUR count each (SEC) clock cycle while SEC_FCTL.CMS is set and the SEC_FSTAT.ACT bit is not set.

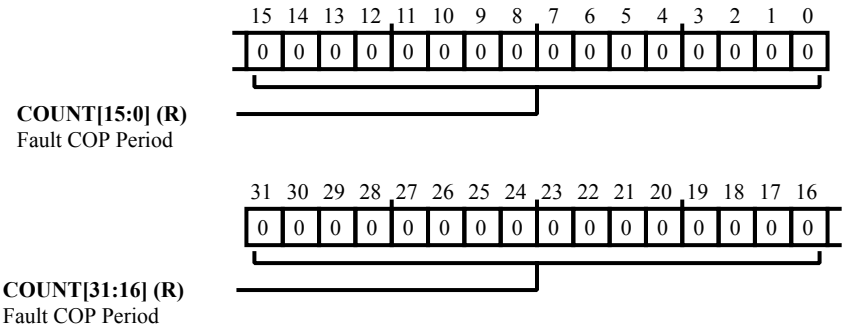

Figure 6-16: SEC_FCOPP_CUR Register Diagram

Table 6-17: SEC_FCOPP_CUR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	COUNT	Fault COP Period. The SEC_FCOPP_CUR.COUNT bit field is the active count for the current phase (high or low) of the computer operating properly (COP) toggled output on the COP pin.

Fault Control Register

The SEC fault control register (SEC_FCTL) contains fault control bits for all SEC channels. This register controls the operation of the System Fault Management Interface (SFI).

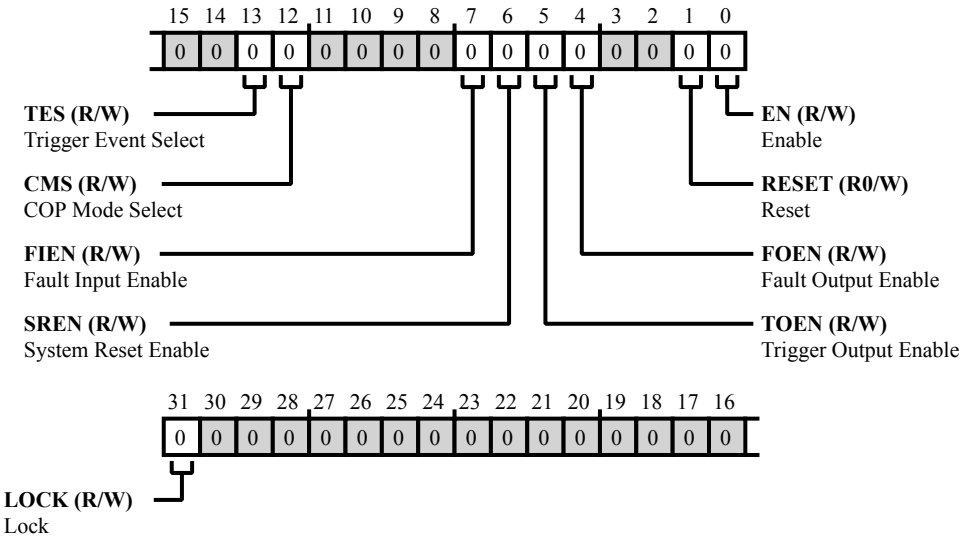

Figure 6-17: SEC_FCTL Register Diagram

Table 6-18: SEC_FCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock is enabled (SPU_CTL.GLCK bit =1) and the SEC_FCTL.LOCK bit is enabled, the SEC_FCTL register is read only.	
		0	UnLock
		1	Lock
13 (R/W)	TES	Trigger Event Select. The SEC_FCTL.TES bit selects the event that directs the SEC to assert trigger output. In fault pending mode, the SEC asserts trigger output when a fault is pending. In fault active mode, the SEC asserts trigger output when a fault is active.	
		0	Fault Active Mode
		1	Fault Pending Mode

Table 6-18: SEC_FCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W)	CMS	COP Mode Select. The SEC_FCTL.CMS selects the SEC mode for handling fault input. In COP mode, the SEC toggles the COP pin to indicate that no fault is active and ceases toggling the pin to indicate that a fault is active. In fault mode, the SEC deasserts the fault pin (=0) and fault_b pin (=1) when no fault is active and asserts the fault pin (=1) and fault_b pin (=0) when a fault is active. Not all processors feature both the fault and fault_b pins. Refer to the product data sheet for details.	
		0	Fault Mode
		1	COP Mode
7 (R/W)	FIEN	Fault Input Enable. The SEC_FCTL.FIEN bit enables the SEC to sample fault input. If SEC_FCTL.FIEN is set (=1), a fault indication from an external device sets the SEC_FSTAT.ACT bit and SEC_FSID.FEXT bit.	
		0	Disable
		1	Enable
6 (R/W)	SREN	System Reset Enable. The SEC_FCTL.SREN bit enables the SEC to issue a system reset request when a fault becomes active.	
		0	Disable
		1	Enable
5 (R/W)	TOEN	Trigger Output Enable. The SEC_FCTL.TOEN bit enables the SEC to produce trigger output when a fault becomes active.	
		0	Disable
		1	Enable
4 (R/W)	FOEN	Fault Output Enable. The SEC_FCTL.FOEN bit enables the SEC to indicate fault status, according to the SEC_FCTL.CMS bit configuration.	
		0	Disable
		1	Enable
1 (R0/W)	RESET	Reset. Setting the SEC_FCTL.RESET bit resets ALL SEC registers to their default values.	
		0	No Action
		1	Reset

Table 6-18: SEC_FCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	EN	Enable. The `SEC_FCTL.EN` bit controls the operational state of the SEC. Clearing the `SEC_FCTL.EN` bit halts the execution of the SEC without resetting status registers. Setting the `SEC_FCTL.EN` bit enables the SEC to begin or resume operation with the current configuration and status.	
		0	Disable
		1	Enable

Fault Delay Register

The SEC fault delay register (SEC_FDLY) contains the number (SEC_FDLY.COUNT field) of (SEC) clock periods to delay from fault pending to fault active, when actions are enabled.

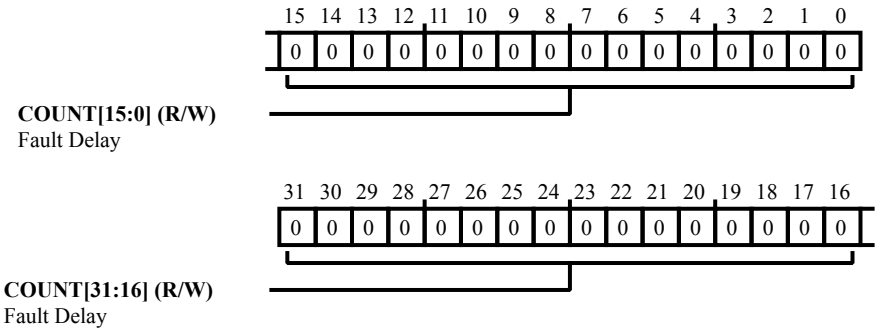

Figure 6-18: SEC_FDLY Register Diagram

Table 6-19: SEC_FDLY Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	COUNT	Fault Delay. The SEC_FDLY.COUNT bit field is the number of (SEC) clock periods to delay from fault pending to fault active, when actions are enabled.

Fault Delay Current Register

The SEC fault delay current register (SEC_FDLY_CUR) contains the active count (SEC_FDLY_CUR.COUNT field) in (SEC) clock periods for the delay from fault pending to fault active, when actions are enabled. The count is loaded from the SEC_FDLY register when a fault becomes pending (SEC_FSTAT.PND bit is set). The SEC decrements the value in SEC_FDLY_CUR each (SEC) clock cycle while the SEC_FSTAT.PND bit is set.

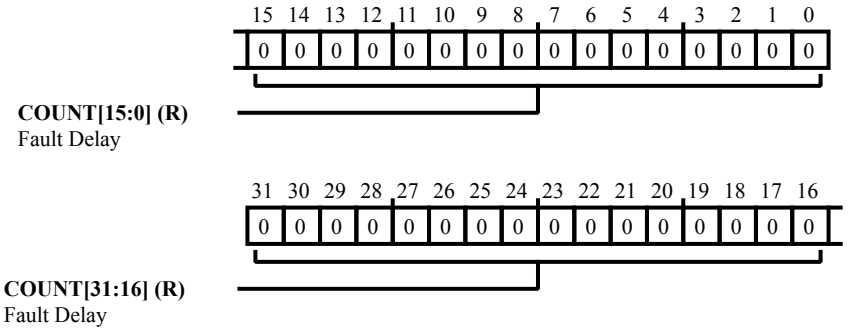

Figure 6-19: SEC_FDLY_CUR Register Diagram

Table 6-20: SEC_FDLY_CUR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	COUNT	Fault Delay. The SEC_FDLY_CUR.COUNT bit field is the active count in (SEC) clock periods for the delay from fault pending to fault active, when actions are enabled.

Fault End Register

The SEC fault end register (SEC_FEND) contains fault source ID and internal/external fields. This register receives fault end indication from a core.

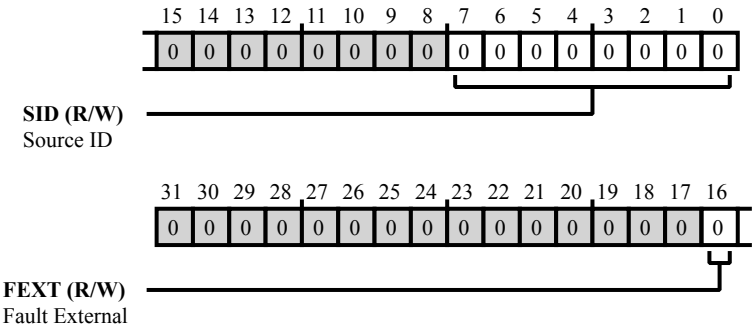

Figure 6-20: SEC_FEND Register Diagram

Table 6-21: SEC_FEND Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/W)	FEXT	Fault External. Setting the SEC_FEND.FEXT bit, when the SEC_FEND.SID field is cleared, clears an active fault from an external source.	
		0	Fault Internal
		1	Fault External
7:0 (R/W)	SID	Source ID. The SEC_FEND.SID identifies a fault to be ended as indicated to the SEC by the core. The core loads the SEC_FEND.SID field value. If the SEC_FEND.SID value matches the SEC_FSID.SID value, the SEC_FSTAT.PND bit and SEC_FSTAT.ACT bit are cleared.	

Fault Source ID Register

The SEC fault source ID register (SEC_FSID) contains a fault source ID and internal/external fields.

NOTE:These bits are not reset by system reset so that a fault that automatically triggers a system reset to avoid a fault may be analyzed after the reset occurs.

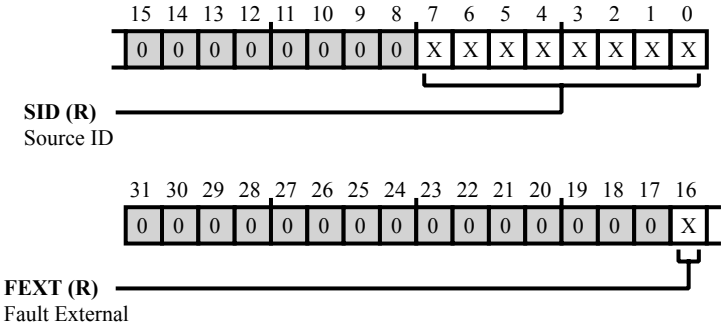

Figure 6-21: SEC_FSID Register Diagram

Table 6-22: SEC_FSID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/NW)	FEXT	Fault External. The SEC_FSID.FEXT bit indicates that the last active fault was asserted by an external device. The SEC sets the SEC_FSID.FEXT bit when the SEC_FSTAT.ACT bit is set by the fault input pins. The SEC_FSID.FEXT bit is cleared when the SEC_FSTAT.ACT bit is set by an internal fault or when the external fault is ended. When the SEC_FSID.FEXT bit is set, the SEC_FSID.SID is cleared.	
		0	Fault Internal
		1	Fault External
7:0 (R/NW)	SID	Source ID. The SEC_FSID.SID identifies the fault assertion detected by the SEC fault interface. The SEC loads the SEC_FSID.SID field value when a system fault indication is asserted. The SEC fault interface does not change the SEC_FSID.SID value until the fault is no longer pending or active, as indicated by the SEC_FSTAT.PND bit and SEC_FSTAT.ACT bit being cleared in the SEC_FSTAT register.	

Fault System Reset Delay Register

The SEC fault system reset delay register (SEC_FSRDLY) contains the number (SEC_FSRDLY.COUNT field) of (SEC) clock periods for the delay from a fault becoming active to system reset request assertion, if enabled.

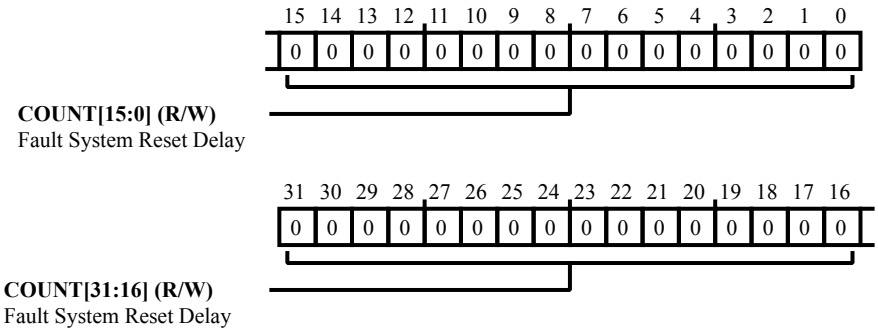

Figure 6-22: SEC_FSRDLY Register Diagram

Table 6-23: SEC_FSRDLY Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	COUNT	Fault System Reset Delay. The SEC_FSRDLY.COUNT bit field is the number of (SEC) clock periods for the delay from a fault becoming active to system reset request assertion.

Fault System Reset Delay Current Register

The SEC fault system reset delay current register (SEC_FSRDLY_CUR) contains the active count (SEC_FSRDLY_CUR.COUNT field) in (SEC) clock periods for the delay from fault active to system reset assertion, if enabled. The count is loaded from the SEC_FSRDLY register when a fault becomes active (SEC_FSTAT.ACT bit is set). The SEC decrements the value in SEC_FSRDLY_CUR each (SEC) clock cycle while the SEC_FSTAT.ACT bit is set.

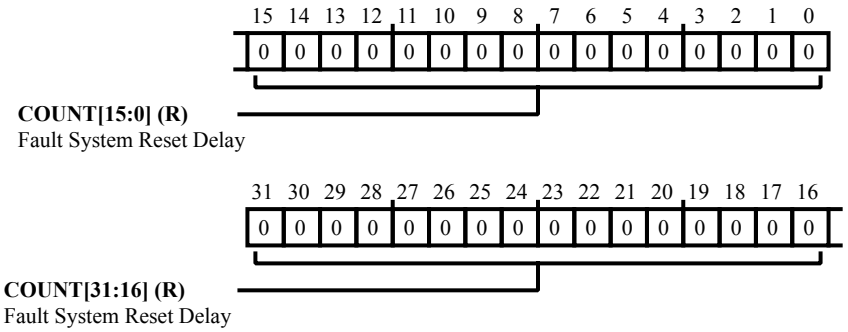

Figure 6-23: SEC_FSRDLY_CUR Register Diagram

Table 6-24: SEC_FSRDLY_CUR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	COUNT	Fault System Reset Delay. The SEC_FSRDLY_CUR.COUNT bit field is the active count in (SEC) clock periods for the delay from fault active to system reset assertion.

Fault Status Register

The SEC fault status register (SEC_FSTAT) indicates the operational status of the SFI.

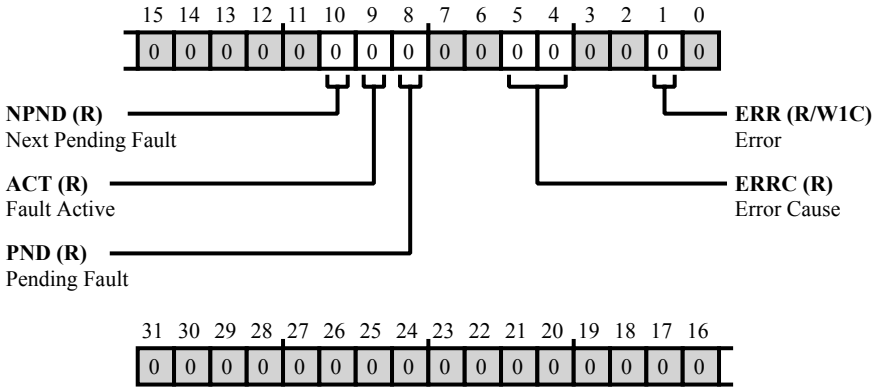

Figure 6-24: SEC_FSTAT Register Diagram

Table 6-25: SEC_FSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
10 (R/NW)	NPND	Next Pending Fault. The SEC_FSTAT.NPND bit indicates that one or more sources have signaled fault assertion, but the input has not yet triggered the fault pending detection in the SEC fault interface. The SEC sets the SEC_FSTAT.NPND bit when the fault interface detects assertion of any enabled fault source input, while either the SEC_FSTAT.PND or SEC_FSTAT.ACT bits are set. The SEC clears the SEC_FSTAT.NPND bit when there are no fault sources waiting.	
		0	Not Pending
		1	Pending
9 (R/NW)	ACT	Fault Active. The SEC_FSTAT.ACT bit indicates that the SEC has received a fault source input, the current fault delay count (in the SEC_FDLY_CUR register) has expired, and the fault actions are enabled. The SEC also sets the SEC_FSTAT.ACT bit on fault input detection if the SEC_FCTL.FIEN bit is set. The SEC_FSTAT.ACT bit is cleared by writing the ID value of the asserted fault from SEC_FSID register to the SEC_FEND register.	
		0	No Fault
		1	Active Fault

Table 6-25: SEC_FSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/NW)	PND	Pending Fault. The SEC_FSTAT.PND bit indicates a fault source has signaled a fault assertion to the SEC, but the SEC has not yet triggered the event actions due to the delay selected with the SEC_FDLY register. The SEC fault interface sets the SEC_FSTAT.PND bit when the SEC_FSID is updated on assertion of a fault source input. The SEC_FSTAT.PND bit is only set when the SEC_FSTAT.ACT bit is cleared. The SEC updates the SEC_FSID register with the SID value when the SEC_FSTAT.PND bit is set. The SEC_FSTAT.PND bit is cleared *either* by the SEC fault interface when the current delay count in the SEC_FDLY_CUR register expires *or* by writing the SEC_FSID.SID field value (which indicates the ID of the asserted fault) to the SEC_FEND register.	
		0	Not Pending
		1	Pending
5:4 (R/NW)	ERRC	Error Cause. When the SEC_FSTAT.ERR bit is asserted, the SEC updates SEC_FSTAT.ERRC field to convey the interrupt source error type. When the error type is source overflow, the status indicates that a source signal assertion occurred or an SEC raise operation was attempted while pending was already set. The source overflow is detected when the source is set for edge only. When the error type is end error, the status indicates that an end was received for a source while the SEC_FSTAT.ACT bit was not set.	
		0	Source Overflow Error
		1	Reserved
		2	End Error
		3	Reserved
1 (R/W1C)	ERR	Error. The SEC_FSTAT.ERR bit indicates an SEC fault interface error. When SEC_FSTAT.ERR is set, the SEC updates the SEC_FSTAT.ERRC field to indicate the corresponding error cause. When multiple errors occur, the SEC_FSTAT register captures the status for the first error and does not capture subsequent errors until the status is cleared.	
		0	No Error
		1	Error Occurred

Global Control Register

The SEC global control register (SEC_GCTL) provides register locking, reset, and enable for the SEC module.

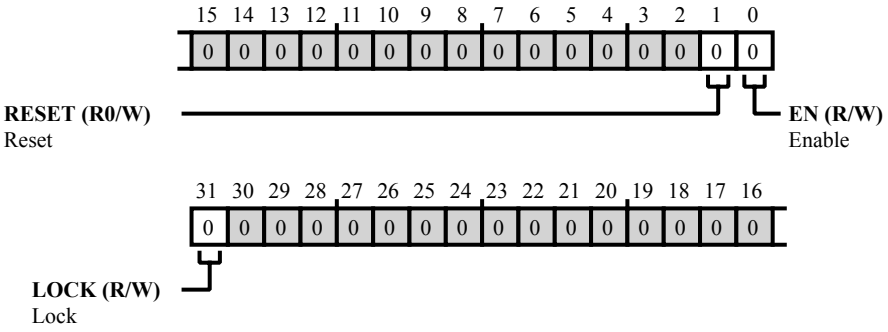

Figure 6-25: SEC_GCTL Register Diagram

Table 6-26: SEC_GCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock is enabled (SPU_CTL.GLCK bit =1) and the SEC_GCTL.LOCK bit is enabled, the SEC_GCTL register is read only.	
		0	Unlock
		1	Lock
1 (R0/W)	RESET	Reset. The SEC_GCTL.RESET bit is write-1-action and triggers a soft reset to all SEC registers.	
		0	No Action
		1	Reset
0 (R/W)	EN	Enable. The SEC_GCTL.EN bit is read/write and must be set for the SEC to begin/resume SEC operation with the current configuration and status. Clearing the SEC_GCTL.EN bit halts the execution of the SFI and all SCIs. All SSIs remain active, along with all error detection, without resetting status registers.	
		0	Disable
		1	Enable

Global Status Register

The SEC global status register (SEC_GSTAT) contains global status bits for the SEC.

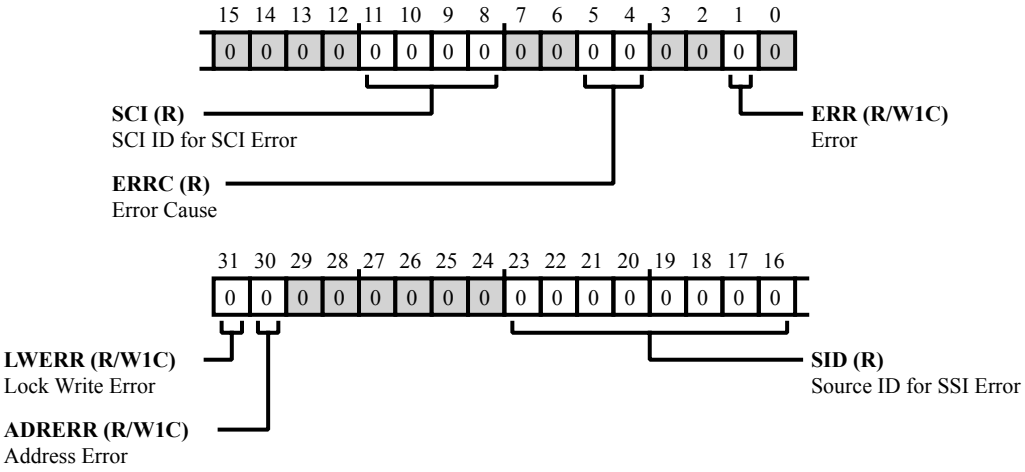

Figure 6-26: SEC_GSTAT Register Diagram

Table 6-27: SEC_GSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W1C)	LWERR	Lock Write Error. The SEC_GSTAT.LWERR bit indicates (when set) there was an attempted write to an SEC register while the SEC_GCTL.LOCK bit was set and while the global lock bit was enabled (SPU_CTL.GLCK bit =1). This status bit is sticky; write-1-to-clear it.	
		0	No Error
		1	Error Occurred
30 (R/W1C)	ADRERR	Address Error. The SEC_GSTAT.ADRERR bit indicates that the SEC generated and address error. This status bit is sticky; write-1-to-clear it.	
		0	No Error
		1	Error Occurred
23:16 (R/NW)	SID	Source ID for SSI Error. The SEC_GSTAT.SID bits indicate the source ID that generated the last SSI error conveyed in the SEC_GSTAT.ERRC field.	
11:8 (R/NW)	SCI	SCI ID for SCI Error. The SEC_GSTAT.SCI bits indicate the number for the specific SCI that generated the last SCI error conveyed in the SEC_GSTAT.ERRC field.	

Table 6-27: SEC_GSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5:4 (R/NW)	ERRC	Error Cause. When the SEC updates the `SEC_GSTAT.ERR` bit, the SEC updates the `SEC_GSTAT.ERRC` bits to indicate the error type. Note that for SCI errors, the error status represents an OR of all the errors from each SCI. Note that for SSI errors, the error status indicates an error is active for any SSI input. This error is an OR of all the interrupt source errors.	
		0	SFI Error
		1	SCI Error
		2	SSI Error
		3	Reserved
1 (R/W1C)	ERR	Error. The `SEC_GSTAT.ERR` bit indicates an error has occurred in the SEC. When the SEC asserts this bit (=1), the SEC updates the `SEC_GSTAT.ERRC` field to indicate the corresponding error cause. Even if multiple errors occur, only the first error is captured on assertion of this bit. This status bit is sticky; write-1-to-clear it.	
		0	No Error
		1	Error Occurred

Global Raise Register

The SEC global raise register (SEC_RAISE) contains a source ID event set-to-pending field (SEC_RAISE.SID). When a source ID value is written to this field, the SEC raises the source's event status to pending.

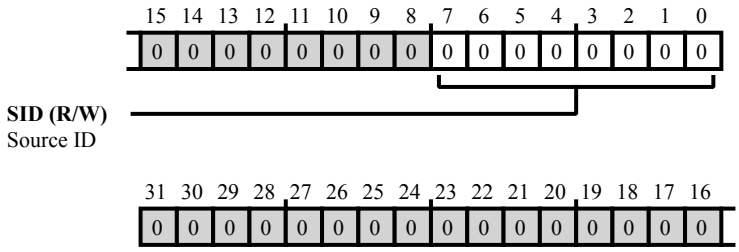

Figure 6-27: SEC_RAISE Register Diagram

Table 6-28: SEC_RAISE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	SID	Source ID. The SEC_RAISE.SID bit field is the source ID of event that is set to pending status.

Source Control Register n

The SEC source control register (SEC_SCTL[n]) contains control bits to configure the SEC event sources. This register controls the configuration of the corresponding SEC event source.

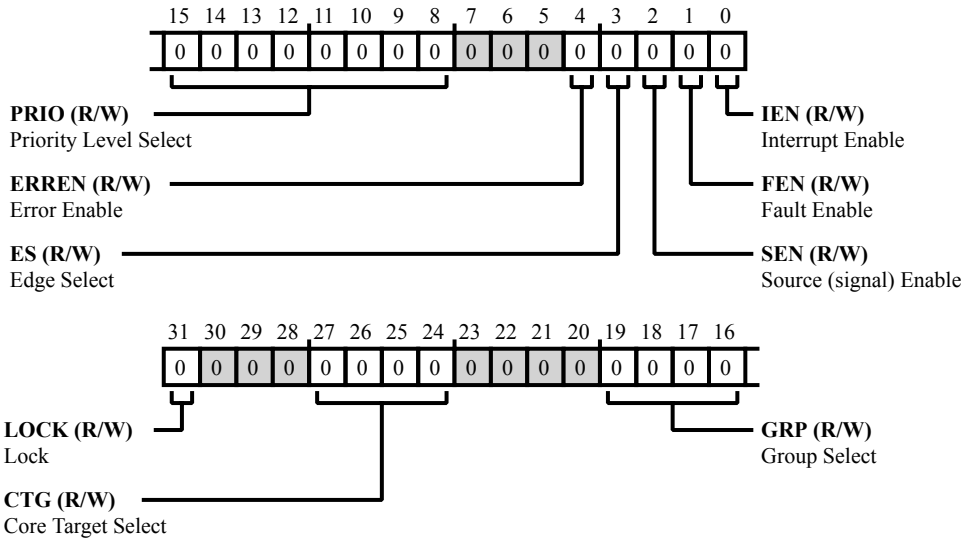

Figure 6-28: SEC_SCTL[n] Register Diagram

Table 6-29: SEC_SCTL[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock is enabled (SPU_CTL.GLCK bit =1) and the SEC_SCTL[n].LOCK bit is enabled, the SEC_SCTL[n] register is read only.	
		0	Unlock
		1	Lock
27:24 (R/W)	CTG	Core Target Select. The SEC_SCTL[n].CTG bits selects the specific SEC core interface to which the interrupt is mapped. Each system interrupt is mapped uniquely to one specific SEC core interface and (as a result) to a specific core.	
		1	CORE1 SHARC0
		2	CORE2 SHARC1

Table 6-29: SEC_SCTL[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
19:16 (R/W)	GRP	Group Select. The SEC_SCTL[n].GRP bits each select a specific group for the interrupt. Each system interrupt can be assigned to any combination of groups supported by the SEC_SCTL[n].GRP field. For example, consider the situation where SEC_SCTL[n].GRP0 represents interrupt group 0, SEC_SCTL[n].GRP1 represents interrupt group 1, and so on. One group might be used for all enabled interrupts (for example, group 0) and an additional group might be used for all wakeup interrupts (for example, group 1). This approach supports a model of all interrupts and just the wakeup subset. Before going to idle or sleep, all non-wakeup interrupts can be masked off to allow only wakeup interrupts to be enabled for service. Selecting no group (all SEC_SCTL[n].GRP bits = 0) places the interrupt source in the category of "ungrouped".	
15:8 (R/W)	PRIO	Priority Level Select. The SEC_SCTL[n].PRIO bits sets the relative priority for an interrupt request. A pending interrupt request forwards its SEC_SCTL[n].PRIO value to the SEC core interface.	
4 (R/W)	ERREN	Error Enable. The SEC_SCTL[n].ERREN bit permits the SEC_SSTAT[n].ERR status bit to be set on error detection. If SEC_SCTL[n].ERREN is cleared, no errors are detected.	
		0	Disable
		1	Enable
3 (R/W)	ES	Edge Select. The SEC_SCTL[n].ES bit selects the operational and sensitivity mode of the SEC source interface input.	
		0	Level Sensitive
		1	Edge Sensitive
2 (R/W)	SEN	Source (signal) Enable. The SEC_SCTL[n].SEN bit controls whether the system event source input signal may affect the pending status of the source. Clearing the SEC_SCTL[n].SEN bit disables the source input signal from affecting the pending status. Setting SEC_SCTL[n].SEN enables the source input signal to affect the pending status.	
		0	Disable
		1	Enable

Table 6-29: SEC_SCTL[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W)	FEN	Fault Enable. The `SEC_SCTL[n].FEN` bit controls whether the SEC may forward an interrupt request to the SEC fault interface as a fault source. This bit does not affect the ability of an interrupt source to set an interrupt as pending. The `SEC_SCTL[n].FEN` bit only affects whether the pending request may be forwarded to the SEC fault interface.	
		0	Disable
		1	Enable
0 (R/W)	IEN	Interrupt Enable. The `SEC_SCTL[n].IEN` bit controls whether the SEC may forward an interrupt request to a core for servicing. This bit does not affect the ability of an interrupt source to set an interrupt as pending.	
		0	Disable
		1	Enable

Source Status Register n

The SEC event source status register (SEC_SSTAT[n]) contains bits indicating the status of the corresponding event source n. An event source may be: pending, active, active and pending, or neither pending nor active.

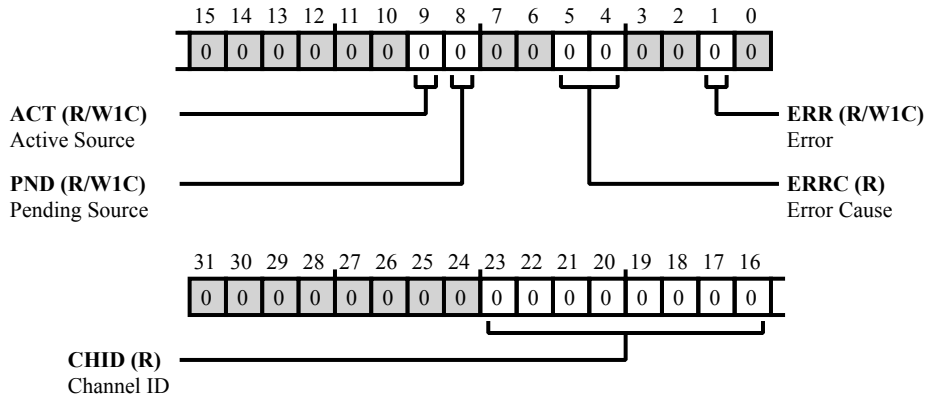

Figure 6-29: SEC_SSTAT[n] Register Diagram

Table 6-30: SEC_SSTAT[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
23:16 (R/NW)	CHID	Channel ID. The SEC_SSTAT[n].CHID bits indicate the ID of the specific source (from a set of sources sharing one SEC source interface input) that asserted the SEC source interface input. An SEC source interface input may support multiple system sources, in which case the assertion must be qualified by an identifier to determine the channel that generated the assertion. The SEC_SSTAT[n].CHID field provides this value in the form of a numeric reference that is mapped to a specific interrupt source. The prioritization for simultaneously asserted sources is according to ID, with 0 being the highest priority. The SEC_SSTAT[n].CHID is captured when the SEC source interface input is acknowledged.	
9 (R/W1C)	ACT	Active Source. The SEC_SSTAT[n].ACT bit indicates the source has been accepted by a core for servicing, but the service is not yet complete. An SEC_SSTAT[n].ACT bit is set by the SEC when the specific system interrupt is acknowledged by the core through the SEC core interface. An SEC_SSTAT[n].ACT bit is cleared by the SEC when the core provides interrupt service end indication for the specific system interrupt through the SEC core interface.	
		0	Not Active
		1	Active

Table 6-30: SEC_SSTAT[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W1C)	PND	Pending Source. The SEC_SSTAT[n].PND bit indicates the source has signaled an event request, but the event request has not been (or is not currently being) serviced. A SEC_SSTAT[n].PND bit is set by the SEC on detection of an assertion of the corresponding system source input. A SEC_SSTAT[n].PND bit is cleared by the SEC when the specific system event is acknowledged by the core through the SEC core interface or by a W1C operation.	
		0	Not Pending
		1	Pending
5:4 (R/NW)	ERRC	Error Cause. When the SEC_SSTAT[n].ERR bit is asserted, the SEC updates SEC_SSTAT[n].ERRC field to convey the interrupt source error type. When the error type is source overflow, the status indicates that a source signal assertion occurred or an SEC raise operation was attempted while pending was already set. The source overflow is detected when the source is set for edge only. When the error type is end error, the status indicates that an end was received for a source while the SEC_SSTAT[n].ACT bit was not set.	
		0	Source Overflow Error
		1	Reserved
		2	End Error
		3	Reserved
1 (R/W1C)	ERR	Error. The SEC_SSTAT[n].ERR bit indicates an error for a specific system interrupt source. When the SEC_SSTAT[n].ERR bit is set, the SEC updates the SEC_SSTAT[n].ERRC field to the value of the corresponding error cause. Even if multiple errors occur, only the first error is captured on assertion of the SEC_SSTAT[n].ERR bit.	
		0	No Error
		1	Error Occurred

GIC Overview

The generic interrupt controller (GIC) provides an interface to the uniprocessor Cortex A55 core in the processor and collects up to 354 interrupt requests from all processor system sources. In addition, the GIC also supports sixteen software generated interrupts and nine private peripheral interrupts that are internal to the Cortex A55 core and not connected to the SECs. All GIC interrupts are also connected to the SEC in the same order.

Each interrupt can be configured as a normal or a secure interrupt. Software force registers and software priority masking are also supported. The “Register Descriptions” section in this chapter provides brief descriptions of these Arm-based registers. For complete information refer to the *Arm® Generic Interrupt Controller Architecture version 3.0 and 4.0 Architecture Specification*.

GIC Functional Description

The GIC interrupt controller consists of three interfaces;

- Distributor interface
- Redistributor interface
- CPU interface

The distributor and the redistributor interfaces are used to configure interrupts; the CPU interface is used to handle interrupts.

GIC Distributer Interface

The distributor registers are memory-mapped. They are used to configures SPIs. The distributor block provides a programming interface to perform the following tasks.

- Interrupt prioritization and distribution of SPIs
- Enable and disable SPIs
- Set the priority level of each SPI
- Set each SPI to be level-sensitive or edge-triggered
- Assign each SPI to an interrupt group
- Control the active and pending state of SPIs.

GIC Redistributer Interface

There is one redistributor per connected core. The redistributors provide a programming interface to perform the following tasks.

- Enable and disable SGIs and PPIs
- Set the priority level of SGIs and PPIs
- Set each PPI to be level-sensitive or edge-triggered
- Assign each SGI and PPI to an interrupt group
- Control the state of SGIs and PPIs.

GIC CPU Interface

Each core contains a CPU interface that includes system registers that are used during interrupt handling. The CPU interfaces provide a programming interface to perform the following tasks.

- Provide general control and configuration to enable interrupt handling
- Acknowledge an interrupt
- Perform a priority drop and deactivation of interrupts
- Set an interrupt priority mask for the processor
- Define the preemption policy for the processor
- Determine the highest priority pending interrupt for the processor

In Arm CoreLink GICv3, the CPU interface registers are accessed as system registers: ICC_*_ELn, where “n” specifies the Exception level: EL1-EL3.

Refer to the GIC Register Descriptions in this chapter for details on the distributor and the redistributor interface registers. Refer to the *Arm® Generic Interrupt Controller Architecture Specification GIC architecture version 3.0 and 4.0* for details on the CPU interface registers.

GIC Block Diagram

The ***GIC Block Diagram*** shows the event management architecture.

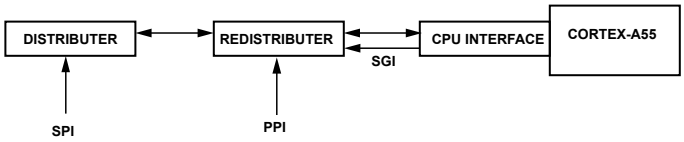

Figure 6-30: GIC Block Diagram

GIC Performance Monitoring Unit (GIC PMU)

The GIC contains a performance monitoring unit (PMU) for counting key GIC events from the distributor. Redistributor events are not tracked by the PMU. The delivery of PPI and SGI interrupts are counted by recording calls to the core interrupt service routine.

The PMU has five counters with snapshot capability and overflow interrupt. For all the GIC events, PMU count configuration and register information, please refer to the *Arm® CoreLink™ GIC 600 Generic Interrupt Controller Technical Reference Manual*.

Overflow interrupt

The overflow interrupt is enabled on a per counter basis by enabling the relevant bit of the register. Similarly, the overflow interrupt enable is disabled by corresponding writes to the register. When enabled, the interrupt activates when there is a write to the register for any counter or overflow on any enabled counter.

Snapshot

Each PMU counter, , has a corresponding snapshot register. On a snapshot event, all five counters are copied to their backup registers so that all consistent data is copied out over a longer period.

The snapshot events are as follows:

- Write of 1 to the GICP_ bit
- An overflow of an enabled counter when the bit is set

ADSP-SC59x GIC Interrupt List

7 Trigger Routing Unit (TRU)

The TRU provides system-level sequence control without core intervention. The TRU maps trigger generators to trigger receivers. Receiver endpoints can be configured to respond to triggers in various ways. Multiple TRUs may be provided in a multiprocessor system to create a trigger network. Common applications enabled by the TRU include:

- Automatically triggering the start of a DMA sequence after a sequence from another DMA channel completes
- Software triggering
- Synchronization of concurrent activities

TRU Features

The TRU supports the following features:

- Automatically triggering the start of a DMA sequence after a sequence from another DMA channel completes. Once a DMA channel completes data transfer, it can act as a trigger generator and signal an internal trigger pulse to the programmed trigger receiver which can also be another DMA channel. The receiver trigger connected to the DMA channel kicks off the DMA transfer automatically. None of this requires core intervention once the initialization is done.
- Software triggers. The best use of triggers is to minimize core intervention. It is also possible to initiate a trigger pulse to a trigger receiver, in the software.
- Synchronization of concurrent activities. A single trigger generator can initiate a trigger pulse to multiple trigger receiver so that several system level activities can be synchronized on an internally or externally generated event.
- Configuration protection through register-level lock bits and global lock indication

TRU Functional Description

The following sections provide a description of the TRU.

ADSP-SC59x TRU Register List

The Trigger Routing Unit (TRU) provides simple sequence control of distributed modules without the penalties associated with core intervention (for example, interrupt overhead). The TRU receives trigger inputs from all trigger generator inputs (MTI) and the TRU trigger receiver register (TRU_MTR). Based on these inputs, the TRU logic generates trigger outputs that initiate receiver operations in the processor core and peripherals. A set of registers governs TRU operations. For more information on TRU functionality, see the TRU register descriptions.

Table 7-1: ADSP-SC59x TRU Register List

Name	Description

TRU Definitions

The following definitions are helpful when using the TRU module.

Trigger Generator

A trigger generator is any system module that provides trigger event indication to the TRU. Trigger generator modules define trigger events and conditions for assertion.

Trigger Generator ID

Trigger generators are assigned a unique numeric ID according to their physical connection to the TRU. Trigger receiver ID 0 is reserved and defined as null.

Trigger Receiver

A trigger receiver is any system module that receives a trigger event indication from the TRU. Trigger receiver modules define a trigger event response.

NOTE: For peripherals configured as a receiver: when the corresponding peripheral DMA is kept waiting for trigger from a generator, it can receive stale or garbage data. The peripheral receiver begins shifting in data as soon as it is enabled, and it does not wait for the trigger generator. Upon receiving the trigger, this data is moved into the DMA FIFO. Therefore, this sequence can result in the receiver getting unusable data.

TRU Block Diagram

The trigger generator and the Generator Trigger register (MTR) generate trigger assertions. Each trigger receiver has a dedicated Receiver Select register (SSR) that specifies the unique trigger generator from which it receives the trigger indication.

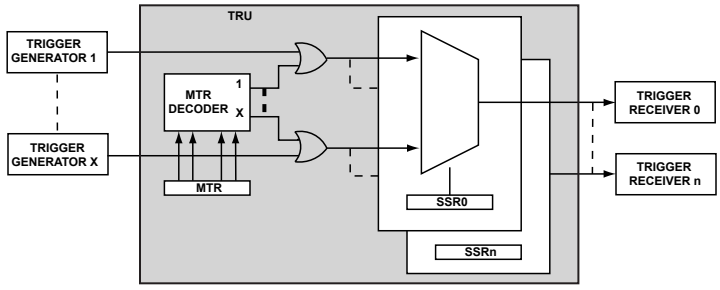

Figure 7-1: TRU Block Diagram

TRU Architectural Concepts

The TRU supports a simple trigger-in/trigger-out model for modules that comply with the triggering functional model. The TRU is the controller of the trigger system. Trigger outputs from trigger generators are mapped to trigger inputs of trigger receivers through a set of programmable registers (`TRU_SSR[n]`).

System modules are trigger generator only, trigger receiver only, or trigger generator and trigger receiver.

All of the trigger input and output signals are connected to a trigger routing unit (TRU) which manages the connections of triggers between modules.

In multi-processor systems, multiple TRU units are provided. These TRUs are networked together. Generic Trigger Ports (GTPs) are provided to forward trigger events from one TRU unit to another, forming a pathway from trigger generator to trigger receivers wherever they might lie in the system.

TRU Programming Model

Implementing sequence control using the TRU requires, at a minimum, proper configuration of a trigger receiver, a trigger generator, and the TRU module itself. The only requirement for the configuration procedure is that the trigger generator is configured and enabled as the last step.

Complete the following other steps:

- Configure the trigger receiver for response to triggers
- Configure the TRU to map the trigger generator to the trigger receiver through the `TRU_SSR[n]` registers
- Configure the trigger generator to generate trigger assertions
- Alternatively, use software triggering for trigger assertion. Writing the trigger generator ID to the MTR register generates software triggers.

Programming Concepts

The following concepts aid in programming the TRU.

- ***Trigger Sequence Configuration.*** A simple sequence consists of one trigger generator and one trigger receiver. More complex trigger sequences consist of several trigger receivers functioning as trigger receiver and trigger generator. Additionally, trigger sequences can loopback to the original generator forming a perpetual sequence.
- ***Software Triggering.*** Writing a trigger generator ID to the MTR generates a trigger within the TRU from the trigger generator ID specified.
- ***Synchronization.*** The TRU can be used to coarsely synchronize events by mapping multiple trigger receivers to the same trigger generator or by generating multiple trigger generator assertions simultaneously through the MTR.
- ***Configuration Protection.*** The `TRU_SSR[n].LOCK` bit and the `TRU_GCTL.LOCK` bit enable register level write-protection when the global lock is asserted in the SPU.

Programming Examples

The following examples shows the steps to create a single trigger.

Configuring a Simple Trigger Sequence

The following example shows the steps to create a simple trigger.

1. Write to the `TRU_GCTL` register to enable the TRU.
2. Write to the `TRU_SSR[n]` register of a specific receiver target to assign it to a specific trigger generator.
3. Enable the trigger receiver to wait for and accept a trigger.
4. Enable the trigger generator to generate a trigger.

TRU Event Control

The TRU is a major part of event control solutions. It is the center of the trigger functional model and can extend to support the interrupt and fault management models as well.

TRU Status and Error Signals

The TRU does not have dedicated status and error output signals other than the MMR interface. Receiver errors are reported to the generator over the standard peripheral bus protocol.

ADSP-SC59x TRU Register Descriptions

Trigger Routing Unit (TRU) contains the following registers.

Table 7-5: ADSP-SC59x TRU Register List

Name	Description
TRU_ERRADDR	Error Address Register
TRU_GCTL	Global Control Register
TRU_MTR	Generator Trigger Register
TRU_SSR[n]	Receiver Select Register
TRU_STAT	Status Information Register

Error Address Register

The TRU error address register (TRU_ERRADDR) holds the address from the memory-mapped register access generating an access error of TRU registers.

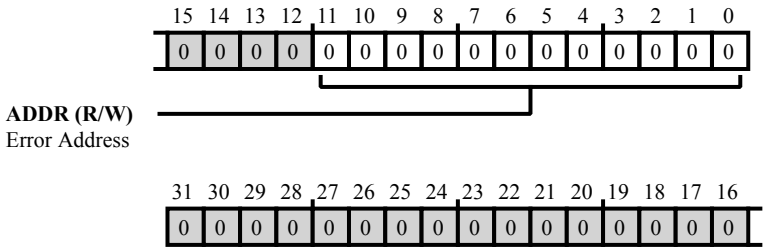

Figure 7-2: TRU_ERRADDR Register Diagram

Table 7-6: TRU_ERRADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
11:0 (R/W)	ADDR	Error Address. The TRU_ERRADDR.ADDR holds the address from the memory-mapped register access generating an access error of TRU registers. These errors occur on access to the TRU_SSR[n] or TRU_MTR registers when these registers are locked or on access to an invalid address. See the TRU_SSR[n] and TRU_MTR register descriptions for more information about locking. The TRU_ERRADDR register holds the address of the first error to occur. In the event of multiple errors occurring, the TRU_ERRADDR register contains the address of the first error. To re-enable the TRU_ERRADDR register for update, both status bits (TRU_STAT.LWERR and TRU_STAT.ADDRERR) in the TRU_STAT register must be cleared.

Global Control Register

The TRU global control register (TRU_GCTL) provides register locking, TRU reset, and TRU enable.

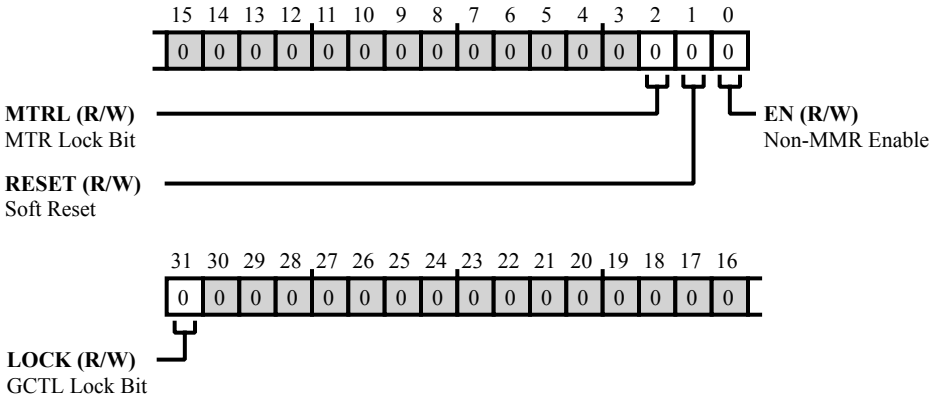

Figure 7-3: TRU_GCTL Register Diagram

Table 7-7: TRU_GCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	GCTL Lock Bit. If the global lock is enabled (SPU_CTL.GLCK bit =1) and the TRU_GCTL.LOCK bit is enabled, the TRU_GCTL register is read only.	
		0	Read write
		1	Read only
2 (R/W)	MTRL	MTR Lock Bit. If the global lock is enabled (SPU_CTL.GLCK bit =1) and the TRU_GCTL.MTRL bit is enabled, the TRU_MTR register is read only.	
		0	Read write
		1	Read only
1 (R/W)	RESET	Soft Reset. The TRU_GCTL.RESET bit is write-1-action and triggers a soft reset to all TRU registers.	
		0	No action
		1	Soft reset

Table 7-7: TRU_GCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	EN	Non-MMR Enable. The `TRU_GCTL.EN` bit is read/write and must be set for the TRU to propagate trigger events. All TRU register read/write operations continue to operate independent of the `TRU_GCTL.EN` bit.	
		0	No trigger events
		1	Propagate trigger events

Generator Trigger Register

The TRU generator trigger register (TRU_MTR) permits trigger generation through software by writing a trigger requester ID value to one of the four fields in the TRU_MTR register. If the global lock is enabled (SPU_CTL.GLCK bit =1) and the TRU_GCTL.LOCK bit is set, the TRU_MTR register is read only. Note this register is primarily used for debug to trigger a TRU output

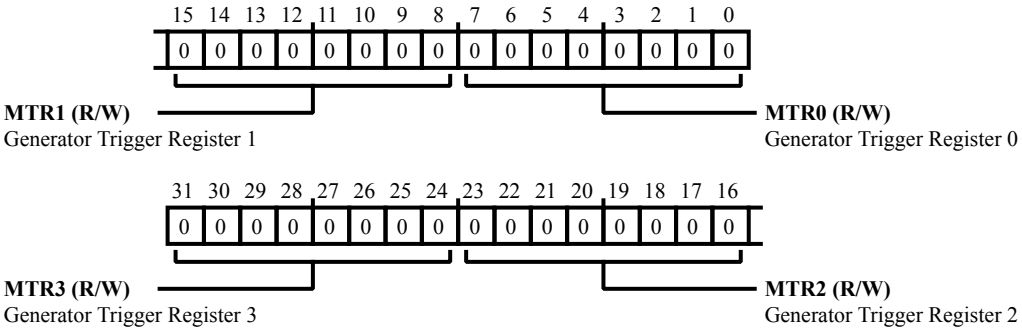

Figure 7-4: TRU_MTR Register Diagram

Table 7-8: TRU_MTR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:24 (R/W)	MTR3	Generator Trigger Register 3. The TRU_MTR.MTR3 bit field is the trigger generator ID value for generator 3.	
		0	No generator specified
		1-197	Range of valid generators
23:16 (R/W)	MTR2	Generator Trigger Register 2. The TRU_MTR.MTR2 bit field is the trigger requester ID value for requester 2.	
		0	No generator specified
		1-197	Range of valid generators
15:8 (R/W)	MTR1	Generator Trigger Register 1. The TRU_MTR.MTR1 bit field is the trigger generator ID value for generator 1.	
		0	No generator specified
		1-197	Range of valid generators
7:0 (R/W)	MTR0	Generator Trigger Register 0. The TRU_MTR.MTR0 bit field is the trigger generator ID value for generator 0.	
		0	No generator specified
		1-197	Range of valid generators

Receiver Select Register

The TRU receiver select registers (TRU_SSR[n]) each provide receiver selection and register locking.

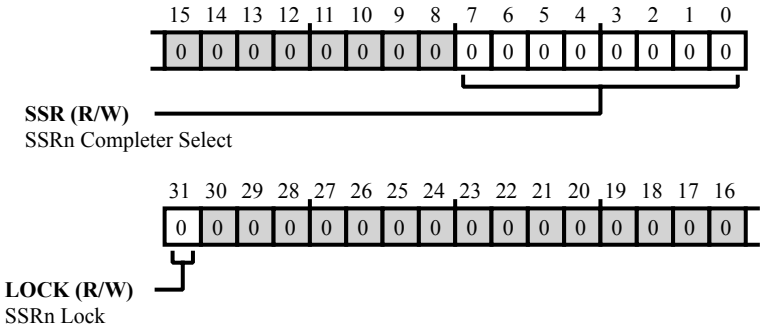

Figure 7-5: TRU_SSR[n] Register Diagram

Table 7-9: TRU_SSR[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	SSRn Lock. If the global lock is enabled (SPU_CTL.GLCK bit =1) and the TRU_SSR[n].LOCK bit is enabled, the TRU_SSR[n] register is read only.	
		0	Unlock register
		1	Lock register
7:0 (R/W)	SSR	SSRn Completer Select. The TRU_SSR[n] register selects the trigger generator ID to which the trigger receiver responds. For example, when a TRU_SSR[n] register is set to respond to trigger generator ID n, a trigger that is generated by trigger generator ID n results in a trigger out to the receiver.	
		0	No generator specified
		1-197	Range of valid generators

Status Information Register

The TRU status register (TRU_STAT) contains the status of TRU_MTR and TRU_SSR[n] register writes and status of bus read/write errors.

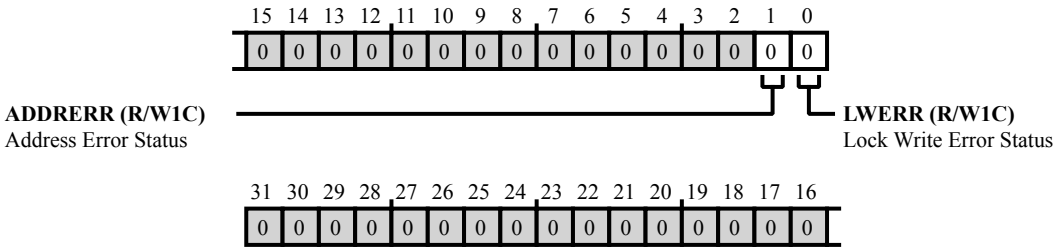

Figure 7-6: TRU_STAT Register Diagram

Table 7-10: TRU_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W1C)	ADDRERR	Address Error Status. The TRU_STAT.ADDRERR bit is set when an invalid address is provided for an MMR access while the TRU is selected. Writing a one to this bit clears the error indication. The TRU_ERRADDR register also is updated when an address error occurs during an MMR access while the TRU is selected.	
		0	No error
		1	Error occurred
0 (R/W1C)	LWERR	Lock Write Error Status. If TRU_STAT.LWERR is set, a lock write error has occurred. Writing a one to this bit clears the error indication.	
		0	No error
		1	Error occurred

8 L2 System Memory

L2 system memories have significant bandwidth for core accesses, but it is important to note that L2 responds slower to core accesses than L1 memories. L2 SRAM is the ideal storage for multiple processor cores to share data and instruction resources, such as semaphores, shared buffers, and code libraries. Due to sophisticated data integrity protection and write protection, L2 SRAM is also ideal for data and instructions critical for safe operation of the application.

L2 System Memory Features

The L2 system memory features include:

- Operation at `SYSCLK` frequency
- ECC protection of SRAM area
- ECC memory refresh
- L2CTL0 contains 2M byte of RAM grouped into eight banks, 256K bytes each and 192K bytes of boot ROM.

L2 System Memory Functional Description

The L2 system memory manages all of the L2 SRAM and ROM memory banks. The system memory interface arbitrates competing accesses, write protection, and ensures SRAM data integrity. The L2 system memory domain is a unified instruction and data memory. It can hold any mixture of code and data required by the system design.

The following sections provide a functional description of the L2 system memory.

ADSP-SC59x L2CTL Register List

The L2 memory controller (L2CTL) includes the controls to manage each L2 memory bank independently. A set of registers governs L2CTL operations. For more information on L2CTL functionality, see the L2CTL register descriptions.

Table 8-1: ADSP-SC59x L2CTL Register List

L2 System Memory Block Diagram

The ***ADSP-SC59x Complete L2 System Memory Block Diagram*** shows the complete L2 system memory, including the memory block instance L2CTL0. The L2CTL0 block contains boot ROM code for Arm and eight banks of L2 RAM containing 256 Kbytes each. The Arm reset ISR (location 0x00000000) is mapped to this block.

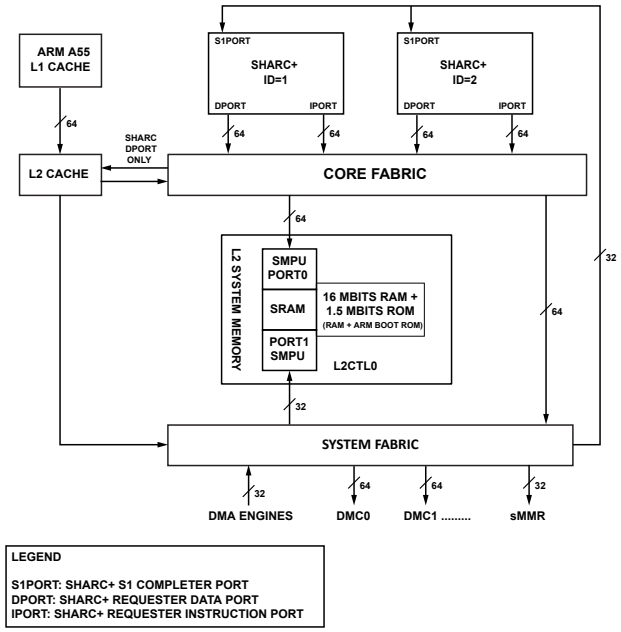

Figure 8-1: ADSP-SC59x Complete L2 System Block Diagram

L2 System Memory Architectural Concepts

The following sections describe the architecture features of the L2 system memory.

Access Characteristics

The L2 system memory interface converts all 8-bit, 16-bit, 32-bit, and 64-bit accesses to 128-bit accesses. Additionally, it converts 8-bit, 16-bit, 32-bit, and 64-bit bursts to an equivalent internal 128-bit access. For example, the L2 system memory interface converts a 128-bit address-aligned burst of 8-bit accesses of burst length 16 to a single 128-bit access.

Read/Write Latency and Throughput

The L2 memory design is optimized for burst accesses at the crossbar interface. The L2 system memory buffers and converts write data of 8/16/32/64-bit to an equivalent 128-bit access. This conversion creates modulo-32-bit writes if the starting addresses are 32-bit aligned. A single 8-bit or 16-bit access, or a non-32-bit address-aligned 8-bit or 16-bit burst access to an ECC-enabled bank creates an extra latency of two SYSCLK cycles. No extra latency is seen if the ECC is disabled.

NOTE: Continuous 8/16-bit core access to an ECC-enabled L2 bank is not recommended from a throughput perspective.

L2 Memory Controller Block Diagram (Instance)

As shown in the ***L2 System Memory Block Diagram***, the L2 controller has five ports that interface to system crossbars. Port 0, port 1, and port 2 are 128-bit interfaces dedicated to core and MDMA3 traffic. Port 3 and port 4 are 128-bit interfaces that connect through DMA. For L2 SRAM, all ports (0/1/2/3/4) have a read channel and a write

channel; for L2 ROM, all ports (0/1/2/3/4) have read channels only. The SRAM is organized in multiple banks; each bank has 256K Bytes. The 192KB ROM is divided into three banks of 64KB.

Within each bank, data is organized into 16384 words, with each word comprising 128 bits of data and 28 bits of ECC checksum. ROM memory is not protected by the ECC scheme. When the L2 controller accesses RAM and ROM cells, it always reads and writes whole 128-bit words. Despite this, the L2 controller supports 8-, 16-, 32-, and 64-bit reads and writes from cores and system by applying respective data masks.

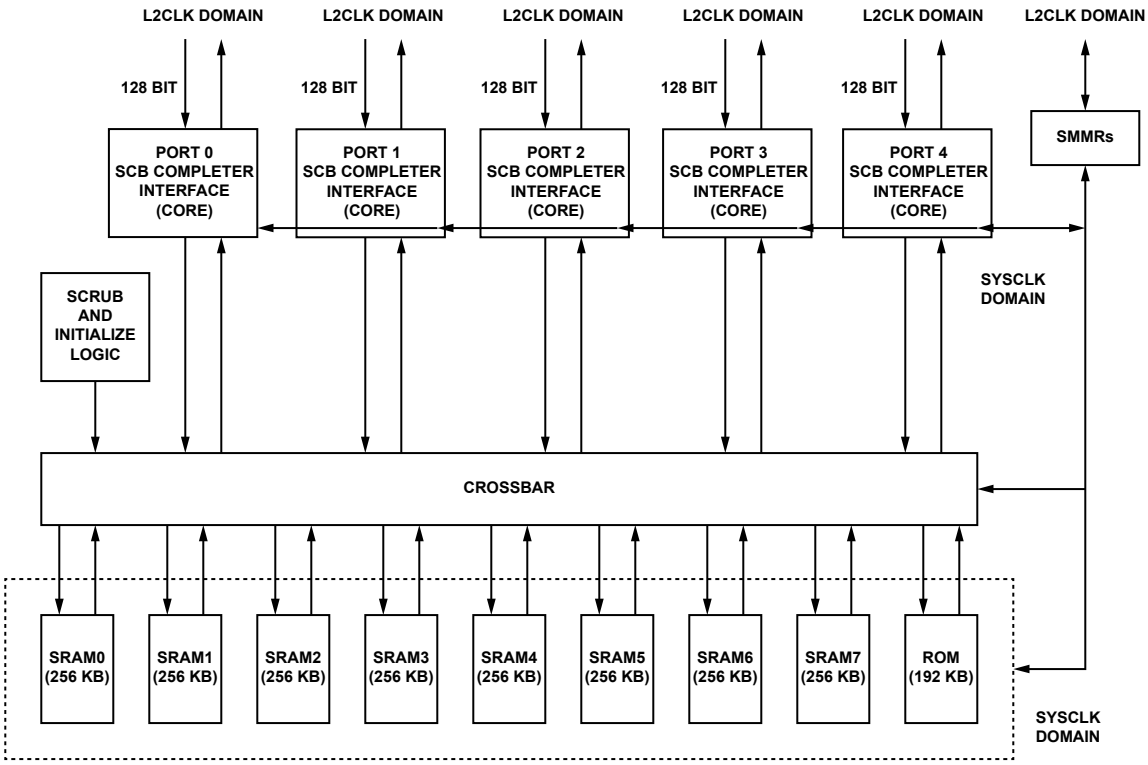

Figure 8-2: L2 System Memory Block Diagram

Arbitration and Priority

Each bank of L2 RAM or ROM has an arbiter which receives requests from the five crossbar ports.

Each arbiter follows a fixed priority scheme for giving grants when more than one channel requests the same bank. The arbiter also supports priority elevation through urgent priority requests.

NOTE: Attempting a write access to both L2 ROM spaces returns an error.

The ***Fixed Priority*** table shows the priority for fixed priority mode (with urgent priority disabled) for each SCB channel.

If two cores (or the 64-bit Max BW DMA) simultaneously try to access L2 for the same instance (both read or both write), even to different banks, software allows only one controller access at a time. One access port can support one read and write at the same time. However, if one core issues a write and the other issues a read, then access can proceed simultaneously. There is no extra latency inside L2, when the accesses are to different banks (assuming pending DMA traffic is also to a non-conflicting bank).

When a core and DMA both access the same bank via the same port (both read or both writes), the best access rate that DMA can achieve is one 128-bit access in every three SYSCLK cycles during the conflict period. This access rate is achieved by programming the read priority count register (`L2CTL_RPCR0.RPC0`) bit and the write priority count register (`L2CTL_WPCR0.WPC0`) to 0, while programming the `L2CTL_RPCR0.RPC1` and the `L2CTL_WPCR0.WPC1` bits to 1.

The arbiters also support priority elevation for a particular channel that has been starved of grants for many SYSCLK cycles. If a channel does not get a grant for *N* cycles after its request, then that channel can elevate the priority of its request by issuing an urgent priority request. This request causes that channel to become the highest priority controller for the next grant cycle (pipelined arbitration for urgent priority). The number of cycles *N*, after which the priority is elevated, can be programmed for each channel separately using the (`L2CTL_RPCR0`) and (`L2CTL_WPCR0`) registers.

Programming the bits in the (`L2CTL_RPCR0`) and (`L2CTL_WPCR0`) registers appropriately achieves the best grant rate for DMA. This grant rate of one in three SYSCLK cycles during the conflict period is achievable under the following conflict conditions:

- An access conflict between the core and DMA to the same memory bank in the fixed priority arbitration scheme with core activity always prioritized over DMA activity
- An access conflict within the pipelined implementation of urgent priority

To disable urgent priority requests, set the `L2CTL_CTL.DISURP` bit. This bit disables the urgent priority requests for all port channels. Each channel can also be prevented from raising the urgent priority request through the priority count register for the specific channel. However, there is no support for disabling urgent priority for a specific memory bank arbiter.

The ***Fixed Priority With Priority Elevation*** table provides the various priority levels for the L2 system memory.

Table 8-5: Fixed Priority With Priority Elevation

Channel	Priority Level
L2 Scrub/Initialization Request	21 (highest)
Port 0 Read Channel Urgent Request	20
Port 0 Write Channel Urgent Request	19
Port 1 Read Channel Urgent Request	18
Port 1 Write Channel Urgent Request	17
Port 2 Read Channel Urgent Request	16
Port 2 Write Channel Urgent Request	15
Port 3 Read Channel Urgent Request	14
Port 3 Write Channel Urgent Request	13
Port 4 Read Channel Urgent Request	12
Port 4 Write Channel Urgent Request	11

Table 8-5: Fixed Priority With Priority Elevation (Continued)

Channel	Priority Level
Port 0 Read Channel Normal Request	10
Port 0 Write Channel Normal Request	9
Port 1 Read Channel Normal Request	8
Port 1 Write Channel Normal Request	7
Port 2 Read Channel Normal Request	6
Port 2 Write Channel Normal Request	5
Port 3 Read Channel Normal Request	4
Port 3 Write Channel Normal Request	3
Port 4 Read Channel Normal Request	2
Port 4 Write Channel Normal Request	1 (lowest)

Data Integrity

The following sections provide information on how the L2 system memory ensures data integrity.

ECC Algorithm

Hsaio encoding calculates the ECC syndrome. A 7-bit syndrome is generated during write operation and stored as a 7-bit parity field along with the 32 data bits. Each data bit contributes to three parity bits according. Each parity bit represents the XOR value of 13 or 14 data bits according to the following mapping:

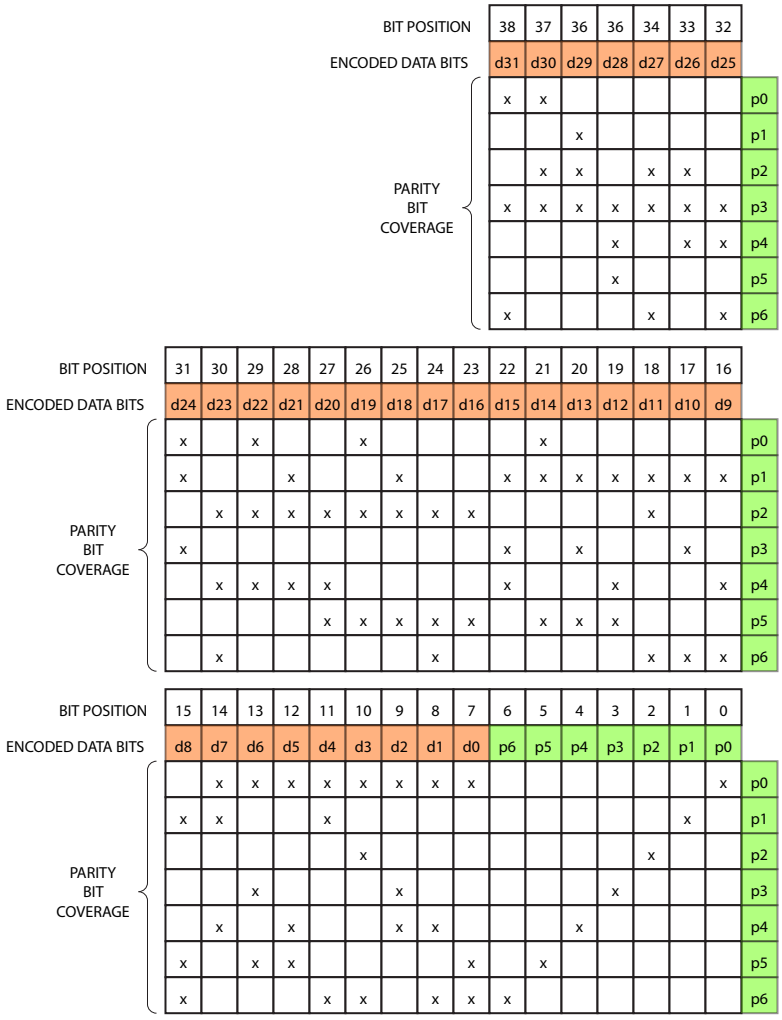

Figure 8-3: Hsaio Parity Bit Mapping

During read operation, the parity bits become part of the syndrome equation. The new syndrome bits are now the XOR values of the 13 or 14 data bits plus the respective stored parity bit. If any of the seven syndrome bits is set, an error situation is detected. An OR gate cross of the 7 bits reports the error, without specifying the type of the error.

If a single parity bit failed, the new 7-bit syndrome has 1 bit that is set. If a single data bit failed, the new syndrome has 3 bits that are set, because all three related parity bits fail. So, an XOR gate cross of all seven syndrome bits detects a single-bit error, indicating that an odd number of syndrome bits is set.

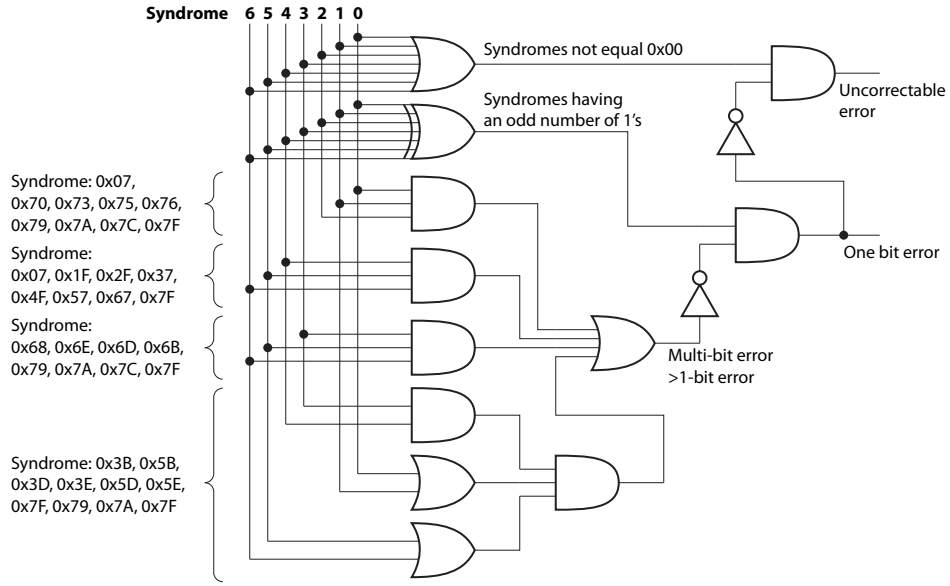

Figure 8-4: Hsiao Error Reports

The XOR gate detects single-bit errors and does not flag any dual-bit error. But the gate does flag 50% of the other multi-bit errors undesirably. Extra logic is implemented to increase the detection rate of multi-bit errors to 68.7% as shown in the figure.

If a single-bit error is detected, the failing bit can be localized and corrected. If all three syndrome bits corresponding to a specific data bit are 1, a data error is assumed. The respective data bit is toggled on its way to the system bus.

ECC Hardware Control

After reset, ECC protection is enabled. The boot code initializes all L2 SRAM data and checksum cells. ECC protection adds some cycle penalty when 8-bit and 16-bit values write L2 memory. Disable ECC protection for individual SRAM banks by setting the `L2CTL_CTL.BK0EDIS` through `L2CTL_CTL.BK7EDIS` disable bits. Due to caching mechanisms of the processor cores and data bursting of the DMA channels, 8-bit and 16-bit write accesses are uncommon. Typically, only two-dimensional DMA operations or un-cached 8-bit and 16-bit store instruction can trigger these writes.

ECC Error Management

The L2 system memory flags 2-bit and multi-bit errors to the system by:

- Raising the ECC_ERR interrupt
- Reporting a read error to the system bus
- Setting the sticky `L2CTL_STAT.ECCERR7-L2CTL_STAT.ECCERR0` status flag
- Latching the address of the failing operation into the respective `L2CTL_ERRADDR7-L2CTL_ERRADDR0` register.

There is one error status bit and one error address register per L2 SRAM bank.

Typically, ECC_ERR events are declared as system faults in the system event controller (SEC). Whether these faults are reported, the interrupt service routine can consult the L2CTL_STAT register and the L2CTL_ERRADDR0 through L2CTL_ERRADDR7 registers to determine whether:

- The data at the failing L2 address was critical enough to require an immediate reboot of the system
- The data at the failing L2 address was less critical or can be restored

The L2CTL_STAT.ECCERR0 through L2CTL_STAT.ECCERR7 flags are cleared with a W1C operation.

Memory Refresh

If data in L2 SRAM contains single-bit errors, the data is corrected on its way to the system buses. The corrected value is not written back to the SRAM location. To prevent any risk of accumulation of single-bit errors over time and to minimize likelihood of multi-bit errors, the L2 system memory provides a special memory refresh mechanism.

If there are dual-bit or multi-bit errors, the ECC_ERR interrupt is raised, and data is not written back to memory.

Program the memory refresh or scrub using:

- TheL2CTL_SADR register with the start address of the scrub
- The L2CTL_SCNT register with the total number of 128-bit addresses to be scrubbed starting from the L2CTL_SADR address

Program the number of cycles between each scrub using the L2CTL_SCTL register. During the scrub, the L2 system memory issues a read, followed by a write-back operation if there is a single-bit ECC error. Once the L2 system memory completes scrubbing the programmed memory region, it generates an interrupt and starts again from the L2CTL_SADR address unless the L2CTL_SCTL.SEN bit is disabled. If the L2CTL_SCTL.SEN bit is cleared before completing the programmed address range, the scrub stops after completing any already issued scrub access. The scrub read/writes always start from the full 128-bit equivalent of the address written into the L2CTL_SADR register. A 128-bit value is always read, and the 128-bit value is written back. The scrub access has the highest priority. Programs can configure 8-bit, 16-bit, or 32-bit addresses in the L2CTL_SADR register. The lower 4 bits of this register are treated as *do-not-care* values because the internal memory array is always accessed when using 128 bits.

Memory refresh operation is meaningless when the L2CTL_CTL.BK0EDIS through L2CTL_CTL.BK7EDIS disable bits are set.

Power Modes

Each L2 memory bank supports low-power modes.

If the bank is not in use, put each L2 system memory bank into the following low-power modes to save power.

Deep Sleep Mode

Set the L2CTL_PCTL.BK7DS through L2CTL_PCTL.BK0DS control bits to enter this mode. This mode preserves the memory contents.

Shut Down Mode

Set the L2CTL_PCTL.BK7SD through L2CTL_PCTL.BK0SD control bits to enter this mode. The memory banks do not retain the data (existing data is lost).

NOTE: It may take up to 11 SYSCLK cycles to deactivate the power mode after writing to the L2CTL_PCTL register. Therefore, L2 access must be issued after this delay.

Access to a memory bank in shut down or deep sleep mode may result in an unpredictable behavior. Ensure that initialization/refresh and memory access to such banks are not issued.

There is no deep sleep or shut down mode for ROM memories.

L2 System Memory Event Control

The following sections describe event control features of the L2 system memory, such as error response.

ECC Error Interrupt

A bus error is signaled under any of the following conditions.

- A write access to ROM address space
- A read/write access to reserved address space
- An ECC multi-bit error in an ECC-enabled bank. A non-modulo, 32-bit write to an ECC-enabled bank can also potentially create a bus error response due to an ECC multi-bit error. This response is because the L2 system memory implements a 32-bit ECC, and therefore a non-modulo, 32-bit write results in a read. This read can create multi-bit errors even if the memory was initialized.

Bus error notifications are stored in the L2CTL_STAT register, and the addresses that generated the error on a given port are stored in the L2CTL_EADDR0/L2CTL_EADDR1 register of that port. The details of the error are stored in the L2CTL_ET0/L2CTL_ET1 register of the port.

ADSP-SC59x L2CTL Register Descriptions

L2 Memory Controller (L2CTL) contains the following registers.

Table 8-6: ADSP-SC59x L2CTL Register List

Name	Description
L2CTL_CTL	Control Register
L2CTL_EADDR0	Error Type 0 Address Register
L2CTL_EADDR1	Error Type 1 Address Register
L2CTL_EADDR2	Error Type 2 Address Register
L2CTL_EADDR3	Error Type 3 Address Register

Table 8-6: ADSP-SC59x L2CTL Register List (Continued)

Name	Description
L2CTL_EADDR4	Error Type 4 Address Register
L2CTL_ERRADDR0	ECC Error Address 0 Register
L2CTL_ERRADDR1	ECC Error Address 1 Register
L2CTL_ERRADDR2	ECC Error Address 2 Register
L2CTL_ERRADDR3	ECC Error Address 3 Register
L2CTL_ERRADDR4	ECC Error Address 4 Register
L2CTL_ERRADDR5	ECC Error Address 5 Register
L2CTL_ERRADDR6	ECC Error Address 6 Register
L2CTL_ERRADDR7	ECC Error Address 7 Register
L2CTL_ERRADDR8	ECC Error Address 8 Register
L2CTL_ET0	Error Type 0 Register
L2CTL_ET1	Error Type 1 Register
L2CTL_ET2	Error Type 2 Register
L2CTL_ET3	Error Type 3 Register
L2CTL_ET4	Error Type 4 Register
L2CTL_INIT	Initialization Register
L2CTL_ISTAT	Initialization Status Register
L2CTL_PCTL	Power Control Register
L2CTL_REVID	Revision ID Register
L2CTL_RPCR0	Read Priority Count Register
L2CTL_RPCR1	Read Priority Count Register
L2CTL_SADR	Scrub Start Address Register
L2CTL_SCNT	Scrub Count Register
L2CTL_SCTL	Scrub Control Register
L2CTL_STAT	Status Register
L2CTL_STAT_1	L2 Port Error Status Register
L2CTL_WPCR0	Write Priority Count Register
L2CTL_WPCR1	Write Priority Count Register

Control Register

The L2CTL_CTL register includes a write protection bit, enables L2 banks, and selects mapping of banks (as ECC RAM or data RAM).

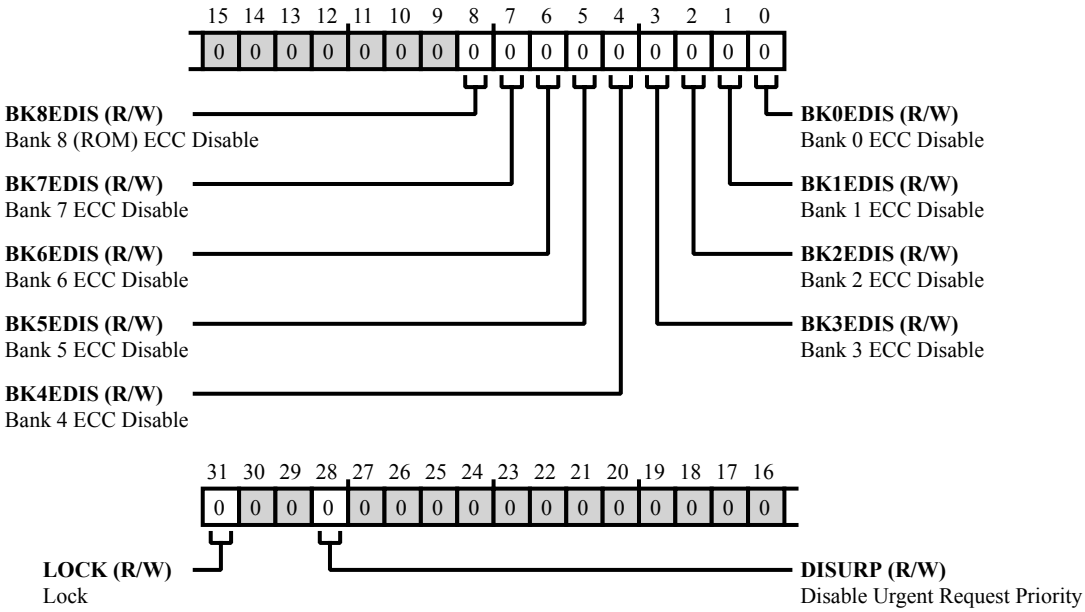

Figure 8-5: L2CTL_CTL Register Diagram

Table 8-7: L2CTL_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock bit is set (SPU_CTL.GLCK bit =1) and the L2CTL_CTL.LOCK bit is set, the L2CTL_CTL register is read only (locked).	
		0	Unlock
		1	Lock
28 (R/W)	DISURP	Disable Urgent Request Priority. The L2CTL_CTL.DISURP disables urgent request priority mode for all L2 banks.	
		0	Enable URP
		1	Disable URP
8 (R/W)	BK8EDIS	Bank 8 (ROM) ECC Disable. The L2CTL_CTL.BK8EDIS bit disables L2 bank 8 (ROM) ECC operation. ECC operation should be enabled or disable before the start of L2 bank access.	
		0	Enable ECC
		1	Disable ECC

Table 8-7: L2CTL_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	BK7EDIS	Bank 7 ECC Disable. The `L2CTL_CTL.BK7EDIS` bit disables L2 bank 7 ECC operation. ECC operation should be enabled or disable before the start of L2 bank access.	
		0	Enable ECC
		1	Disable ECC
6 (R/W)	BK6EDIS	Bank 6 ECC Disable. The `L2CTL_CTL.BK6EDIS` bit disables L2 bank 6 ECC operation. ECC operation should be enabled or disable before the start of L2 bank access.	
		0	Enable ECC
		1	Disable ECC
5 (R/W)	BK5EDIS	Bank 5 ECC Disable. The `L2CTL_CTL.BK5EDIS` bit disables L2 bank 5 ECC operation. ECC operation should be enabled or disable before the start of L2 bank access.	
		0	Enable ECC
		1	Disable ECC
4 (R/W)	BK4EDIS	Bank 4 ECC Disable. The `L2CTL_CTL.BK4EDIS` bit disables L2 bank 4 ECC operation. ECC operation should be enabled or disable before the start of L2 bank access.	
		0	Enable ECC
		1	Disable ECC
3 (R/W)	BK3EDIS	Bank 3 ECC Disable. The `L2CTL_CTL.BK3EDIS` bit disables L2 bank 3 ECC operation. ECC operation should be enabled or disable before the start of L2 bank access.	
		0	Enable ECC
		1	Disable ECC
2 (R/W)	BK2EDIS	Bank 2 ECC Disable. The `L2CTL_CTL.BK2EDIS` bit disables L2 bank 2 ECC operation. ECC operation should be enabled or disable before the start of L2 bank access.	
		0	Enable ECC
		1	Disable ECC

Table 8-7: L2CTL_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W)	BK1EDIS	Bank 1 ECC Disable. The `L2CTL_CTL.BK1EDIS` bit disables L2 bank 1 ECC operation. ECC operation should be enabled or disable before the start of L2 bank access.	
		0	Enable ECC
		1	Disable ECC
0 (R/W)	BK0EDIS	Bank 0 ECC Disable. The `L2CTL_CTL.BK0EDIS` bit disables L2 bank 0 ECC operation. ECC operation should be enabled or disable before the start of L2 bank access.	
		0	Enable ECC
		1	Disable ECC

Error Type 0 Address Register

The L2CTL_EADDR0 register holds the address that created an access error on the L2 port 0 bus interface. This register is be updated only if the corresponding error status bit (L2CTL_STAT.ERR0) is cleared. After the status bit is set for an error, further errors do not update the L2CTL_EADDR0 register until a W1C clears the corresponding status bit. If read and write access errors occur simultaneously, the register captures the write access error address.

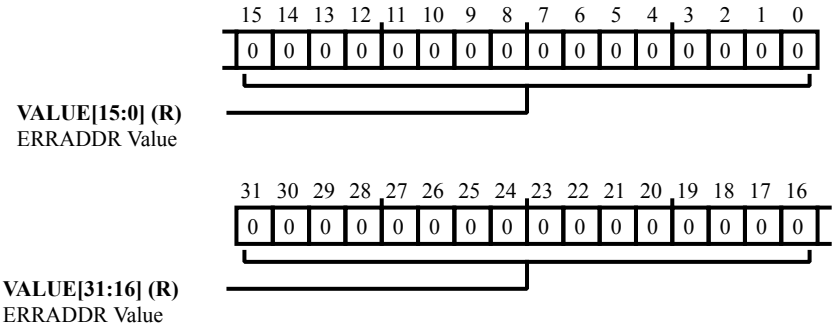

Figure 8-6: L2CTL_EADDR0 Register Diagram

Table 8-8: L2CTL_EADDR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	ERRADDR Value. The L2CTL_EADDR0.VALUE bits hold the address causing the bus error.

Error Type 1 Address Register

The L2CTL_EADDR1 register holds the address that created an access error on the L2 port 1 bus interface. This register is be updated only if the corresponding error status bit (L2CTL_STAT.ERR1) is cleared. After the status bit is set for an error, further errors do not update the L2CTL_EADDR1 register until a W1C clears the corresponding status bit. If read and write access errors occur simultaneously, the register captures the write access error address.

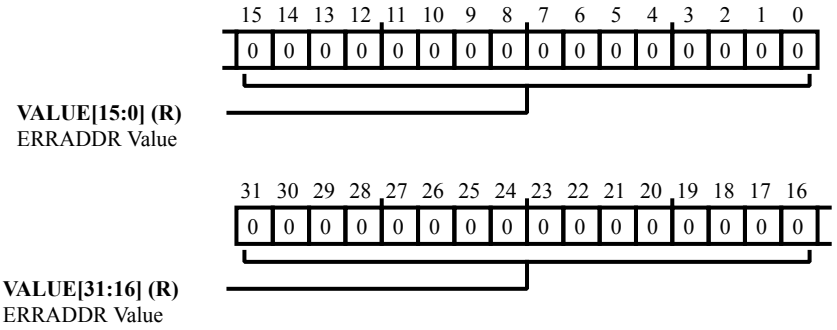

Figure 8-7: L2CTL_EADDR1 Register Diagram

Table 8-9: L2CTL_EADDR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	ERRADDR Value. The L2CTL_EADDR1.VALUE bits hold the address causing the bus error.

Error Type 2 Address Register

The L2CTL_EADDR2 register holds the address that created an access error on the L2 port 2 bus interface (cores). This register is be updated only if the corresponding error status bit (L2CTL_STAT_1.ERR2) is cleared. After the status bit is set for an error, further errors do not update the L2CTL_EADDR2 register until a W1C clears the corresponding status bit. If read and write access errors occur simultaneously, the register captures the write access error address.

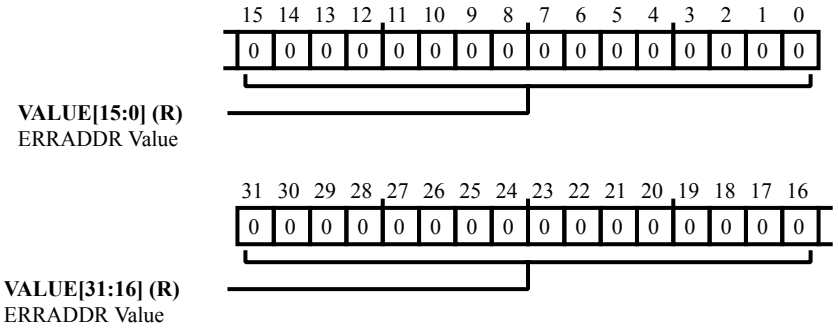

Figure 8-8: L2CTL_EADDR2 Register Diagram

Table 8-10: L2CTL_EADDR2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	ERRADDR Value. The L2CTL_EADDR2.VALUE bits hold the address causing the bus error.

Error Type 3 Address Register

The L2CTL_EADDR3 register holds the address that created an access error on the L2 port 3 bus interface (DMA). This register is be updated only if the corresponding error status bit (L2CTL_STAT_1.ERR3) is cleared. After the status bit is set for an error, further errors do not update the L2CTL_EADDR3 register until a W1C clears the corresponding status bit. If read and write access errors occur simultaneously, the register captures the write access error address.

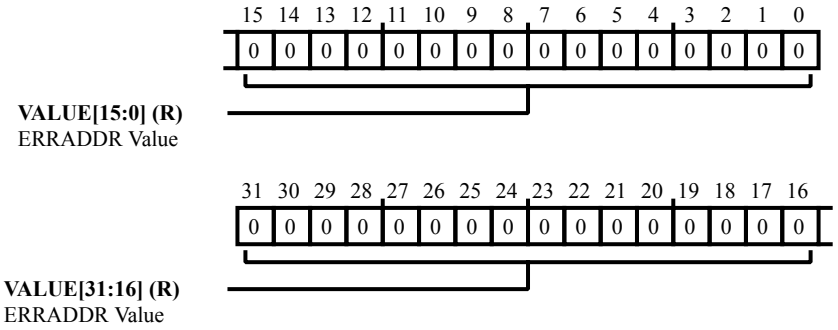

Figure 8-9: L2CTL_EADDR3 Register Diagram

Table 8-11: L2CTL_EADDR3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	ERRADDR Value. The L2CTL_EADDR3.VALUE bits hold the address causing the bus error.

Error Type 4 Address Register

The L2CTL_EADDR4 register holds the address that created an access error on the L2 port 4 bus interface (DMA). This register is be updated only if the corresponding error status bit (L2CTL_STAT_1.ERR4) is cleared. After the status bit is set for an error, further errors do not update the L2CTL_EADDR4 register until a W1C clears the corresponding status bit. If read and write access errors occur simultaneously, the register captures the write access error address.

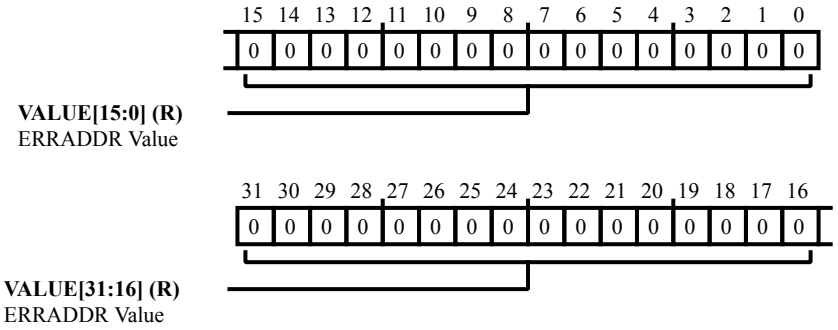

Figure 8-10: L2CTL_EADDR4 Register Diagram

Table 8-12: L2CTL_EADDR4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	ERRADDR Value. The L2CTL_EADDR4.VALUE bits hold the address causing the bus error.

ECC Error Address 0 Register

The L2CTL_ERRADDR0 register holds the address containing an ECC multi-bit error for the corresponding bank. The L2CTL updates this register only if the bank's status bit (L2CTL_STAT.ECCERR0) is cleared. After the bank's status bit is set for an error, further errors in the same bank are not detected until a W1C clears the status bit.

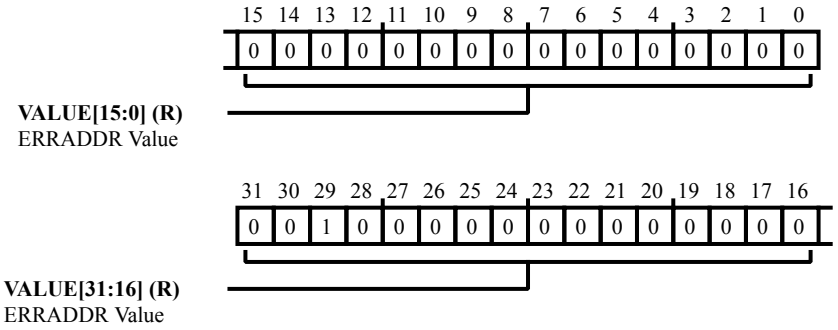

Figure 8-11: L2CTL_ERRADDR0 Register Diagram

Table 8-13: L2CTL_ERRADDR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	ERRADDR Value. The L2CTL_ERRADDR0.VALUE bits hold the address containing the ECC double-bit error.

ECC Error Address 1 Register

The L2CTL_ERRADDR1 register holds the address containing an ECC multi-bit error for the corresponding bank. The L2CTL updates this register only if the bank's status bit (L2CTL_STAT.ECCERR1) is cleared. After the bank's status bit is set for an error, further errors in the same bank are not detected until a W1C clears the status bit.

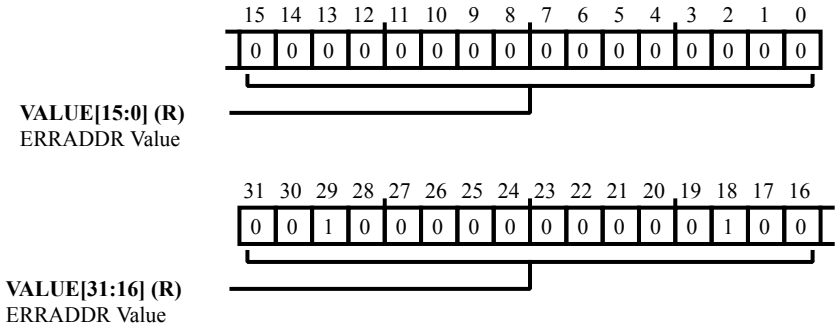

Figure 8-12: L2CTL_ERRADDR1 Register Diagram

Table 8-14: L2CTL_ERRADDR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	ERRADDR Value. The L2CTL_ERRADDR1.VALUE bits hold the address containing the ECC double-bit error.

ECC Error Address 2 Register

The L2CTL_ERRADDR2 register holds the address containing an ECC multi-bit error for the corresponding bank. The L2CTL updates this register only if the bank's status bit (L2CTL_STAT.ECCERR2) is cleared. After the bank's status bit is set for an error, further errors in the same bank are not detected until a W1C clears the status bit.

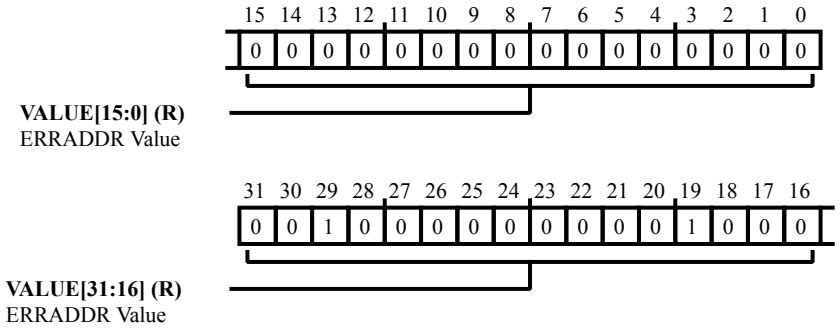

Figure 8-13: L2CTL_ERRADDR2 Register Diagram

Table 8-15: L2CTL_ERRADDR2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	ERRADDR Value. The L2CTL_ERRADDR2.VALUE bits hold the address containing the ECC double-bit error.

ECC Error Address 3 Register

The L2CTL_ERRADDR3 register holds the address containing an ECC multi-bit error for the corresponding bank. The L2CTL updates this register only if the bank's status bit (L2CTL_STAT.ECCERR3) is cleared. After the bank's status bit is set for an error, further errors in the same bank are not detected until a W1C clears the status bit.

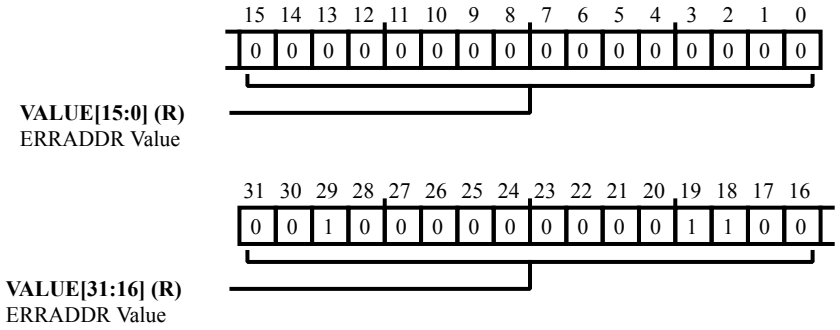

Figure 8-14: L2CTL_ERRADDR3 Register Diagram

Table 8-16: L2CTL_ERRADDR3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	ERRADDR Value. The L2CTL_ERRADDR3.VALUE bits hold the address containing the ECC double-bit error.

ECC Error Address 4 Register

The L2CTL_ERRADDR4 register holds the address containing an ECC multi-bit error for the corresponding bank. The L2CTL updates this register only if the bank's status bit (L2CTL_STAT.ECCERR4) is cleared. After the bank's status bit is set for an error, further errors in the same bank are not detected until a W1C clears the status bit.

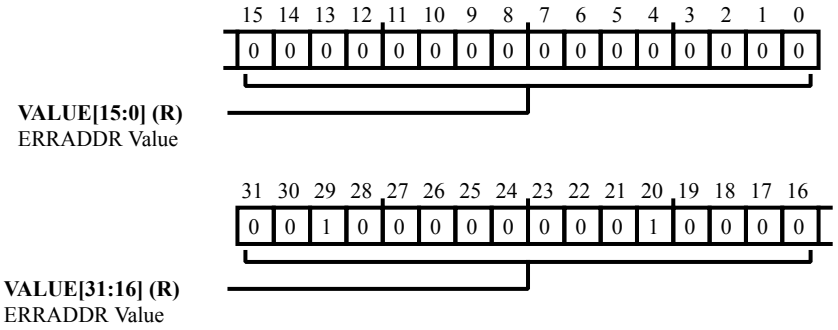

Figure 8-15: L2CTL_ERRADDR4 Register Diagram

Table 8-17: L2CTL_ERRADDR4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	ERRADDR Value. The L2CTL_ERRADDR4.VALUE bits hold the address containing the ECC double-bit error.

ECC Error Address 5 Register

The L2CTL_ERRADDR5 register holds the address containing an ECC multi-bit error for the corresponding bank. The L2CTL updates this register only if the bank's status bit (L2CTL_STAT.ECCERR5) is cleared. After the bank's status bit is set for an error, further errors in the same bank are not detected until a W1C clears the status bit.

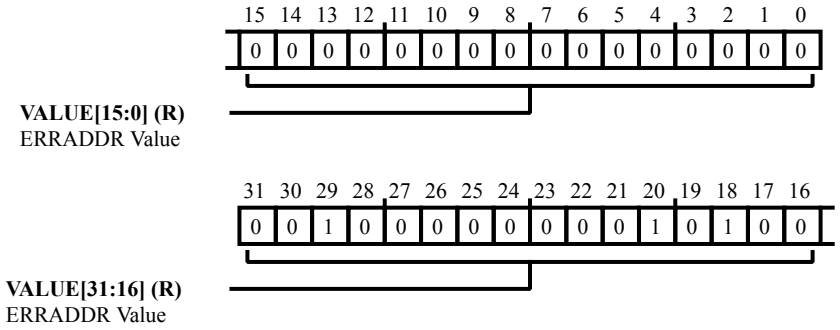

Figure 8-16: L2CTL_ERRADDR5 Register Diagram

Table 8-18: L2CTL_ERRADDR5 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	ERRADDR Value. The L2CTL_ERRADDR5.VALUE bits hold the address containing the ECC double-bit error.

ECC Error Address 6 Register

The L2CTL_ERRADDR6 register holds the address containing an ECC multi-bit error for the corresponding bank. The L2CTL updates this register only if the bank's status bit (L2CTL_STAT.ECCERR6) is cleared. After the bank's status bit is set for an error, further errors in the same bank are not detected until a W1C clears the status bit.

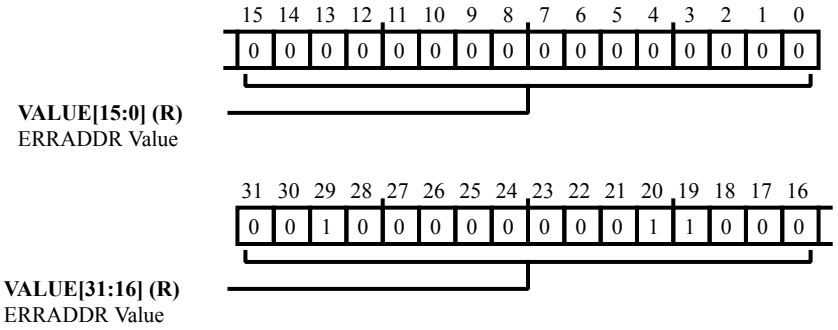

Figure 8-17: L2CTL_ERRADDR6 Register Diagram

Table 8-19: L2CTL_ERRADDR6 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	ERRADDR Value. The L2CTL_ERRADDR6.VALUE bits hold the address containing the ECC double-bit error.

ECC Error Address 7 Register

The L2CTL_ERRADDR7 register holds the address containing an ECC multi-bit error for the corresponding bank. The L2CTL updates this register only if the bank's status bit (L2CTL_STAT.ECCERR7) is cleared. After the bank's status bit is set for an error, further errors in the same bank are not detected until a W1C clears the status bit.

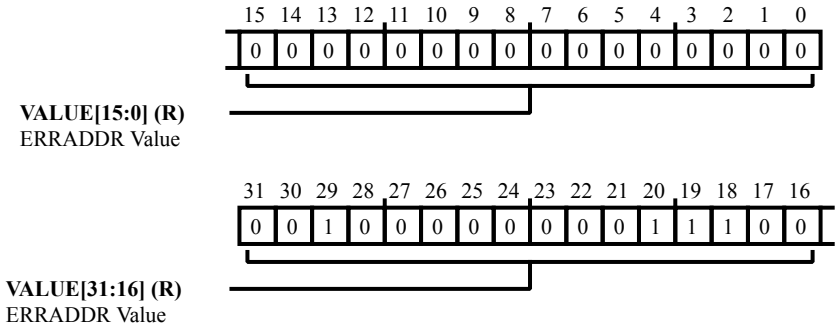

Figure 8-18: L2CTL_ERRADDR7 Register Diagram

Table 8-20: L2CTL_ERRADDR7 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	ERRADDR Value. The L2CTL_ERRADDR7.VALUE bits hold the address containing the ECC double-bit error.

ECC Error Address 8 Register

The L2CTL_ERRADDR8 register holds the address containing an ECC multi-bit error for the corresponding bank. The L2CTL updates this register only if the bank's status bit (L2CTL_STAT.ECCERR8) is cleared. After the bank's status bit is set for an error, further errors in the same bank are not detected until a W1C clears the status bit.

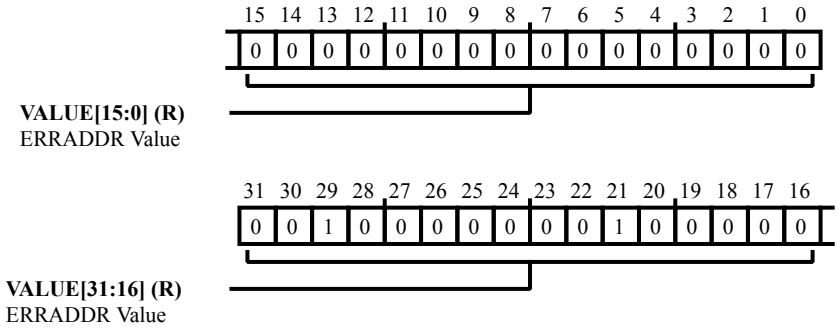

Figure 8-19: L2CTL_ERRADDR8 Register Diagram

Table 8-21: L2CTL_ERRADDR8 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	ERRADDR Value. The L2CTL_ERRADDR8.VALUE bits hold the address containing the ECC double-bit error.

Error Type 0 Register

The L2CTL_ET0 register holds information about the error transaction that has occurred on the bus for the corresponding L2 bus port 0. This register is updated only if the corresponding error status bit L2CTL_STAT.ERR0 is cleared. After the status bit is set for an error, further errors do not update the L2CTL_ET0 register until a W1C clears the corresponding status bit. If read and write access errors occur simultaneously, the L2CTL_ET0 captures the write access error, keeping in sync with the error address register (L2CTL_EADDR0).

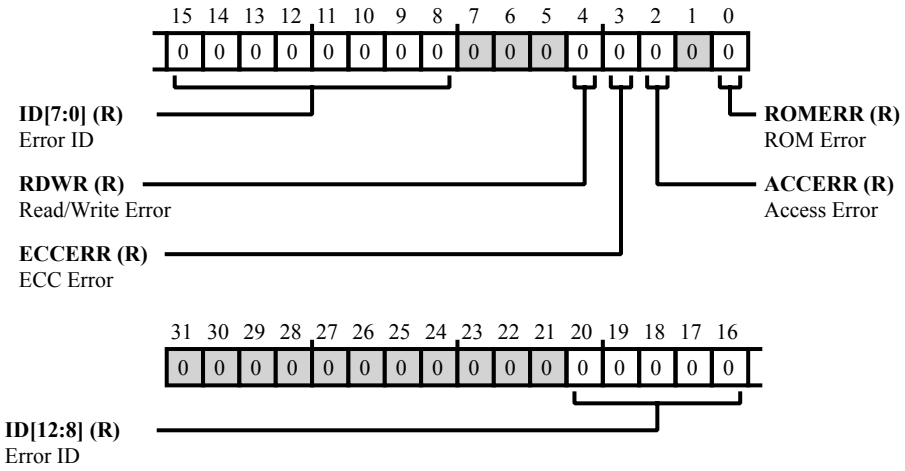

Figure 8-20: L2CTL_ET0 Register Diagram

Table 8-22: L2CTL_ET0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
20:8 (R/NW)	ID	Error ID. The L2CTL_ET0.ID bits hold the bus requester ID of the access that caused an error.	
4 (R/NW)	RDWR	Read/Write Error. The L2CTL_ET0.RDWR bit indicates whether a read or write access caused an error.	
		0	Read Access created Error
		1	Write Access created Error
3 (R/NW)	ECCERR	ECC Error. The L2CTL_ET0.ECCERR bit indicates whether the access had an ECC double-bit error.	
2 (R/NW)	ACCERR	Access Error. The L2CTL_ET0.ACCERR bit indicates whether the access went to a restricted bank.	

Table 8-22: L2CTL_ET0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
0 (R/NW)	ROMERR	ROM Error. The `L2CTL_ET0.ROMERR` bit indicates whether a write access went to a ROM area.

Error Type 1 Register

The L2CTL_ET1 register holds information about the error transaction that has occurred on the bus for the corresponding L2 bus port 1. This register is updated only if the corresponding error status bit L2CTL_STAT.ERR1 is cleared. After the status bit is set for an error, further errors do not update the L2CTL_ET1 register until a W1C clears the corresponding status bit. If read and write access errors occur simultaneously, the L2CTL_ET1 captures the write access error, keeping in sync with the error address register (L2CTL_EADDR1).

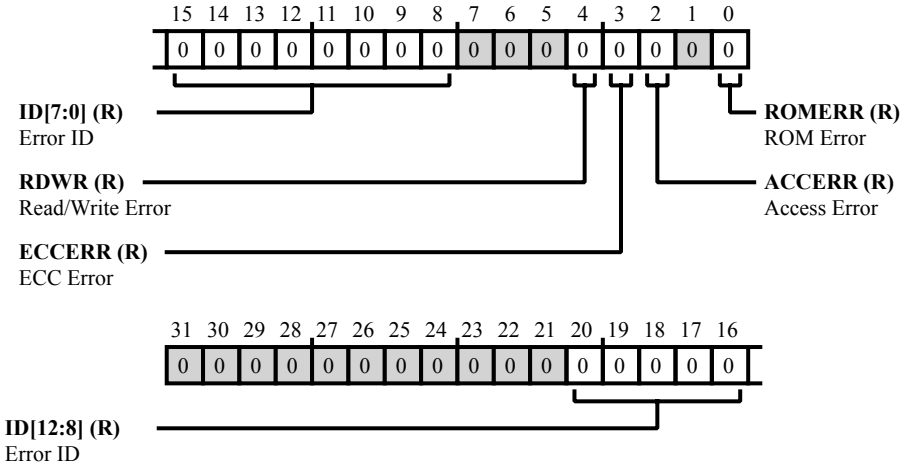

Figure 8-21: L2CTL_ET1 Register Diagram

Table 8-23: L2CTL_ET1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
20:8 (R/NW)	ID	Error ID. The L2CTL_ET1.ID bits hold the bus requester ID of the access that caused an error.	
4 (R/NW)	RDWR	Read/Write Error. The L2CTL_ET1.RDWR bit indicates whether a read or write access caused an error.	
		0	Read access created error
		1	Write access created error
3 (R/NW)	ECCERR	ECC Error. If the L2CTL_ET1.ECCERR bit =1, the access had an ECC double-bit error.	
2 (R/NW)	ACCERR	Access Error. If the L2CTL_ET1.ACCERR bit =1, the access went to a restricted bank.	
0 (R/NW)	ROMERR	ROM Error. If the L2CTL_ET1.ROMERR bit =1, a write access went to a ROM area.	

Error Type 2 Register

The L2CTL_ET2 register holds information about the error transaction that has occurred on the bus for the corresponding L2 bus port 2 (cores). This register is updated only if the corresponding error status bit L2CTL_STAT_1.ERR2 is cleared. After the status bit is set for an error, further errors do not update the L2CTL_ET2 register until a W1C clears the corresponding status bit. If read and write access errors occur simultaneously, the L2CTL_ET2 captures the write access error, keeping in sync with the error address register (L2CTL_EADDR2).

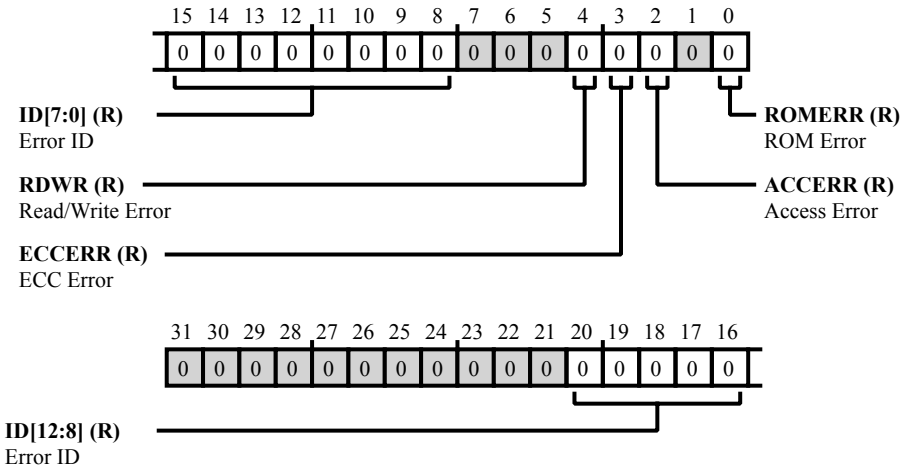

Figure 8-22: L2CTL_ET2 Register Diagram

Table 8-24: L2CTL_ET2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
20:8 (R/NW)	ID	Error ID. The L2CTL_ET2.ID bits hold the bus requester ID of the access that caused an error.
4 (R/NW)	RDWR	Read/Write Error. The L2CTL_ET2.RDWR bit indicates whether a read or write access caused an error.
3 (R/NW)	ECCERR	ECC Error. The L2CTL_ET2.ECCERR bit indicates whether the access had an ECC double-bit error.
2 (R/NW)	ACCERR	Access Error. If the L2CTL_ET2.ACCERR bit =1, the access went to a restricted bank.
0 (R/NW)	ROMERR	ROM Error. If the L2CTL_ET2.ROMERR bit =1, a write access went to a ROM area.

Error Type 3 Register

The L2CTL_ET3 register holds information about the error transaction that has occurred on the bus for the corresponding L2 bus port 3 (DMA). This register is updated only if the corresponding error status bit L2CTL_STAT_1.ERR3 is cleared. After the status bit is set for an error, further errors do not update the L2CTL_ET3 register until a W1C clears the corresponding status bit. If read and write access errors occur simultaneously, the L2CTL_ET3 captures the write access error, keeping in sync with the error address register (L2CTL_EADDR3).

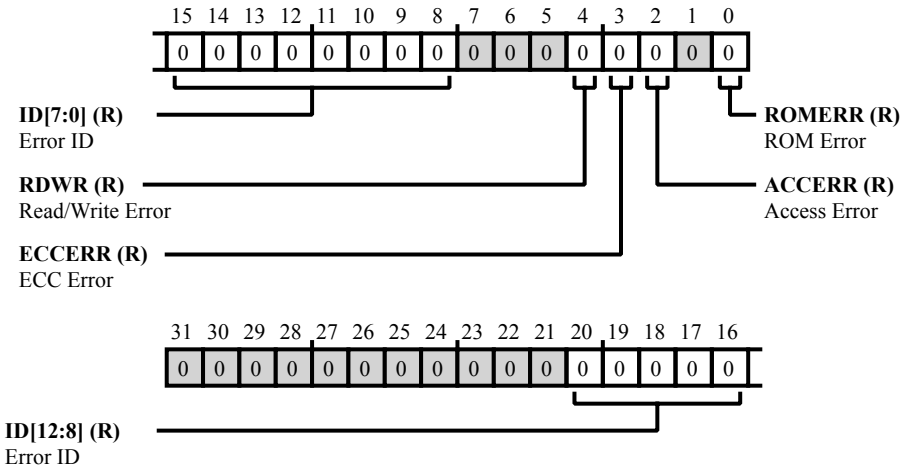

Figure 8-23: L2CTL_ET3 Register Diagram

Table 8-25: L2CTL_ET3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
20:8 (R/NW)	ID	Error ID. The L2CTL_ET3.ID bits hold the bus requester ID of the access that caused an error.
4 (R/NW)	RDWR	Read/Write Error. The L2CTL_ET3.RDWR bit indicates whether a read or write access caused an error.
3 (R/NW)	ECCERR	ECC Error. The L2CTL_ET3.ECCERR bit indicates whether the access had an ECC double-bit error.
2 (R/NW)	ACCERR	Access Error. If the L2CTL_ET3.ACCERR bit =1, the access went to a restricted bank.
0 (R/NW)	ROMERR	ROM Error. If the L2CTL_ET3.ROMERR bit =1, a write access went to a ROM area.

Error Type 4 Register

The L2CTL_ET4 register holds information about the error transaction that has occurred on the bus for the corresponding L2 bus port 4 (DMA). This register is updated only if the corresponding error status bit L2CTL_STAT_1.ERR4 is cleared. After the status bit is set for an error, further errors do not update the L2CTL_ET4 register until a W1C clears the corresponding status bit. If read and write access errors occur simultaneously, the L2CTL_ET4 captures the write access error, keeping in sync with the error address register (L2CTL_EADDR4).

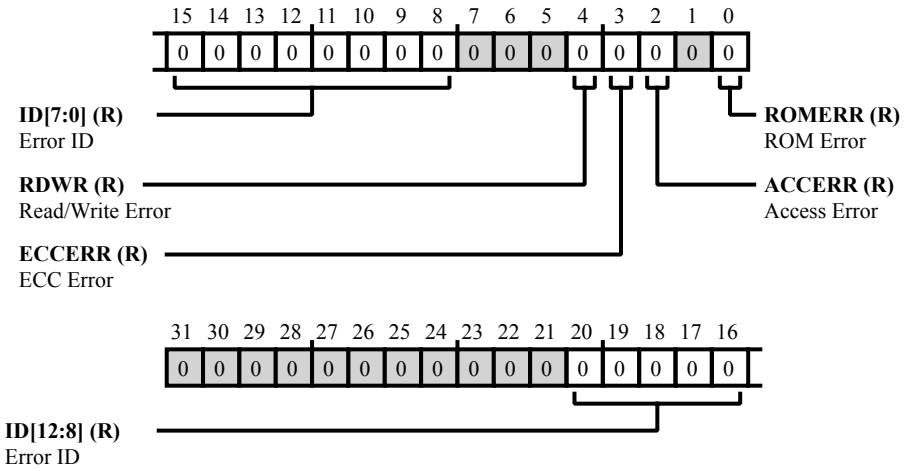

Figure 8-24: L2CTL_ET4 Register Diagram

Table 8-26: L2CTL_ET4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
20:8 (R/NW)	ID	Error ID. The L2CTL_ET4.ID bits hold the bus requester ID of the access that caused an error.
4 (R/NW)	RDWR	Read/Write Error. The L2CTL_ET4.RDWR bit indicates whether a read or write access caused an error.
3 (R/NW)	ECCERR	ECC Error. The L2CTL_ET4.ECCERR bit indicates whether the access had an ECC double-bit error.
2 (R/NW)	ACCERR	Access Error. If the L2CTL_ET4.ACCERR bit =1, the access went to a restricted bank.
0 (R/NW)	ROMERR	ROM Error. If the L2CTL_ET4.ROMERR bit =1, a write access went to a ROM area.

Initialization Register

The L2CTL_INIT register initializes memory banks with 128'b0 and ECC bits corresponding to 128'b0. Any writes to the bits in this register while initialization is occurring to any of the banks is ignored. All bits are W1A (Write 1 for Action).

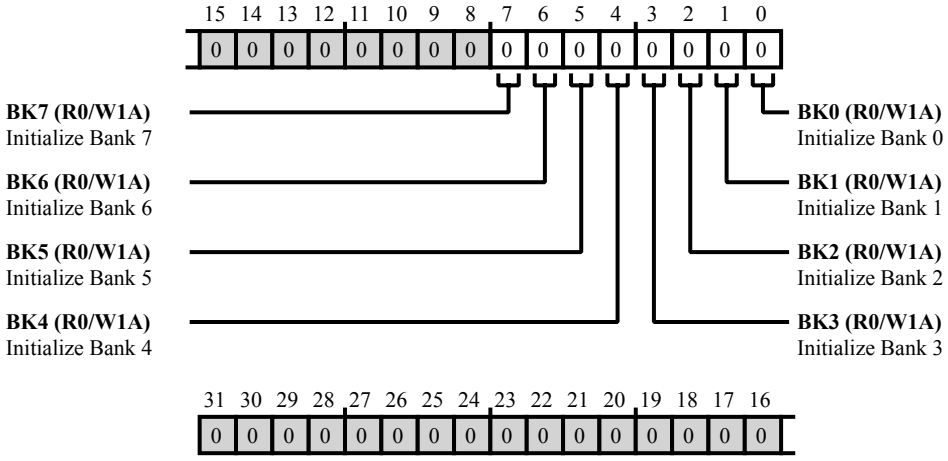

Figure 8-25: L2CTL_INIT Register Diagram

Table 8-27: L2CTL_INIT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7 (R0/W1A)	BK7	Initialize Bank 7. The write-1 to the L2CTL_INIT.BK7 bit initializes bank 7 with 128b0 and ECC bits corresponding to 128b0. Any write to this bit during the initialization of the banks is ignored.
6 (R0/W1A)	BK6	Initialize Bank 6. The write-1 to the L2CTL_INIT.BK6 bit initializes bank 6 with 128b0 and ECC bits corresponding to 128b0. Any write to this bit during the initialization of the banks is ignored.
5 (R0/W1A)	BK5	Initialize Bank 5. The write -1 to the L2CTL_INIT.BK5 bit initializes bank 5 with 128b0 and ECC bits corresponding to 128b0. Any write to this bit during the initialization of the banks is ignored.
4 (R0/W1A)	BK4	Initialize Bank 4. The write-1 to the L2CTL_INIT.BK4 bit initializes bank 4 with 128b0 and ECC bits corresponding to 128b0. Any write to this bit during the initialization of the banks is ignored.

Table 8-27: L2CTL_INIT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
3 (R0/W1A)	BK3	Initialize Bank 3. The write-1 to the `L2CTL_INIT.BK3` bit initializes bank 3 with 128b0 and ECC bits corresponding to 128b0. Any write to this bit during the initialization of the banks is ignored.
2 (R0/W1A)	BK2	Initialize Bank 2. The write-1 to the `L2CTL_INIT.BK2` bit initializes bank 2 with 128b0 and ECC bits corresponding to 128b0. Any write to this bit during the initialization of the banks is ignored.
1 (R0/W1A)	BK1	Initialize Bank 1. The write-1 to the `L2CTL_INIT.BK1` bit initializes bank 1 with 128b0 and ECC bits corresponding to 128b0. Any write to this bit during the initialization of the banks is ignored.
0 (R0/W1A)	BK0	Initialize Bank 0. The write-1 to the `L2CTL_INIT.BK0` bit initializes bank 0 with 128b0 and ECC bits corresponding to 128b0. Any write to this bit during the initialization of the banks is ignored.

Initialization Status Register

The L2CTL_ISTAT register holds the status of the RAM bank initialization. If set, the corresponding bank is initialized.

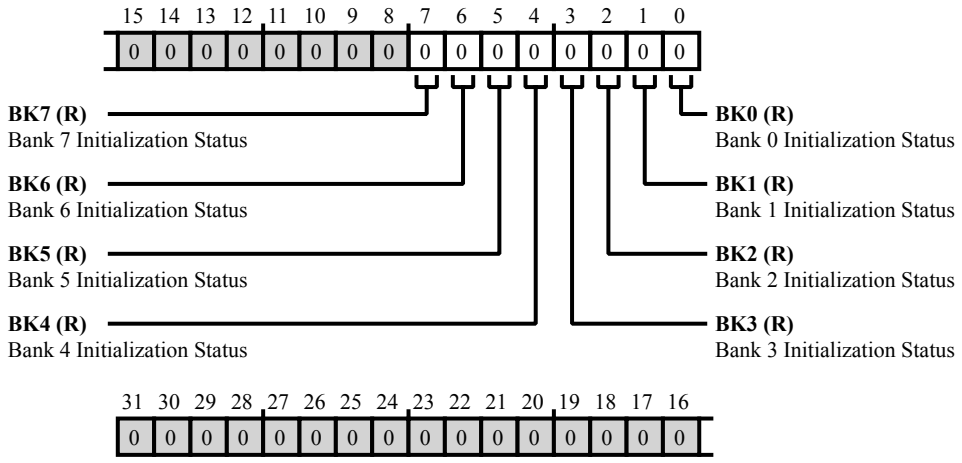

Figure 8-26: L2CTL_ISTAT Register Diagram

Table 8-28: L2CTL_ISTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7 (R/NW)	BK7	Bank 7 Initialization Status. The L2CTL_ISTAT.BK7 bits hold the bank 7 initialization status. A W1A on a BKxINIT bit clears this bit and the bit is set when initialization completes.
6 (R/NW)	BK6	Bank 6 Initialization Status. The L2CTL_ISTAT.BK6 bits hold the bank 6 initialization status. A W1A on a BKxINIT bit clears this bit and the bit is set when initialization completes.
5 (R/NW)	BK5	Bank 5 Initialization Status. The L2CTL_ISTAT.BK5 bits hold the bank 5 initialization status. A W1A on a BKxINIT bit clears this bit and the bit is set when initialization completes.
4 (R/NW)	BK4	Bank 4 Initialization Status. The L2CTL_ISTAT.BK4 bits hold the bank 4 initialization status. A W1A on a BKxINIT bit clears this bit and the bit is set when initialization completes.
3 (R/NW)	BK3	Bank 3 Initialization Status. The L2CTL_ISTAT.BK3 bits hold the bank 3 initialization status. A W1A on a BKxINIT bit clears this bit and the bit is set when initialization completes.
2 (R/NW)	BK2	Bank 2 Initialization Status. The L2CTL_ISTAT.BK2 bits hold the bank 2 initialization status. A W1A on a BKxINIT bit clears this bit and the bit is set when initialization completes.

Table 8-28: L2CTL_ISTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
1 (R/NW)	BK1	Bank 1 Initialization Status. The `L2CTL_ISTAT.BK1` bits hold the bank 1 initialization status. A W1A on a BKxINIT bit clears this bit and the bit is set when initialization completes.
0 (R/NW)	BK0	Bank 0 Initialization Status. The `L2CTL_ISTAT.BK0` bits hold the bank 0 initialization status. A W1A on a BKxINIT bit clears this bit and the bit is set when initialization completes.

Power Control Register

The L2CTL_PCTL register has the various control settings for selectively enabling the deep sleep and shut down power saving features.

NOTE: The corresponding L2 bank should not be accessed if the power control feature is enabled for that bank. An access to a bank in deep sleep/shut down may create unpredictable behavior.

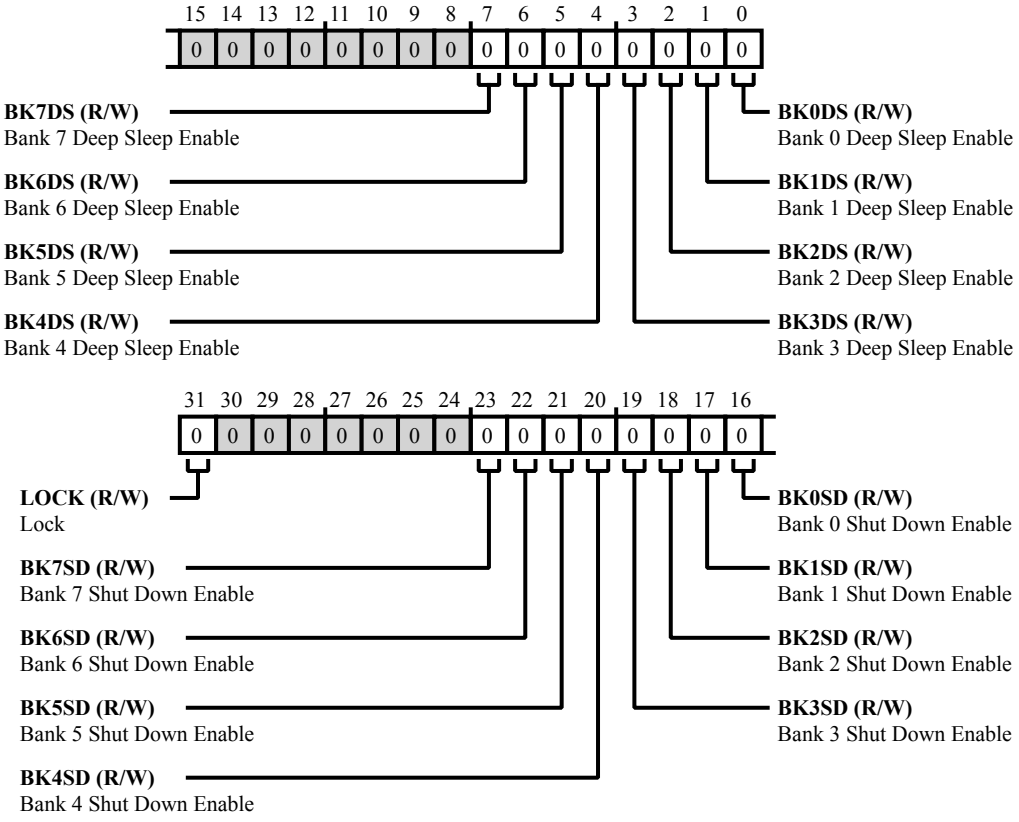

Figure 8-27: L2CTL_PCTL Register Diagram

Table 8-29: L2CTL_PCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock bit is set (SPU_CTL.GLCK bit =1) and the L2CTL_PCTL.LOCK bit is set, the L2CTL_PCTL register is read only (locked).	
		0	Unlock
		1	Lock
23 (R/W)	BK7SD	Bank 7 Shut Down Enable. The L2CTL_PCTL.BK7SD bits enables bank 7 shut down.	

Table 8-29: L2CTL_PCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
22 (R/W)	BK6SD	Bank 6 Shut Down Enable. The L2CTL_PCTL.BK6SD bits enables bank 6 shut down.
21 (R/W)	BK5SD	Bank 5 Shut Down Enable. The L2CTL_PCTL.BK5SD bits enables bank 5 shut down.
20 (R/W)	BK4SD	Bank 4 Shut Down Enable. The L2CTL_PCTL.BK4SD bits enables bank 4 shut down.
19 (R/W)	BK3SD	Bank 3 Shut Down Enable. The L2CTL_PCTL.BK3SD bits enables bank 3 shut down.
18 (R/W)	BK2SD	Bank 2 Shut Down Enable. The L2CTL_PCTL.BK2SD bits enables bank 2 shut down.
17 (R/W)	BK1SD	Bank 1 Shut Down Enable. The L2CTL_PCTL.BK1SD bits enables bank 1 shut down.
16 (R/W)	BK0SD	Bank 0 Shut Down Enable. The L2CTL_PCTL.BK0SD bits enables bank 0 shut down.
7 (R/W)	BK7DS	Bank 7 Deep Sleep Enable. The L2CTL_PCTL.BK7DS bits enables bank 7 deep sleep.
6 (R/W)	BK6DS	Bank 6 Deep Sleep Enable. The L2CTL_PCTL.BK6DS bits enables bank 6 deep sleep.
5 (R/W)	BK5DS	Bank 5 Deep Sleep Enable. The L2CTL_PCTL.BK5DS bits enables bank 5 deep sleep.
4 (R/W)	BK4DS	Bank 4 Deep Sleep Enable. The L2CTL_PCTL.BK4DS bits enables bank 4 deep sleep.
3 (R/W)	BK3DS	Bank 3 Deep Sleep Enable. The L2CTL_PCTL.BK3DS bits enables bank 3 deep sleep.
2 (R/W)	BK2DS	Bank 2 Deep Sleep Enable. The L2CTL_PCTL.BK2DS bits enables bank 2 deep sleep.
1 (R/W)	BK1DS	Bank 1 Deep Sleep Enable. The L2CTL_PCTL.BK1DS bits enables bank 1 deep sleep.
0 (R/W)	BK0DS	Bank 0 Deep Sleep Enable. The L2CTL_PCTL.BK0DS bits enables bank 0 deep sleep.

Revision ID Register

The L2CTL_REVID register provides the L2 Revision ID.

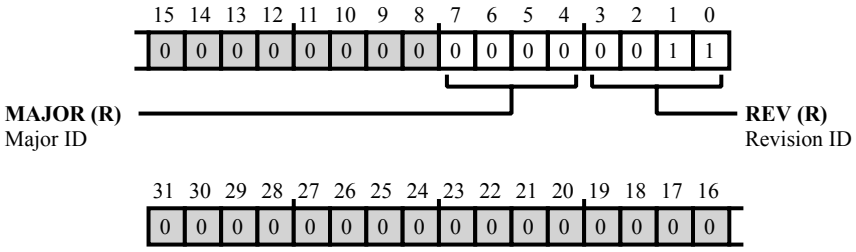

Figure 8-28: L2CTL_REVID Register Diagram

Table 8-30: L2CTL_REVID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:4 (R/NW)	MAJOR	Major ID. The L2CTL_REVID.MAJOR bit indicates L2 Major ID.
3:0 (R/NW)	REV	Revision ID. The L2CTL_REVID.REV bit indicates the L2 Revision ID.

Read Priority Count Register

The L2CTL_RPCR0 register stores the count value to be used for priority elevation for bus read channels of Port0 to Port3. If a bus channel is not granted access from the bank arbiter, the channel waits for the programmed number (stored in RPCx) of SYSCLK cycles, before the request is elevated to a high priority request. If a priority count value is programmed as zero for a channel, that channel does not raise the urgent priority request. Default value wait cycle for each channel is 15..

This is a read/write register, but a new value in the corresponding field must be written only when there are no outstanding transactions on the corresponding bus read channel. A best practice is to program this register before initiating an L2 access.

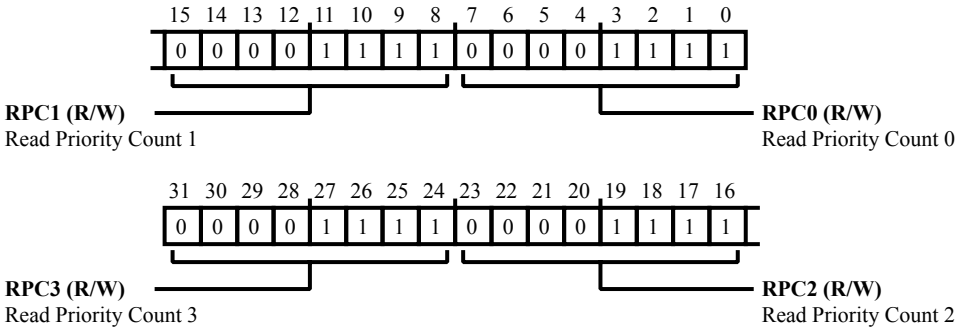

Figure 8-29: L2CTL_RPCR0 Register Diagram

Table 8-31: L2CTL_RPCR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	RPC3	Read Priority Count 3. The L2CTL_RPCR0.RPC3 bits hold the priority count for L2 bus read channel 3.
23:16 (R/W)	RPC2	Read Priority Count 2. The L2CTL_RPCR0.RPC2 bits hold the priority count for L2 bus read channel 2.
15:8 (R/W)	RPC1	Read Priority Count 1. The L2CTL_RPCR0.RPC1 bits hold the priority count for L2 bus read channel 1.
7:0 (R/W)	RPC0	Read Priority Count 0. The L2CTL_RPCR0.RPC0 bits hold the priority count for L2 bus read channel 0.

Read Priority Count Register

The L2CTL_RPCR1 register stores the count value to be used for priority elevation for bus read channel 4. If a bus channel is not granted access from the bank arbiter, the channel waits for the programmed number (stored in RPC4) of SYSCLK cycles, before the request is elevated to a high priority request. If a priority count value is programmed as zero for a channel, that channel does not raise the urgent priority request. Default value of RPC4 is 15.

This is a read/write register, but a new value in the corresponding field must be written only when there are no outstanding transactions on the corresponding bus read channel. A best practice is to program this register before initiating an L2 access.

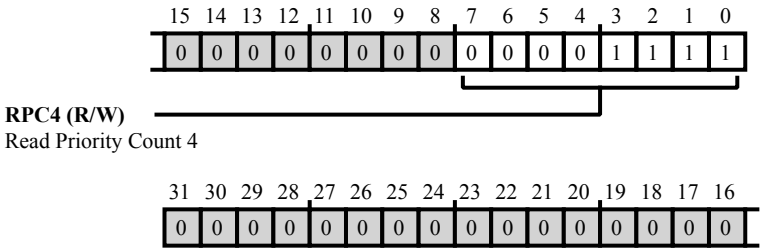

Figure 8-30: L2CTL_RPCR1 Register Diagram

Table 8-32: L2CTL_RPCR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	RPC4	Read Priority Count 4. The L2CTL_RPCR1.RPC4 bits hold the priority count for L2 bus read channel 4.

Scrub Start Address Register

The L2CTL_SADR register stores the scrub start address value. Writes to this register can be prevented by setting the L2CTL_SCTL.LOCK bit and the global lock.

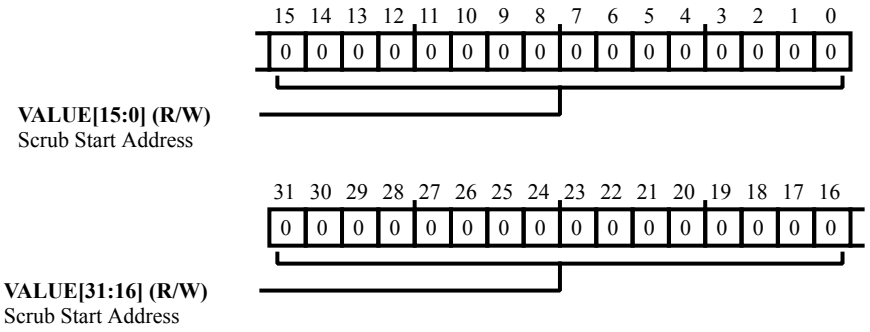

Figure 8-31: L2CTL_SADR Register Diagram

Table 8-33: L2CTL_SADR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Scrub Start Address. The L2CTL_SADR.VALUE bits hold the scrub start address. The writes to this register can be prevented by setting the L2_SCTL.LOCK and the global lock.

Scrub Count Register

The L2CTL_SCNT register determines the number of 128-bit locations scrubbed starting from the start address (L2CTL_SADR register). Writes to the L2CTL_SCNT register can be prevented by setting the L2CTL_CTL.LOCK bit and the global lock.

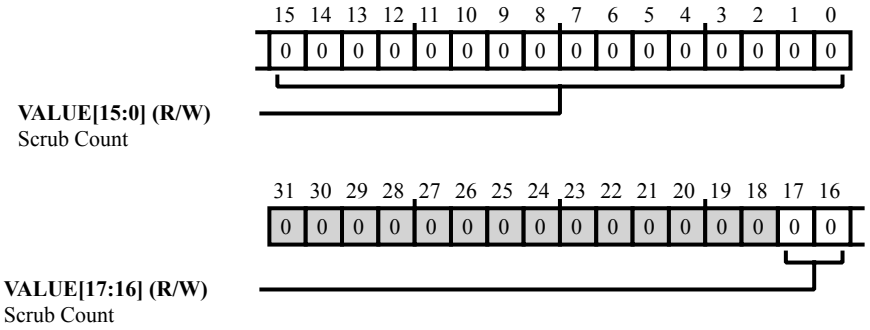

Figure 8-32: L2CTL_SCNT Register Diagram

Table 8-34: L2CTL_SCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
17:0 (R/W)	VALUE	Scrub Count. The L2CTL_SCNT.VALUE bits determines the number of 128-bit locations scrubbed starting from the start address. Ensure value programmed is less than the total addressable 128-bit L2 RAM locations available.

Scrub Control Register

The L2CTL_SCTL register holds the automatic scrub related controls. This is a read/write register. Memory scrub can be performed by programming the L2CTL_SADR (scrub start address) register with the start address of the scrub and the L2CTL_SCNT register with the total number of 128 -bit addresses to be scrubbed starting from the L2CTL_SADR register. The number of cycles between each scrub can be programmed with the L2CTL_SCTL.SRT bit.

During the scrub the controller issues a read followed by write back if there is a single bit ECC error. Once the L2 controller completes scrubbing the memory region mentioned using the L2CTL_SADR and the L2CTL_SCNT registers, an interrupt is generated and scrubbing re-starts from the start unless the scrub enable bit is disabled in the control register. If scrub enable is cleared before completing the address range used in the L2CTL_SADR and L2CTL_SCNT registers, the scrub stops after completing any already issued scrub access.

The scrub read/writes always start from the full 128-bit equivalent of the address written into the L2CTL_SADR register. A 128-bit value is always read and the 128-bit value is written back. The scrub access has the highest priority. Programs can configure 8-, 16-, or 32-bit addresses in the L2CTL_SADR register but the lower 3 bits are treated as don't care because the internal memory array is always accessed in a 128-bit mode.

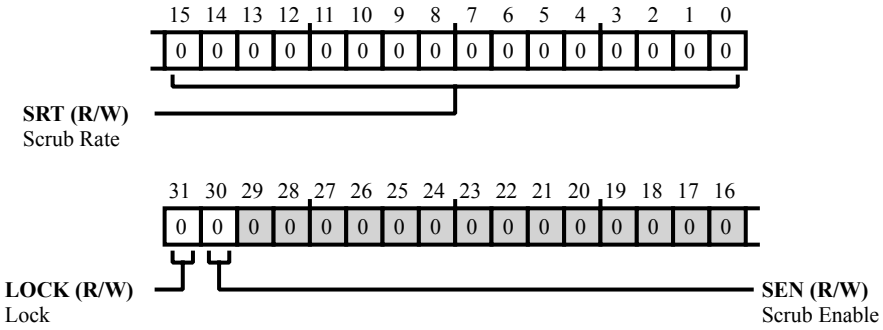

Figure 8-33: L2CTL_SCTL Register Diagram

Bit No. (Access)	Bit Name	Description/Enumeration	
14 (R/W1C)	ECCERR6	ECC Error Bank 6. The `L2CTL_STAT.ECCERR6` bit indicates that an ECC double-bit error occurred inside L2 bank 6.	
		0	No Status
		1	ECC Double Bit Error
13 (R/W1C)	ECCERR5	ECC Error Bank 5. The `L2CTL_STAT.ECCERR5` bit indicates that an ECC double-bit error occurred inside L2 bank 5.	
		0	No Status
		1	ECC Double Bit Error
12 (R/W1C)	ECCERR4	ECC Error Bank 4. The `L2CTL_STAT.ECCERR4` bit indicates that an ECC double-bit error occurred inside L2 bank 4.	
		0	No Status
		1	ECC Double Bit Error
11 (R/W1C)	ECCERR3	ECC Error Bank 3. The `L2CTL_STAT.ECCERR3` bit indicates that an ECC double-bit error occurred inside L2 bank 3.	
		0	No Status
		1	ECC Double Bit Error
10 (R/W1C)	ECCERR2	ECC Error Bank 2. The `L2CTL_STAT.ECCERR2` bit indicates that an ECC double-bit error occurred inside L2 bank 2.	
		0	No Status
		1	ECC Double Bit Error
9 (R/W1C)	ECCERR1	ECC Error Bank 1. The `L2CTL_STAT.ECCERR1` bit indicates that an ECC double-bit error occurred inside L2 bank 1.	
		0	No Status
		1	ECC Double Bit Error

Table 8-36: L2CTL_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W1C)	ECCERR0	ECC Error Bank 0. The `L2CTL_STAT.ECCERR0` bit indicates that an ECC double-bit error occurred inside L2 bank 0.	
		0	No Status
		1	ECC Double Bit Error
5 (R/W1C)	INITDN	Initialization Status. The `L2CTL_STAT.INITDN` bit indicates whether initialization has been completed.	
		0	Initialization Not Complete
		1	Initialization Completed
4 (R/W1C)	SCRBDN	Scrub Status. The `L2CTL_STAT.SCRBDN` bit indicates whether a round of memory scrub has completed.	
		0	Scrub Not Complete
		1	Scrub Completed
1 (R/W1C)	ERR1	Error Port 1. The `L2CTL_STAT.ERR1` indicates whether the L2CTL has detected a bus access error on L2s bus port 1.	
		0	No Error
		1	Bus Access Error
0 (R/W1C)	ERR0	Error Port 0. The `L2CTL_STAT.ERR0` indicates whether the L2CTL has detected a bus access error on L2s bus port 0.	
		0	No Error
		1	Bus Access Error

L2 Port Error Status Register

The L2CTL_STAT_1 register stores the AXI Error Status from Port2 onwards. The register bits are sticky - once set it has to be explicitly reset by writing a 1 to that particular bit.

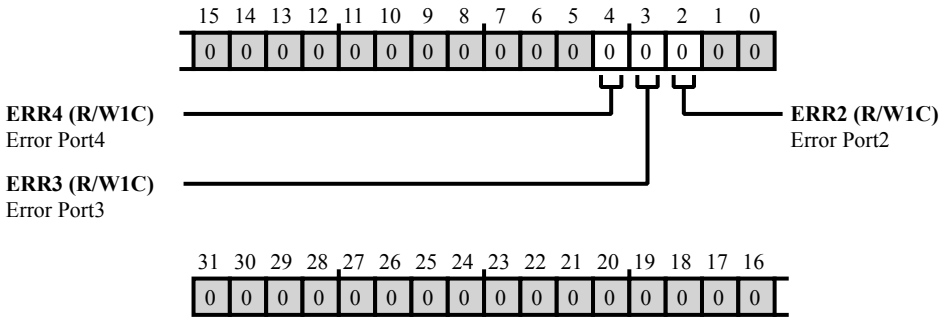

Figure 8-35: L2CTL_STAT_1 Register Diagram

Table 8-37: L2CTL_STAT_1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
4 (R/W1C)	ERR4	Error Port4. The L2CTL_STAT_1.ERR4 indicates whether the L2CTL has detected a bus access error on L2s bus port 4.
3 (R/W1C)	ERR3	Error Port3. The L2CTL_STAT_1.ERR3 indicates whether the L2CTL has detected a bus access error on L2s bus port 3.
2 (R/W1C)	ERR2	Error Port2. The L2CTL_STAT_1.ERR2 indicates whether the L2CTL has detected a bus access error on L2s bus port 2.

Write Priority Count Register

The L2CTL_WPCR0 register stores the count value to be used for priority elevation for bus write channels. If a bus channel is not granted access from the bank arbiter, the channel waits for the programmed number of SYSCLK cycles, before the request is elevated to a high priority request. If a priority count value is programmed as zero for a channel, that channel does not raise the urgent priority request.

This is a read/write register, but a new value in the corresponding field must be written only when there are no outstanding transactions on the corresponding bus write channel. A best practice is to program this register before initiating an L2 access.

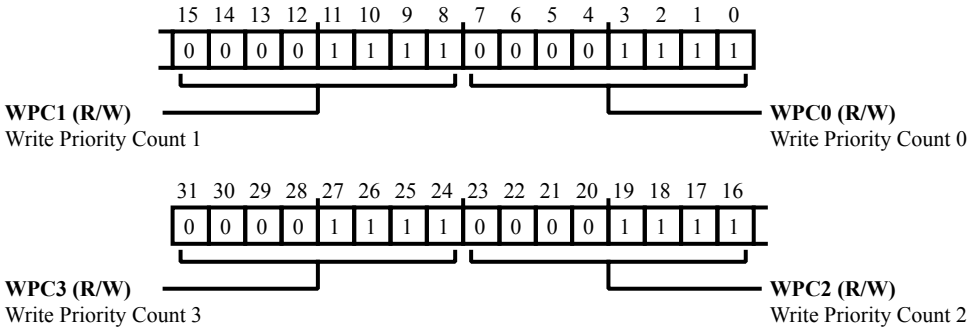

Figure 8-36: L2CTL_WPCR0 Register Diagram

Table 8-38: L2CTL_WPCR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	WPC3	Write Priority Count 3. The L2CTL_WPCR0.WPC3 bits hold the priority count for L2 bus write channel 3.
23:16 (R/W)	WPC2	Write Priority Count 2. The L2CTL_WPCR0.WPC2 bits hold the priority count for L2 bus write channel 2.
15:8 (R/W)	WPC1	Write Priority Count 1. The L2CTL_WPCR0.WPC1 bits hold the priority count for L2 bus write channel 1.
7:0 (R/W)	WPC0	Write Priority Count 0. The L2CTL_WPCR0.WPC0 bits hold the priority count for L2 bus write channel 0.

Write Priority Count Register

The L2CTL_WPCR1 register stores the count value to be used for priority elevation for bus write channels. If a bus channel is not granted access from the bank arbiter, the channel waits for the programmed number of SYSCLK cycles, before the request is elevated to a high priority request. If a priority count value is programmed as zero for a channel, that channel does not raise the urgent priority request.

This is a read/write register, but a new value in the corresponding field must be written only when there are no outstanding transactions on the corresponding bus write channel. A best practice is to program this register before initiating an L2 access.

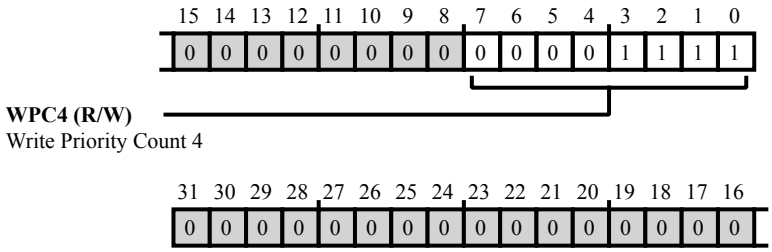

Figure 8-37: L2CTL_WPCR1 Register Diagram

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	WPC4	Write Priority Count 4. The L2CTL_WPCR1.WPC4 bits hold the priority count for L2 bus write channel 4.

9 Dynamic Memory Controller (DMC)

The dynamic memory controller (DMC) provides a glueless interface between DDR3 SDRAMs and the system crossbar interface (SCB). The DMC enables execution of instructions from, as well as transfer of data to and from, DDR3 SDRAM respectively.

NOTE: The term DDR3 is referred to generically as DDR SDRAM in the rest of this chapter unless otherwise noted.

The DMC is partitioned in a manner that allows reconfiguration and maintainability. The memory access protocol state machine along with JEDEC standard specific logic is embedded in the *protocol controller*. An access and operation reordering mechanism is incorporated as an *efficiency controller*. An SCB bus responder interface is provided to interface with the on-chip interconnect. This interface results in an efficient completer implementation owing to its out-of-order transaction capabilities. The control and status registers present in the DMC can be accessed using the MMR access bus.

The DMC supports access to the external memory by core and DMA accesses.

DMC Features

The DMC includes a protocol controller that supports:

- JESD79-3E compatible double data rate DDR3 SDRAM devices

The features of the dynamic memory controller are:

- Provides 16-bit data only interface to SDRAM devices
- Supports a single external rank (one chip select)
- Provides page hit detection that supports multiple column accesses to the same row
- User-specified active, precharge, and refresh commands.
- Programmable SDRAM access timing parameters
- Enables automatic refresh generation with programmable refresh intervals
- Self-refresh mode to reduce system power consumption

- Efficient transaction processing to improve throughput and bandwidth using:
  - Software programmable SCB IDs to allow SCB ID-based priority
  - The ability to postpone up to eight auto-refresh commands
  - Software selectable closed page scheme on a per bank basis
  - Simple transaction scheduling mechanism to reduce read write turnaround frequency on the memory bus
  - Accesses with the same SCB ID are scheduled back-to-back to take advantage of same page access in SDRAM
  - Caching of SDRAM read data burst for specific controllers to reduce the latency for same burst accesses.

The DDR3 features are:

- 512 Mb to 8 Gb device sizes
- Burst length BL = 8
- Support for additive latency
- Support for programmable (and ZQ calibration) ODT and drive impedance
- Support for read leveling
- Support for write leveling

Feature Exclusions

The DMC exclusions are as follows:

For DDR3:

- 4-bit and 8-bit wide DDR3 DRAM memories are not supported
- Burst interleaved accesses are not supported
- Both burst chop-BC4 and BC4-on-the-fly are not supported
- Auto refresh pull-in is not supported
- DLL off mode is not supported

DMC Functional Description

The dynamic memory controller consists of controller and target interfaces, a protocol controller, and an efficiency controller. The following sections describe the function of these interfaces and controllers.

ADSP-SC59x DMC Register List

The Dynamic Memory Controller module (DMC) provides an interface to external double-data-rate SDRAM. This interface supports various DDR standards (see chapter descriptions). A set of registers governs DMC controller operations. For more information on DMC controller functionality, see the DMC Controller Register Descriptions.

Table 9-1: ADSP-SC59x DMC Register List

Name	Description
DMC_CFG	Configuration Register
DMC_CTL	Control Register
DMC_DLLCTL	DLL Control Register
DMC_DT_CALIB_ADDR	Data Calibration Address Register
DMC_DT_DATA_CALIB_DATA0	Data Calibration Data 0 Register
DMC_DT_DATA_CALIB_DATA1	Data Calibration Data 1 Register
DMC_EFFCTL	Efficiency Control Register
DMC_EMR3	Shadow EMR3 Register
DMC_MR	Shadow MR0 Register (DDR3)
DMC_MR1	Shadow MR1 Register (DDR3)
DMC_MR2	Shadow MR2 Register (DDR3)

ADSP-SC59x DMC Register List

DMCPHY (DMC) contains the following registers.

Table 9-2: ADSP-SC59x DMC Register List

Name	Description
DMC_DDR_CA_CTL	DDR CA Lane Control Register
DMC_DDR_LANE0_CTL0	Data Lane 0 Control Register 0
DMC_DDR_LANE0_CTL1	Data Lane 0 Control Register 1
DMC_DDR_LANE1_CTL0	Data Lane 1 Control Register 0
DMC_DDR_LANE1_CTL1	Data Lane 1 Control Register 1
DMC_DDR_ROOT_CTL	DDR ROOT Module Control Register
DMC_DDR_SCRATCH_2	Scratch Register 2
DMC_DDR_SCRATCH_3	Scratch Register 3
DMC_DDR_SCRATCH_4	Scratch Register 4
DMC_DDR_SCRATCH_5	Scratch Register 5
DMC_DDR_SCRATCH_6	Scratch Register 6
DMC_DDR_SCRATCH_7	Scratch Register 7
DMC_DDR_ZQ_CTL0	DDR Calibration Control Register 0
DMC_DDR_ZQ_CTL1	DDR Calibration Control Register 1
DMC_DDR_ZQ_CTL2	DDR Calibration Control Register 2

Protocol Controller

The DDR SDRAM protocol controller translates memory access requests from the SCB (system crossbar) interface to JEDEC protocol-specific transactions used by DDR SDRAM devices.

The protocol controller ensures that the various timing parameters are met before reading and writing the SDRAM. The controller also performs the SDRAM initialization sequence as mandated by the standard. The protocol controller can:

- Issue reads and writes
- Precharge a row in a bank
- Activate a row in a bank
- Put the SDRAM devices in self-refresh and power-down modes

The protocol controller takes mode register writes from the MMR interface and translates them into mode register writes to SDRAM. Writing into the mode register is restricted through a mask register.

Efficiency Controller

The efficiency controller controls the ordering of transfers buffered in the read and write command buffers. It attempts to order transfers to optimize the available memory bandwidth. The DMC uses a number of schemes, described in the following sections, to increase the throughput.

Page-Based Scheduling

The DMC parses each write and read transaction that it buffered and gets the information of the row (page) and bank address. The protocol controller maintains the information about the pages that are opened in each bank. The efficiency controller uses the information about the opened pages while scheduling the buffered transactions. The transactions to the opened pages are given higher priority than the other outstanding transactions.

Same Controller Transaction Scheduling

The DMC also stores the ID of each transaction that it buffered. In most of the cases, the transactions related to a controller result in page hits from the locality of reference rule. The efficiency controller uses the ID information of the transactions while scheduling. When the page-based scheduling of the buffered transactions is complete, same controller transaction scheduling is triggered. If multiple transactions from a controller are received, the efficiency controller schedules the transactions back-to-back.

DMC Read Data Buffer

The DMC read data buffer contains a data buffer and an address buffer. The depth of the data buffer is equal to the burst length that is programmed in SDRAM. The address buffer holds the corresponding SDRAM burst address. When an SDRAM write address from any controller matches an address in the DMC read data buffer, the DMC invalidates the related data in the read buffer. When the DMC_RDDATABUFMSK1 or DMC_RDDATABUFMSK2 register is programmed with a value other than zero, the DMC read data buffer operation is enabled. The set of controllers whose data is buffered and retrieved are programmed in the DMC_RDDATABUFID1 or DMC_RDDATABUFID2 registers. The DMC can use the DMC_RDDATABUFMSK1 and DMC_RDDATABUFMSK2

ID registers to select a set of controllers similar to the programming of the DMC_PRIOMSK and DMC_PRIOMSK2 registers.

See the SCB ID-Based Priority section for details.

Closed Page Per Bank

The DMC_EFFCTL register provides per-bank granularity for closing pages. The software can determine that most accesses to a given bank in memory always result in a missed page. In this case, set the PREC_BANK bit corresponding to the required bank to close the row after every transfer. This proactive step can result in reduced thrashing and increases memory throughput.

SCB ID-Based Priority

The primary goal of the dynamic memory controller is to improve sustainable memory system bandwidth so that the service time for the average request can be reduced. However, to service critical requests from any controller in the system, the DMC provides a mechanism to elevate priority of a given access. The DMC priority ID registers (DMC_PRIO and DMC_PRIO2) can be programmed with up to two SCB IDs with elevated priority.

After every access in a snapshot, the command buffers are searched to determine whether an ID of a command matches with the ID programmed in the DMC_PRIO and DMC_PRIO2 registers. The priority SCB ID access is sent before the subsequent access in the snapshot if:

- A match occurs, and
- The direction of the access (for example write) is the same as the direction of the snapshot (write)

There is an alternative to providing priority to a specific SCB ID. If a number of IDs from the same controller require priority, program the DMC priority mask ID registers (DMC_PRIOMSK and DMC_PRIOMSK2) so that the corresponding bits are 0. The DMC uses a combination of the DMC_PRIO and DMC_PRIO2 registers and the DMC_PRIOMSK/DMC_PRIOMSK2 registers to elevate the priority of a select few or all IDs that belong to a controller. By default, none of the IDs are prioritized. The following are a few possibilities:

- The DMC_PRIOMSK field is set to 0x00000000. If a single ID (7234) needs priority, set the DMC_PRIOMSK field to 0xFFFFFFFF and set the DMC_PRIO field to 7234.
- If the DMC_PRIOMSK field is set to 0xFFFFFFFE, the SCB IDs 7234 and 7235 are given priority.
- If the DMC_PRIOMSK field is set to 0xFFFFFFFC, the SCB IDs 7234, 7235, 7236, and 7237 are given priority.
- If two transactions with priority, one read and the other a write, are outstanding, the priority transaction that does not change the direction of the DMC access gets priority. The other priority transaction is handled at the beginning of the next snapshot. For example, if a write snapshot is in-progress, the write priority transaction is sent. The read priority transaction is sent at the beginning of the next read snapshot.

NOTE: Use SCB ID-based priority judiciously because it can significantly reduce the throughput of the DMC.

Delaying up to Eight Auto-Refresh Commands

The DMC uses this method to ensure that auto-refresh does not interfere with any critical data transfers. Up to eight auto-refresh commands can accumulate in the DMC. The exact number of auto-refresh commands can be programmed using the DMC_EFFCTL.NUMREF bit.

After the first refresh command is accumulated, the DMC constantly looks for an opportunity to schedule a refresh command. When the SCB read and write command buffers become empty for the programmed number of clock cycles (DMC_EFFCTL.IDLECYC bit field), the accumulated number of refresh commands are sent back-to-back to the DRAM. (The empty state of the SCB command buffers implies that no access is outstanding.)

After every refresh, the SCB command buffers are checked to ensure that they stay empty. If the SCB command buffers are always full, once the programmed number of refresh commands accumulates, the refresh operation is elevated to urgent priority. One refresh command is sent immediately. After this process, the DMC continues to wait for an opportunity to send out refresh commands. If self-refresh mode is enabled, all pending refresh commands are given out only after that DMC enters self-refresh mode.

Page and Bank Interleaving

Page and bank interleaving allow consecutive row accesses to fall into the same bank (bank interleaving) or into a different bank (page interleaving). The DMC uses bank interleaving by default (DMC_CTL.ADDRMODE bit =0). If the DMC_CTL.ADDRMODE bit =1, the DMC uses page interleaving. Page misses in one addressing mode result in hits in the other addressing mode.

System Crossbar Completer Interface

The DMC uses the system crossbar completer interface to move all data. The system crossbar interface accepts interleaved write transactions and sends out-of-order responses. The read and write interfaces consist of buffers for address, data, and control information transferred to or from the system crossbar bus.

The system crossbar interface transactions are sent to the SDRAM only after the SDRAM has been initialized. However, if transactions arrive before or during initialization, they accumulate in the system crossbar interface and are sent out to the protocol controller once the initialization completes.

To increase throughput, the system crossbar write-response is sent out as soon as the final DDR burst is scheduled for transfer into the SDRAM. However, if an auto-refresh is needed, the scheduled write data is sent only after the auto-refresh. A delay can occur. The delay is a maximum of 64 clock cycles from the moment the write response is sent on the SCB to the write operation of the data into SDRAM.

The system crossbar interface performs the following operations:

- Buffers read and write command requests from the system crossbar bus
- Processes the requests by converting them to protocol controller user-interface transfers
- Sends and receives data to or from the protocol controller
- Creates a suitable read/write response and sends read data back to the system crossbar bus

The system crossbar completer interface supports the following:

- All burst lengths (1–16)
- Incremental and wrap bursts
- Data transfer sizes of 8-bit, 16-bit, or 32-bit
- Arrival of write data before write address
- Generation of error responses which include:
  - Any access to an unimplemented region of the external memory space
  - Any access when the SDRAM is in self-refresh mode/power-down mode
  - Any access when the direct command interface is in operation

Read/Write Command and Data Buffers

The system crossbar interface consists of a four-deep read command buffer and a four-deep write command buffer. Up to four write commands and four read commands can be waiting for access to the SDRAM. The system crossbar write buffer is 32 deep. It can support write data interleaving of two. The system crossbar read buffer is 32 deep.

Peripheral Bus Completer Interface

The peripheral bus completer interface connects the dynamic memory controller to the peripheral bus and provides a host controller with access to the registers. The peripheral bus completer interface supports the following features:

- Read and write word accesses
- 32-bit data bus

Architectural Concepts

The following sections provide information on the architecture of the interface.

Controller On Die Termination (ODT)

The controller ODT is enabled with the granularity of a byte lane. The description of this feature can be obtained in the description of the corresponding PHY registers. Controller ODT involves extra overhead in terms of power consumption during reads.

The DMC implements dynamic on die termination at processor pads. When controller ODT is enabled, the termination resistors in the pads are turned on when the controller reads data from the DRAM. These resistors are turned off when the controller writes to the DRAM.

Mode Register Set and Extended Mode Register Set Command

The load mode register command initializes the SDRAM operation parameters. The DMC supports the mode register set and extended mode register set commands. The controller automatically issues the mode register set command during power-on initialization and also when the DMC_MR register is written with the DMC_MSK.MR bit. The mode register set command is sent after the ongoing data transfer completes.

DDR3 Reset Functionality

DDR3 contains an additional pin corresponding to reset functionality. Reset is part of the initialization sequence, but it can be performed asynchronously when needed. The reset procedure is similar to the steps involved in the initialization except the initial part of power-up.

To perform reset on the DDR3 module:

1. Check to ensure the module is in the idle state by polling the `DMC_STAT.IDLE` bit (0x0008).
2. Set the `DMC_CTL.RESET` bit (0x0004).
3. Monitor the `DMC_STAT.RESETDONE` bit for the completion of the reset function.

Do not perform any transactions during a module reset. Wait for the `DMC_STAT.RESETDONE` signal.

DDR3 SDRAM Organization

The DMC supports DDR3 SDRAM memory modules ranging from 512 Mb to 8 Gb. The following tables list the address translation mechanism from the user interface to DDR3 memory interface. The controller also supports two types of addressing modes: bank interleaving (`DMC_CTL.ADDRMODE` =1) and page interleaving (`DMC_CTL.ADDRMODE` =0).

Bank Interleaving

The ***DDR3 Bank Interleaving*** table shows DDR3 bank interleaving.

Table 9-3: DDR3 Bank Interleaving

SDRAM size	Bank address bits	Row address bits	Column address bits
512 Mb	25:24	23:11	10:1
1 Gb	26:24	23:11	10:1
2 Gb	27:25	24:11	10:1
8 Gb	29:27	26:11	10:1

Page Interleaving

The ***DDR3 Page Interleaving*** table shows DDR3 page interleaving.

Table 9-4: DDR3 Page Interleaving

SDRAM size	Row address bits	Bank address bits	Column address bits
512 Mb	25:13	12:11	10:1
1 Gb	26:14	13:11	10:1
2 Gb	27:14	13:11	10:1
4 Gb	28:14	13:11	10.1
8 Gb	29:14	13:11	10.1

DMC Clocking

The DMC uses a divided-down version of the *PLLCLK* (PLL clock) to generate an internal clock for clocking the DMC block and interface. The specific value of the *DCLK* frequency is programmed in the CGU_DIV register.

For information on the maximum clock frequency supported for specific modes, refer to the processor data sheet.

NOTE: For details on DMC clocking, see the Clock Generation Unit (CGU) and Clock Generation Unit (CGU) chapters.

DMC DMA

The DMC supports DMA-based transfers to and from external DDR SDRAM memory and internal memory.

The DMC DMA controller, part of the distributed DMA engines (DDE) that are dispersed through the infrastructure, connects to the system crossbar fabric.

The DMC uses two DDEs for memory-to-memory DMA (MDMA). One channel is the source channel, and the second, the destination channel.

DMA transfers on the processor are descriptor-based or register-based. Register-based DMA allows the processor to program DMA control registers directly to initiate a DMA transfer. On completion, the control registers can be automatically updated with their original setup values for continuous transfer, if needed. Descriptor-based DMA transfers require a set of parameters stored within memory to initiate a DMA sequence. This transfer allows the chaining together of multiple DMA sequences. In descriptor-based DMA operations, a DMA channel can be programmed to set up and start another DMA transfer automatically after the current sequence completes.

Enhanced DMA operations (such as delay line DMA, scatter or gather DMA) are also supported to or from the DMC module.

DMC Operating Modes

DDR3 Mode

The DMC module supports JESD79-3E compatible double data rate DDR3 SDRAM. To configure this mode of operation, first set (=1) the DMC_CTL.DDR3EN bit

Self-Refresh Mode

For low-power consumption, the SDRAM can be put in self-refresh mode. When no data activity occurs, the DMC can put the SDRAM in self refresh to save power. The DMC_STAT.IDLE bit indicates the activity on the DMC. If this bit is set, there is no activity in the DMC.

Enable self-refresh mode by writing the DMC_CTL.SRREQ bit. The DMC stays in a self-refresh state when this bit is asserted. The DMC_STAT.SRACK bit indicates when the SDRAM enters self-refresh mode.

When the DMC is in self-refresh mode, the DMC generates an SCB error when any data accesses (read or write requests) is requested.

The DMC can be brought out of self-refresh mode by clearing the DMC_CTL.SRREQ bit again. The controller clears the DMC_STAT.SRACK bit after the self-refresh operation completes.

DMC Event Control

The DMC has no related interrupt or trigger event information.

DMC Programming Model

The dynamic memory controller contains five groups of memory-mapped registers. The DMC uses the MMR access bus to connect to these registers.

- Control and status registers. These registers control the various operation modes of the dynamic memory controller and provide status.
- Timing parameter registers. The value programmed in these registers depends on the speed grade of the SDRAM device used.
- Mode register mirror registers. These shadow registers are copies of the mode registers residing in the SDRAM device.
- PHY control and status registers. The DMC uses these registers to control the operation of the PHY.
- PAD control registers. The DMC uses these registers to control the various aspects of the I/O pads.

The DMC control registers contain sensitive timing parameters and settings for the DDR SDRAM. These registers are programmed with values that are in the operating range of the DDR used.

Writing to reserved fields or writing any reserved values in register bits can cause the dynamic memory controller to function erroneously.

PHY DLL Calibration

The PHY DLL calibration is performed as part of the SDRAM power-up initialization. It calibrates data against the DQS and CLK signal. However, running DLL calibration after self-refresh or at an arbitrary time is required in certain cases.

The DMC allows PHY DLL calibration to start by setting the DMC_CTL.DLLCAL bit. The DMC_STAT.DLLCALDONE bit can be used to monitor the progress of the calibration. Once calibration is over, this bit is set. Once the calibration procedure is started by writing to the DMC_CAL_PADCTL0.CALSTRT bit, the full calibration takes 300 DCLK cycles to complete.

NOTE: DLL calibration can be initiated only when the DMC is idle (DMC_STAT.IDLE= 1).

DDR3 ZQ Calibration Short CMD

The ZQ calibration short command is generally used to correct small variations in ZQ (~0.5%). To perform ZQ calibration, the controller is first checked for its idle state. Once the idle bit is obtained, a ZQCS command can be

issued by setting the DMC_STAT.ZQCSDONE bit (0x0004). The DMC_STAT.ZQCSDONE bit (0x0008) can be used to monitor the calibration sequence. When this bit is 0, it indicates that the calibration is ongoing. When it is 1, it indicates that the calibration is done. As an example, a GP timer can be used to periodically trigger a ZQCS command to address tiny variations.

NOTE: The ZQ calibration function is essential for normal operation of DDR3. With the reference of the external resistance (240 Ω ± 1%) connected to the DMC_RZQ pin, DDR3 calibrates the R_{on} and R_{tt} values of the ZQ pin against temperature and voltage variations.

DDR3 ZQ Calibration Long CMD

Several DDR3 impedance calibrations are implemented for optimal signal integrity. The long ZQ calibration is used after power-up and the short ZQ calibration is used periodically during normal operation to compensate for voltage and temperature drift. These calibration sequences improve connectivity between the SDRAM pads and the PCB trace. The DMC_RZQ pin on the SDRAM is connected to an external precision resistor that adjusts the output driver impedance Rtt and ODT values to match the trace impedance. The connection reduces impedance discontinuity and minimizes signal reflections.

The command has two variants named as ZQ calibration long (ZQCL) and ZQ calibration short (ZQCS). The ZQCL command is issued during initialization and after self-refresh exit command. It can be issued later depending on the system environment.

The DMC pads can be auto calibrated to the required driver impedance Rtt using an external resistance RZQ and the On Die Termination (ODT) value using the corresponding bits (DMC_CAL_PADCTL2). The autocalibration logic translates these values into a corresponding drive strength control inside the PHY and then routed to the PADS. Autocalibration starts as soon as the bit is programmed (set the DCLK at the required frequency before setting this DMC_CAL_PADCTL0.CALSTRT bit). Autocalibration expects the program to select two different member sets of pads (address/command pads versus CLK/Data/DQS/DM pads).

On Die Termination (DDR3)

The DMC supports dynamic On Die Termination (ODT) at the pads. When the controller ODT is set, the termination resistors in the pads are turned on when the controller reads data from the DRAM. These resistors are turned off when the controller is writing to the DRAM. Controller ODT is enabled with the granularity of a byte lane. The description of this feature can be obtained in the description of the corresponding PHY registers.

DDR3 SDRAM provides extended ODT mode.

- *Asynchronous ODT*: ODT timing in the slow exit power-down mode
- *Dynamic ODT*: Function that can dynamically switch the ODT resistance during a write operation without an MRS command. It improves signal quality during a write operation.

Leveling Techniques

The DMC controller supports read and write leveling.

Write Leveling

It is difficult to meet the specifications with the on-board parasitic, trace length variability along with high frequency. The DMC controller supports leveling to compensate the skews between clock and strobe. This skew compensation is done independently for every byte lane. Write leveling is performed by the DDR3 memory controller as a part of initialization by programming the `DMC_MR1.WL` bit.

To dynamically perform write leveling:

1. Ensure that the DMC is idle.
2. Program the `DMC_MR1.WL` bit.
3. Enable the `DMC_MSK` register for the `DMC_MR1` register.
4. Wait for 2000 DMC clock cycles to complete write leveling.

Read Leveling

Read leveling is useful for calibrating read data timing. It is compensated for imbalanced loading on read path. Read leveling can be performed on LSB or byte lane. It is performed as a part of initialization sequence by setting the `DMC_EMR3.MPR` bit.

To dynamically perform read leveling:

1. Ensure that the DMC is idle.
2. Program the `DMC_EMR3.MPR` bit.
3. Enable DMC mask register `DMC_EMR3` register.
4. Wait for 2000 DMC clock cycles to complete read leveling.

Read Leveling during DQS Strobe Gating

To ensure robust read timing, read leveling must be done individually for all data bits. Some DDR3 memory devices do not drive read leveling patterns on all data pins. The devices send pattern only information on the LSBs of each byte lane. In these cases, the `DMC_EMR3` register cannot be used for read leveling. Instead, use the `DMC_CTL.RL_DQS` bit for read leveling.

Read leveling during DQS strobe gating is dynamically supported except during initialization.

Initializing the DMC

Complete the following procedures to initialize the DMC module.

- Resetting the DMC Lane
- Performing ZQ Calibration
- Programming the DMC Controller

Resetting the DMC Lane

If there is a change in the DMC clock frequency, the DDR lane must be reset using the following procedure. Once the lane is reset, wait 9000 DDR clock cycles for the DDR DLL to lock before restarting the DDR.

1. Set the DMC_DDR_LANE0_CTL0.CB_RSTDLL and DMC_DDR_LANE1_CTL0.CB_RSTDLL bits.
2. Change the DMC clock frequency.
3. Clear the DMC_DDR_LANE0_CTL0.CB_RSTDLL and DMC_DDR_LANE1_CTL0.CB_RSTDLL bits.

Performing ZQ Calibration

Perform the following ZQ calibration procedure for the proper impedance matching.

1. Program the DMC_DDR_ZQ_CTL0.IMPWRADD bit field with the drive strength of the address and command signals. A 100Ω drive strength is recommended for the drive strength of address and command signals. When programming a drive strength of 100Ω, write 0x64 into this bit field.
2. Program the DMC_DDR_ZQ_CTL0.IMPWRDQ bit field with the drive strength of the DQ, DQS, DM and clock signals. A 100Ω drive strength is recommended for the drive strength of address and command signals. When programming a drive strength of 100Ω, write 0x64 into this bit field.
3. Program the DMC_DDR_ZQ_CTL0.IMPRTT bit field with the adjusted On Die Termination (ODT) for the Data and DQS signals for the read operation. Due to a correction factor, program this field to 80% of the equivalent ODT.

   DMC_DDR_ZQ_CTL0.IMPRTT value = ODT*2*0.8

   For example, if a 50Ω terminating resistance is required on the data pads to match the trace impedance to the board impedance, there will be two 50Ω resistance data pads in parallel. The value is programmed to 100 × 0.8 = 80.
4. Write 0 to the DMC_DDR_ZQ_CTL1 register.
5. Program 0x70000000 to the DMC_DDR_ZQ_CTL2 register.
6. Program 0x0000000 to the DMC_DDR_CA_CTL register.
7. Program 0x0000000 to the DMC_DDR_ROOT_CTL register.
8. Program 0x00010000 to the DMC_DDR_ROOT_CTL register.
9. Wait for 8000 DMC clock cycles.
10. Program 0x0C000001 to the DMC_DDR_CA_CTL register.
11. Wait for 8000 DMC clock cycles.
12. Program 0x0000000 to the DMC_DDR_CA_CTL register.
13. Program 0x0000000 to the DMC_DDR_ROOT_CTL register.

Programming Duty Cycles

Perform the following procedure to program the DQS duty cycle and clock duty cycle trim.

1. Program the DMC_DDR_LANE0_CTL0 and DMC_DDR_LANE1_CTL0 registers with DMC_DDR_LANE0_CTL0.BYPCODE/DMC_DDR_LANE0_CTL1.BYPCODE , DMC_DDR_LANE1_CTL0.BYPSELP/DMC_DDR_LANE0_CTL1.BYPCODE and DMC_DDR_LANE0_CTL0.BYPENB/DMC_DDR_LANE1_CTL0.BYPENB to trim the DQS duty cycle adjustment.
2. Program DMC_DDR_CA_CTL registers with DMC_DDR_CA_CTL.BYPCODE0, DMC_DDR_CA_CTL.BYPCODE1, DMC_DDR_CA_CTL.BYPSELP and DMC_DDR_CA_CTL.BYPENB to trim the clock duty cycle adjustment.

Programming the DMC Controller

Perform the following procedure to program the DMC controller.

1. Program the DMC_CFG register with the size of the DDR memory device. Program the DMC_CFG.IFWID and DMC_CFG.SDRWID bit fields to 16-bits wide.
2. Program the DMC_TR0, DMC_TR1, DMC_TR2 registers with the timing parameters as required by the DDR memory device.
3. Program the DMC_MR and DMC_MR1 registers with the appropriate values. A memory ODT of 120Ω is recommended. Write leveling is recommended for a 666 MHz operating frequency.
4. Program the DMC_MR2 register. If read leveling is required, program the DMC_EMR3 register. Read leveling is recommended for a 666 MHz operating frequency.
5. Program the DMC_DLLCTL register. Program the DMC_DLLCTL.DATACYC bit field with 15ns/ddr clock period in ns. Program the DMC_DLLCTL.DLLCALRDCNT bit field with 240.
6. Wait for 2000 DMC clock cycles.
7. Set the DMC_DDR_CA_CTL.SW_REFRESH bit, keeping the other bits unchanged.
8. Wait for five DMC clock cycles.
9. Set the DMC_DDR_ROOT_CTL.SW_REFRESH bit. Program the DMC_DDR_ROOT_CTL.PIPE_OFSTDCYCLE bit field with 2.
10. Program the DMC_CTL register.
    - DMC_CTL.RDTOWR = 5
    - Set the DMC_CTL.DDR3EN bit.
    - Set DMC_CTL.AL_EN if the operating frequency is above 667 MHz.

- Set DMC_CTL.RL_DQS if operating frequency above 667 MHz and to enable read leveling during data strobing.
- Set the DMC_CTL.INIT bit.

11. If write leveling is enabled, wait for 600 DMC clock cycles or until the DMC_MR1.WL bit auto clears.
12. If read leveling is enabled wait for 2000 DMC clock cycles or until the DMC_EMR3.MPR bit auto clears.
13. If read leveling during data strobe gating is enabled, wait for 600 DMC clock cycles or until the DMC_CTL.RL_DQS bit auto clears.
14. Wait for 722000 DMC clock cycles to complete DMC initialization or until the DMC_STAT.INITDONE bit is set.
15. Set the DMC_DDR_LANE0_CTL1.COMP_DCYCLE and DMC_DDR_LANE1_CTL1.COMP_DCYCLE bits, without affecting other bits.
16. Wait for 10 DMC clock cycles.
17. Clear the DMC_DDR_LANE0_CTL1.COMP_DCYCLE and DMC_DDR_LANE1_CTL1.COMP_DCYCLE bits, without affecting other bits.
18. Set and then clear the DMC_DDR_LANE0_CTL0.CB_RSTDAT bit, without affecting other bits.
19. Set and then clear DMC_DDR_LANE1_CTL0.CB_RSTDAT bit, without affecting other bits.
20. Wait for 2500 DMC clock cycles.
21. Read the DMC_STAT.PHYRDPHASE bit field. Program this value into the DMC_DLLCTL.DATACYC bit field, without affecting other bits in the DMC_DLLCTL register.
22. Reprogram the DMC_CTL.DDR3EN and DMC_CTL.RDTOWR bits. If the operation frequency is above 667 MHz set the DMC_CTL.AL_EN bit.

Programming DQ Delay Trim

To trim or fine tune the delay on the data lane, the write leveling code should be read first from the data lanes. The write leveling code can be incremented to increase setup time or decremented to increase hold time before writing it back to the data lanes.

For lane 0, complete the following steps:

1. Write 0x000000D0 to the DMC_DDR_LANE0_CTL1 register without changing other bits.
2. Wait 2500 DMC clock cycles.
3. Write 0x00400000 to the DMC_DDR_ROOT_CTL register.
4. Wait 2500 DMC clock cycles.
5. Write 0x00000000 to the DMC_DDR_ROOT_CTL register.

6. Bits [20:16] of the DMC_DDR_SCRATCH_4 holds the write leveling code for lane 0.
7. Increment or decrement the write leveling code as needed. Write it to the DMC_DDR_LANE0_CTL1.BYPCODE bit. Set the DMC_DDR_LANE0_CTL1.BYPDELCHAINEN
8. Wait 2500 DMC clock cycles.

For lane 1, complete the following steps:

1. Write 0x000000D0 to the DMC_DDR_LANE1_CTL1 register without changing other bits.
2. Wait 2500 DMC clock cycles.
3. Write 0x00800000 to the DMC_DDR_ROOT_CTL register.
4. Wait 2500 DMC clock cycles.
5. Write 0x00000000 to the DMC_DDR_ROOT_CTL register.
6. Bits [20:16] of the DMC_DDR_SCRATCH_5 holds the write leveling code for lane 1.
7. Increment or decrement the write leveling code as needed. Write it to the DMC_DDR_LANE1_CTL1.BYPCODE bit. Set the DMC_DDR_LANE1_CTL1.BYPDELCHAINEN
8. Wait 2500 DMC clock cycles.

DMC Performance Monitor (DMCPM)

The dynamic memory controller includes performance monitors to obtain the performance index for SDRAM and SCB fabric. These counters can be used to analyze the DMC access patterns and bus utilization (both DMC and SCB bus) at a system level. The DMCPM provides seven DMC performance counters and five SCB performance counters. The DMCPM has 32-bit counters that (when enabled) increment based on events.

To enable performance monitoring, set the DMC_PM_CTL.PMCNT bit = 1.

ADSP-SC59x DMC Register Descriptions

Dynamic Memory Controller (DMC) contains the following registers.

Table 9-5: ADSP-SC59x DMC Register List

Name	Description
DMC_CFG	Configuration Register
DMC_CTL	Control Register
DMC_DLLCTL	DLL Control Register
DMC_DT_CALIB_ADDR	Data Calibration Address Register
DMC_DT_DATA_CALIB_DATA0	Data Calibration Data 0 Register

Table 9-5: ADSP-SC59x DMC Register List (Continued)

Name	Description
DMC_DT_DATA_CALIB_DATA1	Data Calibration Data 1 Register
DMC_EFFCTL	Efficiency Control Register
DMC_EMR3	Shadow EMR3 Register
DMC_MR	Shadow MR0 Register (DDR3)
DMC_MR1	Shadow MR1 Register (DDR3)
DMC_MR2	Shadow MR2 Register (DDR3)
DMC_MSK	Mask (Mode Register Shadow) Register
DMC_PM_CTL	DMC Performance Control Register
DMC_PM_IDCYDQ_CNT	Performance Monitor Idle Cycle DQ Count Register
DMC_PM_IDPG_CNT	Performance Monitor Idle Page Count Register
DMC_PM_PGHT_CNT	Performance Monitor Page Hit Count
DMC_PM_PGMS_CNT	Performance Monitor Page Miss Count
DMC_PM_RD2WRTA_CNT	Performance Monitor Read to Write Turn Around Count Register
DMC_PM_REF_CNT	Performance Monitor Refresh Count Register
DMC_PM_WR2RDTA_CNT	Performance Monitor Write to Read Turn Around Count Register
DMC_PRIO	Priority ID Register 1
DMC_PRIO2	Priority ID Register 2
DMC_PRIOMSK	Priority ID Mask Register 1
DMC_PRIOMSK2	Priority ID Mask Register 2
DMC_RDDATABUFID1	DMC Read Data Buffer ID Register 1
DMC_RDDATABUFID2	DMC Read Data Buffer ID Register 2
DMC_RDDATABUFMSK1	DMC Read Data Buffer Mask Register 1
DMC_RDDATABUFMSK2	DMC Read Data Buffer Mask Register 2
DMC_RDD_BUFHT_CNT	Performance Monitor Buffer Hit Count Register
DMC_SCB_PM_BRLN_CNT	SCB Performance AXI Transfer Count Register
DMC_SCB_PM_BRSZ_CNT	SCB Performance AXI Transfer Count Register

DMC_SCB_PM_IDWRDCY_CNT	SCB Performance Monitor Idle Cycle Count Register
DMC_STAT	Status Register
DMC_TR0	Timing 0 Register
DMC_TR1	Timing 1 Register

Table 9-5: ADSP-SC59x DMC Register List (Continued)

Name	Description
DMC_TR2	Timing 2 Register

Configuration Register

The DMC_CFG register selects SDRAM device specific parameters and selects the SDRAM interface width.

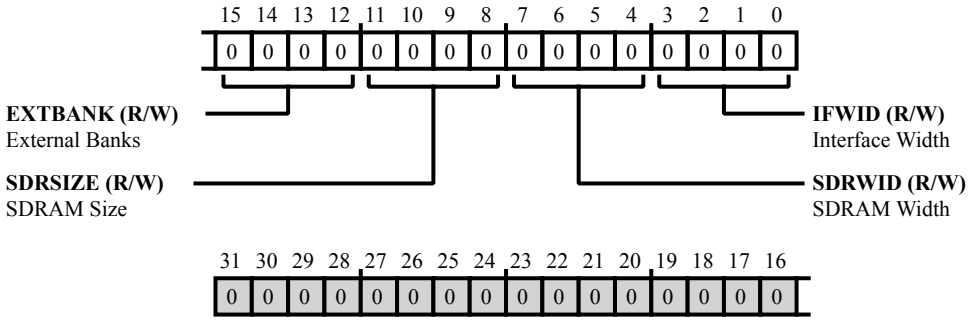

Figure 9-1: DMC_CFG Register Diagram

Table 9-6: DMC_CFG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15:12 (R/W)	EXTBANK	External Banks. The DMC_CFG.EXTBANK bits select the number of external banks connected to the DMC. Note that all values other than those shown are reserved.	
		0	1 External Bank
		1-15	Reserved
11:8 (R/W)	SDRSIZE	SDRAM Size. The DMC_CFG.SDRSIZE bits select the size of individual SDRAM connected to the DMC. Note that all values other than those shown are reserved.	
		3	512M Bit SDRAM
		4	1G Bit SDRAM
		5	2G Bit SDRAM
		6	4G Bit SDRAM
		7	8G Bit SDRAM
7:4 (R/W)	SDRWID	SDRAM Width. The DMC_CFG.SDRWID bits select the width of the individual SDRAM connected to the DMC. Note that all values other than those shown are reserved.	
		0-1	Reserved
		2	16-Bit Wide SDRAM
		3-15	Reserved

Table 9-6: DMC_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3:0 (R/W)	IFWID	Interface Width. The `DMC_CFG.IFWID` bits select the width of the interface between the DMC and SDRAM. Note that all values other than those shown are reserved.	
		0-1	Reserved
		2	16-Bit Wide Interface. All other values are reserved. This field specifies the interface width between the controller and the SDRAM.
		3-15	Reserved

Control Register

The DMC_CTL register controls DMC modes, DLL calibration, and DRAM initialization.

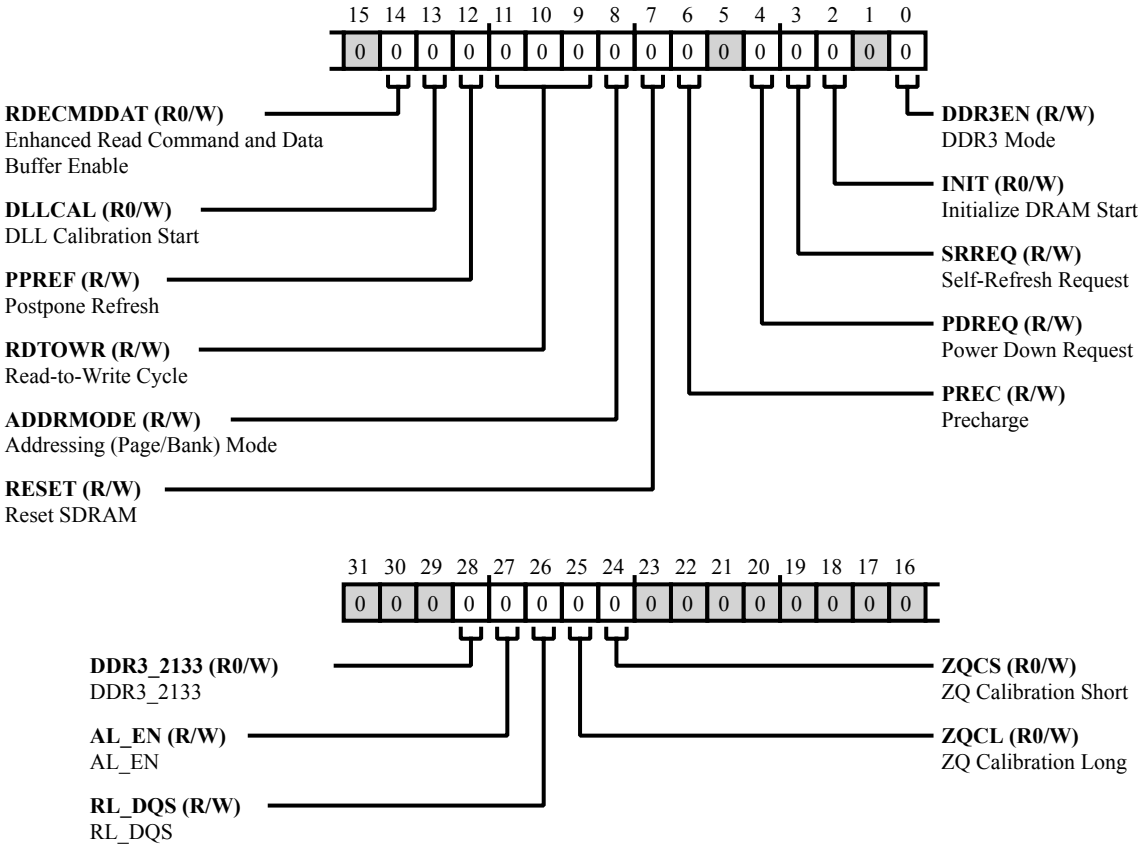

Figure 9-2: DMC_CTL Register Diagram

Table 9-7: DMC_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
28 (R0/W)	DDR3_2133	DDR3_2133. The DMC_CTL.DDR3_2133 bit starts the ZQ calibration long sequence. Note that this bit always reads as 0.	
		0	No effect
		1	Triggers ZQ calibration long sequence
27 (R/W)	AL_EN	AL_EN. When set, enables 800MHz operation	
		0	Disables greater than 667MHz operation
		1	Enables greater than 667MHz operation

Table 9-7: DMC_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
26 (R/W)	RL_DQS	RL_DQS. When set, enables read leveling during DQS gating training. This bit auto-clears on read leveling completion	
		0	Enable
		1	Disable
25 (R0/W)	ZQCL	ZQ Calibration Long. The `DMC_CTL.ZQCL` bit starts the ZQ calibration long sequence. Note that this bit always reads as 0.	
		0	No effect
		1	Triggers ZQ calibration long sequence
24 (R0/W)	ZQCS	ZQ Calibration Short. The `DMC_CTL.ZQCS` bit starts the ZQ calibration short sequence. Note that this bit always reads as 0.	
		0	No effect
		1	Triggers ZQ calibration short sequence
14 (R0/W)	RDECMDDAT	Enhanced Read Command and Data Buffer Enable. Enhanced Read Command and Data Buffer Enable. 0 DDR AXI interface works with legacy Read Data and Command Buffer depth. (default state) 1 DDR AXI interface works with enhanced (double) Read Data and Command Buffer depth. 0 - No effect 1 - Enable	
		0	No effect
		1	Start PHY DLL calibration
13 (R0/W)	DLLCAL	DLL Calibration Start. The `DMC_CTL.DLLCAL` bit starts the PHY DLL calibration sequence. Note that this bit always reads as 0.	
		0	No effect
		1	Start PHY DLL calibration

Table 9-7: DMC_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W)	PPREF	Postpone Refresh. The DMC_CTL.PPREF bit enables postponing the DMCs sending of auto-refresh commands. When enabled, the DMC accumulates refresh commands. The DMC_EFFCTL.NUMREF field selects the number of refresh commands that the DMC may accumulate. When disabled, the DMC_TR1.TREF field selects the interval for auto-refresh command distribution. A maximum of eight auto-refresh commands can be accumulated in DDR3 mode.	
		0	Disable Postpone Refresh
		1	Enable Postpone Refresh
11:9 (R/W)	RDTOWR	Read-to-Write Cycle. The DMC_CTL.RDTOWR bits select the number of cycles that the DMC adds when a write operation follows a read operation. For proper operation, it should be programmed with the value of 010.	
		0	1 Cycle Added from JEDEC Spec Value
		1	2 Cycles Added from JEDEC Spec Value
		2	3 Cycles Added from JEDEC Spec Value
		3	4 Cycles Added from JEDEC Spec Value
		4	5 Cycles Added from JEDEC Spec Value
		5	6 Cycles Added from JEDEC Spec Value
		6	7 Cycles Added from JEDEC Spec Value
		7	8 Cycles Added from JEDEC Spec Value
8 (R/W)	ADDRMODE	Addressing (Page/Bank) Mode. The DMC_CTL.ADDRMODE bit selects whether the DMC uses page or bank interleaving for addressing. When using page interleaving, the bank address bits follow the most significant column address bits. When using bank interleaving, the bank address bits follow the most significant row address bits.	
		0	Bank Interleaving
		1	Page Interleaving
7 (R/W)	RESET	Reset SDRAM. The DMC_CTL.RESET bit starts the reset sequence. Note that this bit always reads as 0.	
		0	No effect
		1	Starts reset sequence

Table 9-7: DMC_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6 (R/W)	PREC	Precharge. The DMC_CTL.PREC bit enables precharge, which closes DRAM rows immediately after access. When disabled, all accesses result in the respective DRAM rows remaining open, until the DMC needs to close them.	
		0	No Effect
		1	Enable Precharge
4 (R/W)	PDREQ	Power Down Request. The DMC_CTL.PDREQ bit enables power-down mode. When the DMC is in power-down mode, any data accesses cause the DMC to generate a bus error. The DRAM remains in power-down mode as along as this bit is 1.	
		0	Disable Power-Down
		1	Enable Power-Down
3 (R/W)	SRREQ	Self-Refresh Request. The DMC_CTL.SRREQ bit enables self-refresh mode. When the DMC is in self-refresh mode, any data accesses cause the DMC to generate a bus error. The DRAM remains in self-refresh mode as along as this bit is 1.	
		0	Disable Self-Refresh
		1	Enable Self-Refresh
2 (R0/W)	INIT	Initialize DRAM Start. The DMC_CTL.INIT bit starts the power up DRAM initialization sequence and DLL calibration sequence. Note that this bit always reads as 0.	
		0	No Effect
		1	Start DRAM Initialization
0 (R/W)	DDR3EN	DDR3 Mode. The DMC_CTL.DDR3EN bit selects whether the DMC operates in DDR3 mode.	
		0	Reserved
		1	Enable DDR3 mode

DLL Control Register

The DMC_DLLCTL register holds the programmable parameters associated with the DLLs within the DMC PHY.

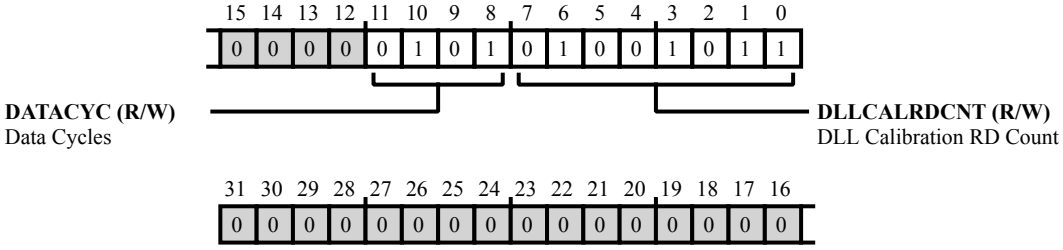

Figure 9-3: DMC_DLLCTL Register Diagram

Table 9-8: DMC_DLLCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
11:8 (R/W)	DATACYC	Data Cycles. The DMC_DLLCTL.DATACYC bits select the latency after which the DMC reads data from the PHY. This field must be written with the value indicated in the DMC_STAT.PHYRDPHASE field, or data corruption occurs on all SDRAM reads.	
		2	2 Clock Cycles Latency
		3	3 Clock Cycles Latency
		4	4 Clock Cycles Latency
		5	5 Clock Cycles Latency
		6	6 Clock Cycles Latency
		7	7 Clock Cycles Latency
		8	8 Clock Cycles Latency
		9	9 Clock Cycles Latency
		10	10 Clock Cycles Latency
		11	11 Clock Cycles Latency
		12	12 Clock Cycles Latency
		13	13 Clock Cycles Latency
		14	14 Clock Cycles Latency
		15	15 Clock Cycles Latency
7:0 (R/W)	DLLCALRDCNT	DLL Calibration RD Count. The DMC_DLLCTL.DLLCALRDCNT field selects the number of read operations that the PHY uses for DLL calibration.	

Data Calibration Address Register

The DMC_DT_CALIB_ADDR register provides the address used for the data calibration for read and write. During the DMC PHY DLL calibration, a particular set of locations in the DRAM is written and a series of reads are performed back to back to calibrate the PHY. The DMC PHY needs prior information about the data that would be read during the PHY DLL calibration. The controller performs one burst write operation to the address programmed in DMC_DT_CALIB_ADDR (0x0090).

Note: While the exact address chosen does not matter much during memory initialization, if calibration of the PHY is performed when the DRAM contains valid data, care needs to be taken to ensure that this address points to an unused address. Else, this operation will modify application data stored at the address selected.

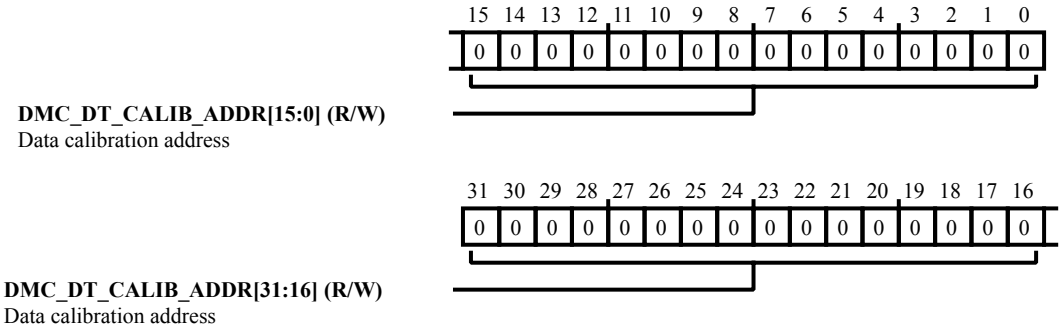

Figure 9-4: DMC_DT_CALIB_ADDR Register Diagram

Table 9-9: DMC_DT_CALIB_ADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	DMC_DT_CALIB_ADDR	Data calibration address. The DMC_DT_CALIB_ADDR.DMC_DT_CALIB_ADDR bit field contains the address to be programmed for the data calibration for read and write.

Data Calibration Data 0 Register

The DMC_DT_DATA_CALIB_DATA0 register contains the first 32-bit data used for the write during the data calibration.

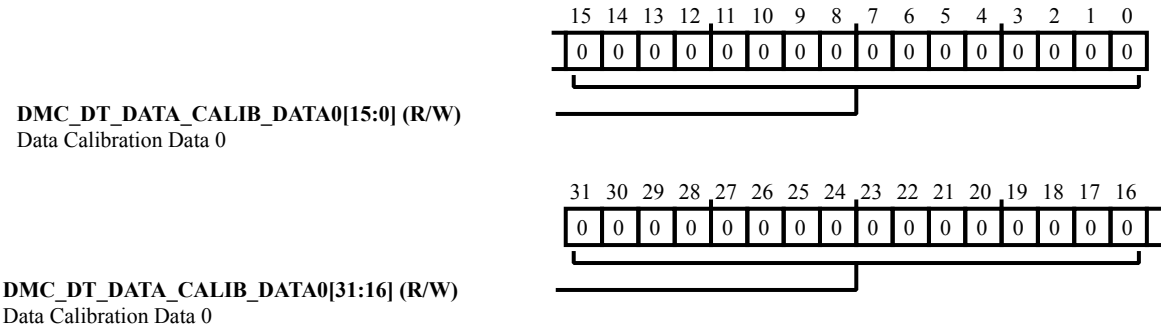

Figure 9-5: DMC_DT_DATA_CALIB_DATA0 Register Diagram

Table 9-10: DMC_DT_DATA_CALIB_DATA0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	DMC_DT_DATA_CALIB_DATA0	Data Calibration Data 0. The DMC_DT_DATA_CALIB_DATA0.DMC_DT_DATA_CALIB_DATA0 bit field contains the first 32 bit data used for the write during the data calibration.

Data Calibration Data 1 Register

The DMC_DT_DATA_CALIB_DATA1 register contains the second 32-bit data used for the write during the data calibration.

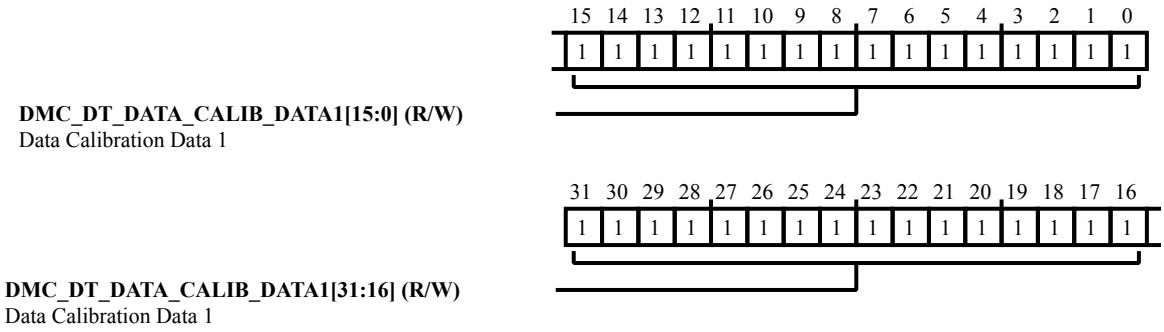

Figure 9-6: DMC_DT_DATA_CALIB_DATA1 Register Diagram

Table 9-11: DMC_DT_DATA_CALIB_DATA1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	DMC_DT_DATA_CALIB_DATA1	Data Calibration Data 1. The DMC_DT_DATA_CALIB_DATA1.DMC_DT_DATA_CALIB_DATA1 bit field contains the second 32 bit data used for the write during the data calibration.

Efficiency Control Register

The DMC_EFFCTL register control DMC features that improve throughput efficiency. These include features such as auto-refresh management, precharge options, and write data options.

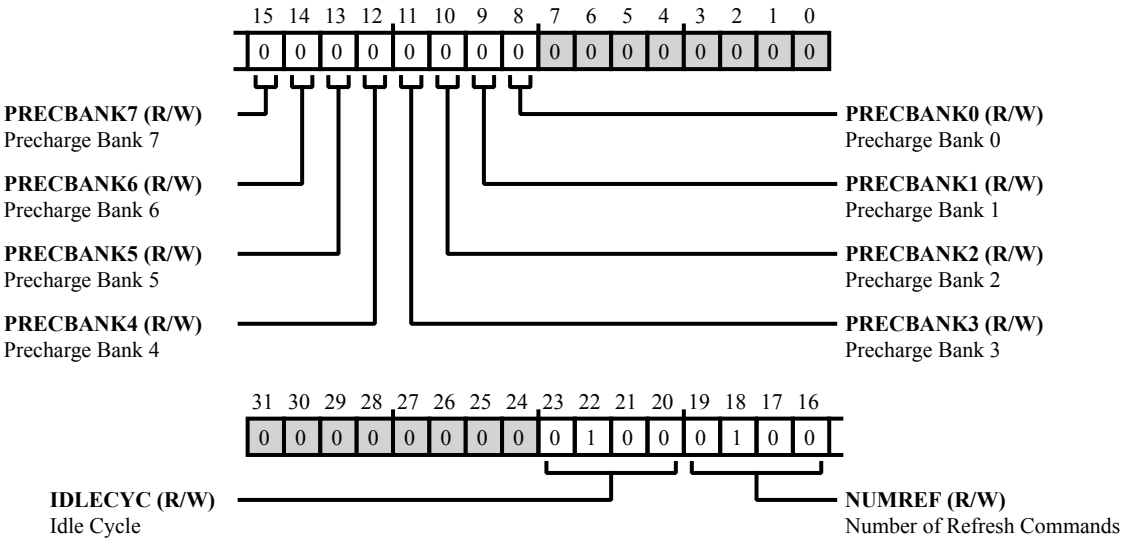

Figure 9-7: DMC_EFFCTL Register Diagram

Table 9-12: DMC_EFFCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
23:20 (R/W)	IDLECYC	Idle Cycle. The DMC_EFFCTL.IDLECYC bits select the number of cycles after which the DMC issues any accumulated auto-refresh commands if postpone refresh is enabled (DMC_CTL.PPREF =1). When DMC_EFFCTL.IDLECYC is set to 0, the DMC ignores the DMC_CTL.PPREF selection and does not accumulate/postpone periodic auto-refresh commands. Note 1: By default, accumulated auto-refresh commands are issued after counting four idle cycles. Note 2: This value is ignored if DMC_CTL.PPREF is not set. Note 3: Setting this value to 0000 overrides the "postpone refresh" feature and does not accumulate/postpone periodic auto refreshes.	
		0-15	0 to 15 Idle Cycles to Postpone Refresh Commands

Table 9-12: DMC_EFFCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
19:16 (R/W)	NUMREF	Number of Refresh Commands. The DMC_EFFCTL.NUMREF bits select the number of auto-refresh commands that the DMC can accumulate if postpone refresh is enabled (DMC_CTL.PPREF =1). In DDR3 mode, the DMC may accumulate up to eight auto-refresh commands. Note 1: By default, accumulated auto-refresh commands are issued after counting four idle cycles. Note 2: This value is ignored if DMC_CTL.PPREF is not set.	
		0	No Refresh Commands Accumulate
		1	1 Refresh Command May Accumulate
		2	2 Refresh Commands May Accumulate
		3	3 Refresh Commands May Accumulate
		4	4 Refresh Commands May Accumulate
		5	5 Refresh Commands May Accumulate
		6	6 Refresh Commands May Accumulate
		7	7 Refresh Commands May Accumulate
		8	8 Refresh Commands May Accumulate
15 (R/W)	PRECBANK7	Precharge Bank 7. The DMC_EFFCTL.PRECBANK7 bit enables precharge (closes the page) of bank 7 after each transfer if the DMC precharge feature is enabled (DMC_CTL.PREC =1). Note: The (DMC_CTL.PREC) takes precedence over value in this register. If (DMC_CTL.PREC =1) then all banks are precharged.	
		0	Disable Precharge Bank 7
		1	Enable Precharge Bank 7
14 (R/W)	PRECBANK6	Precharge Bank 6. The DMC_EFFCTL.PRECBANK6 bit enables precharge (closes the page) of bank 6 after each transfer if the DMC precharge feature is enabled (DMC_CTL.PREC =1). Note: The (DMC_CTL.PREC) takes precedence over value in this register. If (DMC_CTL.PREC =1) then all banks are precharged.	
		0	Disable Precharge Bank 6
		1	Enable Precharge Bank 6

Table 9-12: DMC_EFFCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
13 (R/W)	PRECBANK5	Precharge Bank 5. The DMC_EFFCTL.PRECBANK5 bit enables precharge (closes the page) of bank 5 after each transfer if the DMC precharge feature is enabled (DMC_CTL.PREC =1). Note: The (DMC_CTL.PREC) takes precedence over value in this register. If (DMC_CTL.PREC =1) then all banks are precharged.	
		0	Disable Precharge Bank 5
		1	Enable Precharge Bank 5
12 (R/W)	PRECBANK4	Precharge Bank 4. The DMC_EFFCTL.PRECBANK4 bit enables precharge (closes the page) of bank 4 after each transfer if the DMC precharge feature is enabled (DMC_CTL.PREC =1). Note: The (DMC_CTL.PREC) takes precedence over value in this register. If (DMC_CTL.PREC =1) then all banks are precharged.	
		0	Disable Precharge Bank 4
		1	Enable Precharge Bank 4
11 (R/W)	PRECBANK3	Precharge Bank 3. The DMC_EFFCTL.PRECBANK3 bit enables precharge (closes the page) of bank 3 after each transfer if the DMC precharge feature is enabled (DMC_CTL.PREC =1). Note: The (DMC_CTL.PREC) takes precedence over value in this register. If (DMC_CTL.PREC =1) then all banks are precharged.	
		0	Disable Precharge Bank 3
		1	Enable Precharge Bank 3
10 (R/W)	PRECBANK2	Precharge Bank 2. The DMC_EFFCTL.PRECBANK2 bit enables precharge (closes the page) of bank 2 after each transfer if the DMC precharge feature is enabled (DMC_CTL.PREC =1). Note: The (DMC_CTL.PREC) takes precedence over value in this register. If (DMC_CTL.PREC =1) then all banks are precharged.	
		0	Disable Precharge Bank 2
		1	Enable Precharge Bank 2
9 (R/W)	PRECBANK1	Precharge Bank 1. The DMC_EFFCTL.PRECBANK1 bit enables precharge (closes the page) of bank 1 after each transfer if the DMC precharge feature is enabled (DMC_CTL.PREC =1). Note: The (DMC_CTL.PREC) takes precedence over value in this register. If (DMC_CTL.PREC =1) then all banks are precharged.	
		0	Disable Precharge Bank 1
		1	Enable Precharge Bank 1

Table 9-12: DMC_EFFCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W)	PRECBANK0	Precharge Bank 0. The DMC_EFFCTL.PRECBANK0 bit enables precharge (closes the page) of bank 0 after each transfer if the DMC precharge feature is enabled (DMC_CTL.PREC =1). Note: The (DMC_CTL.PREC) takes precedence over value in this register. If (DMC_CTL.PREC =1) then all banks are precharged.	
		0	Disable Precharge Bank 0
		1	Enable Precharge Bank 0

Shadow EMR3 Register

The DMC_EMR3 register in the DMC shadows the EMR3 register in the SDRAM when the DMC is in DDR3 mode (DMC_CTL.DDR3EN =1). If unmasked by the corresponding bit in the shadow mask register (DMC_MSK.EMR3 =1), a write to DMC_EMR3 triggers an extended “mode register set” command on the memory interface. If masked, a write to DMC_EMR3 only updates the register in the DMC, not the register in the SDRAM.

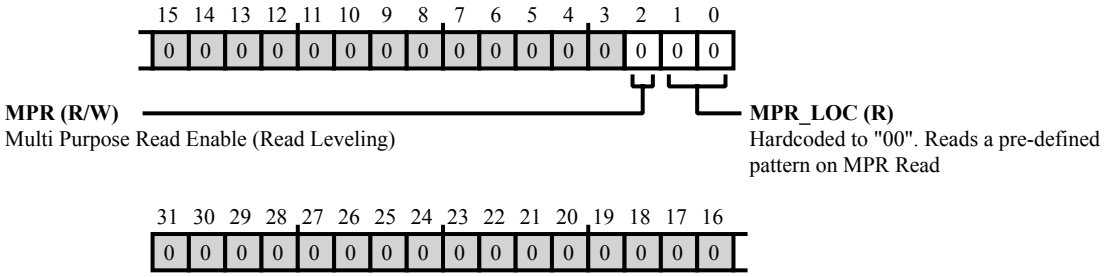

Figure 9-8: DMC_EMR3 Register Diagram

Table 9-13: DMC_EMR3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W)	MPR	Multi Purpose Read Enable (Read Leveling). The DMC_EMR3.MPR bit enables high temperature self-refresh rate.	
		0	Disable
		1	Enable
1:0 (R/NW)	MPR_LOC	Hardcoded to "00". Reads a pre-defined pattern on MPR Read.	

Shadow MR0 Register (DDR3)

The DMC_MR register in the DMC shadows the MR register in the SDRAM when the DMC is DDR3 mode (DMC_CTL.DDR3EN =1). If unmasked by the corresponding bit in the shadow mask register (DMC_MSK.MR =1), a write to DMC_MR triggers a “mode register set” command on the memory interface. If masked, a write to DMC_MR only updates the register in the DMC, not the register in the SDRAM.

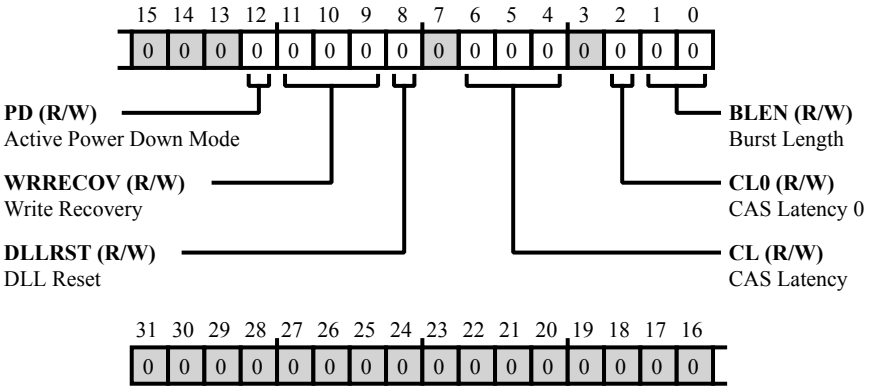

Figure 9-9: DMC_MR Register Diagram

Table 9-14: DMC_MR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W)	PD	Active Power Down Mode. The DMC_MR.PD bit selects the active power-down mode. Note that this parameter applies only for DDR3 mode. For more information about this mode, see the data sheet for the SDRAM being used in your system.	
		0	Fast Exit (normal)
		1	Slow Exit (low power)
11:9 (R/W)	WRRECOV	Write Recovery. The DMC_MR.WRRECOV bit selects the write recovery time in terms of clock cycles (t_{CK}). Note that this parameter applies only for DDR3 mode. For more information about this mode, see the data sheet for the SDRAM being used in your system.	
		0	16 clock cycles for DDR3
		1	5 clock cycles for DDR3
		2	6 clock cycles for DDR3
		3	7 clock cycles for DDR3
		4	8 clock cycles for DDR3
		5	10 clock cycles for DDR3
		6	12 clock cycles for DDR3

Table 9-14: DMC_MR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		7	14 clock cycles for DDR3
8 (R/W)	DLLRST	DLL Reset. The DMC_MR.DLLRST bit initiates a DLL reset on the SDRAM. Note that this parameter applies only for DDR3 mode. For more information about this operation, see the data sheet for the SDRAM being used in your system.	
		0	Normal Operation
		1	Reset DLL
6:4 (R/W)	CL	CAS Latency. The DMC_MR.CL bit field select latency from the assertion of a read/write signal to the SDRAM until the first valid data on the output from the SDRAM in terms of clock cycles. For more information about this operation, see the data sheet for the SDRAM being used in your system. For DDR3 only, Bit[2] of this register must be used along with [6:4]. Following CAS values are seen. "0010": 5 "0100": 6 "0110": 7 "1000": 8 "1010": 9 "1100": 10 "1110": 11 "0001": 12 "0011": 13 "0101": 14 All other combinations are reserved.	
2 (R/W)	CL0	CAS Latency 0. The DMC_MR.CL0 bit is applicable for DDR3 only and is used in conjunction with the DMC_MR.CL bits.	
1:0 (R/W)	BLEN	Burst Length. The DMC_MR.BLEN bits select burst length for transfers. For more information about this operation, see the data sheet for the SDRAM being used in your system. Note that values other than those shown are not supported.	
		0	8-Bit Burst Length - DDR3 only
		2	Reserved
		3	Reserved

Shadow MR1 Register (DDR3)

The DMC_MR1 register is a mirror of the DDR3 SDRAM Mode register 1. This register is used only when the DMC is operating in DDR3 mode. A write to this register triggers an extended "mode register 1 set" command on the memory interface provided the corresponding mask bit is set in the mask register. Else, only the mirror register is updated.

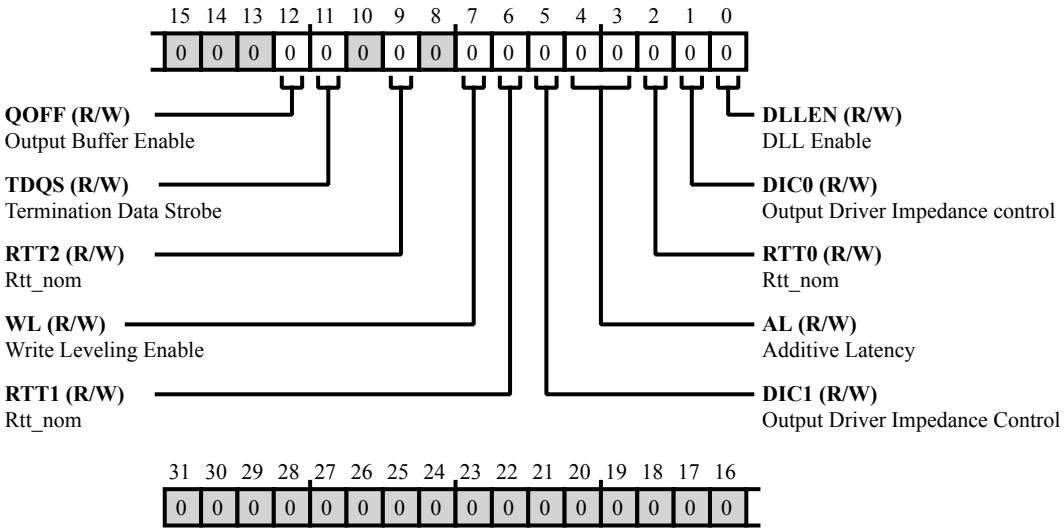

Figure 9-10: DMC_MR1 Register Diagram

Table 9-15: DMC_MR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W)	QOFF	Output Buffer Enable. The DMC_MR1.QOFF bit enables the SDRAM output pins. For more information about this operation, see the data sheet for the SDRAM being used in your system.	
		0	Output buffer enabled
		1	Output buffer disabled
11 (R/W)	TDQS	Termination Data Strobe. The DMC_MR1.TDQS bit provides additional termination resistance outputs that may be useful in some system configurations. The DMC_MR1.TDQS bit is not supported in x4 or x16 configurations. When enabled via the mode register, the same termination resistance function is applied to the TDQS/TDQS# pins that is applied to the DQS/DQS# pins.	
		0	Enable
		1	Disable

Table 9-15: DMC_MR1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
9 (R/W)	RTT2	Rtt_nom. The DMC_MR1.RTT2 bit is used in conjunction with the DMC_MR1.RTT0 and DMC_MR1.RTT1 bits. (9 6 2) 0 0 0 Rtt_Nom disabled 0 0 1 RZQ/4 0 1 0 RZQ/2 0 1 1 RZQ/6 1 0 0 RZQ/12 (reserved if Rtt_Nom is used during writes) 1 0 1 RZQ/8 (reserved if Rtt_Nom is used during writes) 1 1 0 Reserved 1 1 1 Reserved
7 (R/W)	WL	Write Leveling Enable. The DMC_MR1.WL bit enables the SDRAM output pins. For more information about this operation, see the data sheet for the SDRAM being used in your system. 0 Disable 1 Enable
6 (R/W)	RTT1	Rtt_nom. The DMC_MR1.RTT1 bit combines with the DMC_MR1.RTT0 bit to set the termination resistance. See the DMC_MR1.RTT2 and DMC_MR1.RTT0 bit description for more information.
5 (R/W)	DIC1	Output Driver Impedance Control. The DMC_MR1.DIC1 bit is used in conjunction with the DMC_MR1.DIC0 bit. (5, 1) 0 0 RZQ/6 0 1 RZQ/7 1 0 Reserved 1 1 Reserved

Table 9-15: DMC_MR1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
4:3 (R/W)	AL	Additive Latency. The DMC_MR1.AL bits select a number of added latency time for CAS operations in terms of clock cycles (t_{CK}). For more information about this operation, see the data sheet for the SDRAM being used in your system.	
		0	AL disabled
		1	CL-1
		2	CL-2
		3	Reserved
2 (R/W)	RTT0	Rtt_nom. The DMC_MR1.RTT0 bit combines with the DMC_MR1.RTT1 and DMC_MR1.RTT1 bits to set the termination resistance. See the DMC_MR1.RTT1 and DMC_MR1.RTT2 bit descriptions for more information.	
1 (R/W)	DIC0	Output Driver Impedance control. The DMC_MR1.DIC0 bit is used with the DMC_MR1.DIC1 bit.	
0 (R/W)	DLLEN	DLL Enable. The DMC_MR1.DLLEN bit enables the DLL in the SDRAM. For more information about this operation, see the data sheet for the SDRAM being used in your system.	
		0	Enable
		1	Disable

Shadow MR2 Register (DDR3)

The DMC_MR2 register mirrors DDR3 SDRAM device Mode register 2 when the controller is operating in DDR3 mode. A write to this register triggers an extended "mode register set" command on the memory interface provided the corresponding mask bit is set in the mask register. Else, only the mirror register is updated.

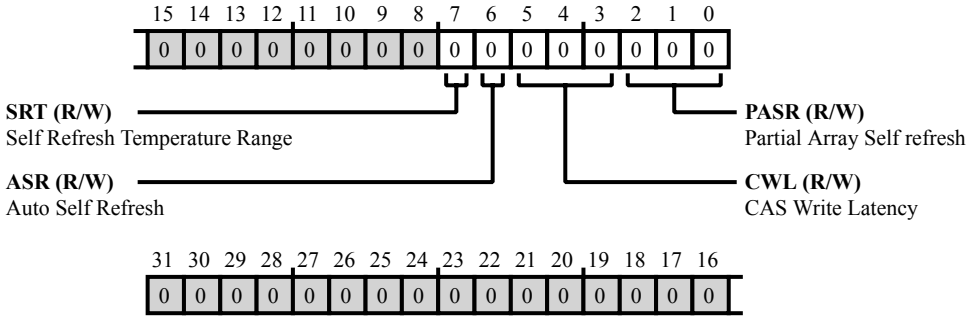

Figure 9-11: DMC_MR2 Register Diagram

Table 9-16: DMC_MR2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	SRT	Self Refresh Temperature Range. The DMC_MR2.SRT bit enables high temperature self-refresh rate.	
		0	Disable
		1	Enable
6 (R/W)	ASR	Auto Self Refresh.	
		0	Manual SR Reference (SRT)
		1	ASR enable (Optional)
5:3 (R/W)	CWL	CAS Write Latency.	
		0	5 clock cycles
		1	6 clock cycles
		2	7 clock cycles
		3	8 clock cycles
		4	9 clock cycles
		5	10 clock cycles
		6	11 clock cycles
		7	12 clock cycles

Table 9-16: DMC_MR2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2:0 (R/W)	PASR	Partial Array Self refresh. The `DMC_MR2.PASR` bits select the amount of memory to be refreshed during self refresh. For more information about this operation, see the data sheet for the SDRAM being used in your system.	
		0	4 banks: full array, 8 banks: full array
		1	4 banks: Half Array (BA[1:0]=00&01), 8 banks: Half Array (BA[2:0] = 000, 001, 010, &011)
		2	4 banks: Quarter Array (BA[1:0]=00), 8 banks: Quarter Array (BA[2:0] = 000&001)
		3	4 banks: not defined, 8 banks: 1/8th array (BA[2:0] = 000)
		4	4 banks: 3/4 Array (BA[1:0]=01, 10&11), 8 banks: 3/4 Array (BA[2:0] = 010, 011, 100, 101, 110, &111)
		5	4 banks: Half Array (BA[1:0]=10&11), 8 banks: Half Array (BA[2:0] = 100, 101, 110, &111)
		6	4 banks: Quarter Array (BA[1:0]=11), 8 banks: Quarter Array (BA[2:0] =110 & 111)
		7	4 banks: not defined, 8 banks: 1/8th array (BA[2:0] = 111)

Mask (Mode Register Shadow) Register

The DMC_MSK register permits masking (disabling) writes to the MR and EMRn registers in the SDRAM in DDR3 Mode. When masked, writes to these registers go instead to shadow copies of these registers (DMC_MR, DMC_MR1, DMC_MR2), which are maintained within the DMC. When a shadow register's corresponding bit is unmasked (enabled), the DMC generates the MRS or EMRS command to transfer the contents of the shadow register (in the DMC) to the actual register (in the SDRAM).

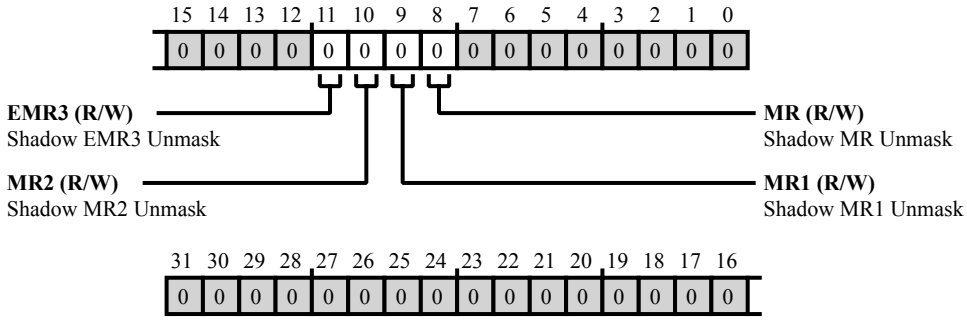

Figure 9-12: DMC_MSK Register Diagram

Table 9-17: DMC_MSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W)	EMR3	Shadow EMR3 Unmask. The DMC_MSK.EMR3 bit masks or unmasks writes to the EMR3 register in the SDRAM. When masked, writes to this register instead go to the EMR3 register. When unmasked, the DMC writes the EMR3 value to the EMR3 register in the SDRAM. After completing the write, the DMC clears this bit.	
		0	Mask (Disable) Write to EMR3
		1	Unmask (Enable) Write to EMR3
10 (R/W)	MR2	Shadow MR2 Unmask. The DMC_MSK.MR2 bit masks or unmasks writes to the MR2 register (in DDR3 mode) in the SDRAM. When masked, writes to this register instead go to the DMC_MR2 register. When unmasked, the DMC writes the DMC_MR2 value to the MR2 register (in DDR3 mode) in the SDRAM. After completing the write, the DMC clears this bit.	
		0	Mask (Disable) Write to EMR2
		1	Unmask (Enable) Write to EMR2

Table 9-17: DMC_MSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W)	MR1	Shadow MR1 Unmask. The DMC_MSK.MR1 bit masks or unmasks writes to the MR1 register in the DDR3 SDRAM. When masked, writes to this register instead go to the DMC_MR1 register. When unmasked, the DMC writes the DMC_MR1 value to the MR1 register in the SDRAM. After completing the write, the DMC clears this bit. Note that this bit is valid only for DDR3 Mode of operation.	
		0	Mask (Disable) Write to EMR1
		1	Unmask (Enable) Write to EMR1
8 (R/W)	MR	Shadow MR Unmask. The DMC_MSK.MR bit masks or unmasks writes to the MR register in the SDRAM. When masked, writes to this register instead go to the DMC_MR register. When unmasked, the DMC writes the DMC_MR value to the MR register in the SDRAM. After completing the write, the DMC clears this bit.	
		0	Mask (Disable) Write to MR
		1	Unmask (Enable) Write to MR

DMC Performance Control Register

The DMC_PM_CTL register generates a performance index. It does this by obtaining a count of various performance indicators.

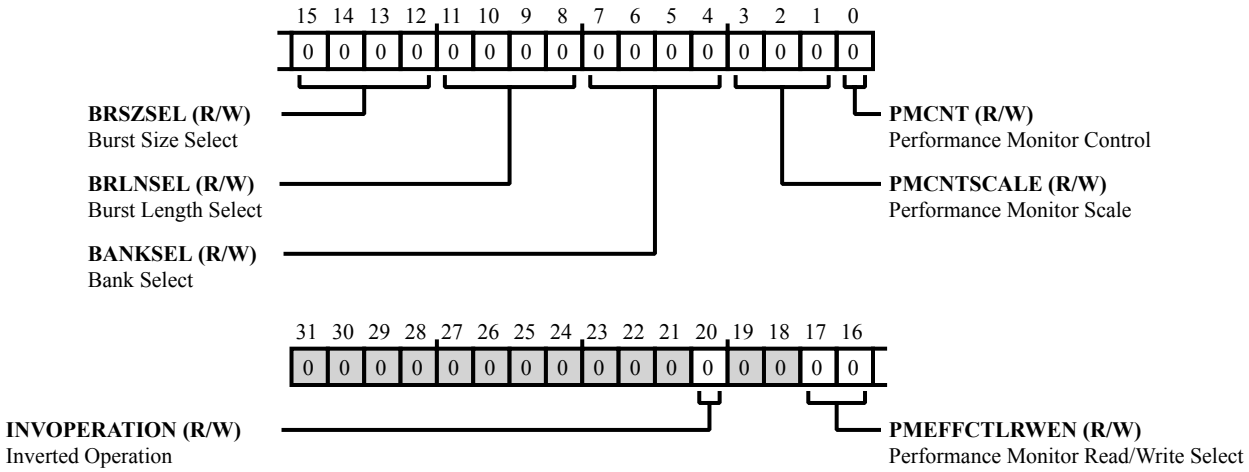

Figure 9-13: DMC_PM_CTL Register Diagram

Table 9-18: DMC_PM_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
20 (R/W)	INVOPERATION	Inverted Operation. The DMC_PM_CTL.INVOPERATION bit is inverts the operation of the idle cycle counter. When enabled the counter reports the number of cycles for which the corresponding bus is NOT idle. Used for the DQ bus, SCB Read data bus and SCB Write data bus.	
		0	Normal operation
		1	Inverted operation
17:16 (R/W)	PMEFFCTLRWEN	Performance Monitor Read/Write Select. The DMC_PM_CTL.PMEFFCTLRWEN bit selects whether the performance monitor efficiency counter is used for read transactions or write transactions	
		1	Read
		2	Write
		3	Read and Write

Table 9-18: DMC_PM_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
15:12 (R/W)	BRSZSEL	Burst Size Select. The DMC_PM_CTL.BRSZSEL bit field reports the value of number of SCB transfers corresponding to the burst size shown by these bits.	
		0	Burst size 8
		1	Burst size 16
		2	Burst size 32
11:8 (R/W)	BRLNSEL	Burst Length Select. The DMC_PM_CTL.BRLNSEL bit field reports the value of number of SCB transfers corresponding to the burst length shown by these bits.	
		0	Burst length 1
		1	Burst length 2
		3	Burst length 4
		7	Burst length 8
		15	Burst length 16
7:4 (R/W)	BANKSEL	Bank Select. The DMC_PM_CTL.BANKSEL bit field chooses which bank or all banks are being selected for the page hit or page miss counters.	
		0	Bank 0
		1	Bank 1
		2	Bank 2
		3	Bank 3
		4	Bank 4
		5	Bank 5
		6	Bank 6
		7	Bank 7
		8	All Banks

Table 9-18: DMC_PM_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3:1 (R/W)	PMCNTSCALE	Performance Monitor Scale. The `DMC_PM_CTL.PMCNTSCALE` bit bit field reports the scale of the main to sub-counter.	
		0	1:1
		1	1:10
		2	1:100
		4	1:1000
0 (R/W)	PMCNT	Performance Monitor Control. The `DMC_PM_CTL.PMCNT` bit enables performance monitoring.	
		0	Disable the counters
		1	Enable the counters

Performance Monitor Idle Cycle DQ Count Register

The DMC_PM_IDCYDQ_CNT register reports the number of idle cycles on the DQ bus.

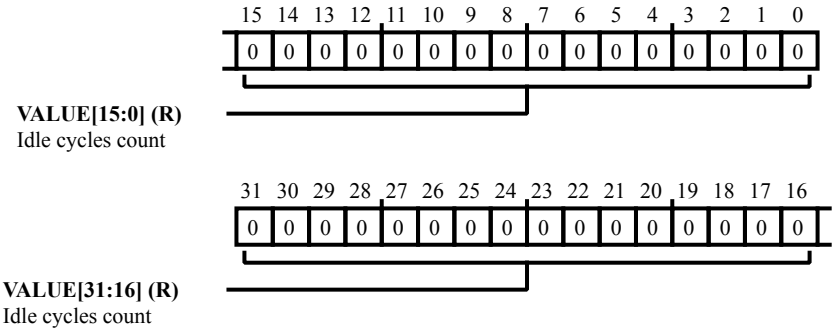

Figure 9-14: DMC_PM_IDCYDQ_CNT Register Diagram

Table 9-19: DMC_PM_IDCYDQ_CNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Idle cycles count.

Performance Monitor Idle Page Count Register

The DMC_PM_IDPG_CNT register reports the number of accesses to idle pages.

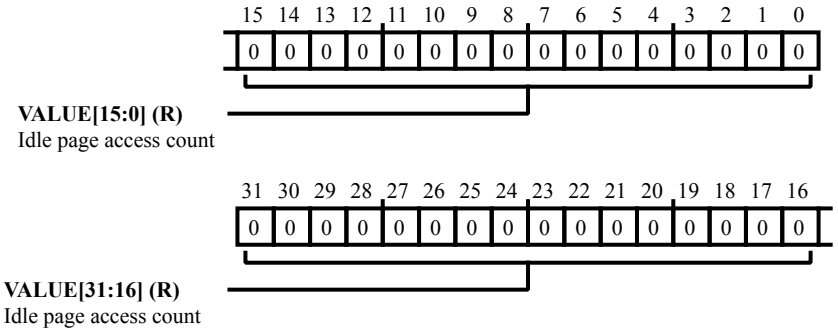

Figure 9-15: DMC_PM_IDPG_CNT Register Diagram

Table 9-20: DMC_PM_IDPG_CNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Idle page access count.

Performance Monitor Page Hit Count

The DMC_PM_PGHT_CNT register reports the number of page hit accesses.

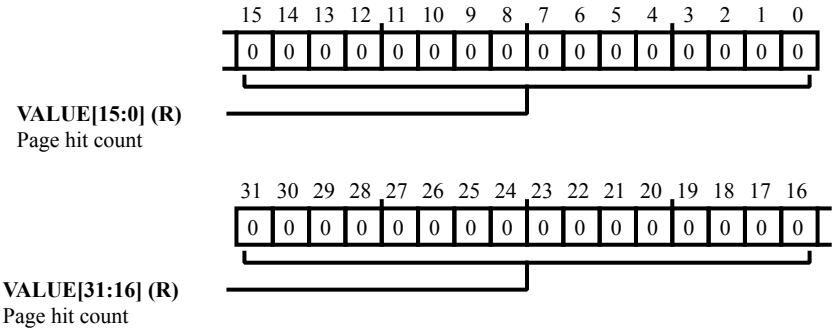

Figure 9-16: DMC_PM_PGHT_CNT Register Diagram

Table 9-21: DMC_PM_PGHT_CNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Page hit count.

Performance Monitor Page Miss Count

The DMC_PM_PGMS_CNT register reports the number of missed page accesses.

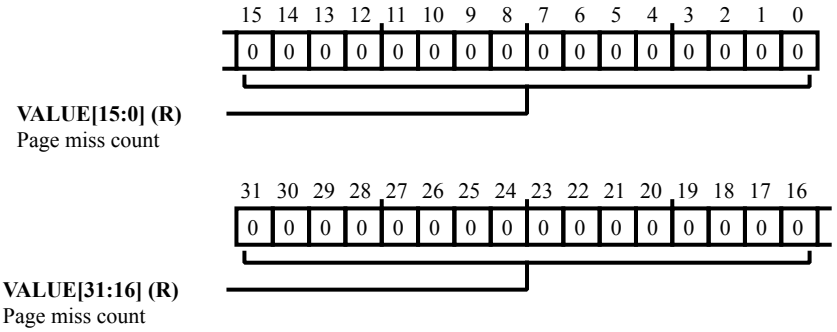

Figure 9-17: DMC_PM_PGMS_CNT Register Diagram

Table 9-22: DMC_PM_PGMS_CNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Page miss count.

Performance Monitor Read to Write Turn Around Count Register

The DMC_PM_RD2WRTA_CNT register reports the number of times the read to write turn around occurs.

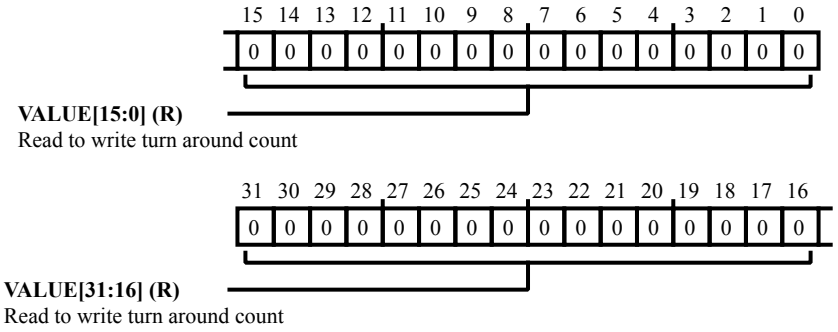

Figure 9-18: DMC_PM_RD2WRTA_CNT Register Diagram

Table 9-23: DMC_PM_RD2WRTA_CNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Read to write turn around count.

Performance Monitor Refresh Count Register

The DMC_PM_REF_CNT register reports the number of times a refresh occurs.

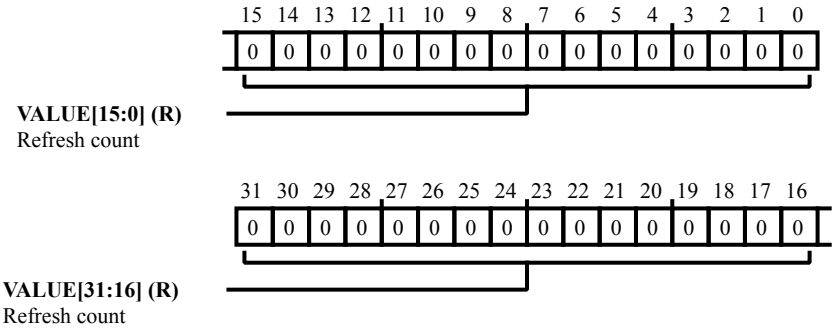

Figure 9-19: DMC_PM_REF_CNT Register Diagram

Table 9-24: DMC_PM_REF_CNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Refresh count.

Performance Monitor Write to Read Turn Around Count Register

The DMC_PM_WR2RDTA_CNT register reports the number of times the write to read turn around occurs.

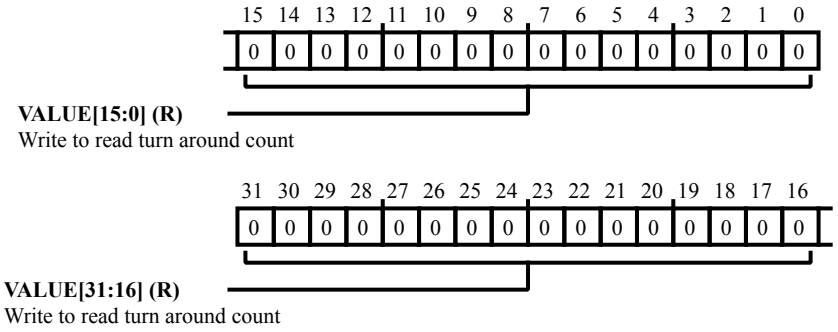

Figure 9-20: DMC_PM_WR2RDTA_CNT Register Diagram

Table 9-25: DMC_PM_WR2RDTA_CNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Write to read turn around count.

Priority ID Register 1

The DMC_PRIO register allows transactions from selected requesters that generate specific SCB IDs to obtain higher priority than the transactions proceeding in the usual fashion. The contents of the register are masked with the contents of the DMC_PRIOMSK register to obtain a single SCB ID or a range of IDs that get elevated priority.

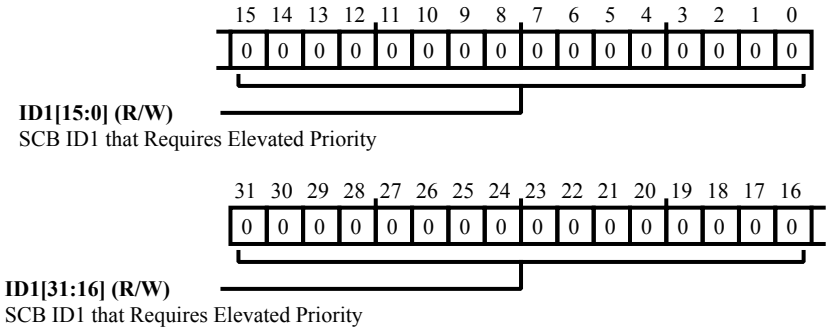

Figure 9-21: DMC_PRIO Register Diagram

Table 9-26: DMC_PRIO Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	ID1	SCB ID1 that Requires Elevated Priority.

Priority ID Register 2

The DMC_PRIO2 register is another register which allows transactions from selected requesters that generate specific SCB IDs to obtain higher priority than the transactions proceeding in the usual fashion. The contents of the register are masked with the contents of the DMC_PRIOMSK2 register to obtain a single SCB ID or a range of IDs that get elevated priority.

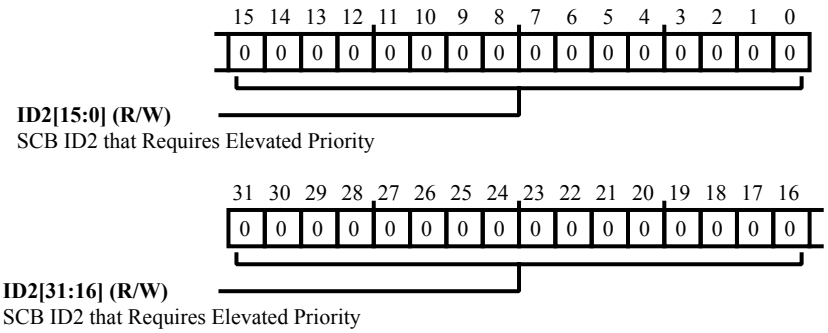

Figure 9-22: DMC_PRIO2 Register Diagram

Table 9-27: DMC_PRIO2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	ID2	SCB ID2 that Requires Elevated Priority.

Priority ID Mask Register 1

The DMC_PRIOMSK register masks the respective ID bits in the DMC_PRIOMSK register. This masking provides for elevating the access priority of either a single ID or a range of IDs.

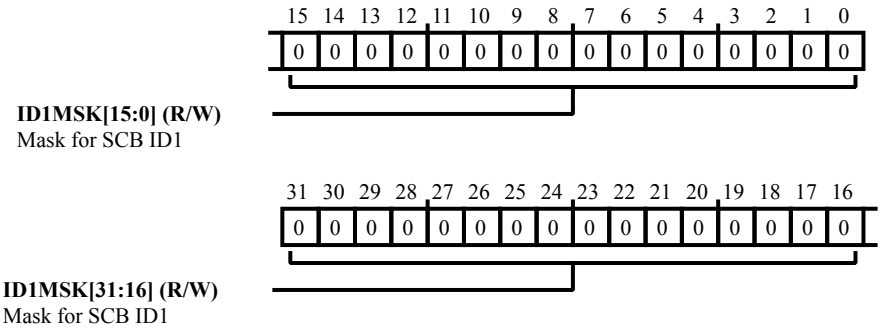

Figure 9-23: DMC_PRIOMSK Register Diagram

Table 9-28: DMC_PRIOMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	ID1MSK	Mask for SCB ID1.

Priority ID Mask Register 2

The DMC_PRIOMSK2 register bits mask the respective ID bits in the DMC_PRIO2 register. This masking provides for elevating the access priority of either a single ID or a range of IDs.

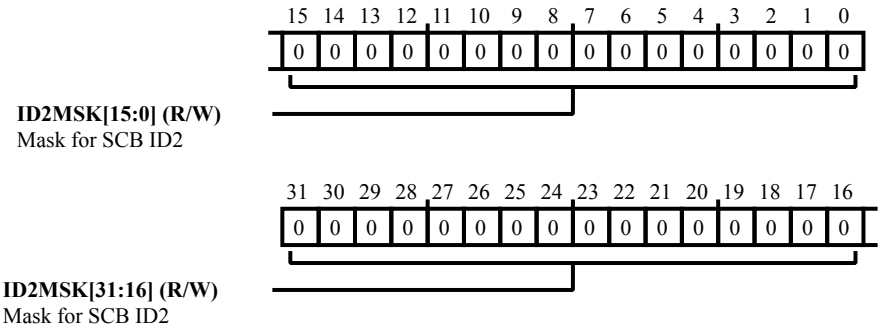

Figure 9-24: DMC_PRIOMSK2 Register Diagram

Table 9-29: DMC_PRIOMSK2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	ID2MSK	Mask for SCB ID2.

DMC Read Data Buffer ID Register 1

The DMC_RDDATABUFID1 register allows read transactions from selected requesters to make use of DMC read data buffer. The contents of the register are masked with the contents of the DMC_RDDATABUFMSK1 register to obtain a single SCB ID or a range of IDs that get elevated priority.

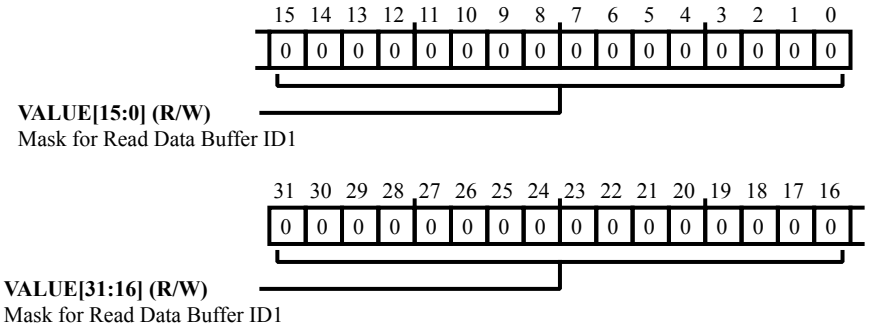

Figure 9-25: DMC_RDDATABUFID1 Register Diagram

Table 9-30: DMC_RDDATABUFID1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Mask for Read Data Buffer ID1.

DMC Read Data Buffer ID Register 2

The DMC_RDDATABUFID2 register allows read transactions from selected requesters to make use of DMC read data buffer. The contents of the register are masked with the contents of the DMC_RDDATABUFMSK2 register to obtain a single SCB ID or a range of IDs that get elevated priority.

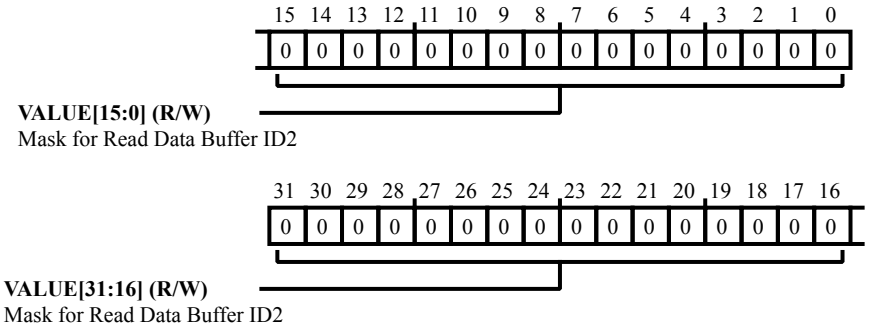

Figure 9-26: DMC_RDDATABUFID2 Register Diagram

Table 9-31: DMC_RDDATABUFID2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Mask for Read Data Buffer ID2.

DMC Read Data Buffer Mask Register 1

The DMC_RDDATABUFMSK1 register bits mask the respective ID bits in the DMC Priority Mask ID register.

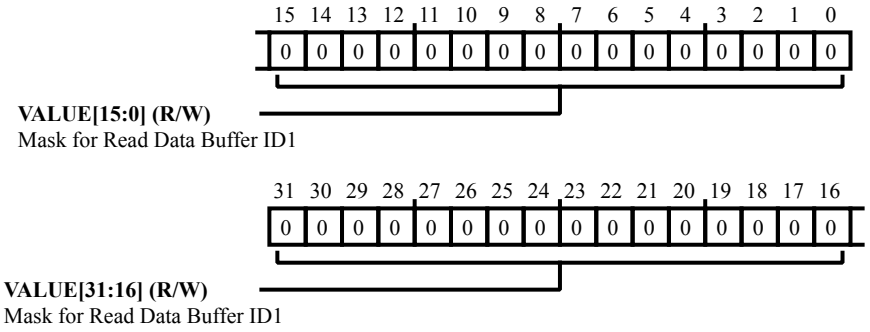

Figure 9-27: DMC_RDDATABUFMSK1 Register Diagram

Table 9-32: DMC_RDDATABUFMSK1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Mask for Read Data Buffer ID1.

DMC Read Data Buffer Mask Register 2

The DMC_RDDATABUFMSK2 register bits mask the respective ID bits in the DMC Priority Mask ID register.

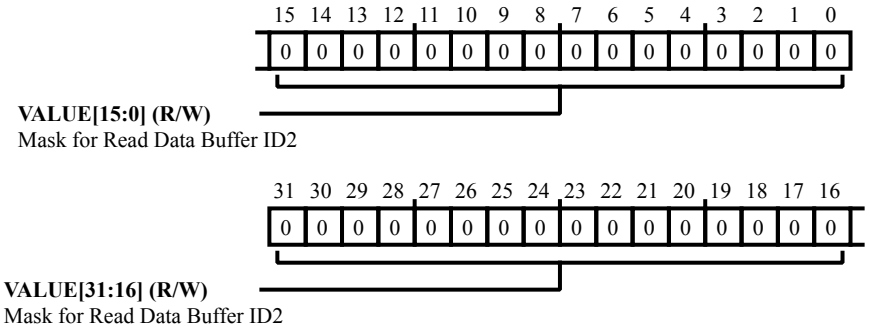

Figure 9-28: DMC_RDDATABUFMSK2 Register Diagram

Table 9-33: DMC_RDDATABUFMSK2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Mask for Read Data Buffer ID2.

Performance Monitor Buffer Hit Count Register

The DMC_RDD_BUFHT_CNT register reports the count of the number of read data buffer hits.

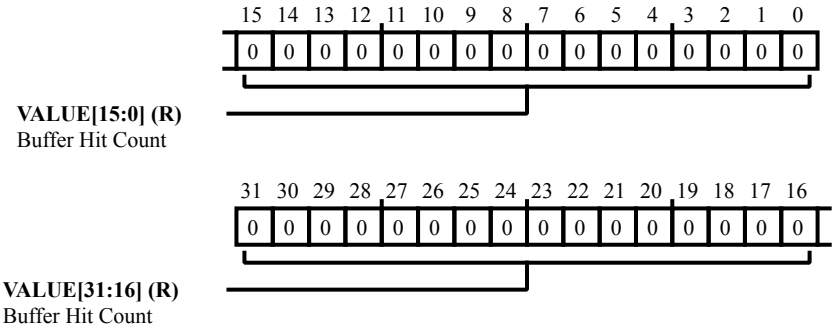

Figure 9-29: DMC_RDD_BUFHT_CNT Register Diagram

Table 9-34: DMC_RDD_BUFHT_CNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Buffer Hit Count.

SCB Performance AXI Transfer Count Register

The DMC_SCB_PM_BRLN_CNT register reports the count of number of times AXI transfer of burst length selected by performance control register is encountered.

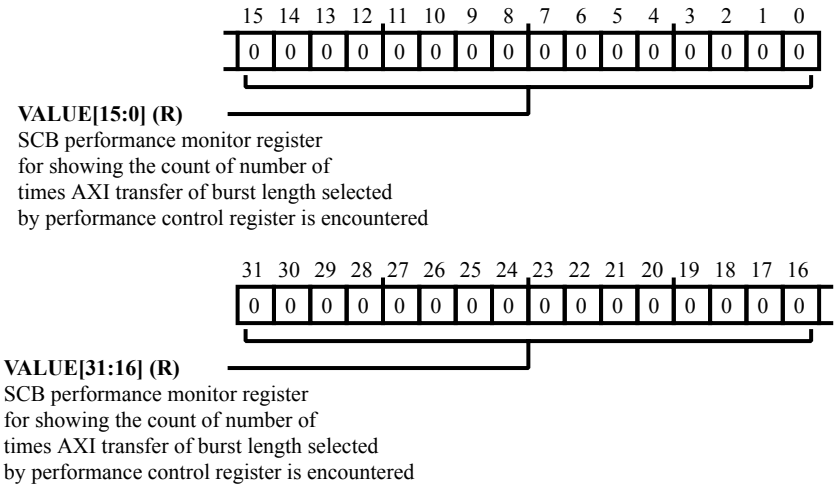

Figure 9-30: DMC_SCB_PM_BRLN_CNT Register Diagram

Table 9-35: DMC_SCB_PM_BRLN_CNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	SCB performance monitor register for showing the count of number of times AXI transfer of burst length selected by performance control register is encountered.

SCB Performance AXI Transfer Count Register

The DMC_SCB_PM_BRSZ_CNT register reports the count of number of times AXI transfer of burst size selected by performance control register is encountered.

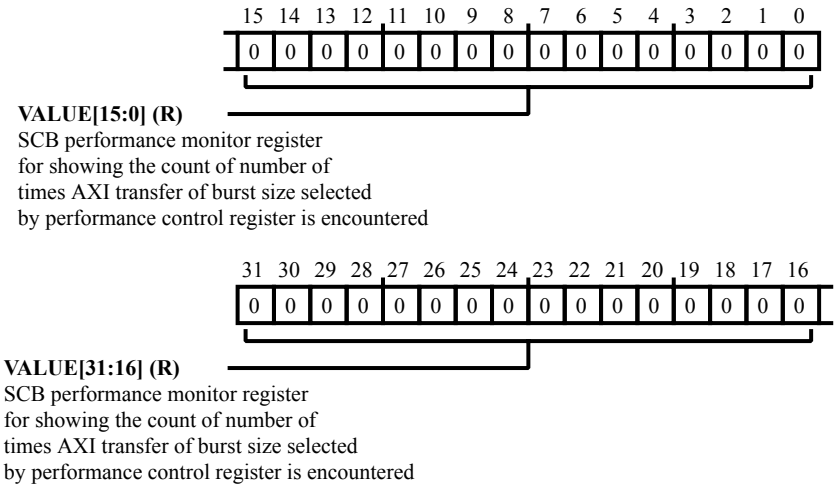

Figure 9-31: DMC_SCB_PM_BRSZ_CNT Register Diagram

Table 9-36: DMC_SCB_PM_BRSZ_CNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	SCB performance monitor register for showing the count of number of times AXI transfer of burst size selected by performance control register is encountered.

SCB Performance Monitor Idle Cycle Count Register

The DMC_SCB_PM_IDRDDCY_CNT register reports the count of the number idle cycles on the read data bus.

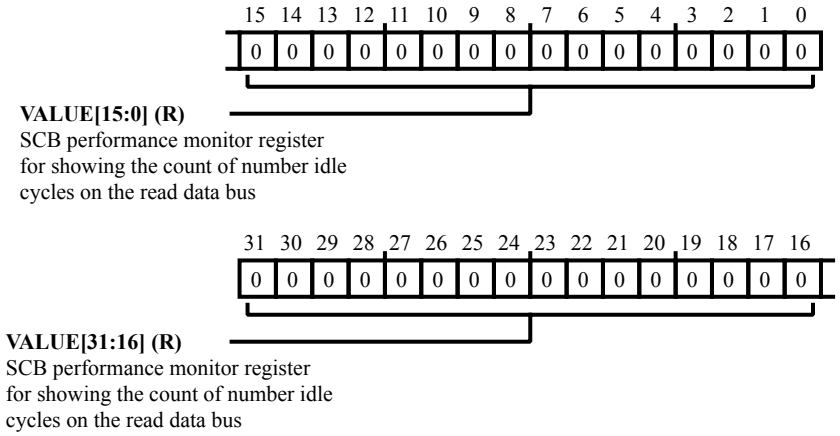

Figure 9-32: DMC_SCB_PM_IDRDDCY_CNT Register Diagram

Table 9-37: DMC_SCB_PM_IDRDDCY_CNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	SCB performance monitor register for showing the count of number idle cycles on the read data bus.

SCB Performance Monitor Idle Cycle Count Register

The DMC_SCB_PM_IDWRDCY_CNT register reports the count of number idle cycles on the write data bus.

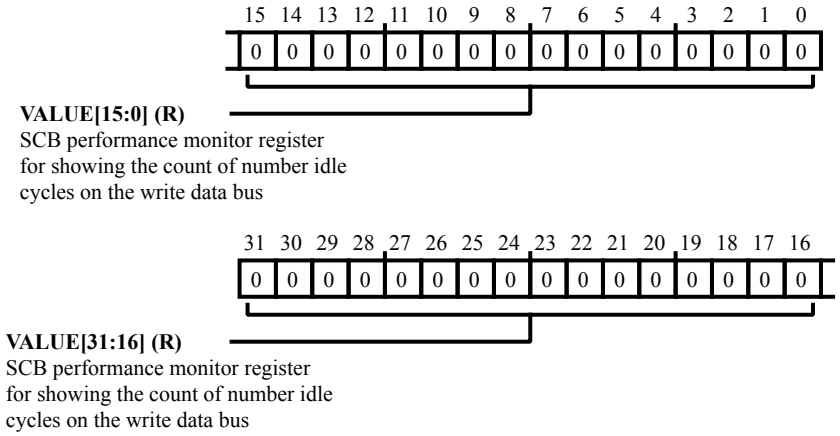

Figure 9-33: DMC_SCB_PM_IDWRDCY_CNT Register Diagram

Table 9-38: DMC_SCB_PM_IDWRDCY_CNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	SCB performance monitor register for showing the count of number idle cycles on the write data bus.

Status Register

The DMC_STAT register indicates status for modes selected with the DMC_CTL register and indicates status DMC operations.

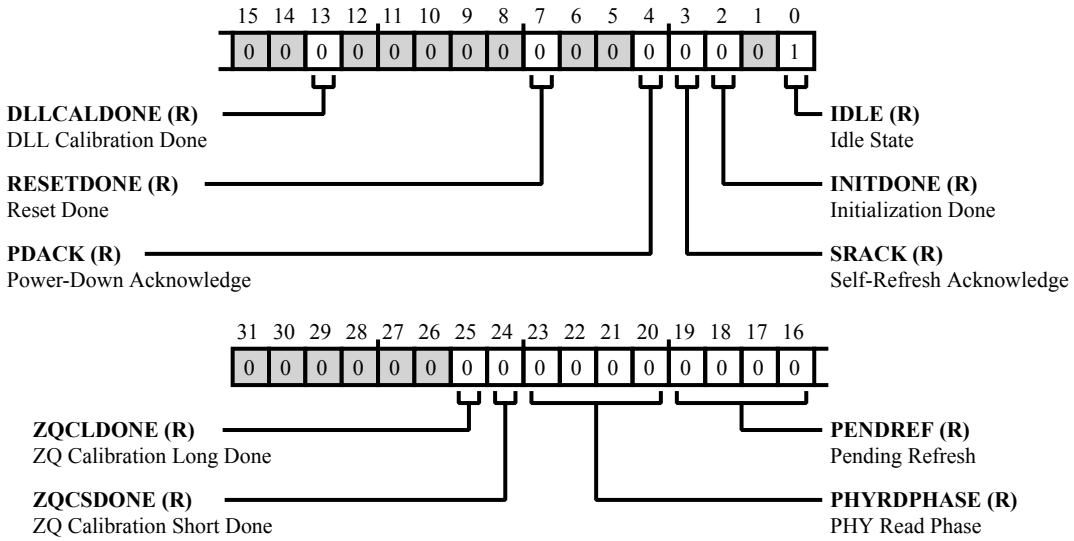

Figure 9-34: DMC_STAT Register Diagram

Table 9-39: DMC_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
25 (R/NW)	ZQCLDONE	ZQ Calibration Long Done. The DMC_STAT.ZQCLDONE bit checks if the ZQ calibration long sub routine is done.	
		0	ZQ Calibration long is ongoing
		1	ZQ Calibration long is done
24 (R/NW)	ZQCSDONE	ZQ Calibration Short Done. The DMC_STAT.ZQCSDONE bit checks if the ZQ calibration short sub routine is done.	
		0	ZQ Calibration short is ongoing
		1	ZQ Calibration Short is done
23:20 (R/NW)	PHYRDPHASE	PHY Read Phase. The DMC_STAT.PHYRDPHASE bits indicate the latency after which the DMC may read from the PHY. Taking round trip delay into account, the DLL indicates the exact number of clock cycles after which the controller needs to read data. Values other than those shown are reserved.	
		2	2 Clock Cycles Latency

Table 9-39: DMC_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		3	3 Clock Cycles Latency
		4	4 Clock Cycles Latency
		5	5 Clock Cycles Latency
		6	6 Clock Cycles Latency
		7	7 Clock Cycles Latency
		8	8 Clock Cycles Latency
		9	9 Clock Cycles Latency
		10	10 Clock Cycles Latency
		11	11 Clock Cycles Latency
		12	12 Clock Cycles Latency
		13	13 Clock Cycles Latency
		14	14 Clock Cycles Latency
		15	15 Clock Cycles Latency
19:16 (R/NW)	PENDREF	Pending Refresh. The DMC_STAT.PENDREF bits indicate the number of pending auto-refresh commands whose value can be from "0000" to "0111".	
13 (R/NW)	DLLCALDONE	DLL Calibration Done. The DMC_STAT.DLLCALDONE indicates that the PHY DLL calibration sequence is complete.	
		0	No Status
		1	Completed PHY DLL Calibration
7 (R/NW)	RESETDONE	Reset Done. The DMC_STAT.RESETDONE bit indicates that the reset sequence is complete.	
		0	SDRAM Reset is ongoing
		1	SDRAM Reset is done
4 (R/NW)	PDACK	Power-Down Acknowledge. The DMC_STAT.PDACK bit indicates that power-down mode is active.	
		0	Not in Power-Down Mode
		1	Power-Down Mode Active

Table 9-39: DMC_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/NW)	SRACK	Self-Refresh Acknowledge. The `DMC_STAT.SRACK` bit indicates that self-refresh mode is active.	
		0	Not in Self-Refresh Mode
		1	Self-Refresh Mode Active
2 (R/NW)	INITDONE	Initialization Done. The `DMC_STAT.INITDONE` bit indicates that the initialization sequence is complete.	
		0	No Status
		1	Initialize Done
0 (R/NW)	IDLE	Idle State. The `DMC_STAT.IDLE` bit indicates whether the DMC is idle or busy.	
		0	Busy
		1	Idle

Timing 0 Register

The DMC_TR0 register selects timing parameters for DMC operation to corresponding with parameters of the SDRAM device that is used in the system. The timing registers must be programmed to match the device for correct operation of the SDRAM and must be programmed before initializing the SDRAM. Note that all values for bit fields in DMC_TR0 are in increments of clock cycle time (t_{CK}).

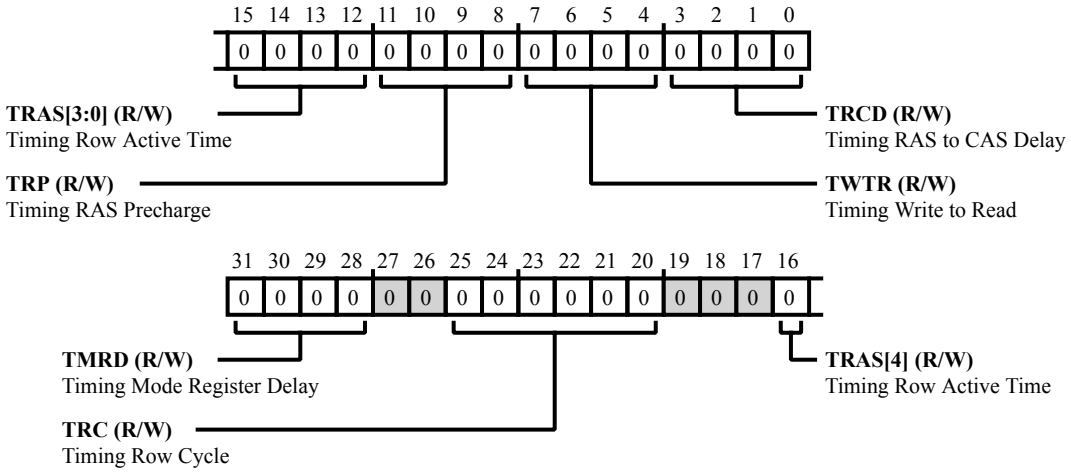

Figure 9-35: DMC_TR0 Register Diagram

Table 9-40: DMC_TR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:28 (R/W)	TMRD	Timing Mode Register Delay. The DMC_TR0.TMRD field selects the set-to-active timing parameter (t_{MRD}), which is the number of clock cycles that occur after the mode registers in the SDRAM are set and before the next command is issued.
25:20 (R/W)	TRC	Timing Row Cycle. The DMC_TR0.TRC field selects the active-to-active time (t_{RC}), which is the minimum number of clock cycles that occur from an active command to the next active command in the same bank.
16:12 (R/W)	TRAS	Timing Row Active Time. The DMC_TR0.TRAS field selects the active-to-precharge time (t_{RAS}), which is the number of clock cycles that occur from an active command until a precharge command is allowed.
11:8 (R/W)	TRP	Timing RAS Precharge. The DMC_TR0.TRP field selects the precharge-to-active time (t_{RP}), which is the number of clock cycles that occur while the SDRAM recovers from a precharge command and becomes ready to accept the next active command.

Table 9-40: DMC_TR0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
7:4 (R/W)	TWTR	Timing Write to Read. The `DMC_TR0.TWTR` field selects the write-to-read delay time (t_{WTR}), which is the number of clock cycles that occur from the last write data to the next read command.
3:0 (R/W)	TRCD	Timing RAS to CAS Delay. The `DMC_TR0.TRCD` field selects the RAS to CAS delay time (t_{RCD}), which is the number of clock cycles that occur from an active command to a read/write assertion.

Timing 1 Register

The DMC_TR1 register selects timing parameters for DMC operation to corresponding with parameters of the SDRAM device that is used in the system. The timing registers must be programmed to match the device for correct operation of the SDRAM and must be programmed before initializing the SDRAM. Note that all values for bit fields in DMC_TR1 are in increments of clock cycle time (t_{CK}).

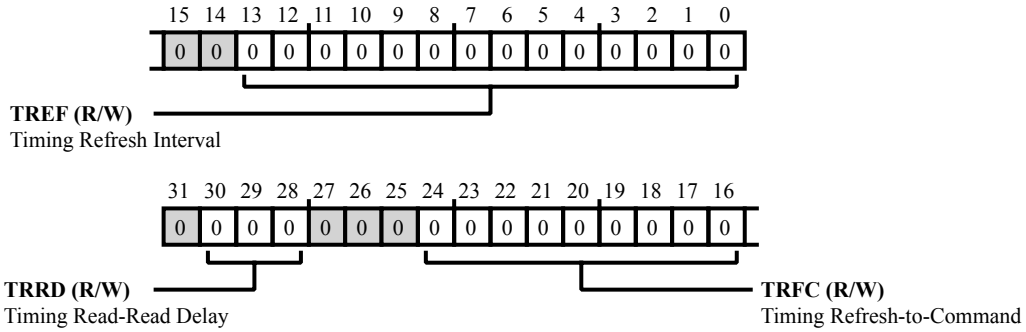

Figure 9-36: DMC_TR1 Register Diagram

Table 9-41: DMC_TR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
30:28 (R/W)	TRRD	Timing Read-Read Delay. The DMC_TR1.TRRD field selects the active-to-active time (t_{RRD}), which is the minimum number of clock cycles occurring from a bank x active command to a bank y active command.
24:16 (R/W)	TRFC	Timing Refresh-to-Command. The DMC_TR1.TRFC field selects the refresh-to-active command delay (t_{RFC}), which is the number of clock cycles required for the SDRAM to recover from a refresh signal to be ready to take the next command. It is also the number of clock cycles needed for the SDRAM to recover from executing one active command and ready to accept the next active command.
13:0 (R/W)	TREF	Timing Refresh Interval. The DMC_TR1.TREF field selects the refresh interval time (t_{REF}), which is the number of clock cycles occurring from one refresh command to the next refresh command. The actual timing of issuing a precharge command may be delayed by if the SDRAM is processing a normal access. However, the delay is not accumulative so there is no need to shorten the refresh interval to account for the memory access time. The non-accumulative refresh delay typically increases memory bandwidth by a few percentage points.

Timing 2 Register

The DMC_TR2 register selects timing parameters for DMC operation to corresponding with parameters of the SDRAM device that is used in the system. The timing registers must be programmed to match the device for correct operation of the SDRAM and before initializing the SDRAM.

Note that all values for bit fields in DMC_TR2 are in increments of clock cycle time (t_{CK}).

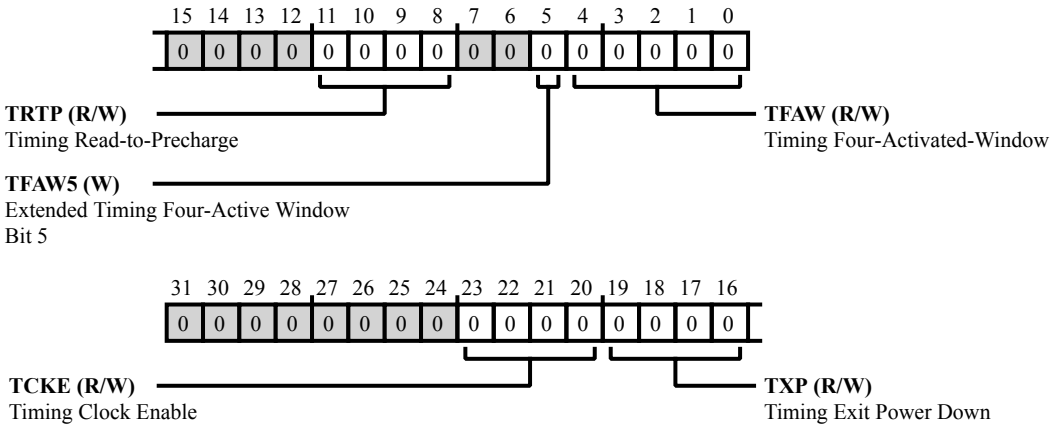

Figure 9-37: DMC_TR2 Register Diagram

Table 9-42: DMC_TR2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
23:20 (R/W)	TCKE	Timing Clock Enable. The DMC_TR2.TCKE field selects the CKE minimum pulsewidth (t_{CKE}).
19:16 (R/W)	TXP	Timing Exit Power Down. The DMC_TR2.TXP field selects the exit power down to next valid command time (t_{XP}).
11:8 (R/W)	TRTP	Timing Read-to-Precharge. The DMC_TR2.TRTP field selects the internal read to precharge time (t_{RTP}). If the resulting value is less than 2, the register needs to be programmed with two. Note: Minimum t_{RTP} that needs to be programmed is 2.
5 (RX/W)	TFAW5	Extended Timing Four-Active Window Bit 5. The DMC_TR2.TFAW5 bit is the extended bit for FAW timing for 800 MHz operation for values greater than 31. It is only applicable when DMC_CTL. AL_EN= 1. When DMC_CTL. AL_EN = 0, the DMC_TR2.TFAW5 bit is reserved. When DMC_CTL. AL_EN = 1, the total FAW[5:0] = {TFAW5,TFAW[4:0]}. NOTE: This bit is write-only. Read as zero.

Table 9-42: DMC_TR2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
4:0 (R/W)	TFAW	Timing Four-Activated-Window. The DMC_TR2.TFAW field selects the four-banks activated window time (t_{FAW}). No more than four SDRAM banks should be activated within this window.

ADSP-SC59x DMC Register Descriptions

1600MHz DMCPHY (DDR3/DDR3L) (DMC) contains the following registers.

Table 9-43: ADSP-SC59x DMC Register List

Name	Description
DMC_DDR_CA_CTL	DDR CA Lane Control Register
DMC_DDR_LANE0_CTL0	Data Lane 0 Control Register 0
DMC_DDR_LANE0_CTL1	Data Lane 0 Control Register 1
DMC_DDR_LANE1_CTL0	Data Lane 1 Control Register 0
DMC_DDR_LANE1_CTL1	Data Lane 1 Control Register 1
DMC_DDR_ROOT_CTL	DDR ROOT Module Control Register
DMC_DDR_SCRATCH_2	Scratch Register 2
DMC_DDR_SCRATCH_3	Scratch Register 3
DMC_DDR_SCRATCH_4	Scratch Register 4
DMC_DDR_SCRATCH_5	Scratch Register 5
DMC_DDR_SCRATCH_6	Scratch Register 6
DMC_DDR_SCRATCH_7	Scratch Register 7
DMC_DDR_ZQ_CTL0	DDR Calibration Control Register 0
DMC_DDR_ZQ_CTL1	DDR Calibration Control Register 1
DMC_DDR_ZQ_CTL2	DDR Calibration Control Register 2

DDR CA Lane Control Register

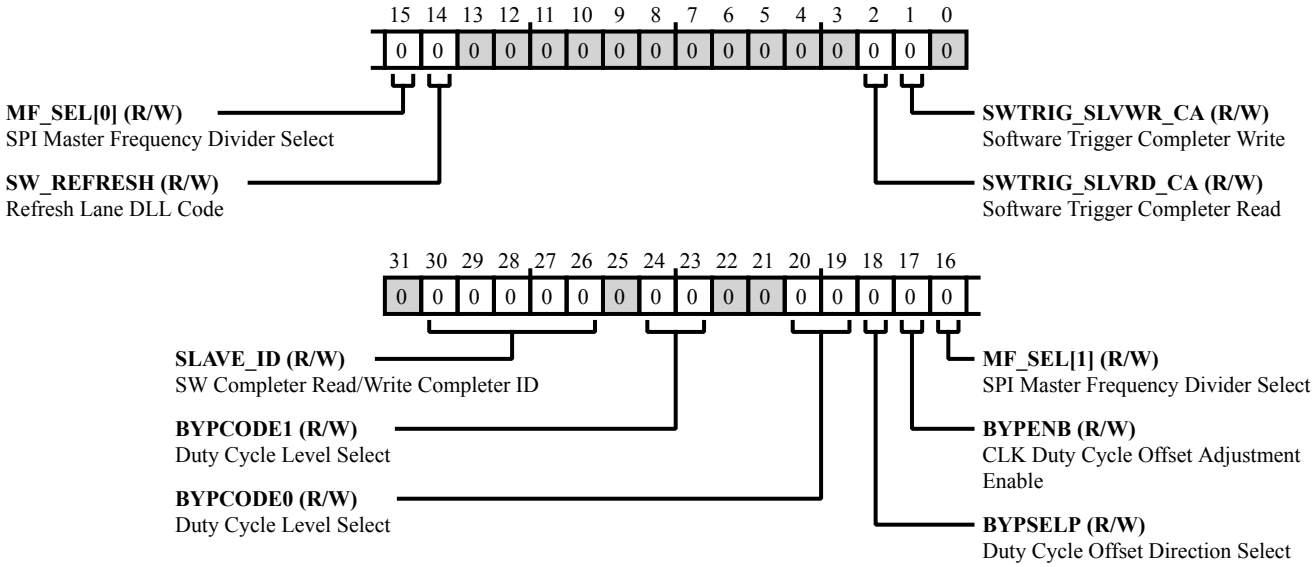

Figure 9-38: DMC_DDR_CA_CTL Register Diagram

Table 9-44: DMC_DDR_CA_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
30:26 (R/W)	SLAVE_ID	SW Completer Read/Write Completer ID. The `DMC_DDR_CA_CTL.SLAVE_ID` bit field is the completer ID for SW Completer read or write transactions.	
24:23 (R/W)	BYPCODE1	Duty Cycle Level Select. The `DMC_DDR_CA_CTL.BYPCODE1` bit field combines with BYPCODE0 to select one of four levels of duty cycle adjustment. Valid values for this bit field are 8,4,2,1, and 0. A larger value implies a larger offset. The default setting is 0.	
20:19 (R/W)	BYPCODE0	Duty Cycle Level Select. The `DMC_DDR_CA_CTL.BYPCODE0` bit field combines with BYPCODE1 to select one of four levels of duty cycle adjustment. Valid values for this bit field are 8,4,2,1, and 0. A larger value implies a larger offset. The default setting is 0.	
18 (R/W)	BYPSELP	Duty Cycle Offset Direction Select. The `DMC_DDR_CA_CTL.BYPSELP` bit selects the direction of the duty cycle offset.	
		0	Negative
		1	Positive

Table 9-44: DMC_DDR_CA_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/W)	BYPENB	CLK Duty Cycle Offset Adjustment Enable. The `DMC_DDR_CA_CTL.BYPENB` bit enables the CLK duty cycle offset adjustment.	
		0	Disable
		1	Enable
16:15 (R/W)	MF_SEL	SPI Master Frequency Divider Select. The `DMC_DDR_CA_CTL.MF_SEL` bit selects the SPI master frequency divider for root to lane transfers.	
		0	Divide by 2
		1	Divide by 4
		2	Divide by 8
		3	Divide by 16
14 (R/W)	SW_REFRESH	Refresh Lane DLL Code.	
2 (R/W)	SWTRIG_SLVRD_CA	Software Trigger Completer Read.	
1 (R/W)	SWTRIG_SLVWR_CA	Software Trigger Completer Write.	

Data Lane 0 Control Register 0

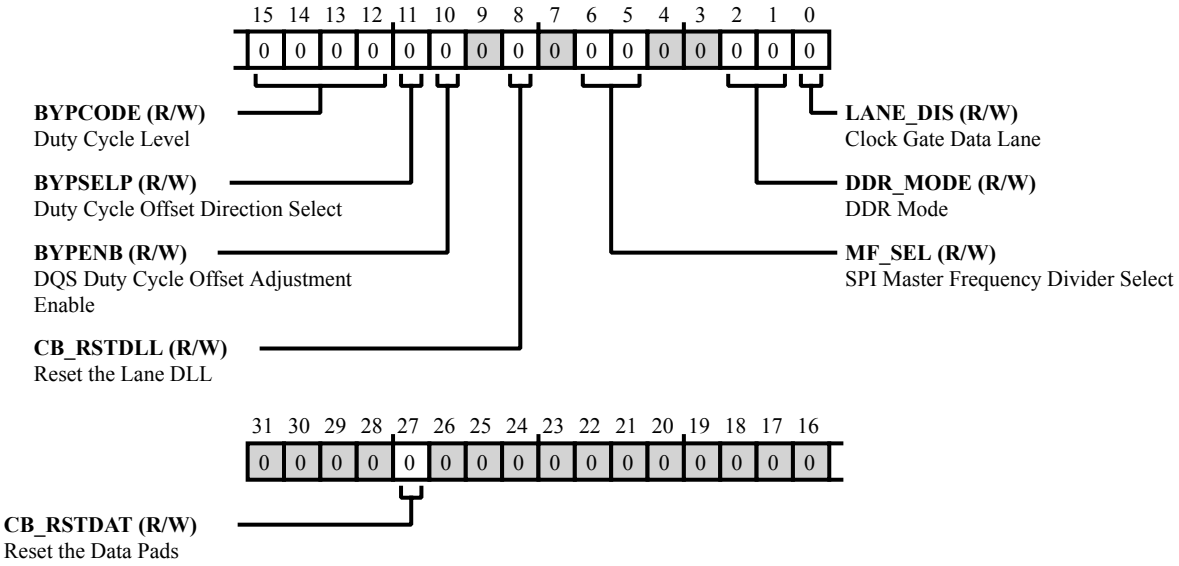

Figure 9-39: DMC_DDR_LANE0_CTL0 Register Diagram

Table 9-45: DMC_DDR_LANE0_CTL0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
27 (R/W)	CB_RSTDAT	Reset the Data Pads.	
15:12 (R/W)	BYPCODE	Duty Cycle Level. Valid values for this bit field are 8,4,2,1, and zero. A larger value implies a larger offset. The default setting is 0.	
11 (R/W)	BYPSELP	Duty Cycle Offset Direction Select. The `DMC_DDR_LANE0_CTL0.BYPSELP` bit selects the direction of the duty cycle offset.	
		0	Negative
		1	Positive
10 (R/W)	BYPENB	DQS Duty Cycle Offset Adjustment Enable. The `DMC_DDR_LANE0_CTL0.BYPENB` bit enables the DQS duty cycle offset adjustment.	
		0	Disable
		1	Enable
8 (R/W)	CB_RSTDLL	Reset the Lane DLL.	

Table 9-45: DMC_DDR_LANE0_CTL0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6:5 (R/W)	MF_SEL	SPI Master Frequency Divider Select. The `DMC_DDR_LANE0_CTL0.MF_SEL` bit selects the SPI master frequency divider for root to lane transfers.	
		0	Divide by 2
		1	Divide by 4
		2	Divide by 8
		3	Divide by 16
2:1 (R/W)	DDR_MODE	DDR Mode.	
		0	DDR3/3L Mode
0 (R/W)	LANE_DIS	Clock Gate Data Lane.	
		0	Lane is Enabled
		1	Lane is Clock Gated

Data Lane 0 Control Register 1

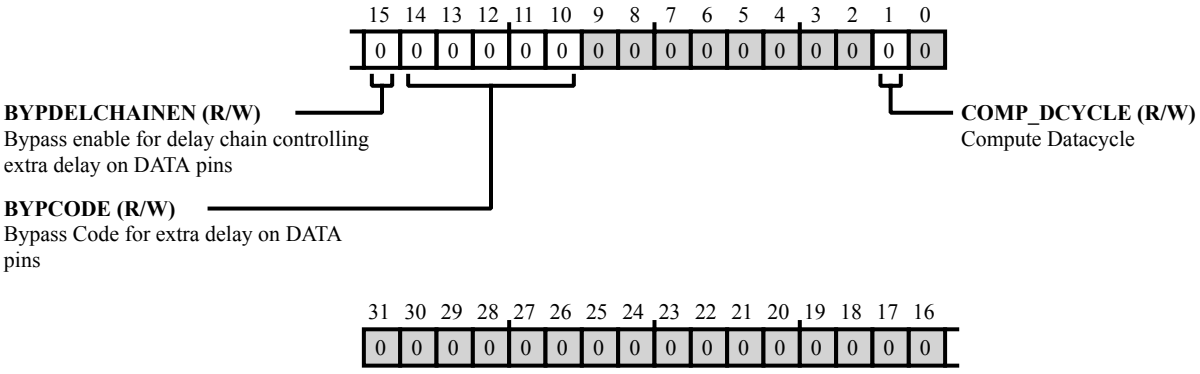

Figure 9-40: DMC_DDR_LANE0_CTL1 Register Diagram

Table 9-46: DMC_DDR_LANE0_CTL1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W)	BYPDELCHAINEN	Bypass enable for delay chain controlling extra delay on DATA pins.
14:10 (R/W)	BYPCODE	Bypass Code for extra delay on DATA pins.
1 (R/W)	COMP_DCYCLE	Compute Datacycle.

Data Lane 1 Control Register 0

Table 9-47: DMC_DDR_LANE1_CTL0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
27 (R/W)	CB_RSTDAT	Reset the Data Pads.	
15:12 (R/W)	BYPCODE	Duty Cycle Level. Valid values for this bit field are 8,4,2,1, and zero. A larger value implies a larger offset. The default setting is 0.	
11 (R/W)	BYPSELP	Duty Cycle Offset Direction Select. The `DMC_DDR_LANE1_CTL0.BYPSELP` bit selects the direction of the duty cycle offset.	
		0	Negative
		1	Positive
10 (R/W)	BYPENB	DQS Duty Cycle Offset Adjustment Enable. The `DMC_DDR_LANE1_CTL0.BYPENB` bit enables the DQS duty cycle offset adjustment.	
		0	Disable
		1	Enable
8 (R/W)	CB_RSTDLL	Reset the Lane DLL.	

Table 9-47: DMC_DDR_LANE1_CTL0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6:5 (R/W)	MF_SEL	SPI Master Frequency Divider Select. The `DMC_DDR_LANE1_CTL0.MF_SEL` bit selects the SPI master frequency divider for root to lane transfers.	
		0	Divide by 2
		1	Divide by 4
		2	Divide by 8
		3	Divide by 16
2:1 (R/W)	DDR_MODE	DDR Mode.	
		0	DDR3/3L Mode
0 (R/W)	LANE_DIS	Clock Gate Data Lane.	
		0	Lane is Enabled
		1	Lane is Clock Gated

Data Lane 1 Control Register 1

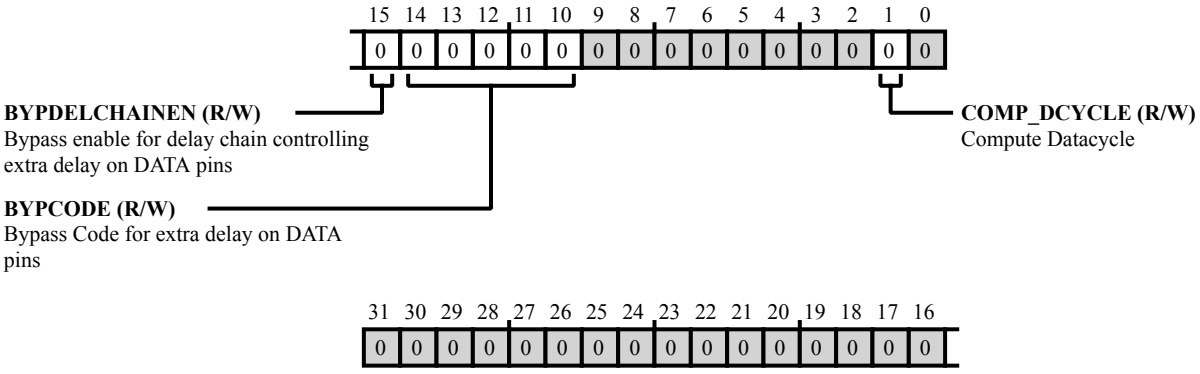

Figure 9-42: DMC_DDR_LANE1_CTL1 Register Diagram

Table 9-48: DMC_DDR_LANE1_CTL1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W)	BYPDELCHAINEN	Bypass enable for delay chain controlling extra delay on DATA pins.
14:10 (R/W)	BYPCODE	Bypass Code for extra delay on DATA pins.
1 (R/W)	COMP_DCYCLE	Compute Datacycle.

DDR ROOT Module Control Register

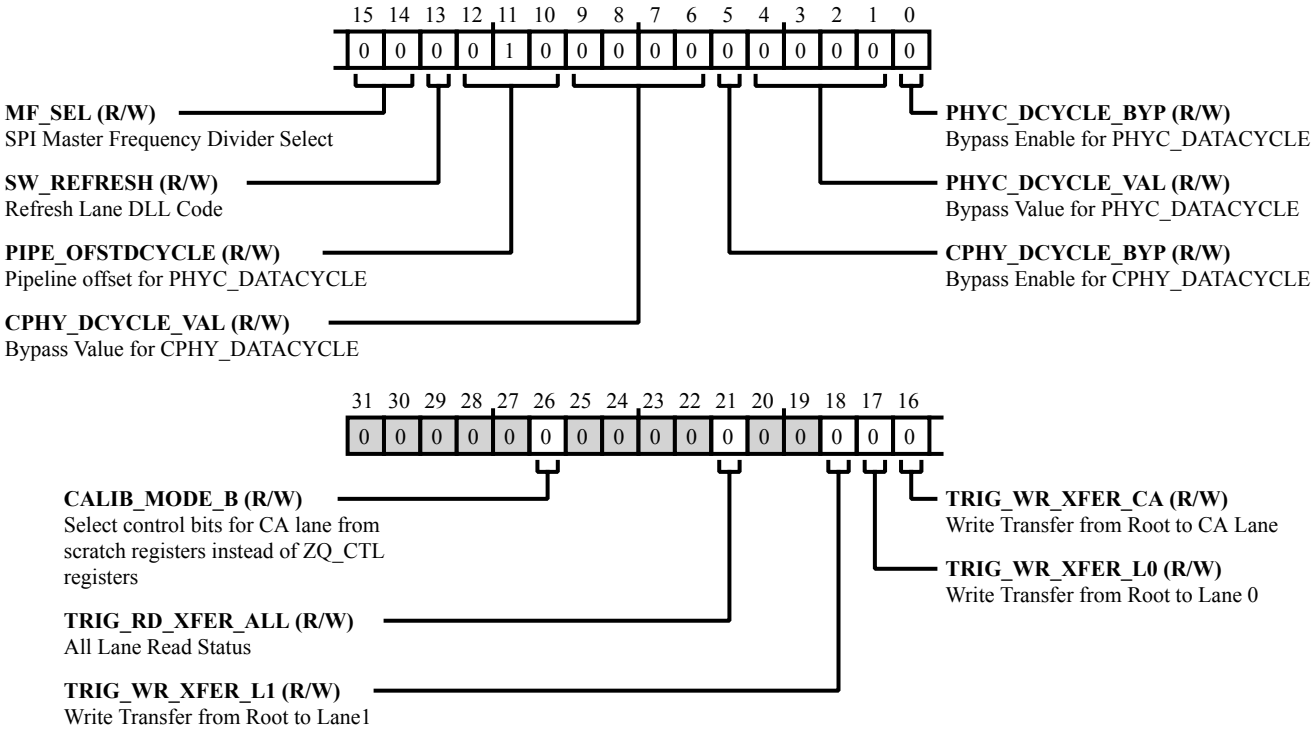

Figure 9-43: DMC_DDR_ROOT_CTL Register Diagram

Table 9-49: DMC_DDR_ROOT_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
26 (R/W)	CALIB_MODE_B	Select control bits for CA lane from scratch registers instead of ZQ_CTL registers.
21 (R/W)	TRIG_RD_XFER_ALL	All Lane Read Status. Software trigger to read the status data from all lanes.
18 (R/W)	TRIG_WR_XFER_L1	Write Transfer from Root to Lane1. Software trigger for a write transfer from the root to lane 1.
17 (R/W)	TRIG_WR_XFER_L0	Write Transfer from Root to Lane 0. Software trigger for a write transfer from the root to lane 0.
16 (R/W)	TRIG_WR_XFER_CA	Write Transfer from Root to CA Lane. Software trigger for a write transfer from the root to CA lane.

Table 9-49: DMC_DDR_ROOT_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
15:14 (R/W)	MF_SEL	SPI Master Frequency Divider Select. The `DMC_DDR_ROOT_CTL.MF_SEL` bit selects the SPI master frequency divider for root to lane transfers.	
		0	Divide by 2
		1	Divide by 4
		2	Divide by 8
		3	Divide by 16
13 (R/W)	SW_REFRESH	Refresh Lane DLL Code.	
12:10 (R/W)	PIPE_OFSTDCYCLE	Pipeline offset for PHYC_DATACYCLE.	
9:6 (R/W)	CPHY_DCYCLE_VAL	Bypass Value for CPHY_DATACYCLE.	
5 (R/W)	CPHY_DCYCLE_BYP	Bypass Enable for CPHY_DATACYCLE.	
4:1 (R/W)	PHYC_DCYCLE_VAL	Bypass Value for PHYC_DATACYCLE.	
0 (R/W)	PHYC_DCYCLE_BYP	Bypass Enable for PHYC_DATACYCLE.	

Scratch Register 2

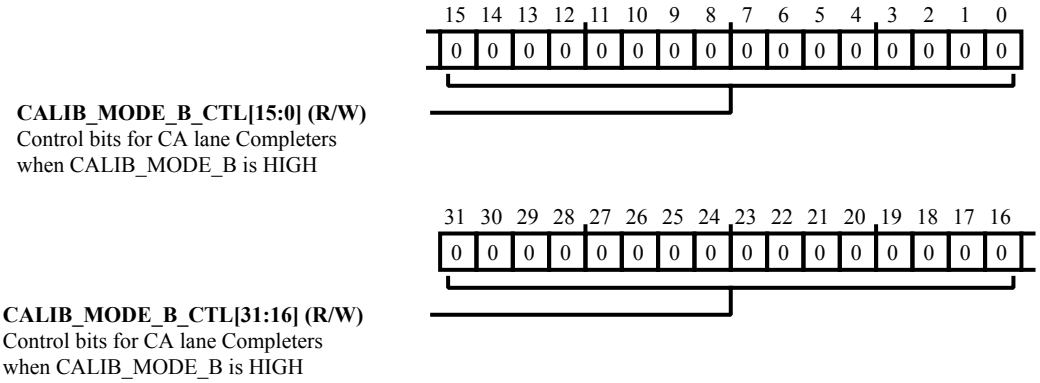

Figure 9-44: DMC_DDR_SCRATCH_2 Register Diagram

Table 9-50: DMC_DDR_SCRATCH_2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	CALIB_MODE_B_CTL	Control bits for CA lane Completers when CALIB_MODE_B is HIGH.

Scratch Register 3

31:0 (R/W)	CALIB_CODE_STAT	Calibration code read back from CALIB PAD Completer.

DDR Calibration Control Register 0

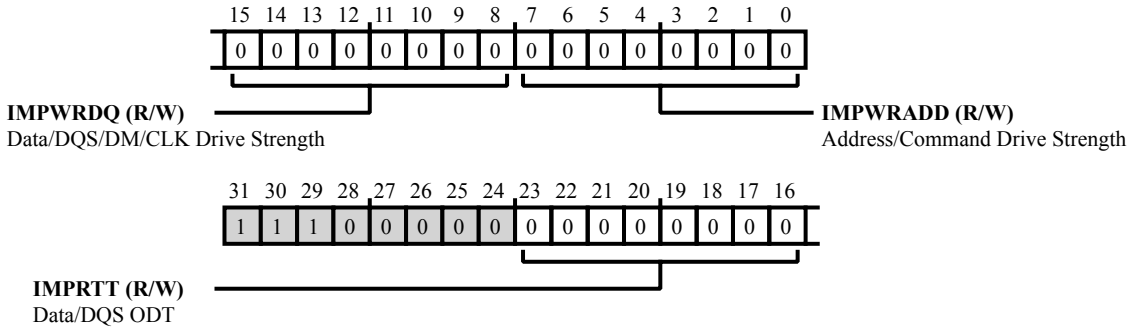

Figure 9-50: DMC_DDR_ZQ_CTL0 Register Diagram

Table 9-56: DMC_DDR_ZQ_CTL0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
23:16 (R/W)	IMPRTT	Data/DQS ODT. Desired ODT in ohms for Data and DQS pads.
15:8 (R/W)	IMPWRDQ	Data/DQS/DM/CLK Drive Strength. Desired drive strength in ohms for Data, DQS, DM, and clock pads. A drive strength of 100 ohms is recommended.
7:0 (R/W)	IMPWRADD	Address/Command Drive Strength. Desired drive strength in ohms for address and command pads. A drive strength of 100 ohms is recommended.

DDR Calibration Control Register 1

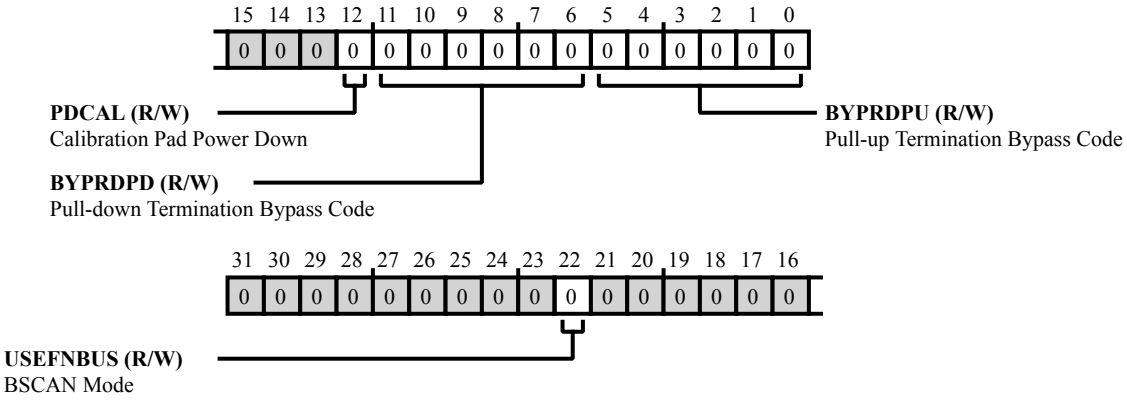

Figure 9-51: DMC_DDR_ZQ_CTL1 Register Diagram

Table 9-57: DMC_DDR_ZQ_CTL1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
22 (R/W)	USEFNBUS	BSCAN Mode. The bit controls whether to use bypass codes or functional codes in BSCAN mode.
12 (R/W)	PDCAL	Calibration Pad Power Down. Software bypass to power down the calibration pad.
11:6 (R/W)	BYPRDPD	Pull-down Termination Bypass Code.
5:0 (R/W)	BYPRDPU	Pull-up Termination Bypass Code.

DDR Calibration Control Register 2

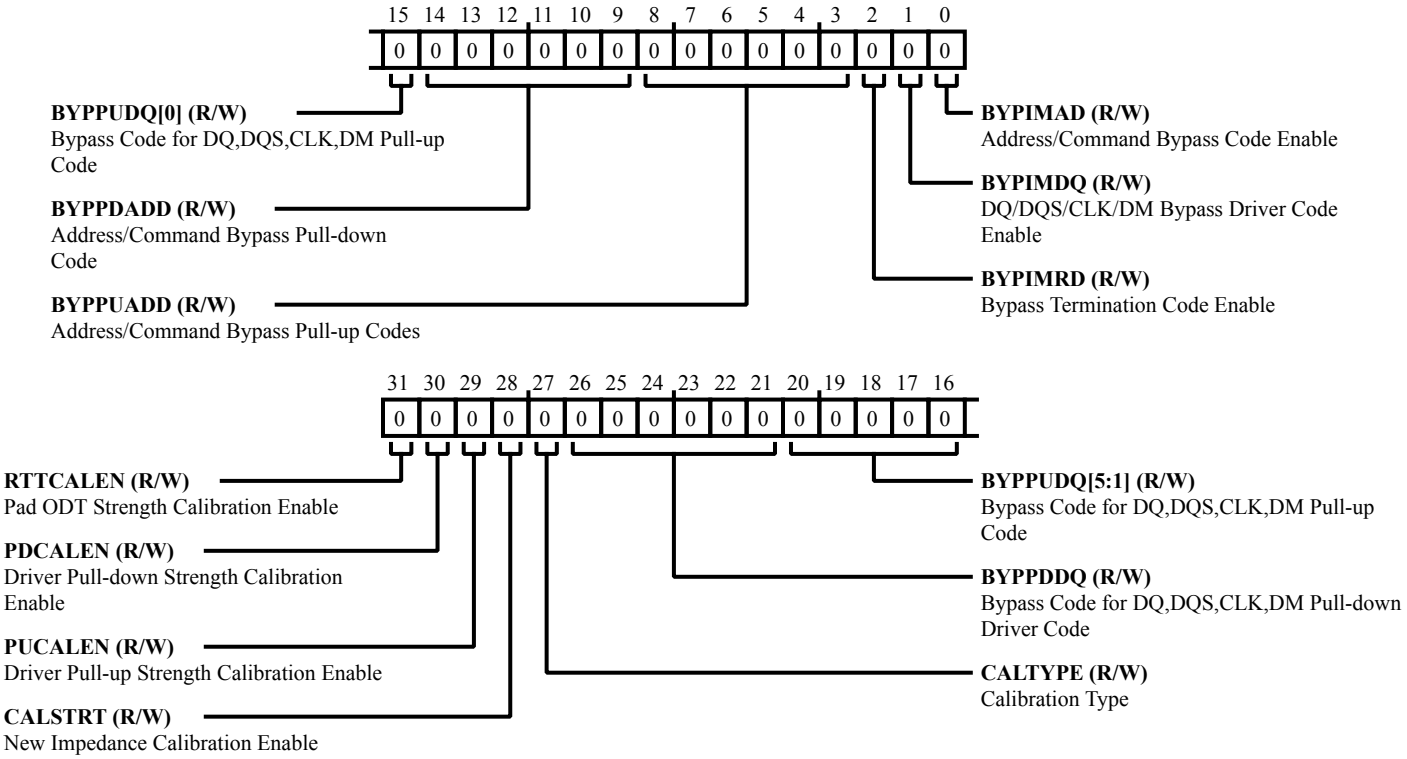

Figure 9-52: DMC_DDR_ZQ_CTL2 Register Diagram

Table 9-58: DMC_DDR_ZQ_CTL2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	RTTCALEN	Pad ODT Strength Calibration Enable.
30 (R/W)	PDCALEN	Driver Pull-down Strength Calibration Enable.
29 (R/W)	PUCALEN	Driver Pull-up Strength Calibration Enable.
28 (R/W)	CALSTRT	New Impedance Calibration Enable.
27 (R/W)	CALTYPE	Calibration Type. Short or Long Calibration
26:21 (R/W)	BYPPDDQ	Bypass Code for DQ,DQS,CLK,DM Pull-down Driver Code.

Table 9-58: DMC_DDR_ZQ_CTL2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
20:15 (R/W)	BYPPUDQ	Bypass Code for DQ,DQS,CLK,DM Pull-up Code.
14:9 (R/W)	BYPPDADD	Address/Command Bypass Pull-down Code.
8:3 (R/W)	BYPPUADD	Address/Command Bypass Pull-up Codes. Bypass pull-up codes for address and command pads
2 (R/W)	BYPIMRD	Bypass Termination Code Enable.
1 (R/W)	BYPIMDQ	DQ/DQS/CLK/DM Bypass Driver Code Enable.
0 (R/W)	BYPIMAD	Address/Command Bypass Code Enable. Bypass code enable for address and command pads.

10 DDR Pre-fetch Buffer (DDRPFB)

The DDR Pre-fetch buffer is designed to reduce the latency for fetching instructions or reading data from DDR memory. The Pre-fetch buffer works in the background to reduce the latency of a subsequent data or instruction access by pre-fetching the next data for next address (using the principle of locality). The DDR pre-fetch buffer is integrated in the DDR path and uses the following features.

- SMART pre-fetching decision which is a direct access or pre-fetch based on the pattern seen in the previous read transactions issued
- ID based direct access where in a multi-controller scenario with more than four controllers avoids a slow controller (for example the SPORT) to flush out a buffer line that is being used by a fast requester (for example HSMDMA)
- Range based return zero feature

The *Pre-fetch Buffer Block Diagram* figure shows the functional blocks within the DDRPFB.

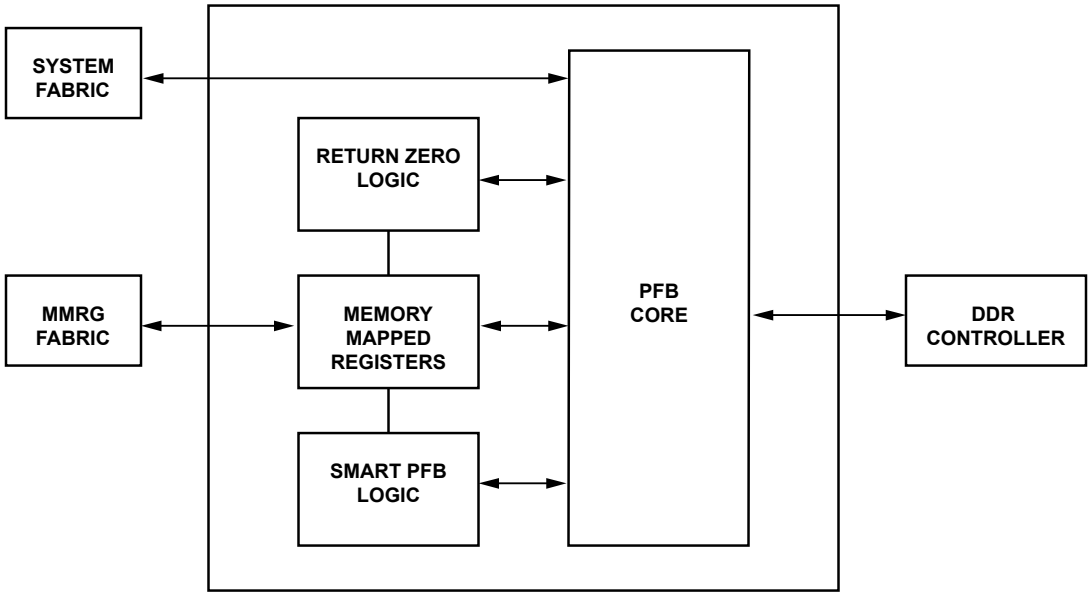

Figure 10-1: Pre-fetch Buffer Block Diagram

DDRPFB Features

The DDRPFB supports the following features:

- Smart Pre-fetch
- Direct DMC access
- Return Zero
- Controller ID based direct access
- Range based pre-fetch

Smart Pre-fetch

Smart pre-fetch is used for the worst case scenario where the controller fetches data at non continuous addresses which results no hits in the DDRPFB. To avoid fetching excess data for such non continuous read transactions, smart pre-fetching choses to start to fetch and/or pre-fetch requests from the DDRPFB to the DMC or gives direct access for such read requests. The decision is made based on the history of read transactions received at the input of the prefetch buffer. The `DDRPFB_CTL1.SMART_FEATURE_EN` bit is used to enable this feature.

Data Invalidation

When the `DDRPFB_CTL0.DATA_INVALIDATION` bit is set (=1), the complete pre-fetch buffer is invalidated. Clear this bit manually after setting it to make use of pre-fetch buffer.

Direct Access

In direct access, there are no pre-fetch accesses and the accesses are forwarded to the DMC directly. There is a one cycle latency while the pre-fetch buffer decides whether the access is direct or not. The read data from the DMC is directly forwarded to the controller without any latency impact and is not stored in the buffer.

Return Zero

This feature allows the program to configure a range of addresses range in L3 memory to always returns zero. To enable this feature, set (=1) the `DDRPFB_CTL0.RETURN_ZERO` bit. The address range which require all zeros to be read is configured using the `DDRPFB_ZERO_START.VAL` and `DDRPFB_ZERO_END.VAL` registers. All the requests which that fall between the start and end addresses (that are aligned to 256 bytes) are returned with all zeros.

Controller ID Based Direct Access

This section explains how to configure a specific SCB controller for direct access or DDR pre-fetch access. Set the `DDRPFB_CTL1.RQSTR_ID_FEATURE_EN` bit = 1 to use this feature. The following registers and bits are used to manage ID based direct access.

- The SCB controller ID is the ID of the SCB requester that is requesting data from the DDR. For ID information, see .

- The DDRPFB_RQSTR_ID_EN.VAL bit field has four bits. It can take all 16 combinations. If this bit is cleared (=0) the corresponding SCB requester has direct access.
- The DDRPFB_RQSTR0_ID, DDRPFB_RQSTR1_ID, DDRPFB_RQSTR2_ID and DDRPFB_RQSTR3_ID registers are four IDs that are preprogrammed with the SCB ID. The configuration of these registers determine whether the DDRPFB gives a normal PFB enabled access or a direct access (if the corresponding DDRPFB_RQSTR_ID_EN.VAL bit is set). If the SCB ID of the requester matches with the DDRPFB_MSTRx_ID, then the DDR pre-fetch operation is enabled.
- The DDRPFB_RQSTR0_ID_MSK, DDRPFB_RQSTR1_ID_MSK, DDRPFB_RQSTR2_ID_MSK and DDRPFB_RQSTR3_ID_MSK: When the DDRPFB_RQSTR_ID_EN bit is set for some DDRPFB_MSTRx_ID, then the PFB enabled access is provided for a partial ID match of the SCB ID with the corresponding preprogrammed DDRPFB_MSTRx_ID. Clearing a bit masks the corresponding bit and the masked bits are not checked for a match.

The *DDRPFB Access Configurations* table shows the register configurations for different access types.

Table 10-1: DDRPFB Access Configurations

SCB Requester ID	DDRPFB_MSTR_ID_EN[0]	DDRPFB_MSTR0_ID	DDRPFB_MSTR0_ID_MASK	Access Type
XXXX	0	XXXX	XXXX	Direct access Irrespective of SCB requester ID, DDRPFB_RQSTR0_ID and DDRPFB_RQSTR0_ID_MSK, direct access is given to all the requests.
MMMM	1	NNNN	0000	DDRPFB enabled access DDRPFB does not check any bits of the SCB requester ID if it matches with DDRPFB_RQSTR0_ID. Therefore, DDRPFB performs prefetch operation for all IDs. This is an example where DDR prefetch is enabled, though none of the bits of SCB ID matches with DDRPFB_RQSTR0_ID.
MMXX	1	MMXX	1100	DDRPFB enabled access DDRPFB looks for only two MSBs from SCB ID matching the two MSBs of DDRPFB_RQSTR0_ID. If they match, the DDRPFB performs a prefetch operation. Otherwise, direct access is given to such requests. In this example the two MSBs matching with the two MSBs of DDRPFB_RQSTR0_ID configures a normal DDRPFB enabled access.
MMXX	1	NNXX	1100	Direct access The PFB looks for only the two MSBs from the SCB ID that match with the two MSBs of DDRPFB_RQSTR0_ID. If they match, the PFB performs a normal operation. Otherwise, direct access is given to such requests. In this example, since the two MSBs do not match with the two MSBs of DDRPFB_RQSTR0_ID, it is a direct access.

Range Based Pre-fetch

Range based prefetch allows an entire address range to be divided into 16 address ranges to selectively disable the pre-fetch buffer (while pre-fetching is enabled) for this address range using the DDRPFB_RANGE_SELECT register. For example, the *Range Based Pre-fetch* table shows that if DDRPFB_RANGE_SELECT [9] = 0, then the PFB is disabled for address range 90000000 to 9FFFFFFF.

The DDRPFB_CTL1.RANGE_SHIFT bit field is used to configure pre-fetching 16 sections of the address map based on the most significant nibble in the input address. In the example DDRPFB_CTL1.RANGE_SHIFT is 28.

Table 10-2: Range Based Pre-fetch

Sr. No.		PFB Operation
1	DDRPFB_RANGE_SELECT [ARADDR_IN[31:28]] = 1 && DDRPFB_CTL0.PREFETCH_EN = 1	PFB enabled operation
2	DDRPFB_RANGE_SELECT [ARADDR_IN[31:28]] = 0 && DDRPFB_CTL0.PREFETCH_EN = 1	PFB disabled operation
3	DDRPFB_RANGE_SELECT [ARADDR_IN[31:28]] = X && DDRPFB_CTL0.PREFETCH_EN = 0	PFB disabled operation

Table 10-3: Range Based Address Range Selections

Input bit	Address range for Pre-fetch
RANGE_SELECT[0]	00000000 – 0FFFFFFF
RANGE_SELECT[1]	10000000 – 1FFFFFFF
RANGE_SELECT[2]	20000000 – 2FFFFFFF
RANGE_SELECT[3]	30000000 – 3FFFFFFF
RANGE_SELECT[4]	40000000 – 4FFFFFFF
RANGE_SELECT[5]	50000000 – 5FFFFFFF
RANGE_SELECT[6]	60000000 – 6FFFFFFF
RANGE_SELECT[7]	70000000 – 7FFFFFFF
RANGE_SELECT[8]	80000000 – 8FFFFFFF
RANGE_SELECT[9]	90000000 – 9FFFFFFF
RANGE_SELECT[10]	A0000000 – AFFFFFFF
RANGE_SELECT[11]	B0000000 – BFFFFFFF
RANGE_SELECT[12]	C0000000 – CFFFFFFF
RANGE_SELECT[13]	D0000000 – DFFFFFFF
RANGE_SELECT[14]	E0000000 – EFFFFFFF
RANGE_SELECT[15]	F0000000 – FFFFFFFF

Programming Notes

The following guidelines should be noted when using range based pre-fetch.

- DDRPFB_RANGE_SELECT.VAL is used to change the prefetch range
- When DDRPFB_RANGE_SELECT.VAL = 5'bN, then ARADDR_IN[N+3:N] are used for range selection (here, N is programmable number)
  - When DDRPFB_CTL1.RANGE_SHIFT = 28, logic behavior is same as above table
  - When DDRPFB_CTL1.RANGE_SHIFT = 26, then ARADDR_IN[29:26] are used for range selection

For finer control of a small range the configurations in the following table can be used.

Sr. No.		PFB Operation
1	DDRPFB_RANGE_SELECT [ARADDR_IN[N+3:N]] = 1 && DDRPFB_CTL0.PREFETCH_EN = 1	PFB enabled operation
2	DDRPFB_RANGE_SELECT [ARADDR_IN[N+3:N]] = 0 && DDRPFB_CTL0.PREFETCH_EN = 1	PFB disabled operation
3	DDRPFB_RANGE_SELECT [ARADDR_IN[N+3:N]] = X(don't care) && DDRPFB_CTL0.PREFETCH_EN = 0	PFB disabled operation

DDRPFB Programming Model

The following sections describe how to program the DDRPFB.

Enabling the Pre-fetch Buffer and PFB Idle State

Set the DDRPFB_CTL0.PREFETCH_EN bit (=1) to enable the DDR pre-fetch buffer.

When the DDRPFB_STS0.PFB_IDLE bit = 1 there are no pending transactions between the DDRPFB and the DMC. When this bit = 0, there is at least one pending transaction between the DDRPFB and the DMC.

General Programming Guidelines

The following are few guidelines which need to be followed for proper functioning of DDR PFB.

- The DDRPFB_STS0.PFB_IDLE indicates whether the DDRPFB is IDLE or not and can be polled to add delay to allow pending requests from the PFB to completer get completed.
- To issue a DMC reset during operation, the following steps are used to maintain data coherence and prevent system hangs.
  1. Block all requesters that are currently accessing DDR
  2. Check that the PFB is in the IDLE state by checking DDRPFB_STS0.PFB_IDLE
  3. Issue a DMC reset
  4. Invalidate the PFB
  5. Unblock all requesters that need access to DDR
- During DDR initialization the PFB should be disabled. If the program needs to have the PFB enabled during DDR initialization, perform a PFB invalidation after DDR initialization is completed.
- The maximum possible value of DDRPFB_CTL1.RANGE_SHIFT is ‘b11100. Any value that is more than ‘b11100 has no significance because the address bus width is 32-bits.

Guidelines For Achieving Maximum Performance

To achieve maximum performance, please note the following:

- Each DDR PFB line can hold 256 bytes of data. To achieve maximum performance the starting address of sequential memory accesses should be 256 bytes aligned

- Enable DDRPFB for requesters that support burst mode
- Burst mode with a burse size of 128 bits provide good performance compared to other combinations of burst size less than 128 bits
- Use the Requester ID based direct access feature for the SPORTs and IIR when there are more than four requesters acting at a time.
- Multiple requesters can be combined as a one requester when they are fetching data in interleaved fashion. This is accomplished by placing data in DDR in such a way that (for example), address A is for requester 1, A+x for requester 2, A+2x for again requester 1 and A +3x for requester 2. So in this example for requester 1 addresses A + 2nx are used and for requester 2 addresses A + (2n+1)x are used, where n = 0,1,2, and so on.
- Avoiding wrap access – Data defined in source code can be placed in memory in such a way that all requests from requester A55 is cache line aligned so that all requests from cache onwards are incremental accesses.
- The decision should be made on what is most suitable with respect to performance out of the various DDRPFB configurations, including DDRPFB disabled. In most cases PFB = enabled and the smart feature = enabled has better performance. For few use-cases PFB = enabled, smart feature disabled work best.

ADSP-SC59x DDRPFB Register Descriptions

Prefetch buffer mmr registers (DDRPFB) contains the following registers.

Table 10-5: ADSP-SC59x DDRPFB Register List

Name	Description
DDRPFB_CTL0	Control Register 0
DDRPFB_CTL1	Control Register 1
DDRPFB_RANGE_SELECT	Range Select Register
DDRPFB_RQSTR0_ID	Requester ID 0 Register
DDRPFB_RQSTR0_ID_MSK	Requester ID 0 Mask Register
DDRPFB_RQSTR1_ID	Requester ID 1 Register
DDRPFB_RQSTR1_ID_MSK	Requester ID 1 Mask Register
DDRPFB_RQSTR2_ID	Requester ID 2 Register
DDRPFB_RQSTR2_ID_MSK	Requester ID 2 Mask Register
DDRPFB_RQSTR3_ID	Requester ID 3 Register
DDRPFB_RQSTR3_ID_MSK	Requester ID 3 Mask Register
DDRPFB_RQSTR_ID_EN	Requester ID Enable Register
DDRPFB_STS0	Prefetch Buffer First Status Register
DDRPFB_ZERO_END	Return Zero End Address Register
DDRPFB_ZERO_START	Return Zero Start Address Register

Control Register 0

The DDRPFB_CTL0 register disables prefetching for up to sixteen address ranges. Bits[31:16] bits control the range selection for the instruction cache, and bits [15:0] control the range selection for the data cache.

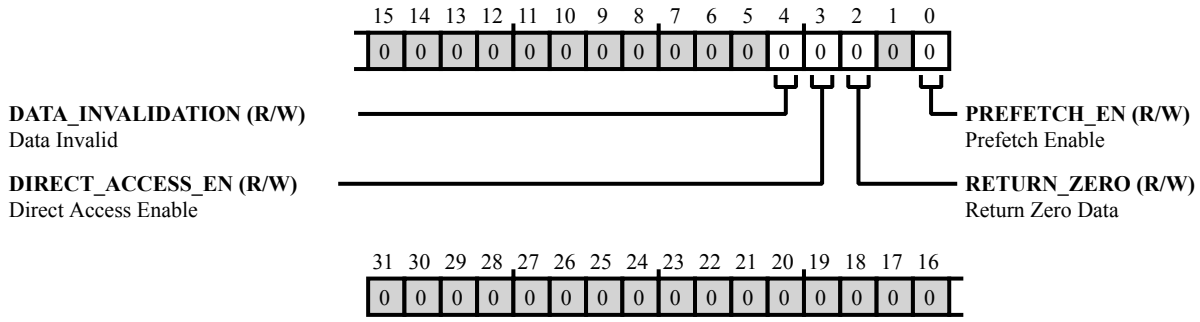

Figure 10-2: DDRPFB_CTL0 Register Diagram

Table 10-6: DDRPFB_CTL0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/W)	DATA_INVALIDATION	Data Invalid. When the DDRPFB_CTL0.DATA_INVALIDATION bit is set the prefetch buffer is invalid. The program must clear this bit manually.	
		0	Buffer valid
		1	Buffer invalid
3 (R/W)	DIRECT_ACCESS_EN	Direct Access Enable. When the DDRPFB_CTL0.DIRECT_ACCESS_EN bit is set (=1) the prefetch buffer passes requests as is from a requester to a completer. No excess data is fetched and stored in prefetch buffer. When the DDRPFB_CTL0.DIRECT_ACCESS_EN bit is cleared (=0) the prefetch buffer behaves as if it is disabled.	
		0	Direct access disabled
		1	Direct access enabled
2 (R/W)	RETURN_ZERO	Return Zero Data. When the DDRPFB_CTL0.RETURN_ZERO bit is set, the prefetch buffer returns zero data for the address range configured in the DDRPFB_ZERO_START and DDRPFB_ZERO_END registers. The addresses in the DDRPFB_ZERO_START and DDRPFB_ZERO_END registers should be 128 byte aligned.	
		0	Return zero disabled
		1	Return zero data in selected address range

Table 10-6: DDRPFB_CTL0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	PREFETCH_EN	Prefetch Enable. When the `DDRPFB_CTL0.PREFETCH_EN` bit is set (=1), the prefetch buffer is enabled. Otherwise, the prefetch buffer is disabled.	
		0	Prefetch disabled
		1	Prefetch enabled

Control Register 1

The DDRPFB_CTL1 register enables smart prefetch, range shifting, and direct access.

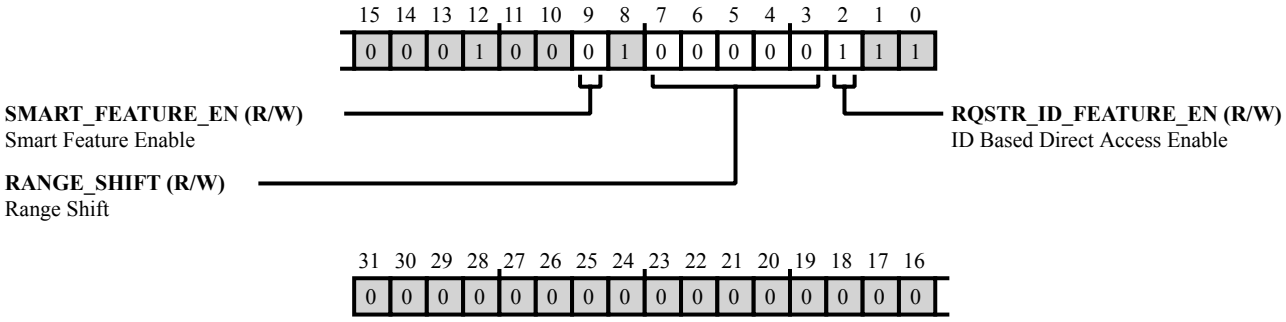

Figure 10-3: DDRPFB_CTL1 Register Diagram

Table 10-7: DDRPFB_CTL1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W)	SMART_FEATURE_EN	Smart Feature Enable. Setting the DDRPFB_CTL1.SMART_FEATURE_EN bit enables the SMART feature.	
		0	Smart prefetch disabled
		1	Smart prefetch enabled
7:3 (R/W)	RANGE_SHIFT	Range Shift. The DDRPFB_CTL1.RANGE_SHIFT bit field determines which bits of the read address (that appear at the input of prefetch buffer) are used for the range select operation. By default this is the four MSBs are used. When this bit field is programmed to 5hN then [N+3:N] address bits are used for the range select operation.	
2 (R/W)	RQSTR_ID_FEATURE_EN	ID Based Direct Access Enable. The DDRPFB_CTL1.RQSTR_ID_FEATURE_EN bit, when set (=1) enables the ID based direct access feature.	
		0	ID based direct access disabled
		1	ID based direct access enabled

Range Select Register

The DDRPFB_RANGE_SELECT register determines whether the prefetch buffer is enabled or disabled in the specified address range.

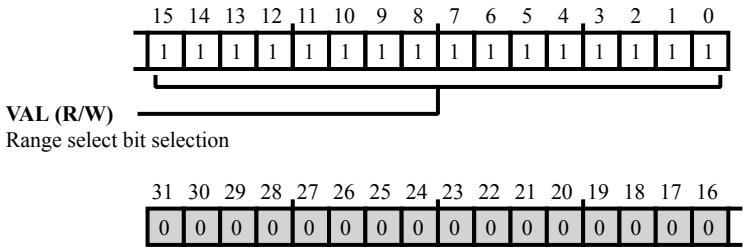

Figure 10-4: DDRPFB_RANGE_SELECT Register Diagram

Table 10-8: DDRPFB_RANGE_SELECT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VAL	Range select bit selection. Each bit in this bit field determines prefetch buffer should be enabled or disabled in that address range. This bit field is used in conjunction with RANGE_SHIFT bit field.

Requester ID 0 Register

The DDRPFB_RQSTR0_ID register is used to configure the first requester ID for controller ID based direct access operations.

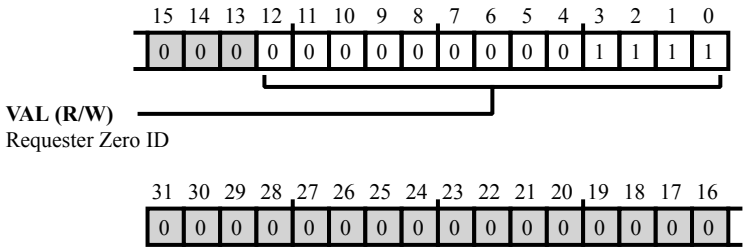

Figure 10-5: DDRPFB_RQSTR0_ID Register Diagram

Table 10-9: DDRPFB_RQSTR0_ID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
12:0 (R/W)	VAL	Requester Zero ID. The DDRPFB_RQSTR0_ID.VAL bit field identifies the first requester ID to be considered for ID based direct access.

Requester ID 0 Mask Register

The DDRPFB_RQSTR0_ID_MSK register is used to mask the first requester ID for controller ID based direct access operations. The masked bits are not used in direct access operations.

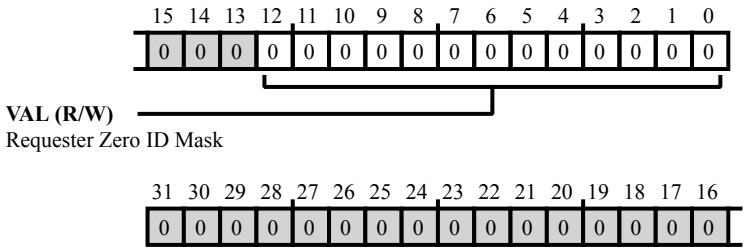

Figure 10-6: DDRPFB_RQSTR0_ID_MSK Register Diagram

Table 10-10: DDRPFB_RQSTR0_ID_MSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
12:0 (R/W)	VAL	Requester Zero ID Mask. The DDRPFB_RQSTR0_ID_MSK.VAL bit field masks the first requester ID to exclude from ID based direct access.

Requester ID 1 Register

The DDRPFB_RQSTR1_ID register is used to configure the first requester ID for controller ID based direct access operations.

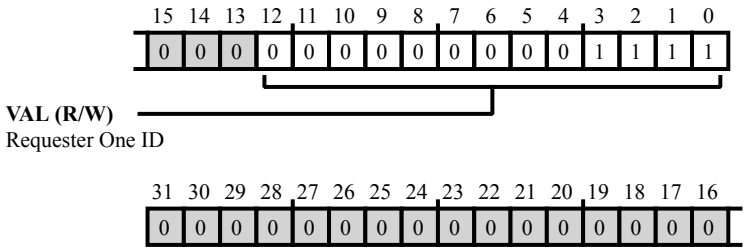

Figure 10-7: DDRPFB_RQSTR1_ID Register Diagram

Table 10-11: DDRPFB_RQSTR1_ID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
12:0 (R/W)	VAL	Requester One ID. The DDRPFB_RQSTR1_ID.VAL bit field identifies the second requester ID to be considered for ID based direct access.

Requester ID 1 Mask Register

The DDRPFB_RQSTR1_ID_MSK register is used to mask the second requester ID for controller ID based direct access operations. The masked bits are not used in direct access operations.

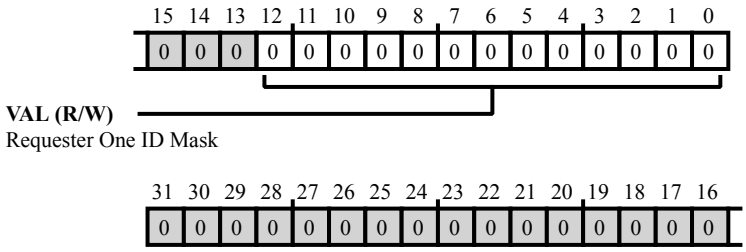

Figure 10-8: DDRPFB_RQSTR1_ID_MSK Register Diagram

Table 10-12: DDRPFB_RQSTR1_ID_MSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
12:0 (R/W)	VAL	Requester One ID Mask. The DDRPFB_RQSTR1_ID_MSK.VAL bit field masks the second requester ID to exclude from ID based direct access.

Requester ID 2 Register

The DDRPFB_RQSTR2_ID register is used to configure the third requester ID for controller ID based direct access operations.

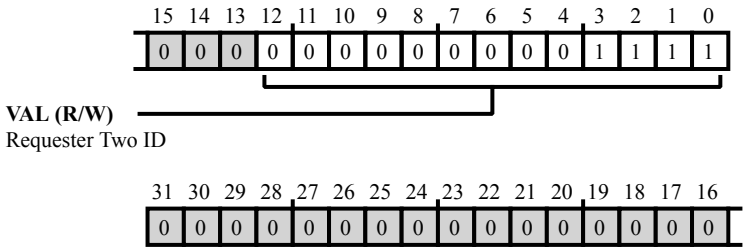

Figure 10-9: DDRPFB_RQSTR2_ID Register Diagram

Table 10-13: DDRPFB_RQSTR2_ID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
12:0 (R/W)	VAL	Requester Two ID. The DDRPFB_RQSTR2_ID.VAL bit field identifies the third requester ID to be considered for ID based direct access.

Requester ID 2 Mask Register

The DDRPFB_RQSTR2_ID_MSK register is used to mask the third requester ID for controller ID based direct access operations. The masked bits are not used in direct access operations.

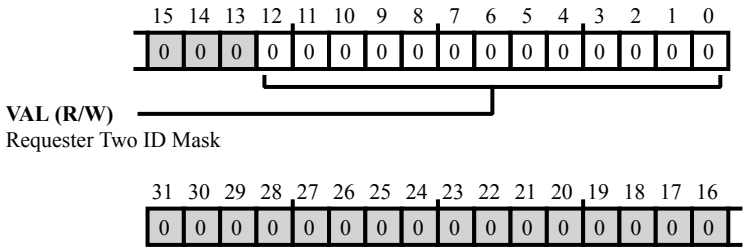

Figure 10-10: DDRPFB_RQSTR2_ID_MSK Register Diagram

Table 10-14: DDRPFB_RQSTR2_ID_MSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
12:0 (R/W)	VAL	Requester Two ID Mask. The DDRPFB_RQSTR2_ID_MSK.VAL bit field masks the third requester ID to exclude from ID based direct access.

Requester ID 3 Register

The DDRPFB_RQSTR3_ID register is used to configure the fourth requester ID for controller ID based direct access operations.

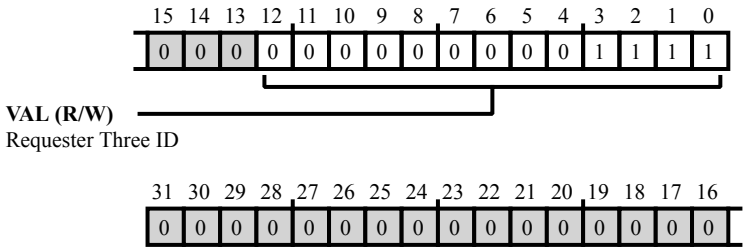

Figure 10-11: DDRPFB_RQSTR3_ID Register Diagram

Table 10-15: DDRPFB_RQSTR3_ID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
12:0 (R/W)	VAL	Requester Three ID. The DDRPFB_RQSTR3_ID.VAL bit field identifies the fourth requester ID to be considered for ID based direct access.

Requester ID 3 Mask Register

The DDRPFB_RQSTR3_ID_MSK register is used to mask the fourth requester ID for controller ID based direct access operations. The masked bits are not used in direct access operations.

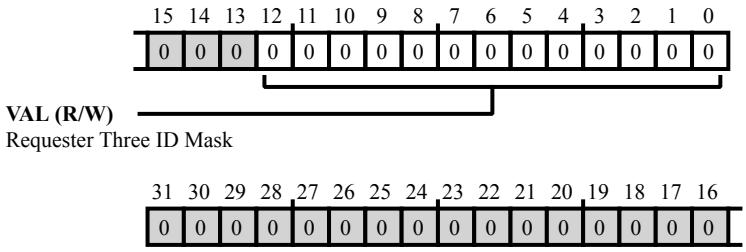

Figure 10-12: DDRPFB_RQSTR3_ID_MSK Register Diagram

Table 10-16: DDRPFB_RQSTR3_ID_MSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
12:0 (R/W)	VAL	Requester Three ID Mask. The DDRPFB_RQSTR3_ID_MSK.VAL bit field masks the fourth requester ID to exclude from ID based direct access.

Requester ID Enable Register

The DDRPFB_RQSTR_ID_EN register is used to configure controller based direct access. As many as four controller IDs can be programmed for direct access. For more information, see "Controller ID Based Direct Access".

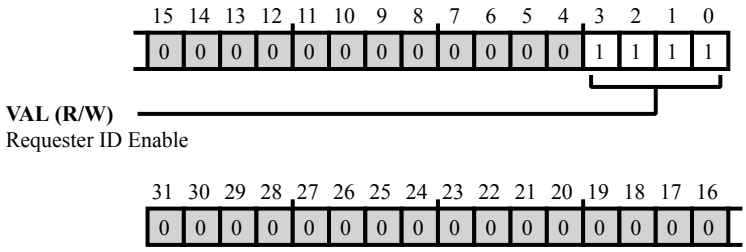

Figure 10-13: DDRPFB_RQSTR_ID_EN Register Diagram

Table 10-17: DDRPFB_RQSTR_ID_EN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
3:0 (R/W)	VAL	Requester ID Enable. The DDRPFB_RQSTR_ID_EN.VAL bits are used to configure controller based direct access. As many as four controller IDs can be programmed for direct access. For more information, see "Controller ID Based Direct Access".

Prefetch Buffer First Status Register

The DDRPFB_STS0 register indicates whether all fetch and prefetch operations from the PFB to the DDR are complete.

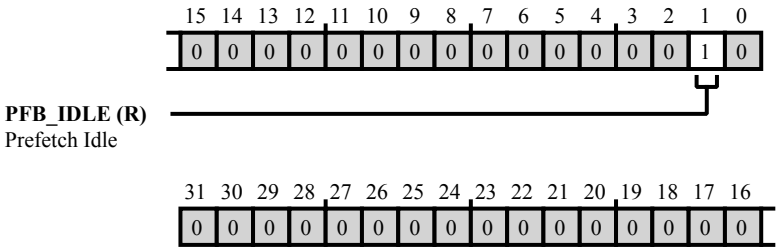

Figure 10-14: DDRPFB_STS0 Register Diagram

Table 10-18: DDRPFB_STS0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
1 (R/NW)	PFB_IDLE	Prefetch Idle. The DDRPFB_STS0.PFB_IDLE bit, when set (=1), indicates all fetch and prefetch operations from the PFB to the DDR are complete.

Return Zero End Address Register

The DDRPFB_ZERO_END register is used with the DDRPFB_ZERO_START register to configure an address range in L3 memory to always returns zero.

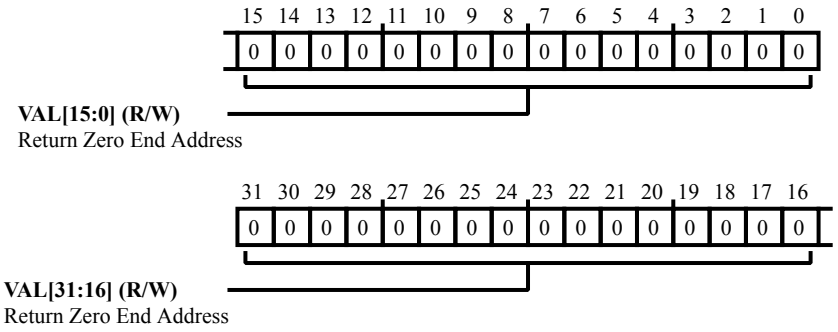

Figure 10-15: DDRPFB_ZERO_END Register Diagram

Table 10-19: DDRPFB_ZERO_END Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VAL	Return Zero End Address. The DDRPFB_ZERO_END.VAL bit field is used to configure the end address (that are aligned to 256 bytes) that are returned with all zeros.

Return Zero Start Address Register

The DDRPFB_ZERO_START register is used with the DDRPFB_ZERO_END register to configure a range of addresses in L3 memory to always returns zero.

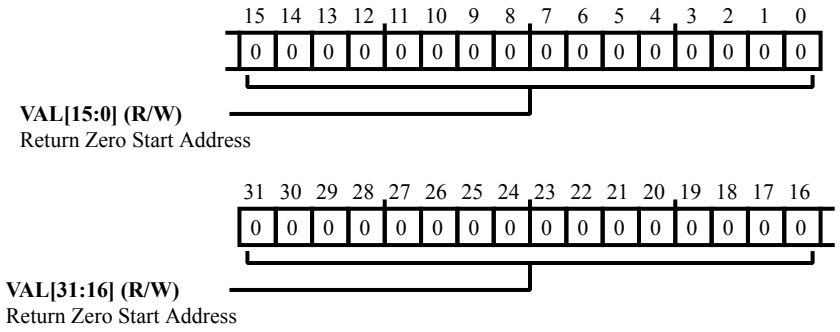

Figure 10-16: DDRPFB_ZERO_START Register Diagram

Table 10-20: DDRPFB_ZERO_START Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VAL	Return Zero Start Address. The DDRPFB_ZERO_START.VAL bit field is used to configure the start address (that are aligned to 256 bytes) that are returned with all zeros.

11 One-Time Programmable Memory Controller (OTPC)

This chapter describes the operation of the OTP controller. The OTP module is a complete system integrating an OTP memory core with a programming controller, charge pump, and voltage regulator. A built-in Hamming Code Error Correction (ECC), and a fully implemented double-redundant program or read scheme protect the OTP data.

CAUTION: OTP memory does not support burst transfers, which are required to support cache line fills. As such, OTP memory should not be made cacheable. If it is, the OTP controller returns an error when a read access is attempted.

OTPC Features

The OTP memory and controller have the following features:

- Built-in redundant read mode
- Built-in integrated power supply
- Built-in Hamming Code Error Correction (ECC)
- Full word serial (single bit at a time) programming with internal VPP

NOTE: The OTP module is protected by the System Memory Protection Unit (SMPU) and is always secure by default. Non secure access to the OTP by any module will fail unless allowed by the SMPU.

OTPC Functional Description

ADSP-SC59x OTPC Register List

The One-Time-Programmable Memory controller (OTPC) supports programming the OTP memory. A set of registers governs OTPC operations. For more information on OTPC functionality, see the OTPC register descriptions.

Error Correction

The OTP memory features a Hamming error correction implementation. Signal bit errors are automatically corrected, and dual-bit errors are detected. Refer to OTPC Interrupt Signals.

ECC is always enabled. ECC applies to each 16-bit segment. Because of this functionality, each 16-bit location can only be written to once. Writing to a 16-bit location a second time results in unexpected behavior.

OTPC Event Control

The following sections provide information on OTP events and error management.

OTPC Interrupt Signals

When making 32-bit accesses to OTP memory, a double-bit error in any 16-bit segment triggers the OTPC_INT interrupt. The OTPC also has the OTPC dual bit error (OTPC0_ERR) with the interrupt ID of 6. See the System Event Controller (SEC) chapter for more information.

OTPC Status and Error Signals

The OTP controller does not produce error signals.

OTPC Programming Model

OTP programming is supported through the SSLDD OTP library which is a part of CCES 2.11.0.

ADSP-SC59x OTPC Register Descriptions

OTP Memory Controller (OTPC) contains the following registers.

Table 11-4: ADSP-SC59x OTPC Register List

Name	Description
OTPC_SECU_STATE	OTP Security State Register
OTPC_STAT	OTP Status Register

OTP Security State Register

The OTPC_SECU_STATE register indicates the secure state. The register is updated only after the part is rebooted and locked.

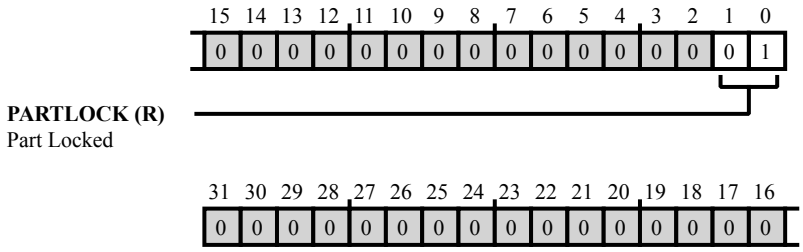

Figure 11-1: OTPC_SECU_STATE Register Diagram

Table 11-5: OTPC_SECU_STATE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
1:0 (R/NW)	PARTLOCK	Part Locked. The OTPC_SECU_STATE.PARTLOCK field indicates a locked part.	
		0	OPEN part
		1	Locked part
		2	Reserved

OTP Status Register

The OTPC_STAT register bits indicate errors and flag status and control the protection bits.

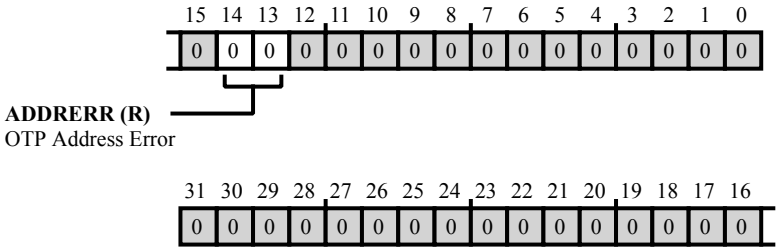

Figure 11-2: OTPC_STAT Register Diagram

Table 11-6: OTPC_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
14:13 (R/NW)	ADDRERR	OTP Address Error. The OTPC_STAT.ADDRERR bit field indicates errors which occur when the OTP programming address is out of range or tries to access protected space.	
		0	No error - proper OTP address
		1	OTP address out of range
		2	8-bit OTP address
		3	Protected OTP address

12 System Memory Protection Unit (SMPU)

The SMPU provides a flexible way of protecting memory regions against read or write access from any or all bus requester in the system. In addition, it can guard against memory access depending on security privileges of the system bus requester.

SMPU Features

The system memory protection unit has the following features.

- On reset, secure transactions are only allowed; non secure transactions are disabled.
- Each SMPU instance can be configured to monitor multiple regions. Each can be individually enabled.
- Each region can be configured with its own protection settings.
- Provides general read or write protection.
- Read and write transactions are restricted or allowed depending on the transaction ID.

Table 12-1: SMPU Instances

Module	SMPU Instance	Controller Allowed	L2 Memory Address Range
L2-Core Port 0 (CL2_0)	2	Data Port of both SHARC+ and ARM and IIR Accelerator Port	0x20000000 – 0x200FFFFF (L2 SRAM Banks 0-3) 0x20200000 – 0x2020FFFF (L2 Boot ROM0)
L2 DMA Port 0 (DL2_0)	3	HSMDMA	0x20000000 – 0x201FFFFF (L2 SRAM Banks 0-7) 0x20200000 – 0x2022FFFF (L2 Boot ROM 0-2)
L2-Core Port 1 (CL2_1)	4	Data Port of both SHARC+ and ARM and IIR AcceleratorPort	0x20100000 – 0x201FFFFF (L2 SRAM Banks 4-7) 0x20210000 – 0x2020FFFF (L2 Boot ROM 1-2)
L2 DMA Port 1 (DL2_1)	5	Peripheral and remaining DMA	0x20000000 – 0x201FFFFF (L2 SRAM Banks 0-7) 0x20200000 – 0x2022FFFF (L2 Boot ROM 0-2)
L2-Core Port 2 (CL2_2)	6	Instruction Port of both SH+ and FIR Accelerator Port	0x20000000 – 0x201FFFFF (L2 SRAM Banks 0-7) 0x20200000 – 0x2022FFFF(L2 Boot ROM 0-2)
DMC0	9	All Allowed Requesters	Entire Range

Table 12-1: SMPU Instances (Continued)

Module	SMPU Instance	Controller Allowed	L2 Memory Address Range
SPI2/OSPI0 Flash Address Space	11	All Allowed Requesters	Entire Range
OTP Memory	12	All Allowed Requesters	Entire Range

All the SMPU instances can be configured up to eight regions.

- Up to eight outstanding read or write transactions supported on SMPU instances for Core_L2 and DMC0. Up to four outstanding read or write transactions supported on the SMPU instances for DMA_L2 and SPI flash address space.

SMPU Functional Description

The following sections provide details on the function of the SMPU module. If the region security settings allow transactions to go through, the ID in the ID-based region protection settings can still filter the transactions.

For the memory that an SMPU protects, programs can configure region-based settings with the `SMPU_RCTL[n]` registers. (There can be multiple SMPUs in a system.) The `SMPU_RCTL[n]` registers define the ID-based protection for memory regions.

If the target address does not reside in any configured memory region, the transaction permission resorts back to the global configuration setting.

Protection Units

Each SMPU provides two protection units, A and B for ID-based matching in the region-based memory protection. This feature provides a degree of flexibility for the user to match against multiple IDs.

Instruction Fetches

When the core executes instructions from memory, this operation is also considered a memory transaction. If the SMPU is configured to protect a memory region from read accesses that contain instructions, the core cannot fetch and execute these instructions.

Using Cache

When the processor uses both cache and the SMPU, there are a few issues to be aware of. If the SMPU is configured to protect a memory region from write accesses, instruction fetches from a core are still possible since instructions are not updated and replaced during run time.

NOTE: The debugger typically replaces an instruction with a breakpoint instruction for software breakpoints. If a memory region is protected against write accesses, software breakpoints are not possible unless the SMPU is configured with the appropriate system controller ID of the debugger. The configuration allows it to perform a write-access.

In the case where memory is used for data, a read access or cache fill is not possible if the memory is blocked from read accesses. If read accesses are allowed but write accesses are disallowed, then there is an issue with coherency. The cache is filled but when the cache is updated and must be written back to the SMPU protected memory, the write-access is blocked.

In general, exercise caution when using both the SMPU and cache.

Speculative Reads

If speculative reads are enabled (`SMPU_CTL.RSDIS` =0), the SMPU forwards the read transaction directly to the memory before checking the protection setting corresponding to the addressed memory region. This functionality saves one clock cycle in the clock domain of the SMPU. The SMPU checks the protection setting while the read transaction occurs with the memory. If the protection setting dictates that the target memory address is blocked, the SMPU blocks the read to the controller.

If speculative reads are disabled (`SMPU_CTL.RSDIS` =1), the SMPU checks the protection settings first and forwards the transaction to memory only if it passes the configured protection settings. This functionality incurs a one-cycle latency per read.

NOTE: Reads affect certain memory operations such as automatic clearing of the memory (that is, FIFOs). When the SMPU protects this type of memory, disable read speculation since the blocking can occur without the read transaction reaching the target memory.

ADSP-SC59x SMPU Register List

The System Memory Protection Unit (SMPU) provides selective protection of the processor's memory resources. The SMPU includes a set of processor events that can be monitored during program execution. A set of registers governs SMPU operations. For more information on SMPU functionality, see the SMPU register descriptions.

Table 12-2: ADSP-SC59x SMPU Register List

Name	Description
`SMPU_BADDR`	Bus Error Address Register
`SMPU_BDTLS`	Bus Error Details Register
`SMPU_CTL`	SMPU Control Register
`SMPU_EXACADD[n]`	Exclusive Access IDn Address
`SMPU_EXACSTAT[n]`	Exclusive Access Status
`SMPU_IADDR`	Interrupt Address Register
`SMPU_IDTLS`	Interrupt Details Register
`SMPU_RADDR[n]`	Region n Address Register
`SMPU_RCTL[n]`	Region n Control Register
`SMPU_REVID`	SMPU Revision ID Register

Table 12-2: ADSP-SC59x SMPU Register List (Continued)

Name	Description
SMPU_RIDA[n]	Region n ID A Register
SMPU_RIDB[n]	Region n ID B Register
SMPU_RIDMSKA[n]	Region n ID Mask A Register
SMPU_RIDMSKB[n]	Region n ID Mask B Register
SMPU_SECURECTL	SMPU Control Secure Accesses Register
SMPU_SECURERCTL[n]	Region n Control Secure Accesses Register
SMPU_STAT	SMPU Status Register

SMPU Interrupts

The SMPU has one interrupt with the SEC ID = 217.

See the SEC chapter for complete information on interrupt generation and use.

Memory Writes

A write transaction to address n is prevented when the following is true.

Address n is in memory region m and memory region m is write-protected (SMPU_RCTL[n].WPROTEN =1) and ID is not a match. (See ID Comparison). The block occurs because the memory region is configured for write-protection and the ID comparison does not result in a match. If an ID comparison results in a match, the write transaction is allowed through.

Memory Reads

A read transaction from address n is prevented when the following is true:

- Address n is in memory region and memory region m is read-protected (SMPU_RCTL[n].RPROTEN =1) and
- ID is not a match

The block occurs because the memory region is configured for read protection and the ID comparison does not result in a match. If the ID comparison results in a match, the read transaction is permitted. (See ID Comparison).

ID Comparison

ID comparison automatically occurs during region-based memory protection. ID matches allow the transaction to bypass the configured memory protection for that region. The following sections describe the calculation of a write ID match and read ID match.

Write Transaction

The state of the following values determines the ID value that is compared with the ID of an incoming write transaction:

- The SMPU_RCTL[n].WIDCINV bit
- The SMPU_RIDA[n].ID and SMPU_RIDB[n].ID bit fields
- The SMPU_RIDMSKA[n].MSK and SMPU_RIDMSKB[n].MSK bit fields

Write IDA match = ((ID of incoming write transaction AND SMPU_RIDMSKA[n].MSK) == (SMPU_RIDA[n].ID AND SMPU_RIDMSKA[n].MSK))

Write IDB match = ((ID of incoming write transaction AND SMPU_RIDMSKB[n].MSK) == (SMPU_RIDB[n].ID AND SMPU_RIDMSKB[n].MSK))

Write ID match = (Write IDA match OR Write IDB match) XOR SMPU_RCTL[n].WIDCINV bit

Read Transaction

The state of the following values determines the ID value that is compared with the ID of an incoming read transaction:

- The SMPU_RCTL[n].RIDCINV bit
- The SMPU_RIDA[n].ID and SMPU_RIDB[n].ID bit fields
- The SMPU_RIDMSKA[n].MSK and SMPU_RIDMSKB[n].MSK bit fields

Read IDA match = ((ID of incoming read transaction AND SMPU_RIDMSKA[n].MSK) == (SMPU_RIDA[n].ID AND SMPU_RIDMSKA[n].MSK))

Read IDB match = ((ID of incoming read transaction AND SMPU_RIDMSKB[n].MSK) == (SMPU_RIDB[n].ID AND SMPU_RIDMSKB[n].MSK))

Read ID match = (Read IDA match OR Read IDB match) XOR SMPU_RCTL[n].RIDCINV

In the two cases described above, the incoming transaction (either write or read) ID is AND'ed with the configured mask value in protection unit A. It is then compared to the value of the configured ID value which is also AND'ed with the configured mask value in protection unit A. The mask provides a method to allow a group of IDs to match. This process is also performed for protection unit B. The two outcomes (from A and B) are then OR'ed together.

Depending on the setting of the SMPU_RCTL[n].RIDCINV or the SMPU_RCTL[n].WIDCINV bits, the ID match comparison is inverted or not. The final result after applying the inversion, SMPU_RCTL[n].RIDCINV, or SMPU_RCTL[n].WIDCINV, determines whether the transaction bypasses the protection.

Usage

The masks, SMPU_RIDMSKA[n] and SMPU_RIDMSKB[n], are AND'ed with both the incoming transaction ID and the configured ID in SMPU_RIDA[n].ID and SMPU_RIDB[n].ID, respectively. By default the masks

are zero. If ID-based region protection is enabled by setting the SMPU_RCTL[n].WPROTEN or SMPU_RCTL[n].RPROTEN bit fields and the masks are not set, the ID comparison essentially compares zeros. The comparison allows all transactions to bypass (if the region-based security setting is also configured in a way to allow transactions to go through for the region). To have the ID-based region protection to function, the mask registers and ID registers must also be set.

System IDs

The ***System controller IDs*** table provides the IDs for the system controllers. An x means that the bit can be a 0 or a 1. There are multiple IDs associated with that system controller.

Table 12-3: System Controller IDs

Memory Region

Memory regions can start at address 0x00000000 or at any address that is a multiple of its size. The ***Supported Memory Region Size and Alignment*** table shows the memory region sizes that the processor supports and the alignment of the memory region. (X values are do-not-care).

SMPU supports a maximum of eight regions.

Table 12-4: Supported Memory Region Size and Alignment

Size	SMPU_RCTLn.SIZE	Address	Possible Values for N
4KB	0b00000	0xXXXXX000	-
8KB	0b00001	0xXXXXN000	0x0, 0x2, 0x4, 0x8, 0xA, 0xC, 0xE

2GB	0b10011	0xN0000000	0x0, 0x8
4GB	0b10100	0x00000000	-

For the case where the region size is selected as 4 GB, the region address must be at address 0x00000000.

NOTE: If a memory region address is not aligned to its size, the memory region start address protected by the SMPU is the configured address with the corresponding least significant bits masked. For example, if the size is configured for 16 KB (`SMPU_RCTL[n].SIZE` =0b00010), and the base address is configured for `SMPU_RADDR[n].BADDR`=0x00005018, the actual base address used by the SMPU is 0x00004000. When `SMPU_RADDR[n].BADDR` is read back, the program reads 0x00005000. This functionality is because only bits [11:0] are reserved as 0's. Programs must use care when setting the base address as it is not always the true base address.

SMPU Definitions

To make the best use of the SMPU, it is useful to understand the terms in this section.

Global Protection

Guarding of the entire memory space for the SMPU instantiation.

Region-Based Protection

Guarding individual segments of memory inside the memory space for the SMPU instantiation.

ID Match

A successful comparison of the ID associated with the incoming transaction and the ID and MASK configured in the SMPU.

SMPU Block Diagram

The *SMPU Top-Level Block Diagram* shows the SMPU block.

As seen in the diagram, the SMPU sits between the memory port (SCB requester port) and the SCB fabric (SCB completer port). It acts as a gateway analyzing the transaction requests. It either rejects the transaction request or allows access based on the user-programmed configuration of the SMPU.

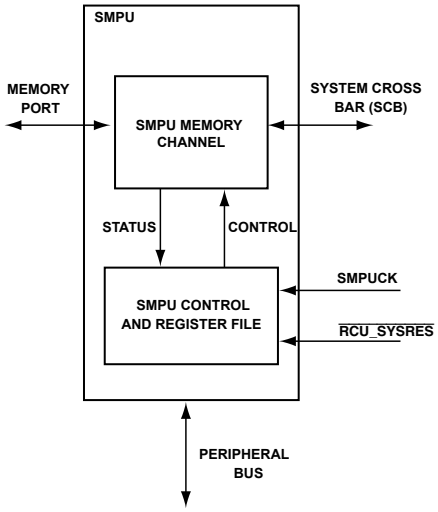

Figure 12-1: SMPU Top-Level Block Diagram

SMPU Architectural Concepts

The following sections provide brief descriptions of the architecture of the SMPU module.

Default Setting

At reset, the default state of the system is fully open. The SMPUs admit any access to memory spaces.

Latency

The SMPU adds latency to all the transactions to the memory except reads when read speculation is enabled (SMPU_CTL.RSDIS =0). In this case, read accesses are always forwarded to the memory and read responses are generated according to the SMPU settings. If read speculation is disabled (SMPU_CTL.RSDIS =1), reads are blocked if they cause a security or protection violation. The SMPU generates the SCB read response that corresponds to a blocked transaction.

If read speculation is enabled, the SMPU adds 1 clock cycle latency to the read transaction. If read speculation is disabled, the SMPU adds 2 clock cycles latency to the read transaction.

SMPU Operating Modes

The SMPU does not have any strict modes of operation. However, it can be configured for region-based protection where a controller with a particular ID can be blocked or allowed based on settings in the SMPU_RCTL[n] register.

Region-based protection is programmed with registers:

- SMPU_RCTL[n]
- SMPU_RADDR[n]
- SMPU_RIDA[n]
- SMPU_RIDMSKA[n]
- SMPU_RIDB[n]
- SMPU_RIDMSKB[n]

SMPU Interrupt Signals

There is one interrupt signal associated with the SMPU. If interrupts are enabled, the SMPU_STAT.IRQ bit is set. The SMPU_IRQ signal is asserted when the SMPU detects a memory access violation. The target address triggering the interrupt is found in the SMPU_IADDR register. The SMPU_IDTLS register provides further details about the cause of the interrupt.

Write errors are prioritized over read errors.

Protection violations (an ID-based violation) can trigger the SMPU interrupt and can be enabled independently. The protection violation interrupt is enabled by setting the SMPU_CTL.PINTEN bit.

The SMPU interrupt is asserted for any of the following conditions:

If a second memory access violation occurs while the SMPU_STAT.IRQ bit is set, the SMPU_STAT.IOVR (interrupt overrun) bit is set. The SMPU_IADDR and the SMPU_IDTLS registers are not updated until the SMPU_STAT.IRQ bit is cleared. Any information on the subsequent interrupt is lost. Once the

SMPU_STAT.IRQ bit and the SMPU_STAT.IOVR bit are cleared, any new memory access violations can trigger an interrupt and its details can be captured.

NOTE: When a blocked access occurs, the SMPU triggers an interrupt when interrupt generation is enabled. The SMPU can also be configured to generate a bus error that propagates back to the system controller. The system controller can also trigger an interrupt due to this bus error.

NOTE: On the processor, each SMPU instance has an interrupt. All of the SMPU interrupts are OR'ed and mapped to a single SMPU interrupt on the SEC. While servicing the SMPU interrupt, check all of the SMPU_STAT registers to determine which triggered the interrupt. The interrupt service routine clears the SMPU_STAT.IRQ bit of all of the SMPU_STAT registers for which the interrupt is triggered.

SMPU Status and Error Signals

If bus errors are enabled (SMPU_CTL.PBEDIS =0), the SMPU generates and returns a bus error to the controller initiating the blocked access. This bit also sets the SMPU_STAT.BERR bit. The SMPU_BADDR and SMPU_BDTLS registers can be read to get the address and details of the transaction that caused the SMPU to generate the error.

Write errors are prioritized over read errors.

A bus error status is returned to the system controller if:

- an ID-based violation happened and the SMPU_CTL.PBEDIS bit =0

If a second memory access violation occurs while the SMPU_STAT.BERR bit is set, the SMPU_STAT.BEOVR bit (bus error overrun) is set. The SMPU_BADDR and the SMPU_BDTLS registers are not updated until the SMPU_STAT.IRQ bit is cleared. The information about the transaction that caused the SMPU_STAT.BEOVR bit to be set is lost.

NOTE: If both the protection violation interrupt is not enabled (SMPU_CTL.PINTEN =0) and the protection bus error is disabled (SMPU_CTL.PBEDIS =1), the SMPU blocks invalid transactions. However, it does not provide any status or interrupt information indicating that a transaction is blocked.

ADSP-SC59x SMPU Register Descriptions

The System Memory Protection Unit (SMPU) contains the following registers.

Table 12-5: ADSP-SC59x SMPU Register List

Name	Description
SMPU_BADDR	Bus Error Address Register
SMPU_BDTLS	Bus Error Details Register
SMPU_CTL	SMPU Control Register

Table 12-5: ADSP-SC59x SMPU Register List (Continued)

Name	Description
SMPU_EXACADD[n]	Exclusive Access IDn Address
SMPU_EXACSTAT[n]	Exclusive Access Status
SMPU_IADDR	Interrupt Address Register
SMPU_IDTLS	Interrupt Details Register
SMPU_RADDR[n]	Region n Address Register
SMPU_RCTL[n]	Region n Control Register
SMPU_REVID	SMPU Revision ID Register
SMPU_RIDA[n]	Region n ID A Register
SMPU_RIDB[n]	Region n ID B Register
SMPU_RIDMSKA[n]	Region n ID Mask A Register
SMPU_RIDMSKB[n]	Region n ID Mask B Register
SMPU_SECURECTL	SMPU Control Secure Accesses Register
SMPU_SECURERCTL[n]	Region n Control Secure Accesses Register
SMPU_STAT	SMPU Status Register

Bus Error Address Register

Programs read the SMPU_BADDR and the SMPU_BDTLS registers to determine the cause of a bus error. Write errors are prioritized over read errors.

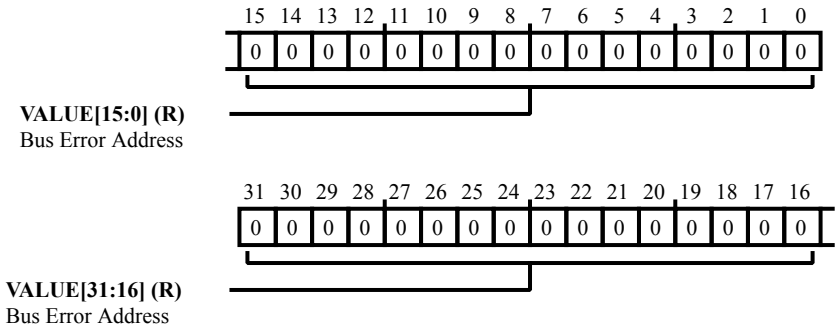

Figure 12-2: SMPU_BADDR Register Diagram

Table 12-6: SMPU_BADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Bus Error Address. The SMPU_BADDR.VALUE bit field contains the address of the bus error.

Bus Error Details Register

The SMPU_BDTLS register indicates the ID of the bus error transaction, whether the transaction that caused the last bus error was a read, a write, secure or non-secure.

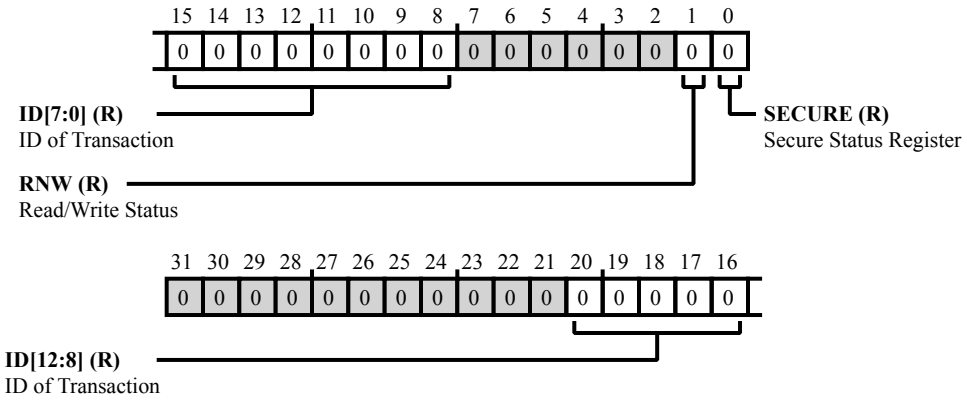

Figure 12-3: SMPU_BDTLS Register Diagram

Table 12-7: SMPU_BDTLS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
20:8 (R/NW)	ID	ID of Transaction. The SMPU_BDTLS.ID bit field provides the ID of the transaction that caused the bad address error.	
1 (R/NW)	RNW	Read/Write Status. The SMPU_BDTLS.RNW bit indicates whether the last transaction that caused the bad address error was a read or write.	
		0	Transaction that caused last bus error was a write
		1	Transaction that caused last bus error was a read
0 (R/NW)	SECURE	Secure Status Register. The SMPU_BDTLS.SECURE bit indicates whether the last transaction that caused the bad address error was secure or non-secure.	
		0	Transaction that caused last bus error was non-secure
		1	Transaction that caused last bus error was secure

SMPU Control Register

The SMPU_CTL register provides access to the locking control, error interrupts and SMPU violations.

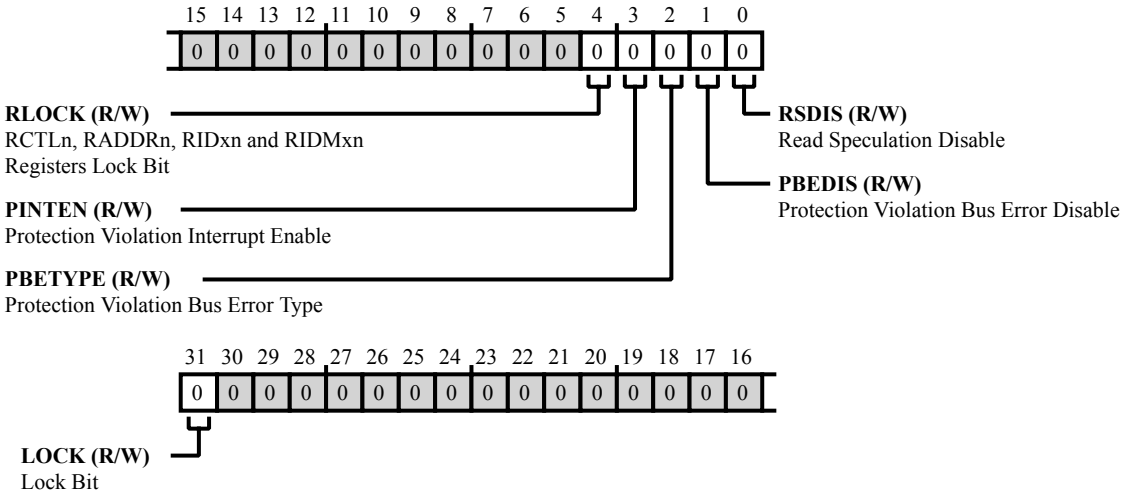

Figure 12-4: SMPU_CTL Register Diagram

Table 12-8: SMPU_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock Bit. When the SMPU_CTL.LOCK bit is set and the global lock signal is asserted from the SPU, the SMPU_CTL register is write-protected. Write-protection is disabled only when the global lock signal becomes deasserted again.	
		0	CTL Global Lock Disable. The SMPU_CTL register is not write-protected.
		1	CTL Global Lock Enable. The SMPU_CTL register is write-protected.
4 (R/W)	RLOCK	RCTLn, RADDRn, RIDxn and RIDMxn Registers Lock Bit. When the SMPU_CTL.RLOCK bit is set, all the registers associated with region-based control (SMPU_RCTL[n], SMPU_RADDR[n], SMPU_RIDA[n], SMPU_RIDB[n], SMPU_RIDMSKA[n] and SMPU_RIDMSKB[n]) are write-protected when the global lock signal is active from the SPU. Write access is allowed again when the global lock signal is deasserted.	
		0	Region Registers Write-Protect Enable. All region registers are not write-protected.
		1	Region Registers Write-Protect Disable. All region registers are write-protected.

Table 12-8: SMPU_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	PINTEN	Protection Violation Interrupt Enable. The SMPU_CTL.PINTEN bit controls whether or not an interrupt is generated when a protection violation occurs.	
		0	Protection Violation IRQ Disable. The protection violation interrupt is disabled.
		1	Protection Violation IRQ Enable. The protection violation interrupt is enabled.
2 (R/W)	PBETYPE	Protection Violation Bus Error Type. The SMPU_CTL.PBETYPE bit controls whether a protection violation produces a decode error or a completer error.	
		0	Decode Error Type. Decode error for transactions that violate the configured protection.
		1	Completer Error Type. Completer error for transactions which violate the configured protection.
1 (R/W)	PBEDIS	Protection Violation Bus Error Disable. If set, the SMPU_CTL.PBEDIS bit blocks protection violations, but does not cause a bus error.	
		0	Bus Error Generation Enable. Transactions which violate the configured protection are blocked and cause a bus error.
		1	Bus Error Generation Disable. Transactions which violate the configured protection are blocked but do not cause a bus error.
0 (R/W)	RSDIS	Read Speculation Disable. The SMPU_CTL.RSDIS bit controls whether or not the read addresses are checked before being sent to the completer.	
		0	Read Speculation Enable. Read addresses are sent to the completer without checking.
		1	Read Speculation Disable. Read addresses are checked before being sent to the completer.

Exclusive Access IDn Address

The SMPU_EXACADD[n] register provides the address ID of an exclusive access.

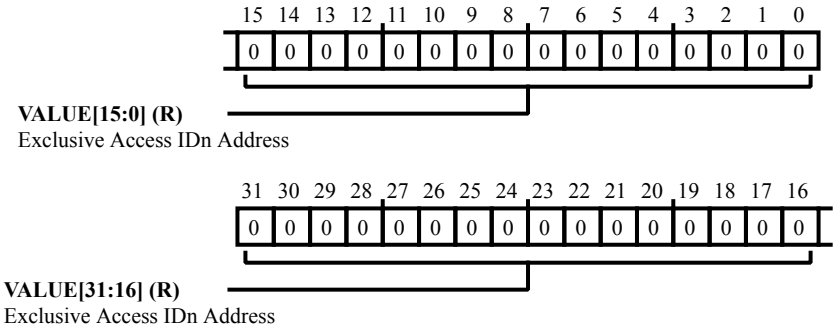

Figure 12-5: SMPU_EXACADD[n] Register Diagram

Table 12-9: SMPU_EXACADD[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Exclusive Access IDn Address.

Exclusive Access Status

The SMPU_EXACSTAT[n] register provides the exclusive access ID, read size and read length as well as the indication that the access was valid.

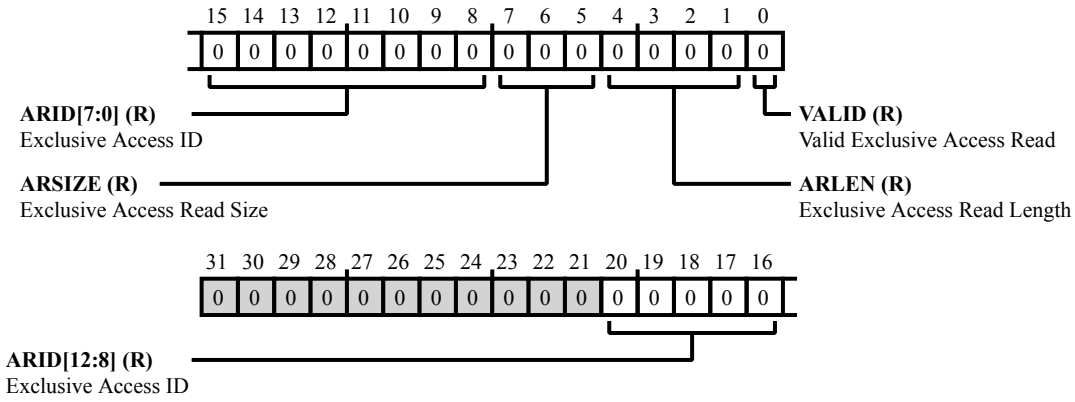

Figure 12-6: SMPU_EXACSTAT[n] Register Diagram

Table 12-10: SMPU_EXACSTAT[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
20:8 (R/NW)	ARID	Exclusive Access ID.
7:5 (R/NW)	ARSIZE	Exclusive Access Read Size.
4:1 (R/NW)	ARLEN	Exclusive Access Read Length.
0 (R/NW)	VALID	Valid Exclusive Access Read.

Interrupt Address Register

The SMPU_IADDR register indicates an attempt to make a read or write access to unimplemented addresses or accesses are non-aligned. The SMPU issues a bus error for this condition.

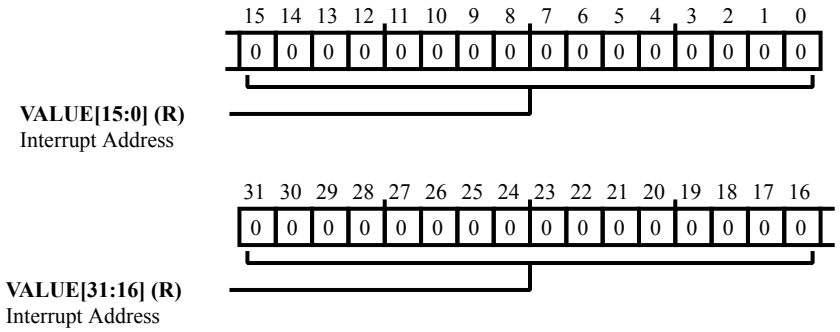

Figure 12-7: SMPU_IADDR Register Diagram

Table 12-11: SMPU_IADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Interrupt Address. The SMPU_IADDR.VALUE bit field is the address where an attempt to access an unimplemented address or a non-aligned access has occurred.

Interrupt Details Register

The SMPU_IDTLS register provides the ID of the last signaled interrupt, whether the interrupt was caused by a read or write, and whether the transaction that caused the last signaled interrupt was secure.

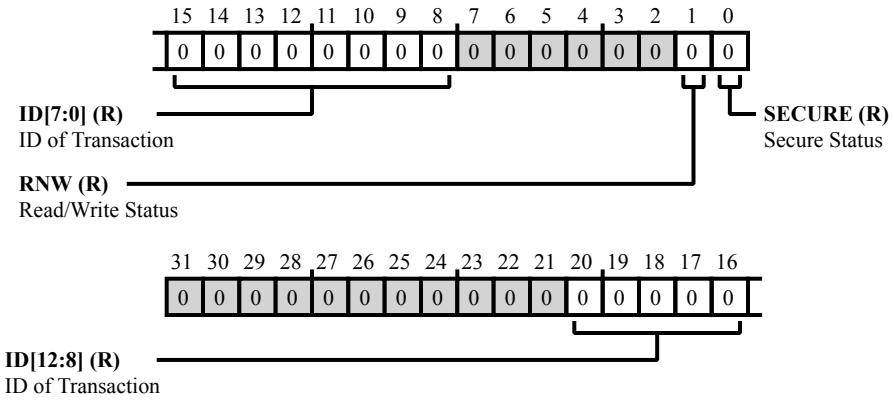

Figure 12-8: SMPU_IDTLS Register Diagram

Table 12-12: SMPU_IDTLS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
20:8 (R/NW)	ID	ID of Transaction. The SMPU_IDTLS.ID bit field provides the ID of the transaction that caused the interrupt.	
1 (R/NW)	RNW	Read/Write Status. The SMPU_IDTLS.RNW bit indicates whether the last transaction that caused the interrupt was a read or write.	
		0	Transaction that caused last signaled interrupt was a write
		1	Transaction that caused last signaled interrupt was a read
0 (R/NW)	SECURE	Secure Status. The SMPU_IDTLS.SECURE bit indicates whether the last transaction that caused the interrupt was secure or non-secure.	
		0	Transaction that caused last signaled interrupt was non-secure
		1	Transaction that caused last signaled interrupt was secure

Region n Address Register

The SMPU_RADDR[n] register is used to define the base address for a memory region to be protected.

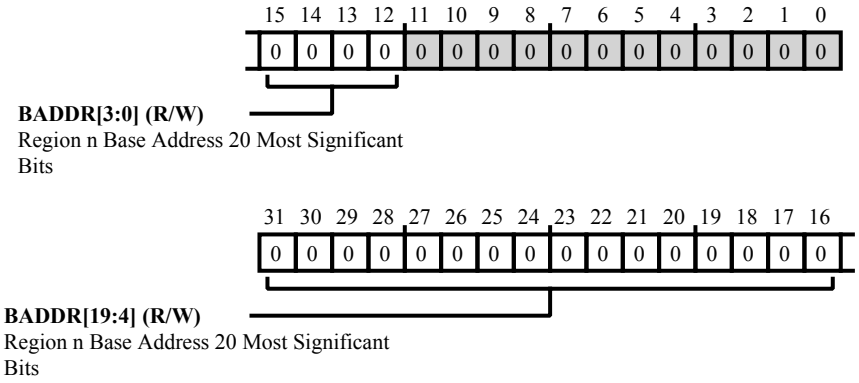

Figure 12-9: SMPU_RADDR[n] Register Diagram

Table 12-13: SMPU_RADDR[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:12 (R/W)	BADDR	Region n Base Address 20 Most Significant Bits. The SMPU_RADDR[n].BADDR bit field defines the base address for a memory region to be protected.

Region n Control Register

The SMPU_RCTL[n] register is used to define the level of protection for a region of memory. The protection of a region is controlled and defined by this register and the SMPU_RADDR[n], SMPU_RIDA[n], SMPU_RIDB[n], SMPU_RIDMSKA[n], and SMPU_RIDMSKB[n] registers.

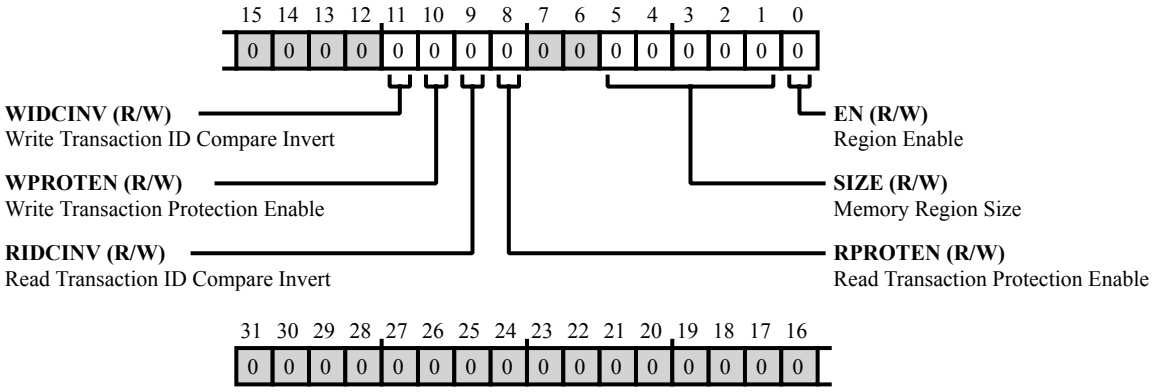

Figure 12-10: SMPU_RCTL[n] Register Diagram

Table 12-14: SMPU_RCTL[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W)	WIDCINV	Write Transaction ID Compare Invert. The SMPU_RCTL[n].WIDCINV bit inverts the write ID match result.	
		0	Write transaction ID comparison result not inverted
		1	Write transaction ID comparison result inverted
10 (R/W)	WPROTEN	Write Transaction Protection Enable. The SMPU_RCTL[n].WPROTEN bit enables protection against ID-based write transactions for the memory region.	
		0	Write transaction ID-based protection disabled
		1	Write transaction ID-based protection enabled
9 (R/W)	RIDCINV	Read Transaction ID Compare Invert. When the SMPU_RCTL[n].RIDCINV bit is set, the read ID match result is inverted.	
		0	Read transaction ID comparison result not inverted
		1	Read transaction ID comparison result inverted

Table 12-14: SMPU_RCTL[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W)	RPROTEN	Read Transaction Protection Enable. The `SMPU_RCTL[n].RPROTEN` bit enable bit to turn on protection against ID-based read transactions for the memory region.	
		0	Read transaction ID-based protection disabled
		1	Read transaction ID-based protection enabled
5:1 (R/W)	SIZE	Memory Region Size. The `SMPU_RCTL[n].SIZE` bit defines the size of the memory region to be protected.	
		0	4 KB
		1	8 KB
		2	16 KB
		3	32 KB
		4	64 KB
		5	128 KB
		6	256 KB
		7	512 KB
		8	1 MB
		9	2 MB
		10	4 MB
		11	8 MB
		12	16 MB
		13	32 MB
		14	64 MB
		15	128 MB
		16	256 MB
		17	512 MB
		18	1 GB
		19	2 GB
		20	4 GB
		21-31	Reserved

Table 12-14: SMPU_RCTL[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	EN	Region Enable. The `SMPU_RCTL[n].EN` bit enables the protection of a region.	
		0	Disabled
		1	Enabled

SMPU Revision ID Register

The SMPU_REVID register provides the major and minor revision numbers of this module.

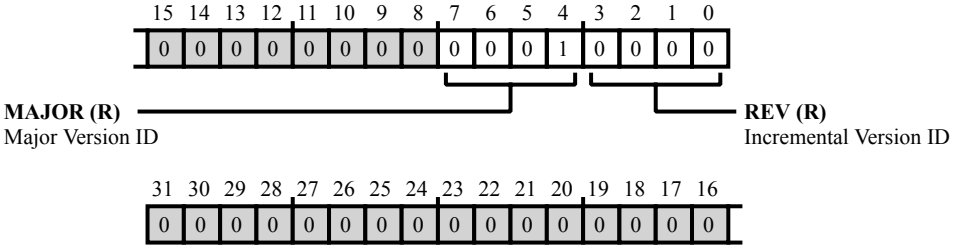

Figure 12-11: SMPU_REVID Register Diagram

Table 12-15: SMPU_REVID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:4 (R/NW)	MAJOR	Major Version ID.
3:0 (R/NW)	REV	Incremental Version ID.

Region n ID A Register

The SMPU_RIDA[n] register is used for ID comparison 'A'. This comparison is performed after a mask is applied to both the transaction ID (from either the read or write IDs) and the register value. An ID match means that the ID is the exception to the rule and the read or write is allowed even if the region is read or write-protected. For more detail, refer to the ID Comparison section.

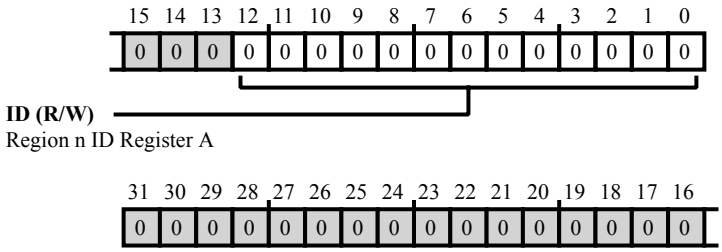

Figure 12-12: SMPU_RIDA[n] Register Diagram

Table 12-16: SMPU_RIDA[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
12:0 (R/W)	ID	Region n ID Register A. The SMPU_RIDA[n].ID bit field, combined with the mask provides the means to bypass the configured memory protection for a region.

Region n ID B Register

The SMPU_RIDB[n] register is used for ID comparison 'B'. This comparison is performed after a mask is applied to both the transaction ID (from either the read or write IDs) and the register value. An ID match means that the ID is the exception to the rule and the read or write is allowed even if the region is read or write-protected. For more details, refer to the ID Comparison section.

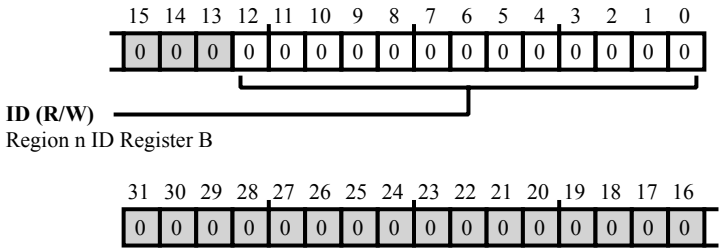

Figure 12-13: SMPU_RIDB[n] Register Diagram

Table 12-17: SMPU_RIDB[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
12:0 (R/W)	ID	Region n ID Register B. The SMPU_RIDB[n].ID bit field, combined with the mask provides the means to bypass the configured memory protection for a region.

Region n ID Mask A Register

The SMPU_RIDMSKA[n] register is used for ID comparison 'A'. The mask allows or disallows certain IDs from affecting the final result of the ID match. For more details, refer to the ID Comparison section.

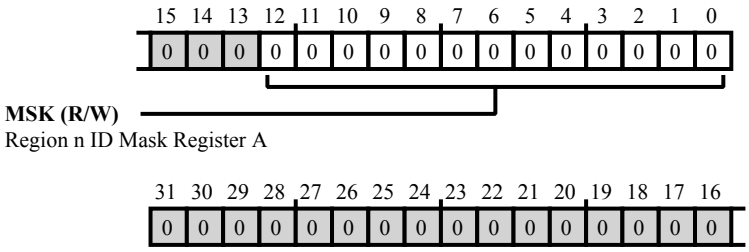

Figure 12-14: SMPU_RIDMSKA[n] Register Diagram

Table 12-18: SMPU_RIDMSKA[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
12:0 (R/W)	MSK	Region n ID Mask Register A. The SMPU_RIDMSKA[n].MSK bit field, combined with the incoming transaction, provides the means to bypass the configured memory protection for a region.

Region n ID Mask B Register

The SMPU_RIDMSKB[n] register is used for ID comparison 'B'. The mask allows or disallows certain IDs from affecting the final result of the ID match. For more details, refer to the ID Comparison section.

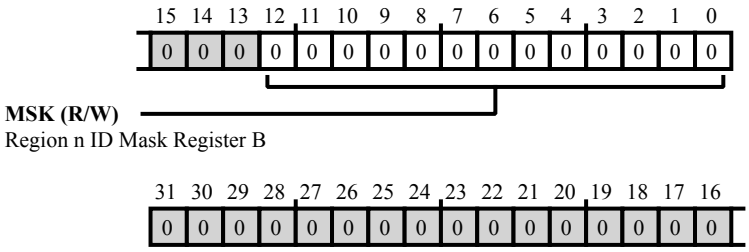

Figure 12-15: SMPU_RIDMSKB[n] Register Diagram

Table 12-19: SMPU_RIDMSKB[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
12:0 (R/W)	MSK	Region n ID Mask Register B. The SMPU_RIDMSKB[n].MSK bit field, combined with the incoming transaction provides the means to bypass the configured memory protection for a region.

SMPU Control Secure Accesses Register

The SMPU_SECURECTL register provides the bits required to set up the security settings for the processor. These settings includes error generation and read/write security.

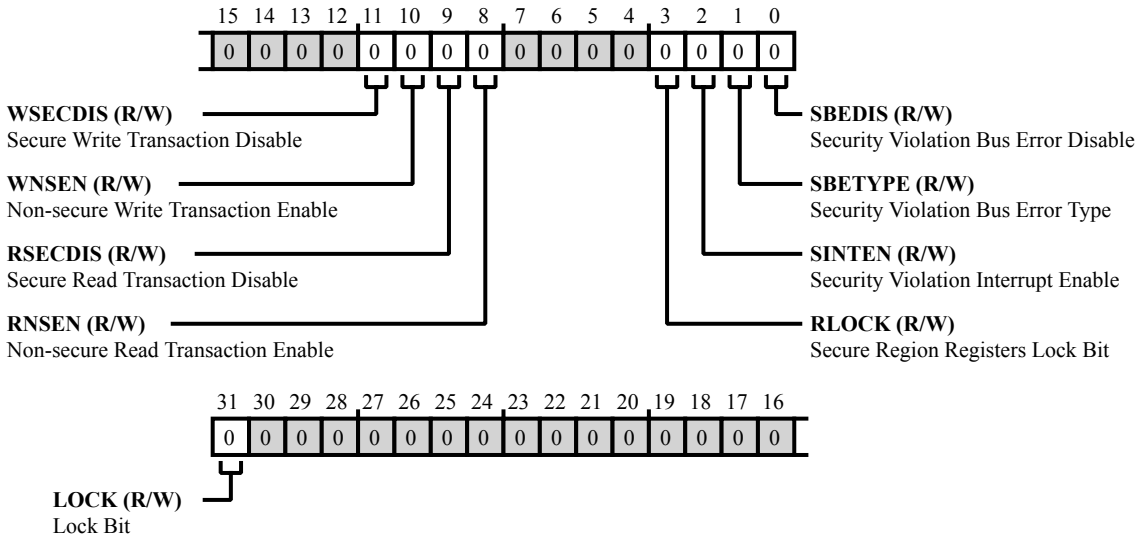

Figure 12-16: SMPU_SECURECTL Register Diagram

Table 12-20: SMPU_SECURECTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock Bit. When the SMPU_SECURECTL.LOCK bit is set and the global lock signal is asserted from the SPU, the SMPU_SECURECTL register is write-protected. Write-protection is disabled only when the global lock signal becomes deasserted again.	
		0	SMPU_SECURECTL is not write-protected
		1	SMPU_SECURECTL is write-protected
11 (R/W)	WSECDIS	Secure Write Transaction Disable. The SMPU_SECURECTL.WSECDIS bit disables secure write transactions.	
		0	Enable secure write transactions
		1	Disable secure write transactions
10 (R/W)	WNSEN	Non-secure Write Transaction Enable. The SMPU_SECURECTL.WNSEN bit enables non-secure write transactions.	
		0	Disable non-secure writes
		1	Enable non-secure writes

Table 12-20: SMPU_SECURECTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W)	RSECDIS	Secure Read Transaction Disable. The SMPU_SECURECTL.RSECDIS bit disables secure read transactions.	
		0	Enable secure read transactions
		1	Disable secure read transactions
8 (R/W)	RNSEN	Non-secure Read Transaction Enable. The SMPU_SECURECTL.RNSEN bit enables non-secure read transactions.	
		0	Disable non-secure read transactions
		1	Enable non-secure read transactions
3 (R/W)	RLOCK	Secure Region Registers Lock Bit. When the SMPU_SECURECTL.RLOCK bit is set, the secure region control registers, SMPU_SECURERCTL[n], are write-protected when the global lock signal is active from the SPU. When the global lock signal is deasserted, write access is allowed again.	
		0	Disable write-protection on secure region registers
		1	Enable write-protection on secure region registers
2 (R/W)	SINTEN	Security Violation Interrupt Enable. The SMPU_SECURECTL.SINTEN bit enables interrupt generation when a security violation occurs.	
		0	Disable security settings violation interrupt
		1	Enable security settings violation interrupt
1 (R/W)	SBETYPE	Security Violation Bus Error Type. The SMPU_SECURECTL.SBETYPE bit controls whether a decode error or a completer error is returned when a security violation occurs.	
		0	Decode error
		1	Completer error
0 (R/W)	SBEDIS	Security Violation Bus Error Disable. The SMPU_SECURECTL.SBEDIS bit controls whether or not a bus error is caused when a security violation occurs.	
		0	Enable bus error
		1	Disable bus error

Region n Control Secure Accesses Register

The SMPU_SECURERCTL[n] register contains bits that configure read/write security for a specific region.

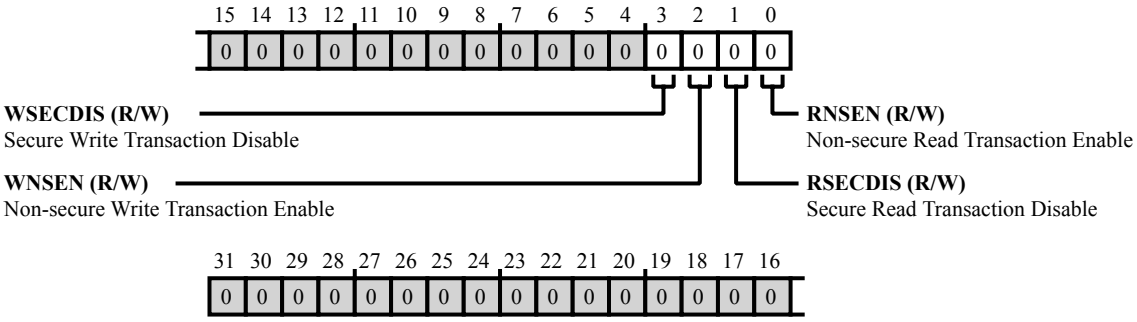

Figure 12-17: SMPU_SECURERCTL[n] Register Diagram

Table 12-21: SMPU_SECURERCTL[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	WSECDIS	Secure Write Transaction Disable. The SMPU_SECURERCTL[n].WSECDIS bit disables secure write transactions for the memory region.	
		0	Enable secure write transactions to this region
		1	Disable secure write transactions to this region
2 (R/W)	WNSEN	Non-secure Write Transaction Enable. This SMPU_SECURERCTL[n].WNSEN bit enables non-secure write transactions for the memory region.	
		0	Disable non-secure write transactions to this region
		1	Enable non-secure write transactions to this region
1 (R/W)	RSECDIS	Secure Read Transaction Disable. The SMPU_SECURERCTL[n].RSECDIS bit disables secure read transactions for the memory region.	
		0	Enable secure read transactions to this region
		1	Disable secure read transactions to this region
0 (R/W)	RNSEN	Non-secure Read Transaction Enable. The SMPU_SECURERCTL[n].RNSEN bit enables non-secure read transactions for the memory region.	
		0	Disable non-secure read transactions to this region
		1	Enable non-secure read transactions to this region

SMPU Status Register

The SMPU_STAT register provides the state of the SMPU and indicates various errors. All bits in this register are write 1 to clear.

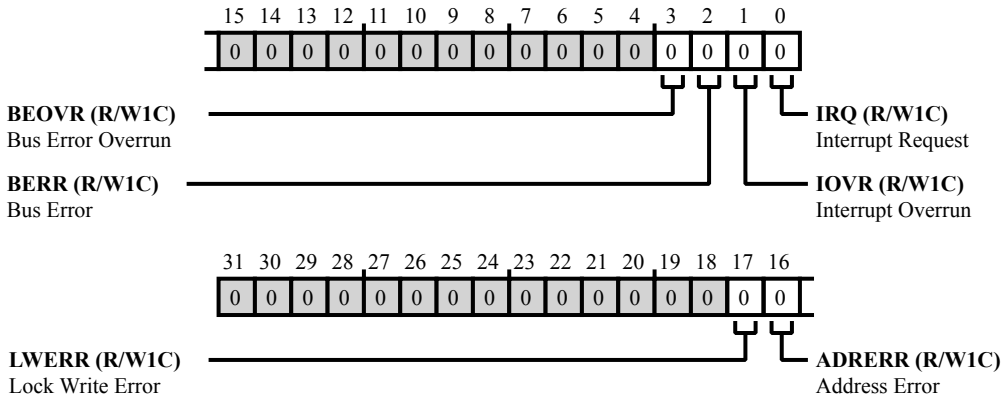

Figure 12-18: SMPU_STAT Register Diagram

Table 12-22: SMPU_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/W1C)	LWERR	Lock Write Error. The SMPU_STAT.LWERR bit is set when SMPU_CTL.LOCK bit =1, the global lock signal is asserted from the SPU and a read or write attempt was made to the SMPU_CTL MMR.	
		0	No Lock Write Error
		1	Lock Write Error
16 (R/W1C)	ADRERR	Address Error. The SMPU_STAT.ADRERR bit is set when the SMPU MMR is accessed as an un-aligned address, or when a read-only MMR is written to.	
		0	No Address Error
		1	Address Error
3 (R/W1C)	BEOVR	Bus Error Overrun. The SMPU_STAT.BEOVR bit indicates that another bus error had occurred. Any new information about the most recent violation which caused the bus error is not captured.	
		0	No Bus Error overrun
		1	Bus Error overrun has occurred

Table 12-22: SMPU_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W1C)	BERR	Bus Error. This `SMPU_STAT.BERR` bit indicates if a bus error was generated.	
		0	No Bus Error since this bit has been cleared
		1	Bus Error has been generated
1 (R/W1C)	IOVR	Interrupt Overrun. The `SMPU_STAT.IOVR` bit indicates if another violation occurred while the previous violation interrupt was not finished being serviced. Information about the most recent violation is then not captured.	
		0	No Interrupt overrun
		1	Interrupt overrun has occurred
0 (R/W1C)	IRQ	Interrupt Request. The `SMPU_STAT.IRQ` bit provides an indication that an interrupt has been generated.	
		0	No Interrupt since this bit has been cleared
		1	Interrupt has been generated

13 General-Purpose Ports (PORT)

This section describes general-purpose ports, pin multiplexing, general-purpose input/output (GPIO) functionality, and pin interrupts. The general-purpose ports provide the following three functions:

- Pin multiplexing scheme
- GPIO functionality
- Pin interrupt requests

NOTE: In this chapter, the naming convention for registers and bits omits the alphabetic group enumeration to refer to any and all of the ports. For example, `PORT_FER` represents registers `PORTA_FER`, `PORTB_FER`, and so on. Likewise `PORT_FER.PX1` represents bits PA1, PB1, and so on.

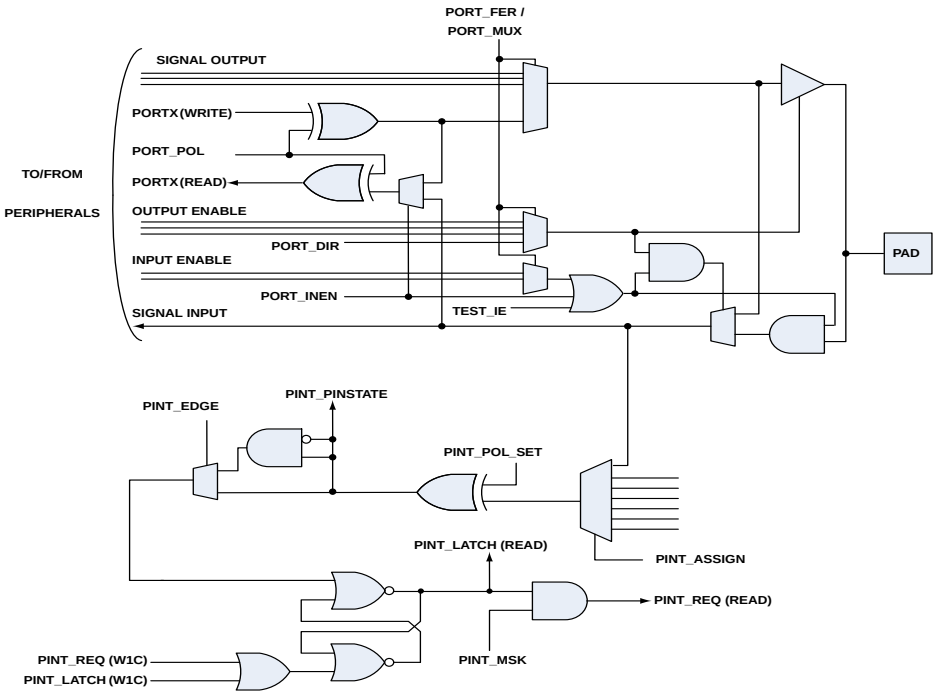

Figure 13-1: Simplified GPIO and Pin Interrupt Signal Flow

PORT Features

The PORTs include the following features:

- Input mode, output mode, and open-drain mode of GPIO operation
- Port multiplexing controlled on a pin-by-pin basis
- No external glue hardware required for unused pins
- All port pins provide interrupt request functionality
- Byte-wide pin-to-interrupt request assignment

PORT Functional Description

The number of ports and each's composition are defined in the processor data sheet. Each port has a dedicated set of MMR registers that control pin functions and operates in general-purpose I/O (GPIO) mode by default, as controlled by the port-specific PORT_FER register. Each bit in this register, as well as the other PORT MMRs, represents a specific GPIO pin on the specified port.

Input Mode, Output Mode, and Open-Drain Mode of GPIO Operation

At reset, every GPIO pin defaults to input mode with the input drivers disabled. To enable any GPIO input driver, set the bits corresponding to the individual pins in the appropriate input enable register (PORT_INEN).

The GPIO output drivers are enabled by setting the corresponding bits in the direction registers (PORT_DIR).

The PORT can use every GPIO in open-drain mode by clearing the respective bit in the PORT_DATA register or setting the respective bit in the PORT_DATA_CLR register. Then, set the corresponding bit in the PORT_INEN register. Read from the PORT_DATA register to obtain the status from the pin.

Port Multiplexing Controlled on Pin-by-Pin Basis

Each port has two dedicated MMRs that control the port multiplexing, the 16-bit function enable (PORT_FER) registers and the 32-bit port multiplexing (PORT_MUX) registers.

All Port Pins Provide Interrupt Functionality

Pin interrupts are completely decoupled from GPIO functionality. Pins are connected to the system event controller (SEC) via the PINTx modules, each of which is configurable in terms of which port pins are sensed for interrupt generation.

ADSP-SC59x PORT Register List

The PORT module (PORT) regulates the use of the multiplexable processor pins. Every port pin can operate in general-purpose I/O (GPIO) mode or as an alternate function. This GPIO operation is the default after processor reset and is controlled by a set of registers that control GPIO functionality. Every bit in these registers represents a certain GPIO pin of a specific port. For more information on PORT functionality, see the PORT register descriptions.

Table 13-1: ADSP-SC59x PORT Register List

Name	Description
PORT_DATA	Port x GPIO Data Register
PORT_DATA_CLR	Port x GPIO Data Clear Register
PORT_DATA_SET	Port x GPIO Data Set Register
PORT_DATA_TGL	Port x GPIO Output Toggle Register
PORT_DIR	Port x GPIO Direction Register
PORT_DIR_CLR	Port x GPIO Direction Clear Register
PORT_DIR_SET	Port x GPIO Direction Set Register
PORT_FER	Port x Function Enable Register
PORT_FER_CLR	Port x Function Enable Clear Register
PORT_FER_SET	Port x Function Enable Set Register
PORT_INEN	Port x GPIO Input Enable Register

ADSP-SC59x PINT Register List

The Pin Interrupt module (PINT) controls the pin-to-interrupt assignment in a byte-wide manner. The pin-interrupt assignment registers do not consist of 32 individual bits. They consist of four control bytes, each functioning as a multiplexer control. For more information, see the PINT register descriptions.

All PINT registers are 32 bits wide and can be accessed by 32-bit load/store instructions. They also support 16-bit operation where the upper 16 bits are ignored and the application uses the lower 16 bits only. Consequently, all PINT registers support 32-bit accesses as well as 16-bit accesses for the lower half words. Applications may use faster 16-bit accesses as long as they do not require functionality of upper register halves.

PORT Architectural Concepts

These sections describe in more detail how the PORT module connects externally to pins and internally to the MMR bus. Ports are named alphabetically beginning with A.

- Internal Interfaces
- External Interfaces
- GPIO Pin Function
- Port Multiplexing Control

Internal Interfaces

All of the pin multiplexing, GPIO, and pin interrupt control block MMRs can be accessed through the MMR bus. There is no DMA support. Each of the pin interrupt (PINTx) modules has its own dedicated interrupt request output signal that connects directly to the system event controller (SEC).

External Interfaces

The pin multiplexing hardware can be seen as a layer between the on-chip peripherals and the silicon pads connecting to the physical pins/balls or the package, as controlled by the PORT unit.

GPIO Pin Function

By default, the PORT sets every GPIO pin to input mode. The input drivers are not enabled, which avoids the need for unnecessary current sinks and external termination resistors on unused pins.

Input Mode

The default mode of every GPIO pin after reset is input mode, but the input drivers are not enabled. To enable GPIO input drivers, set the bits corresponding to the PORT pins in the appropriate input enable register (`PORT_INEN`). When enabled, a read from the `PORT_DATA` register returns the logical state of the input pins. However, the input signal does not overwrite the state of the internal flip-flop used for providing output to the same pin. Only software can alter the state. If the input driver is enabled, a write to the `PORT_DATA` register can alter the state of the flip-flop, but the change cannot be read back.

Output Mode

Any GPIO pin can be configured for output mode. The GPIO output drivers are enabled by setting the bits corresponding to the PORT pins in the appropriate direction register. The PORT implements direction registers as a pair of write-1-to-set (W1S) and write-1-to-clear (W1C) MMRs called `PORT_DIR_SET` and `PORT_DIR_CLR`, respectively. As such, software can alter the direction of the signal flow on individual GPIO pins without impacting other GPIOs on the same port.

Both the `PORT_DIR_SET` and `PORT_DIR_CLR` registers return the same value when read, and a logical 1 indicates an enabled output. The `PORT_DATA` registers control the state of output pins. A logical 0 drives the output low while a logical 1 drives the output high.

While writes to the `PORT_DATA` register can alter all of the GPIOs on a specific port at once, there are also a pair of W1S and W1C MMRs called `PORT_DATA_SET` and `PORT_DATA_CLR`, respectively. These registers enable

the manipulation of individual GPIO outputs. The state of the outputs can be obtained by reading the PORT_DATA registers. Because the state of the GPIO output can be controlled before the output driver is enabled, set or clear the internal flip-flop first by programming this register to avoid volatile levels on the output pin.

Trigger Toggle Mode

Any GPIO pin that has been configured for output mode can be toggled using a trigger input from the Trigger Routing Unit (TRU). To enable this functionality for a particular GPIO, set the appropriate bit in the PORT_TRIG_TGL register. Any subsequent trigger for the designated port causes all GPIO outputs set in the PORT_TRIG_TGL register to toggle.

To avoid unpredictable behavior, do not set, clear, or toggle the PORT_DATA, PORT_DATA_SET, PORT_DATA_CLR, or PORT_DATA_TGL registers when the GPIO output has the corresponding PORT_TRIG_TGL bit set. To change the state of the GPIO output using one of these registers, first clear the corresponding bit in the PORT_TRIG_TGL register.

Open-Drain Mode

Every GPIO can also be used in open-drain mode. First, either clear the respective bit in the PORT_DATA register or set the respective bit in the PORT_DATA_CLR register. Then, set the appropriate bit in the PORT_INEN register. Read from the PORT_DATA register to return the status from the pin rather than the state of the internal flip-flop.

By toggling the output driver through the PORT_DIR_SET and PORT_DIR_CLR register pair, the output signal can be pulled low or three-stated, as required. The polarity of the driven signal can be inverted when the internal flip-flop is set. When using a GPIO port in open-drain mode, take care to not exceed the V_{IH} operating condition associated with the respective pins.

Port Multiplexing Control

To configure pins properly, consult the processor data sheet to determine which bits in the PORT_FER and PORT_MUX register map to the pin of interest, and then set these registers appropriately for the desired function.

After reset, all port pins default to GPIO input mode with their output and input drivers disabled. As a result, all unused port pins can be left unconnected. Disabled pins appear as a high impedance to external circuits.

Each port has two dedicated MMRs that control the port multiplexing, the 16-bit function enable (PORT_FER) registers and the 32-bit port multiplexing (PORT_MUX) registers.

The function enable register specifies whether the pin is used as a GPIO pin or allocated for use by a specific peripheral, but it does not specify what the peripheral function is. Each bit in the 16-bit PORT_FER register corresponds to an individual port pin. For example, if bit 1 (PA1) of the PORTA_FER register is cleared, the PA_01 pin is configured as a GPIO. When set, one of the available peripheral functions becomes active on the PA_01 pin instead.

Pairs of bits in the PORT_MUX register control the multiplexing between the peripheral functions available to an individual pin, as some PORT pins provide up to four possible peripheral functions.

Refer to the Signal Muxing table in the data sheet for the specific PORT_MUX settings.

PORT Event Control

The following sections describe event generation in the PORT module.

PORT Interrupt Signals

The pin interrupts are decoupled from GPIO functionality, providing the following advantages.

- Flexible mapping scheme enables pins from up to four different ports to be grouped into one common interrupt scheme.
- Interrupt requests work on input and output pins regardless of whether the pin is functioning as a GPIO or a peripheral.

The processor has a number of interrupt channels dedicated to pin interrupts, managed by a set of pin interrupt (PINTx) blocks. Each PINTx block can sense up to 32 GPIO pins, as described in the following list and figure.

- PINT0 can sense pin activity on PORTA and PORTB
- PINT1 can sense pin activity on PORTB and PORTC
- PINT2 can sense pin activity on PORTC and PORTD
- PINT3 can sense pin activity on PORTD and PORTE
- PINT4 can sense pin activity on PORTE and PORTF
- PINT5 can sense pin activity on PORTF and PORTG
- PINT6 can sense pin activity on PORTG and PORTH
- PINT7 can sense pin activity on PORTH and PORTI

The processor supports both 32-bit and 16-bit peripheral bus accesses to PINTx registers.

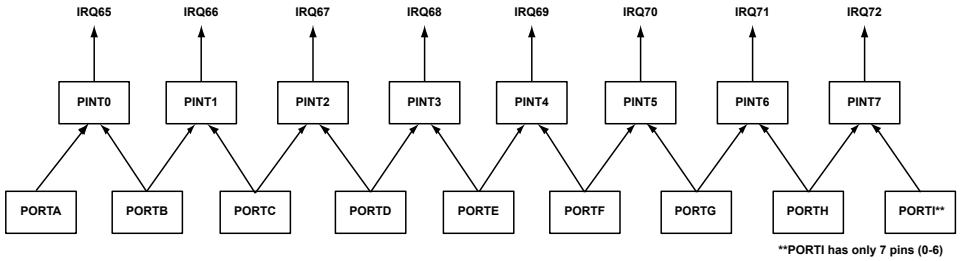

Figure 13-2: GPIO to PINTx Assignment

Pins connect to the PINTx module and then to the system event controller (SEC), as shown in the ***PINTx Block Diagram***.

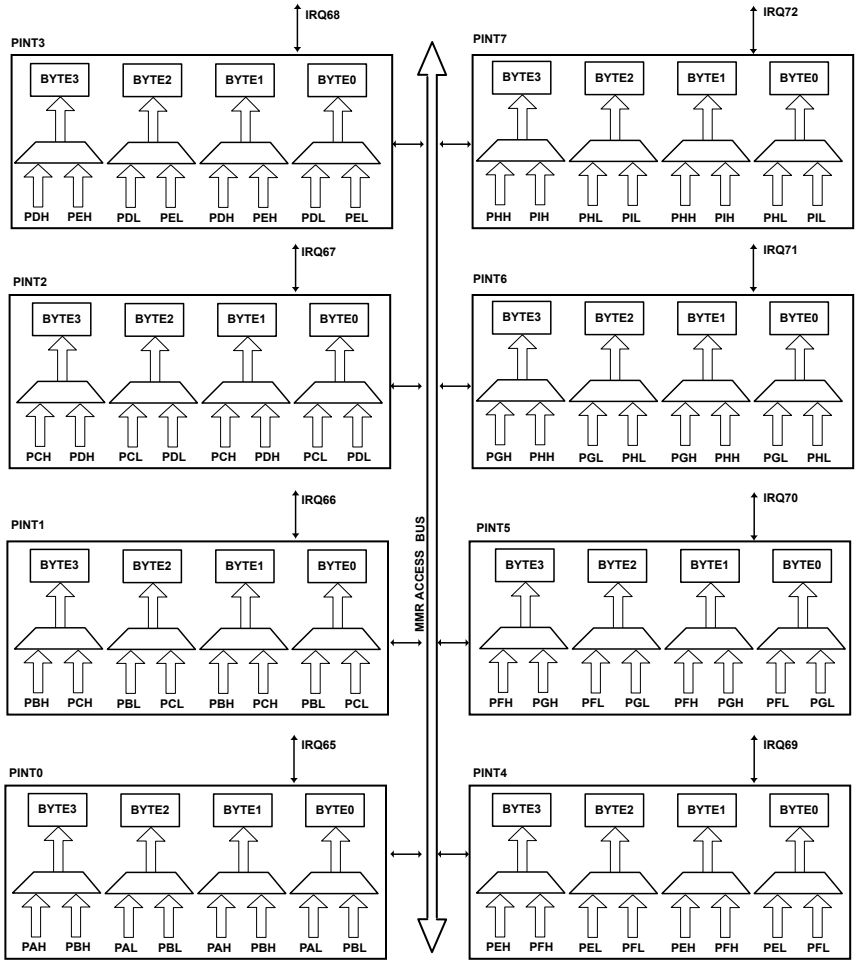

Figure 13-3: PINTx Block Diagram

As shown in the ***PINTx Block Diagram***, each port is subdivided into two 8-pin half ports, upper (`PxH`) and lower (`PxL`). The `PINT_ASSIGN` registers control the 8-bit multiplexers associated with these half ports, where the lower half units (eight pins) can be forwarded to either byte 0 or byte 2 of the PINTx blocks, and the upper half units (eight pins) can be forwarded to either byte 1 or byte 3 of the PINTx blocks.

When a half port is assigned to a byte in any PINTx block, the state of the eight pins appears in the `PINT_PINSTATE` register, regardless of whether the pin is enabled for GPIO or peripheral functions (input or output). When neither the input nor output drivers of the pin are enabled, the pin state is read as zero. The `PINT_PINSTATE` register reports the inverted state of the pin when the `PINT_INV_SET` register activates the signal inverter. The inverter can be enabled on an individual bit-by-bit basis. Each bit in the `PINT_INV_SET`/`PINT_INV_CLR` register pair represents a pin signal.

By default, PORT interrupt request generation is level-sensitive, and an interrupt request occurs when the enabled pin is sensed as active high. Use the `PINT_EDGE_SET` register to change the interrupt request genearion scheme to instead be edge-sensitive (rising edge generates the interrupt request). Use the `PINT_INV_SET` register to invert the polarity such that the PINTx block generates the interrupt request on active-low signals or falling edges.

The PINTx modules also assist when both signal edges must generate unique interrupt requests. If two different interrupt requests are required, the PINT_ASSIGN registers can route a single input signal to two different PINTx blocks, where one block inverts the signal in the PINT_INV_SET register and the other one does not. In this fashion, a unique software routine is associated with the hardware PINTx block that is generating the unique interrupt request for each signal edge. When both signal edges can be serviced by the same interrupt request, each half port can be routed to two separate bytes within a single PINTx block using the PINT_ASSIGN register, and then one of the half ports needs to have the inversion enabled in the PINT_INV_SET register. The servicing software routine can then detect from the PINT_LATCH register whether a falling, rising, or both edges have occurred.

Regardless of whether level-sensitive or edge-sensitive mode is used, the hardware always latches an interrupt request. Latched signals can be read from the PINT_LATCH registers. Only a software or hardware reset clears the latches. To clear the latch, a W1C operation must be performed to the PINT_REQ or PINT_LATCH register. When in level-sensitive mode, the interrupt request remains asserted if the pin state does not change by the time the interrupt service routine exits.

Because every PINTx block groups up to 32 pin signals, the PINT_MSK_SET/ PINT_MSK_CLR register pair can control which of the signals can request an interrupt at the system level. Software can interrogate the PINT_REQ register for signaling pins. The PINT_REQ bits represent a logical AND between the mask and the latch. When any of these bits is set, the block output interrupt request is asserted.

PORT Programming Model

The ***GPIO Programming Model Flow (Part 1)***, ***GPIO Programming Model Flow (Part 2)***, and ***GPIO Programming Model Flow (Part 3)*** figures show the programming model for the general-purpose ports. This programming includes the GPIO input and output operation, open-drain mode, and the pin interrupt PINTx modules.

NOTE: These process flow diagrams connect where call-out letters appear. For example, call-out A in the ***GPIO Programming Model Flow (Part 1)*** diagram connects to call-out A in the ***GPIO Programming Model Flow (Part 2)*** diagram.

The following flowcharts describe the processes for setting up pins for various functions. Begin the process from the start label in the ***GPIO Programming Model Flow (Part 1)*** figure. The first decision (GPIO or peripheral) determines how to program the PORT_FER register. Set the bit(s) corresponding to the pin(s) to 1 to enable peripheral functionality or to 0 to enable GPIO mode. For more information on setting up for peripheral functions, refer to Port Multiplexing Control.

If the pin is to be a GPIO pin, a subsequent series of decisions must be made that will impact how the PORT_DATA, PORT_POL, PORT_DIR, and PORT_INEN configuration registers must be programmed. Depending on the type of GPIO pin desired, some configurations do not apply and can have different meanings. The following paragraphs briefly describe the function of the different settings for each of the pin functions in the input, output, and open-drain GPIO modes. It is a best practice to use the SET or CLR versions of the PORT registers, where applicable, to effect changes on a pin-by-pin basis rather than on the full port.

For output mode, first clear the PORT_DATA register to set all the pins low. Then write the PORT_DIR register to define the direction of each pin (set the bits associated with the desired output pins to 1). In output mode, the other registers are not significant. The ***GPIO Programming Model Flow (Part 1)*** chart shows this flow starting at label 2.

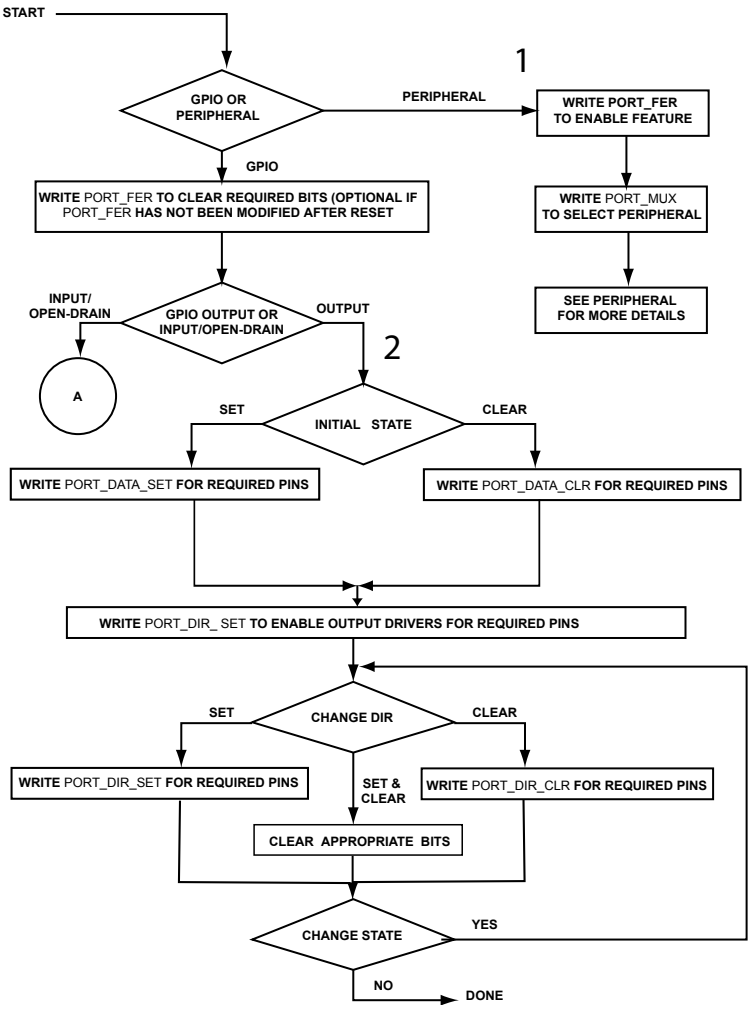

Figure 13-4: GPIO Programming Model Flow (Part 1)

For input mode, first decide the polarity for each pin using the PORT_POL register. Program the PORT_DIR register to define the appropriate pins as inputs (write a 0 to the bit location associated with the pin). If interrupt requests are desired, configure the PINT module as shown in the ***GPIO Programming Model Flow (Part 3)*** figure starting at label B. Finally, write the PORT_INEN register to enable the associated input drivers. The ***GPIO Programming Model Flow (Part 2)*** chart shows this entire flow starting at label 3.

For open-drain mode, set all pins low by clearing the PORT_DATA register. Then, use the PORT_INEN register to enable the appropriate input drivers. Set the PORT_DIR register in this mode to indicate whether the pin is in an active state or not (active being 0). The ***GPIO Programming Model Flow (Part 2)*** chart shows this flow starting at label 4.

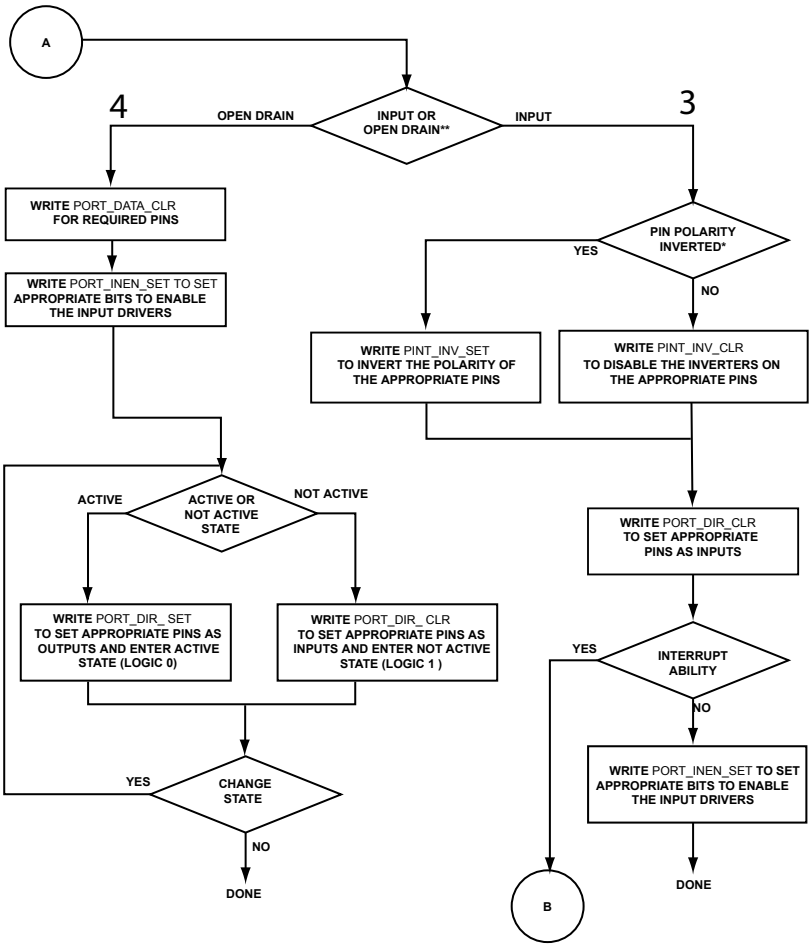

Figure 13-5: GPIO Programming Model Flow (Part 2)

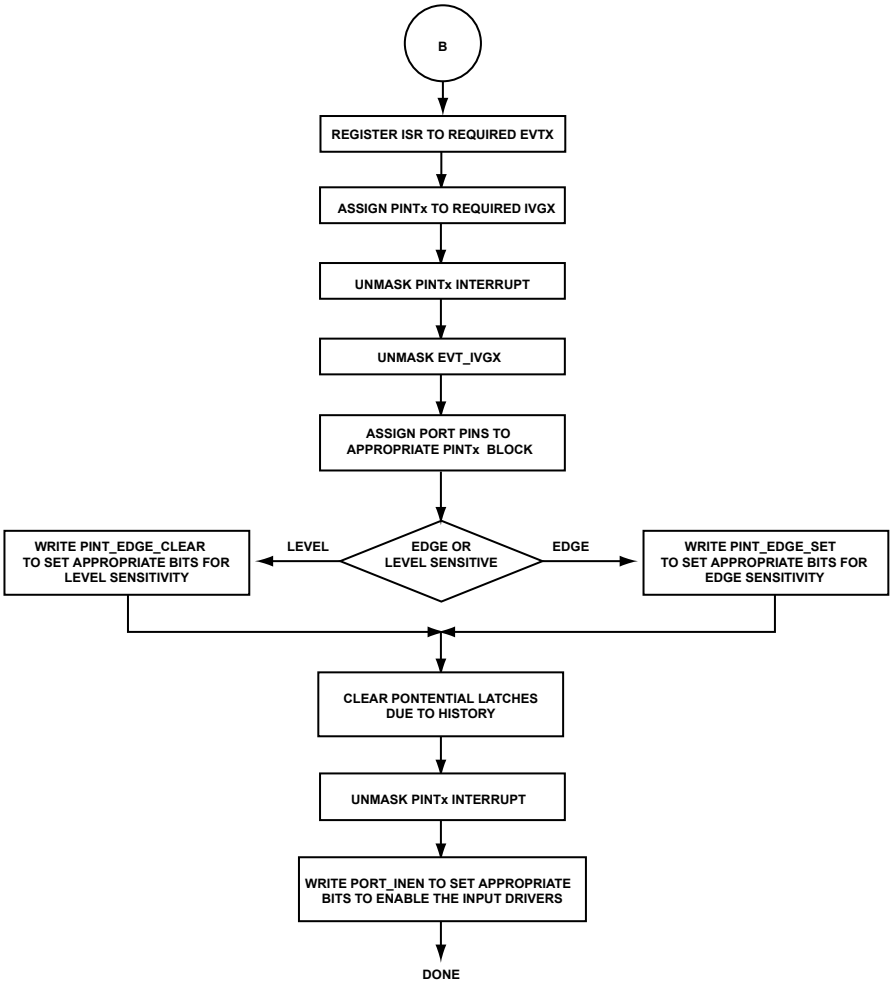

Figure 13-6: GPIO Programming Model Flow (Part 3)

Programmable Pull-up Resistors for PORT and DAI

There are programmable weak pull-up resistors for DAI and PORT pins. These resistors can be enabled or disabled by configuring the `PADS_DAI[n]_PUE`, `PADS_PORT[n]_PUE`, `PADS_DAI[n]_PDE`, and `PADS_PORT[n]_PDE` registers.

For DAI pins, if both the `PADS_DAI[n]_PDE` and `PADS_DAI[n]_PUE` registers are set (=1) for the same pin, then the `PADS_DAI[n]_PDE` register takes priority over `PADS_DAI[n]_PUE` register.

NOTE: For unused PORT/DAI pins, ensure that any unused pin does not go to floating state. Clear (=0) the PUD bit of that pin.

Refer to the ***DAI Pull-up Resistor States*** table. To enable the pull-up on a DAI pin, the `PADS_DAI[n]_PDE.PDE` bit must be cleared (=0) ***AND*** the `PADS_DAI[n]_PUE.PUE` bit must be set (=1). To disable the pull-up on a DAI pin, the `PADS_DAI[n]_PDE.PDE` bit must be set (=1) and `PADS_DAI[n]_PUE.PUE` bit can be any value.

Table 13-9: DAI Pull-up Resistor States

PADS_DAI[n]_PUE.PUE	PADS_DAI[n]_PDE.PDE	Pull-up Resistor State
0	0	Disabled
0	1	Disabled
1	0	Enabled
1	1	Disabled

Similarly, for PORT pins, if both PADS_PORT[n]_PDE.PDE and PADS_PORT[n]_PUE registers are set (=1) for the same pin, then the PADS_PORT[n]_PDE.PDE register takes priority over PADS_PORT[n]_PUE register.

Refer to the ***PORT Pull-up Resistor States*** table. To enable the pull-up on a PORT pin, the PADS_PORT[n]_PDE.PDE bit must be cleared (=0) ***AND*** the PADS_PORT[n]_PUE.PUE bit must be set (=1). To disable the pull-up on a PORT pin, PADS_DAI[n]_PDE.PDE bit must be set (=1) and PADS_PORT[n]_PUE.PUE bit can be any value.

Table 13-10: PORT Pull-up Resistor States

PADS_PORT[n]_PUE.PUE	PADS_PORT[n]_PDE.PDE	Pull-up Resistor State
0	0	Disabled
0	1	Disabled
1	0	Enabled
1	1	Disabled

NOTE: Refer to the ***Designer Quick Reference*** section of the data sheet for handling unused PORT and DAI pins.

NOTE: The internal pull-up on GPIO pins are very weak. These pins hold a defined logic level when pins are left floating. The internal pull-up resistance varies over a wide range. If an application needs a specified pull-up on the pin, use an external resistor.

NOTE: For unused PORT/DAI pins, ensure that any unused pin does not go to floating state. Clear (=0) the PUD bit of that pin.

ADSP-SC59x PORT Register Descriptions

The General-Purpose Input/Output Port (PORT) contains the following registers.

Table 13-11: ADSP-SC59x PORT Register List

Name	Description
PORT_DATA	Port x GPIO Data Register
PORT_DATA_CLR	Port x GPIO Data Clear Register

Table 13-11: ADSP-SC59x PORT Register List (Continued)

Name	Description
PORT_DATA_SET	Port x GPIO Data Set Register

PORT_POL_SET	Port x GPIO Polarity Invert Set Register
PORT_TRIG_TGL	Port x GPIO Trigger Toggle Register

Port x GPIO Data Register

The operation of the PORT_DATA register depends on whether the bit/pin is in output mode or input mode. In both modes, a set bit in the PORT_DATA register corresponds to a signal high on a GPIO pin. A cleared bit in the PORT_DATA register corresponds to a signal low on a GPIO pin.

The PORT_DATA, PORT_DATA_SET, and PORT_DATA_CLR registers control the state of GPIO pins in output mode. To enable output mode (and output drivers), use the PORT_DIR_SET and PORT_DIR_CLR registers.

Writes to the PORT_DATA register affect the state of all pins of the port that are in output mode. To set or clear specific pins without impacting other pins of the port, use the PORT_DATA_SET and PORT_DATA_CLR registers.

When the GPIO pins are in input mode (input driver is enabled with the PORT_INEN register), reads from the PORT_DATA, PORT_DATA_SET, and PORT_DATA_CLR registers return the state of the respective GPIO pins.

Note that when the input driver is not enabled, reads from the PORT_DATA, PORT_DATA_SET, and PORT_DATA_CLR registers return the value previously written to the registers.

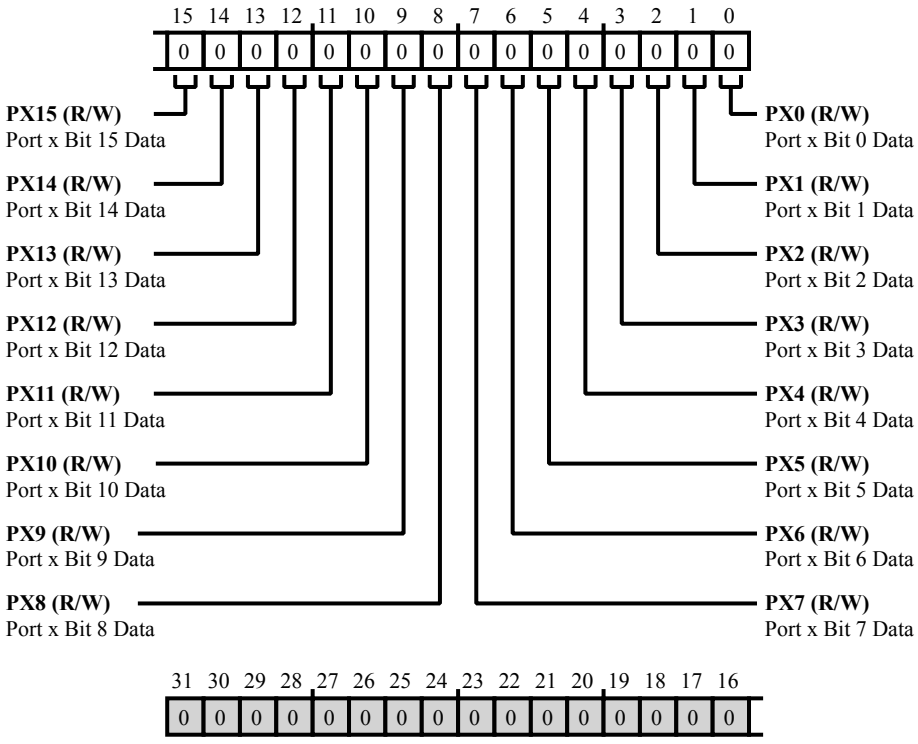

Figure 13-7: PORT_DATA Register Diagram

Table 13-12: PORT_DATA Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	PX15	Port x Bit 15 Data. The PORT_DATA.PX15 bit indicates a signal on a GPIO pin.	
		0	Signal Low
		1	Signal High

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W)	PX8	Port x Bit 8 Data. The PORT_DATA.PX8 bit indicates a signal on a GPIO pin.	
		0	Signal Low
		1	Signal High
7 (R/W)	PX7	Port x Bit 7 Data. The PORT_DATA.PX7 bit indicates a signal on a GPIO pin.	
		0	Signal Low
		1	Signal High
6 (R/W)	PX6	Port x Bit 6 Data. The PORT_DATA.PX6 bit indicates a signal on a GPIO pin.	
		0	Signal Low
		1	Signal High
5 (R/W)	PX5	Port x Bit 5 Data. The PORT_DATA.PX5 bit indicates a signal on a GPIO pin.	
		0	Signal Low
		1	Signal High
4 (R/W)	PX4	Port x Bit 4 Data. The PORT_DATA.PX4 bit indicates a signal on a GPIO pin.	
		0	Signal Low
		1	Signal High
3 (R/W)	PX3	Port x Bit 3 Data. The PORT_DATA.PX3 bit indicates a signal on a GPIO pin.	
		0	Signal Low
		1	Signal High
2 (R/W)	PX2	Port x Bit 2 Data. The PORT_DATA.PX2 bit indicates a signal on a GPIO pin.	
		0	Signal Low
		1	Signal High

Table 13-12: PORT_DATA Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W)	PX1	Port x Bit 1 Data. The `PORT_DATA.PX1` bit indicates a signal on a GPIO pin.	
		0	Signal Low
		1	Signal High
0 (R/W)	PX0	Port x Bit 0 Data. The `PORT_DATA.PX0` bit indicates a signal on a GPIO pin.	
		0	Signal Low
		1	Signal High

Port x GPIO Data Clear Register

The PORT_DATA_CLR register operates differently for port bits/pins, depending on whether the bit/pin is output mode or input mode. For more information, see the PORT_DATA register description.

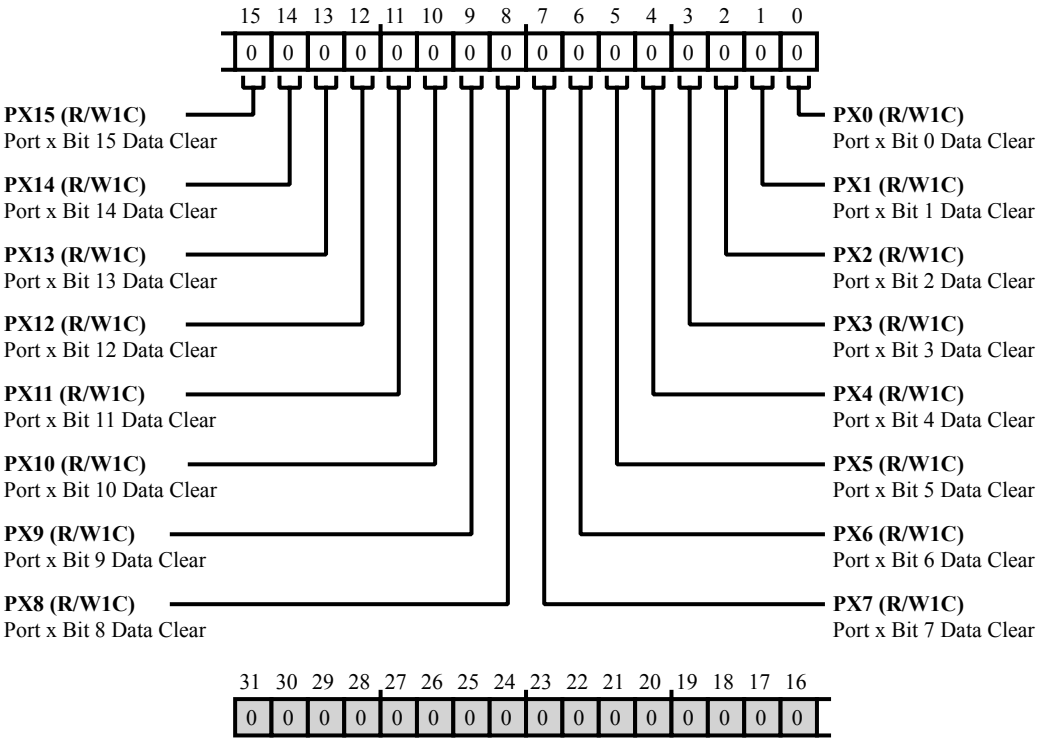

Figure 13-8: PORT_DATA_CLR Register Diagram

Table 13-13: PORT_DATA_CLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W1C)	PX15	Port x Bit 15 Data Clear. The PORT_DATA_CLR.PX15 bit clears the pin without impacting other pins of the port.	
		0	No Effect
		1	Clear Bit. Write 1 for signal low in output mode.
14 (R/W1C)	PX14	Port x Bit 14 Data Clear. The PORT_DATA_CLR.PX14 bit clears the pin without impacting other pins of the port.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Clear Bit. Write 1 for signal low in output mode.

Table 13-13: PORT_DATA_CLR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
13 (R/W1C)	PX13	Port x Bit 13 Data Clear. The `PORT_DATA_CLR.PX13` bit clears the pin without impacting other pins of the port.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Clear Bit. Write 1 for signal low in output mode.
12 (R/W1C)	PX12	Port x Bit 12 Data Clear. The `PORT_DATA_CLR.PX12` bit clears the pin without impacting other pins of the port.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Clear Bit. Write 1 for signal low in output mode.
11 (R/W1C)	PX11	Port x Bit 11 Data Clear. The `PORT_DATA_CLR.PX11` bit clears the pin without impacting other pins of the port.	
		0	No Effect
		1	Clear Bit. Write 1 for signal low in output mode.
10 (R/W1C)	PX10	Port x Bit 10 Data Clear. The `PORT_DATA_CLR.PX10` bit clears the pin without impacting other pins of the port.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Clear Bit. Write 1 for signal low in output mode.
9 (R/W1C)	PX9	Port x Bit 9 Data Clear. The `PORT_DATA_CLR.PX9` bit clears the pin without impacting other pins of the port.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Clear Bit. Write 1 for signal low in output mode.
8 (R/W1C)	PX8	Port x Bit 8 Data Clear. The `PORT_DATA_CLR.PX8` bit clears the pin without impacting other pins of the port.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Clear Bit. Write 1 for signal low in output mode.

Table 13-13: PORT_DATA_CLR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W1C)	PX7	Port x Bit 7 Data Clear. The `PORT_DATA_CLR.PX7` bit clears the pin without impacting other pins of the port.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Clear Bit. Write 1 for signal low in output mode.
6 (R/W1C)	PX6	Port x Bit 6 Data Clear. The `PORT_DATA_CLR.PX6` bit clears the pin without impacting other pins of the port.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Clear Bit. Write 1 for signal low in output mode.
5 (R/W1C)	PX5	Port x Bit 5 Data Clear. The `PORT_DATA_CLR.PX5` bit clears the pin without impacting other pins of the port.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Clear Bit. Write 1 for signal low in output mode.
4 (R/W1C)	PX4	Port x Bit 4 Data Clear. The `PORT_DATA_CLR.PX4` bit clears the pin without impacting other pins of the port.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Clear Bit. Write 1 for signal low in output mode.
3 (R/W1C)	PX3	Port x Bit 3 Data Clear. The `PORT_DATA_CLR.PX3` bit clears the pin without impacting other pins of the port.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Clear Bit. Write 1 for signal low in output mode.
2 (R/W1C)	PX2	Port x Bit 2 Data Clear. The `PORT_DATA_CLR.PX2` bit clears the pin without impacting other pins of the port.	
		0	No Effect Write 0 has no effect in output mode.
		1	Clear Bit Write 1 for signal low in output mode.

Table 13-13: PORT_DATA_CLR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W1C)	PX1	Port x Bit 1 Data Clear. The `PORT_DATA_CLR.PX1` bit clears the pin without impacting other pins of the port.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Clear Bit. Write 1 for signal low in output mode.
0 (R/W1C)	PX0	Port x Bit 0 Data Clear. The `PORT_DATA_CLR.PX0` bit clears the pin without impacting other pins of the port.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Clear Bit. Write 1 for signal low in output mode.

Port x GPIO Data Set Register

The PORT_DATA_SET register operates differently for port bits/pins, depending on whether the bit/pin is output mode or input mode. For more information, see the PORT_DATA register description.

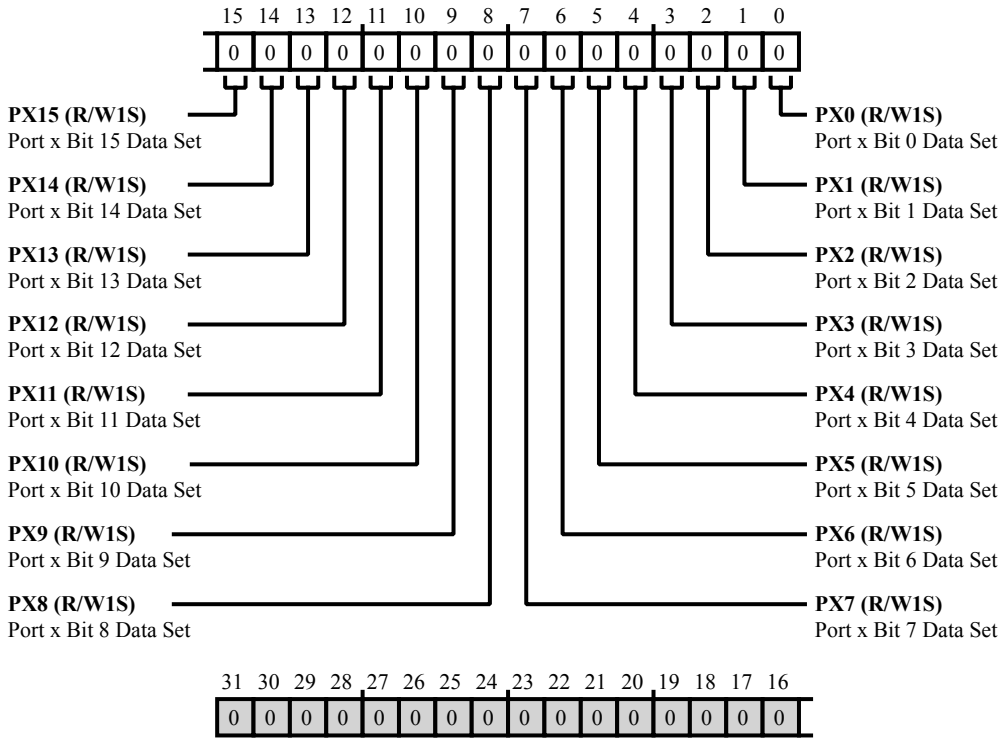

Figure 13-9: PORT_DATA_SET Register Diagram

Table 13-14: PORT_DATA_SET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W1S)	PX15	Port x Bit 15 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit. Write 1 for signal high in output mode.
14 (R/W1S)	PX14	Port x Bit 14 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit. Write 1 for signal high in output mode.
13 (R/W1S)	PX13	Port x Bit 13 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit. Write 1 for signal high in output mode.

Table 13-14: PORT_DATA_SET Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W1S)	PX12	Port x Bit 12 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit. Write 1 for signal high in output mode.
11 (R/W1S)	PX11	Port x Bit 11 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit.
10 (R/W1S)	PX10	Port x Bit 10 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit. Write 1 for signal high in output mode.
9 (R/W1S)	PX9	Port x Bit 9 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit. Write 1 for signal high in output mode.
8 (R/W1S)	PX8	Port x Bit 8 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit. Write 1 for signal high in output mode.
7 (R/W1S)	PX7	Port x Bit 7 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit. Write 1 for signal high in output mode.
6 (R/W1S)	PX6	Port x Bit 6 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit. Write 1 for signal high in output mode.
5 (R/W1S)	PX5	Port x Bit 5 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit. Write 1 for signal high in output mode.
4 (R/W1S)	PX4	Port x Bit 4 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit. Write 1 for signal high in output mode.
3 (R/W1S)	PX3	Port x Bit 3 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit. Write 1 for signal high in output mode.

Table 13-14: PORT_DATA_SET Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W1S)	PX2	Port x Bit 2 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit. Write 1 for signal high in output mode.
1 (R/W1S)	PX1	Port x Bit 1 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit. Write 1 for signal high in output mode.
0 (R/W1S)	PX0	Port x Bit 0 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit. Write 1 for signal high in output mode.

Port x GPIO Output Toggle Register

The PORT_DATA_TGL register permits toggling the state of output GPIO pins. Setting bits in the PORT_DATA_TGL register affects the state of specific pins without impacting other pins of the port.

Reading the PORT_DATA_TGL returns the state of the PORT_DATA register output pin state, but does not return the input pin/signal state.

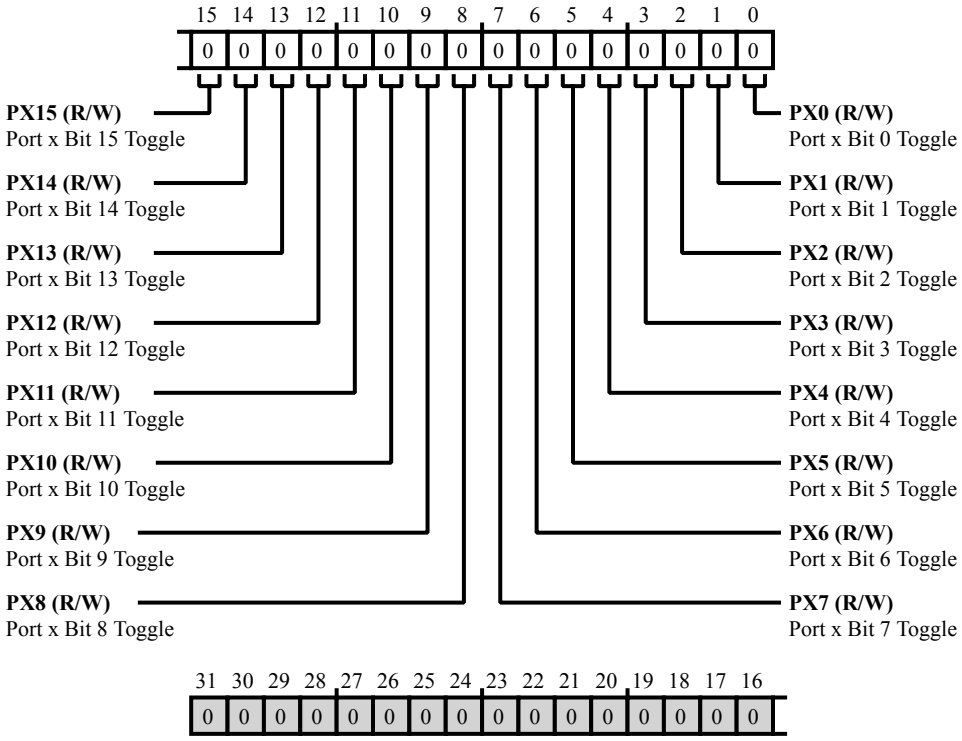

Figure 13-10: PORT_DATA_TGL Register Diagram

Table 13-15: PORT_DATA_TGL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	PX15	Port x Bit 15 Toggle. The PORT_DATA_TGL.PX15 bit toggles the output GPIO bit/pin state.	
		0	No Effect
		1	Toggle Bit.
14 (R/W)	PX14	Port x Bit 14 Toggle. The PORT_DATA_TGL.PX14 bit toggles the output GPIO bit/pin state.	
		0	No Effect
		1	Toggle Bit

		0	No Effect
		1	Toggle Bit
7 (R/W)	PX7	Port x Bit 7 Toggle. The PORT_DATA_TGL.PX7 bit toggles the output GPIO bit/pin state.	
		0	No Effect
		1	Toggle Bit

Table 13-15: PORT_DATA_TGL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6 (R/W)	PX6	Port x Bit 6 Toggle. The PORT_DATA_TGL.PX6 bit toggles the output GPIO bit/pin state.	
		0	No Effect
		1	Toggle Bit
5 (R/W)	PX5	Port x Bit 5 Toggle. The PORT_DATA_TGL.PX5 bit toggles the output GPIO bit/pin state.	
		0	No Effect
		1	Toggle Bit
4 (R/W)	PX4	Port x Bit 4 Toggle. The PORT_DATA_TGL.PX4 bit toggles the output GPIO bit/pin state.	
		0	No Effect
		1	Toggle Bit
3 (R/W)	PX3	Port x Bit 3 Toggle. The PORT_DATA_TGL.PX3 bit toggles the output GPIO bit/pin state.	
		0	No Effect
		1	Toggle Bit
2 (R/W)	PX2	Port x Bit 2 Toggle. The PORT_DATA_TGL.PX2 bit toggles the output GPIO bit/pin state.	
		0	No Effect
		1	Toggle Bit
1 (R/W)	PX1	Port x Bit 1 Toggle. The PORT_DATA_TGL.PX1 bit toggles the output GPIO bit/pin state.	
		0	No Effect
		1	Toggle Bit
0 (R/W)	PX0	Port x Bit 0 Toggle. The PORT_DATA_TGL.PX0 bit toggles the output GPIO bit/pin state.	
		0	No Effect
		1	Toggle Bit

Port x GPIO Direction Register

The PORT_DIR, PORT_DIR_SET, and PORT_DIR_CLR registers select output or input mode for GPIO pins and enable output drivers. Use the PORT_INEN, PORT_INEN_SET, and PORT_INEN_CLR registers to enable or disable input drivers.

Writes to the PORT_DIR register affect the state of all pins of the port. To select a direction for specific pins without impacting other pins of the port, use the PORT_DIR_SET and PORT_DIR_CLR registers.

Setting a bit in the PORT_DIR register enables output mode on the corresponding a GPIO pin. Clearing a bit in the PORT_DIR register disables output mode on the corresponding GPIO pin.

Input Mode - The default mode of every GPIO pin after reset is the input mode, but the input drivers are not enabled. To enable GPIO input drivers, set the corresponding bits in the PORT_INEN register. When enabled, a read from the PORT_DATA register returns the logical state of the input pin. The input signal does not overwrite the state of the bit used for the output case. That state can only be altered by software. If the input driver is enabled, a write to the PORT_DATA register can alter the state of the bit, but the change cannot be read back.

Output Mode - Any GPIO pin can be configured for output mode. The GPIO output drivers are enabled by setting the corresponding bits in the PORT_DIR, PORT_DIR_SET, or PORT_DIR_CLR registers. By using the PORT_DIR_SET and PORT_DIR_CLR registers, the direction of the signal flow of individual GPIO pins can be altered by separate software threads without mutually impacting other GPIOs on the same port. Both registers return the same value when read. Because the state of the GPIO output can already be controlled before the output driver is enabled, it is recommended to first set or clear the bit (using the PORT_DATA, PORT_DATA_SET, or PORT_DATA_CLR registers) to avoid any volatile levels on the output.

Open-Drain Mode - Every GPIO can also be used in open-drain mode. To accomplish this, first, clear the respective bit in the PORT_DATA or PORT_DATA_CLR register. Then, set the one bit in the PORT_INEN register. Reads from the PORT_DATA register then return the status from the pin and do not return the state of the internal flip-flop. By toggling the output driver through the PORT_DIR_SET and PORT_DIR_CLR register pair, the output signal can be pulled low or three-stated as required. Note that the polarity of the driven signal can be inverted when the internal flip-flop is set instead. When a GPIO port is used in open-drain mode, take care to not exceed the V_{IH} operating condition associated with the respective pin.

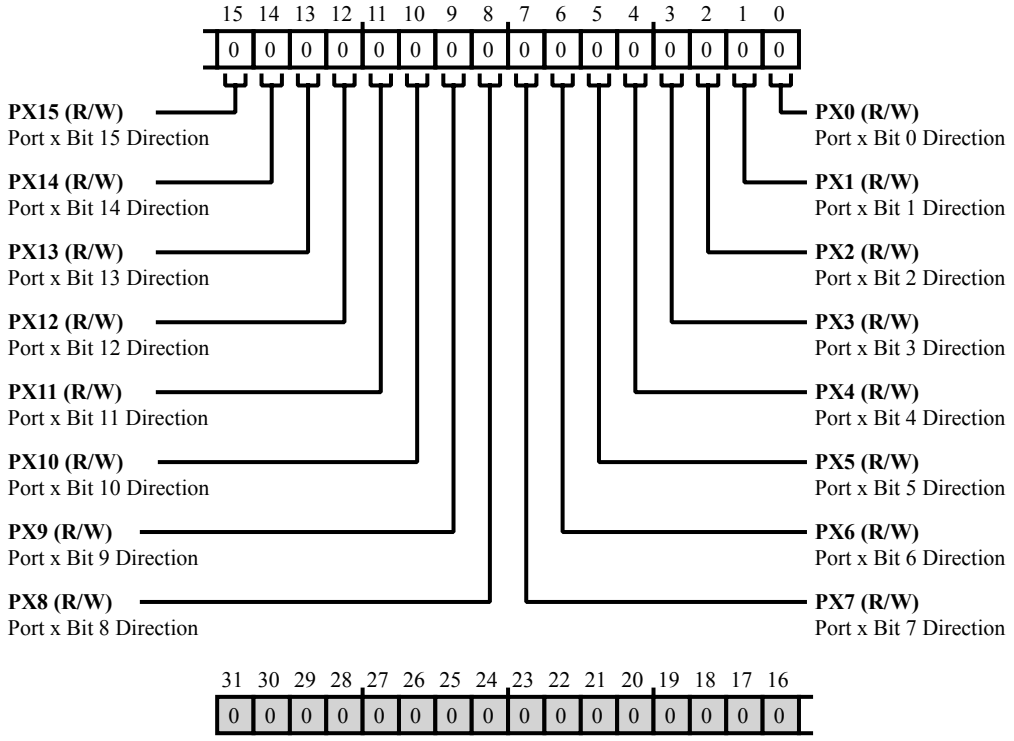

Figure 13-11: PORT_DIR Register Diagram

Table 13-16: PORT_DIR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	PX15	Port x Bit 15 Direction.	
		0	Input mode. The output driver is disabled.
		1	Output mode. The output driver is enabled.
14 (R/W)	PX14	Port x Bit 14 Direction.	
		0	Input mode. The output driver is disabled.
		1	Output mode. The output driver is enabled.
13 (R/W)	PX13	Port x Bit 13 Direction.	
		0	Input mode. The output driver is disabled.
		1	Output mode. The output driver is enabled.
12 (R/W)	PX12	Port x Bit 12 Direction.	
		0	Input mode. The output driver is disabled.
		1	Output mode. The output driver is enabled.

Table 13-16: PORT_DIR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W)	PX11	Port x Bit 11 Direction.	
		0	Input mode. The output driver is disabled.
		1	Output mode. The output driver is enabled.
10 (R/W)	PX10	Port x Bit 10 Direction.	
		0	Input mode. The output driver is disabled.
		1	Output mode. The output driver is enabled.
9 (R/W)	PX9	Port x Bit 9 Direction.	
		0	Input mode. The output driver is disabled.
		1	Output mode. The output driver is enabled.
8 (R/W)	PX8	Port x Bit 8 Direction.	
		0	Input mode. The output driver is disabled.
		1	Output mode. The output driver is enabled.
7 (R/W)	PX7	Port x Bit 7 Direction.	
		0	Input mode. The output driver is disabled.
		1	Output mode. The output driver is enabled.
6 (R/W)	PX6	Port x Bit 6 Direction.	
		0	Input mode. The output driver is disabled.
		1	Output mode. The output driver is enabled.
5 (R/W)	PX5	Port x Bit 5 Direction.	
		0	Input mode. The output driver is disabled.
		1	Output mode. The output driver is enabled.

Bit No. (Access)	Bit Name	Description/Enumeration	
6 (R/W1S)	PX6	Port x Bit 6 Direction Set. The PORT_DIR_SET.PX6 bit enables the output mode/driver for port x.	
		0	No Effect
		1	Enable output mode/driver
5 (R/W1S)	PX5	Port x Bit 5 Direction Set. The PORT_DIR_SET.PX5 bit enables the output mode/driver for port x.	
		0	No Effect
		1	Enable output mode/driver
4 (R/W1S)	PX4	Port x Bit 4 Direction Set. The PORT_DIR_SET.PX4 bit enables the output mode/driver for port x.	
		0	No Effect
		1	Enable output mode/driver
3 (R/W1S)	PX3	Port x Bit 3 Direction Set. The PORT_DIR_SET.PX3 bit enables the output mode/driver for port x.	
		0	No Effect
		1	Enable output mode/driver
2 (R/W1S)	PX2	Port x Bit 2 Direction Set. The PORT_DIR_SET.PX2 bit enables the output mode/driver for port x.	
		0	No Effect
		1	Enable output mode/driver
1 (R/W1S)	PX1	Port x Bit 1 Direction Set. The PORT_DIR_SET.PX1 bit enables the output mode/driver for port x.	
		0	No Effect
		1	Enable output mode/driver
0 (R/W1S)	PX0	Port x Bit 0 Direction Set. The PORT_DIR_SET.PX0 bit enables the output mode/driver for port x.	
		0	No Effect
		1	Enable output mode/driver

Port x Function Enable Register

The PORT_FER register bits indicate each port bit's operating mode: general purpose I/O mode or peripheral mode. After reset, all pins default to GPIO mode. Setting a bit in the PORT_FER registers enables a peripheral module to take ownership of the pin. The function enable bits impact output control only. Regardless of the setting of the function enable bits, both GPIO and peripherals can still sense the pin input. After a function is enabled, it is up to the PORT_MUX registers as to which peripheral takes control.

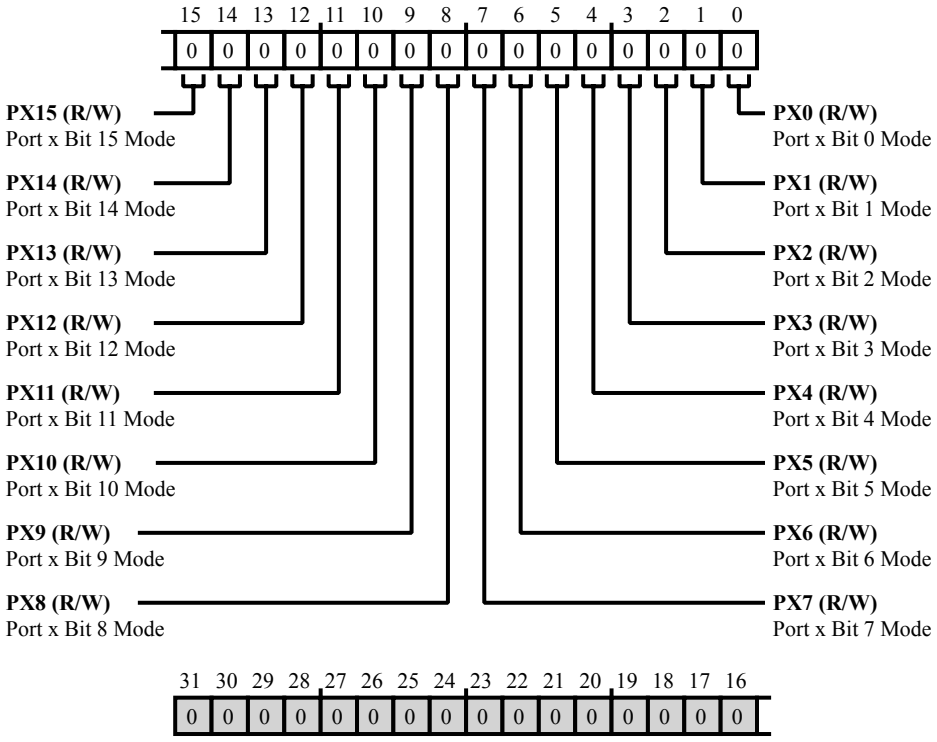

Figure 13-14: PORT_FER Register Diagram

Port x Function Enable Clear Register

The PORT_FER_CLR register permits enabling GPIO mode for each bit and corresponding GPIO pin. Writing 1 to a bit in PORT_FER_CLR enables GPIO mode for the corresponding pin.

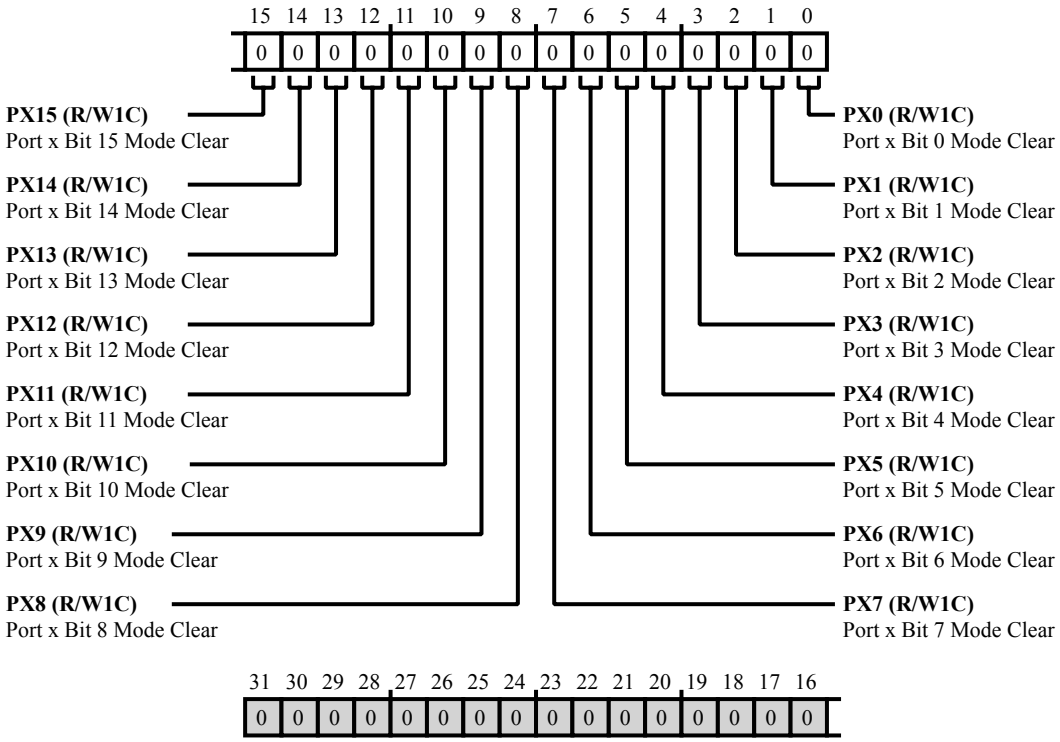

Figure 13-15: PORT_FER_CLR Register Diagram

Table 13-20: PORT_FER_CLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W1C)	PX15	Port x Bit 15 Mode Clear. The PORT_FER_CLR.PX15 bit enables GPIO mode.

		0	No Effect
		1	Set Bit for Peripheral Mode

Port x GPIO Input Enable Register

The PORT_INEN, PORT_INEN_SET, and PORT_INEN_CLR registers enable or disable input drivers, which are required for using a GPIO pin in input mode.

Writes to the PORT_INEN register affect the input drivers for all pins of the port. To set or clear specific pin drivers without impacting other pin drivers of the port, use the PORT_INEN_SET and PORT_INEN_CLR registers.

If the input is enabled, reads from the PORT_DATA, PORT_DATA_SET, or PORT_DATA_CLR registers return the state of the pins. However, the state of the output is not overwritten by the input. It is altered by software writes only. Input and output drivers can be enabled at the same time. In this case, a read of the data register returns the true value of the data register and not the pin state.

For more information, see the PORT_DATA register description and the PORT_DIR register description.

Port x GPIO Lock Register

The PORT_LOCK register enables (unlocks) or disables (locks) write access selectively for the PORT control registers.

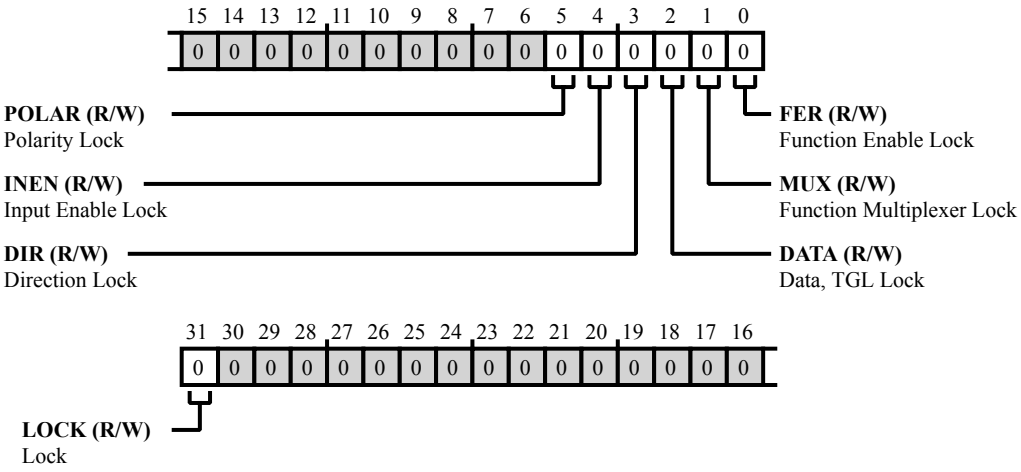

Figure 13-20: PORT_LOCK Register Diagram

Table 13-25: PORT_LOCK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock bit is set (SPU_CTL.GLCK bit =1) and the PORT_LOCK.LOCK bit is set, the PORT_LOCK register is read only (locked).	
		0	Unlock
		1	Lock
5 (R/W)	POLAR	Polarity Lock. The PORT_LOCK.POLAR disables write access to the PORT_POL, PORT_POL_SET, and PORT_POL_CLR registers.	
		0	Unlock POL
		1	Lock POL
4 (R/W)	INEN	Input Enable Lock. The PORT_LOCK.INEN disables write access to the PORT_INEN, PORT_INEN_SET, and PORT_INEN_CLR registers.	
		0	Unlock INEN
		1	Lock INEN

Table 13-25: PORT_LOCK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	DIR	Direction Lock. The PORT_LOCK.DIR disables write access to the PORT_DIR, PORT_DIR_SET, PORT_DIR_CLR registers.	
		0	Unlock DIR
		1	Lock DIR
2 (R/W)	DATA	Data, TGL Lock. The PORT_LOCK.DATA disables write access to the PORT_DATA, PORT_DATA_SET, PORT_DATA_CLR, and PORT_DATA_TGL registers.	
		0	Unlock DATA
		1	Lock DATA
1 (R/W)	MUX	Function Multiplexer Lock. The PORT_LOCK.MUX disables write accesses to the PORT_MUX register.	
		0	Unlock MUX
		1	Lock MUX
0 (R/W)	FER	Function Enable Lock. The PORT_LOCK.FER disables write access to the PORT_FER, PORT_FER_SET, and PORT_FER_CLR registers.	
		0	Unlock FER
		1	Lock FER

Port x Multiplexer Control Register

When a pin is in peripheral mode (not GPIO mode), the PORT_MUX register controls which peripheral takes ownership of a pin. Ports may have multiple, different peripheral functions. Two bits are required to describe every multiplexer on an individual pin-by-pin scheme. For example, bit 0 and bit 1 of the PORT_MUX register control the multiplexer of pin 0, bit 2 and bit 3 of PORT_MUX control the multiplexer of pin 1, and so on. The value of any PORT_MUX bit has no effect on the port pins when the associated bit in the PORT_FER register is 0 (selects GPIO mode). Even if a port has only one function, the PORT_MUX register is still present. For single function ports (no multiplexing is needed), leave the PORT_MUX bits at 0 (default). For all PORT_MUX bit fields: 00 = default/reset peripheral option, 01 = first alternate peripheral option, 10 = second alternate peripheral option, and 11 = third alternate peripheral option.

See the processor data sheet for details regarding the peripheral options associated with each port.

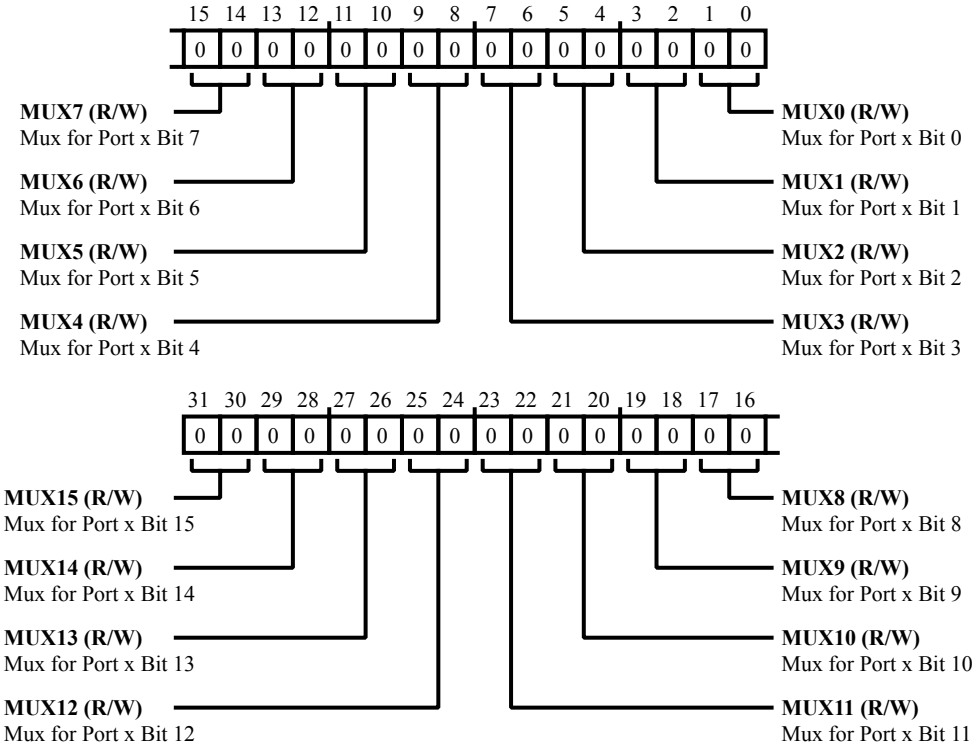

Figure 13-21: PORT_MUX Register Diagram

Table 13-26: PORT_MUX Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:30 (R/W)	MUX15	Mux for Port x Bit 15. The PORT_MUX.MUX15 bit provides multiplexer control for port x bit 15.

Table 13-26: PORT_MUX Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
29:28 (R/W)	MUX14	Mux for Port x Bit 14. The PORT_MUX.MUX14 bit provides multiplexer control for port x bit 14.
27:26 (R/W)	MUX13	Mux for Port x Bit 13. The PORT_MUX.MUX13 bit provides multiplexer control for port x bit 13.
25:24 (R/W)	MUX12	Mux for Port x Bit 12. The PORT_MUX.MUX12 bit provides multiplexer control for port x bit 12.
23:22 (R/W)	MUX11	Mux for Port x Bit 11. The PORT_MUX.MUX11 bit provides multiplexer control for port x bit 11.
21:20 (R/W)	MUX10	Mux for Port x Bit 10. The PORT_MUX.MUX10 bit provides multiplexer control for port x bit 10.
19:18 (R/W)	MUX9	Mux for Port x Bit 9. The PORT_MUX.MUX9 bit provides multiplexer control for port x bit 9.
17:16 (R/W)	MUX8	Mux for Port x Bit 8. The PORT_MUX.MUX8 bit provides multiplexer control for port x bit 8.
15:14 (R/W)	MUX7	Mux for Port x Bit 7. The PORT_MUX.MUX7 bit provides multiplexer control for port x bit 7.
13:12 (R/W)	MUX6	Mux for Port x Bit 6. The PORT_MUX.MUX6 bit provides multiplexer control for port x bit 6.
11:10 (R/W)	MUX5	Mux for Port x Bit 5. The PORT_MUX.MUX5 bit provides multiplexer control for port x bit 5.
9:8 (R/W)	MUX4	Mux for Port x Bit 4. The PORT_MUX.MUX4 bit provides multiplexer control for port x bit 4.
7:6 (R/W)	MUX3	Mux for Port x Bit 3. The PORT_MUX.MUX3 bit provides multiplexer control for port x bit 3.
5:4 (R/W)	MUX2	Mux for Port x Bit 2. The PORT_MUX.MUX2 bit provides multiplexer control for port x bit 2.
3:2 (R/W)	MUX1	Mux for Port x Bit 1. The PORT_MUX.MUX1 bit provides multiplexer control for port x bit 1.
1:0 (R/W)	MUX0	Mux for Port x Bit 0. The PORT_MUX.MUX0 bit provides multiplexer control for port x bit 0.

Port x GPIO Polarity Invert Register

The PORT_POL, PORT_POL_SET, and PORT_POL_CLR registers enable or disable inverting polarity of GPIO signals. To invert polarity of peripheral signals, use the inversion selection programming in the signal's corresponding module.

Writes to the PORT_POL register affect the polarity inversion selection of all pins of the port. To enable or disable polarity inversion for specific pins without impacting other pins of the port, use the PORT_POL_SET and PORT_POL_CLR registers.

Setting a bit in the PORT_POL register enables polarity inversion on the corresponding inversion GPIO pin, making the pin active-low or falling-edge sensitive. Clearing a bit in the PORT_POL register disables polarity (default state) on the corresponding GPIO pin, making it active-high or rising-edge sensitive.

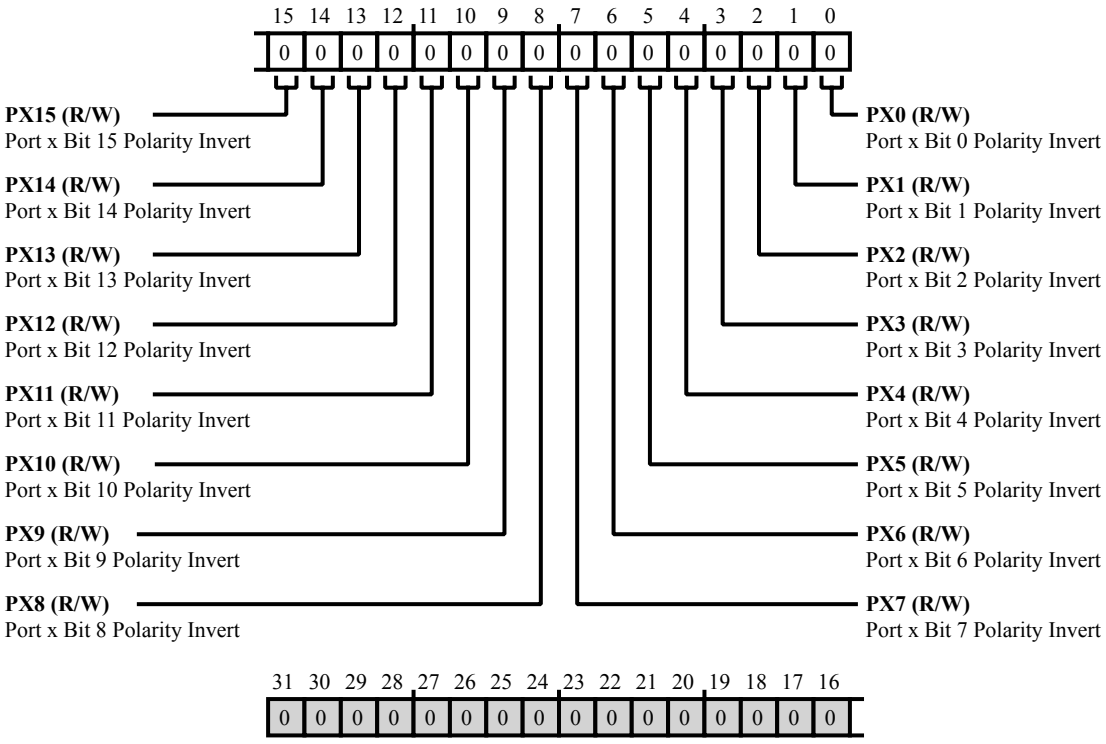

Figure 13-22: PORT_POL Register Diagram

Table 13-27: PORT_POL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	PX15	Port x Bit 15 Polarity Invert. The PORT_POL.PX15 bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.

Table 13-27: PORT_POL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
14 (R/W)	PX14	Port x Bit 14 Polarity Invert. The PORT_POL.PX14 bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.
13 (R/W)	PX13	Port x Bit 13 Polarity Invert. The PORT_POL.PX13 bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.
12 (R/W)	PX12	Port x Bit 12 Polarity Invert. The PORT_POL.PX12 bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.
11 (R/W)	PX11	Port x Bit 11 Polarity Invert. The PORT_POL.PX11 bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.
10 (R/W)	PX10	Port x Bit 10 Polarity Invert. The PORT_POL.PX10 bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.
9 (R/W)	PX9	Port x Bit 9 Polarity Invert. The PORT_POL.PX9 bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.
8 (R/W)	PX8	Port x Bit 8 Polarity Invert. The PORT_POL.PX8 bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.

Table 13-27: PORT_POL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	PX7	Port x Bit 7 Polarity Invert. The PORT_POL.PX7 bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.
6 (R/W)	PX6	Port x Bit 6 Polarity Invert. The PORT_POL.PX6 bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.
5 (R/W)	PX5	Port x Bit 5 Polarity Invert. The PORT_POL.PX5 bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.
4 (R/W)	PX4	Port x Bit 4 Polarity Invert. The PORT_POL.PX4 bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.
3 (R/W)	PX3	Port x Bit 3 Polarity Invert. The PORT_POL.PX3 bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.
2 (R/W)	PX2	Port x Bit 2 Polarity Invert. The PORT_POL.PX2 bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.
1 (R/W)	PX1	Port x Bit 1 Polarity Invert. The PORT_POL.PX1 bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.

Table 13-27: PORT_POL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	PX0	Port x Bit 0 Polarity Invert. The `PORT_POL.PX0` bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.

Port x GPIO Polarity Invert Clear Register

The PORT_POL_CLR register disables polarity inversion for GPIO pins. For more information, see the PORT_POL register description.

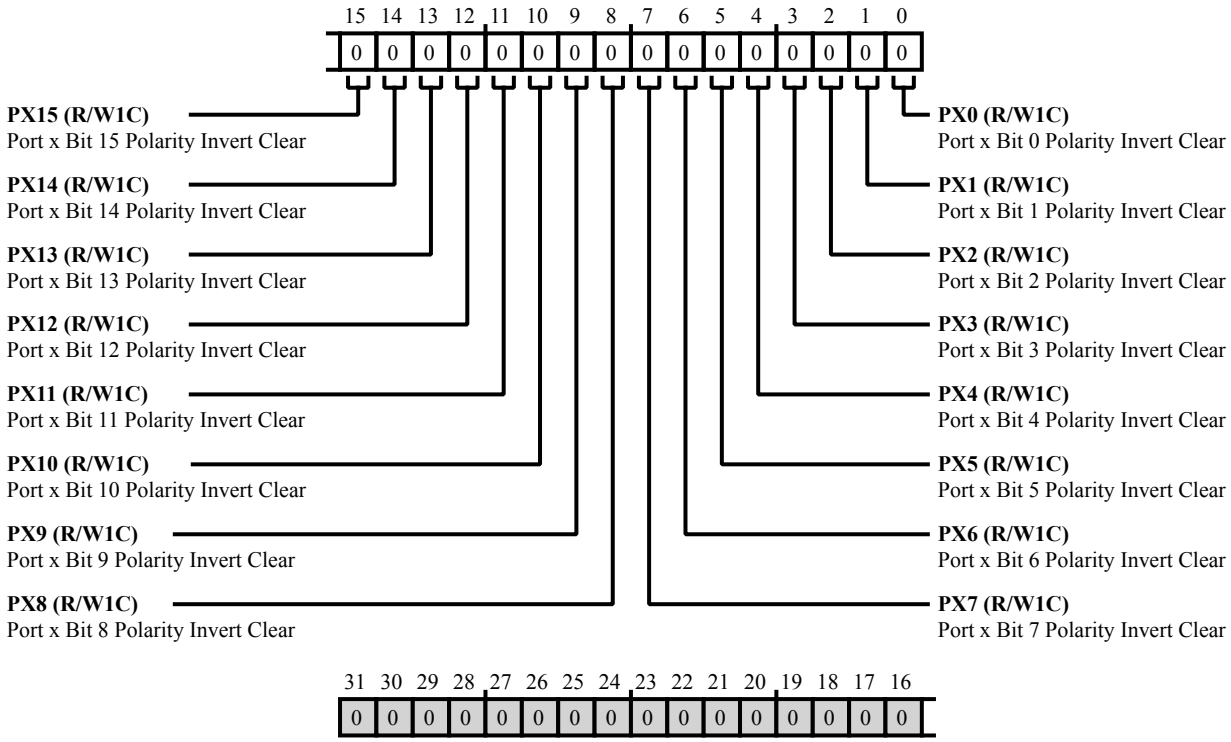

Figure 13-23: PORT_POL_CLR Register Diagram

Table 13-28: PORT_POL_CLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W1C)	PX15	Port x Bit 15 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.
14 (R/W1C)	PX14	Port x Bit 14 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.
13 (R/W1C)	PX13	Port x Bit 13 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.

Table 13-28: PORT_POL_CLR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W1C)	PX12	Port x Bit 12 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.
11 (R/W1C)	PX11	Port x Bit 11 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.
10 (R/W1C)	PX10	Port x Bit 10 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.
9 (R/W1C)	PX9	Port x Bit 9 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.
8 (R/W1C)	PX8	Port x Bit 8 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.
7 (R/W1C)	PX7	Port x Bit 7 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.
6 (R/W1C)	PX6	Port x Bit 6 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.
5 (R/W1C)	PX5	Port x Bit 5 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.
4 (R/W1C)	PX4	Port x Bit 4 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.
3 (R/W1C)	PX3	Port x Bit 3 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.

Table 13-28: PORT_POL_CLR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W1C)	PX2	Port x Bit 2 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.
1 (R/W1C)	PX1	Port x Bit 1 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.
0 (R/W1C)	PX0	Port x Bit 0 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.

Port x GPIO Polarity Invert Set Register

The PORT_POL_SET register enables polarity inversion for GPIO pins. For more information, see the PORT_POL register description.

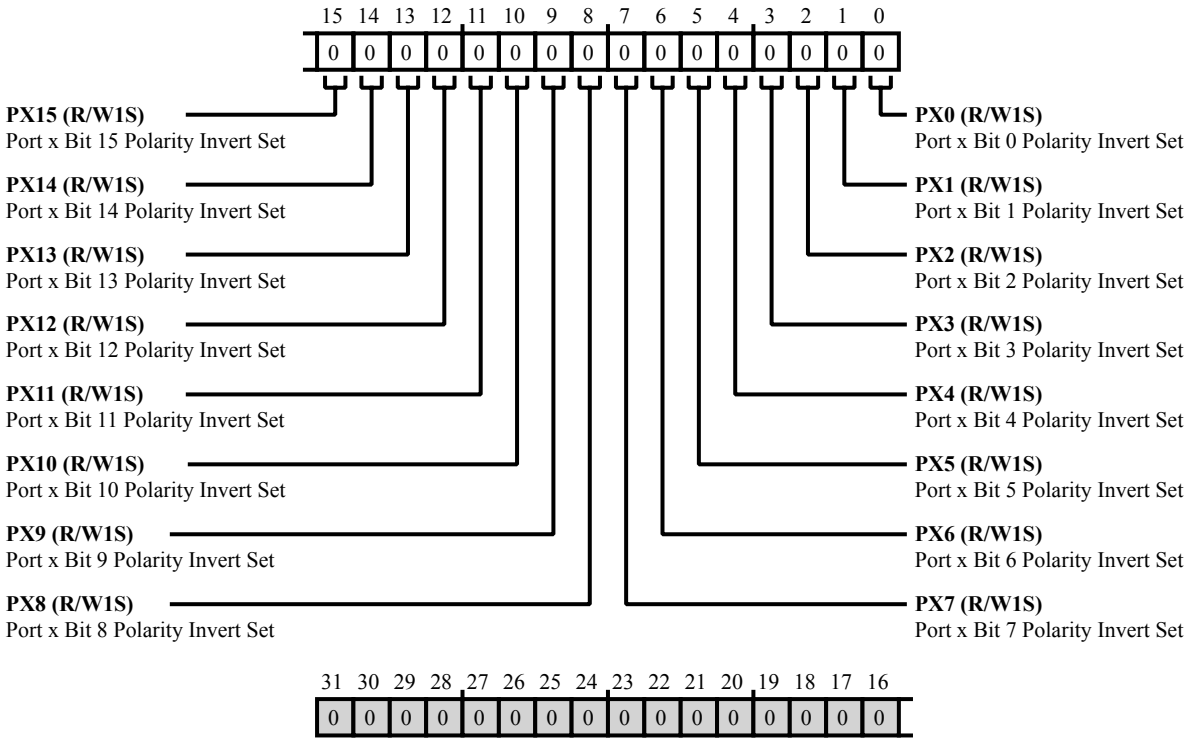

Figure 13-24: PORT_POL_SET Register Diagram

Table 13-29: PORT_POL_SET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W1S)	PX15	Port x Bit 15 Polarity Invert Set. The PORT_POL_SET.PX15 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.
14 (R/W1S)	PX14	Port x Bit 14 Polarity Invert Set. The PORT_POL_SET.PX14 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.

Table 13-29: PORT_POL_SET Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
13 (R/W1S)	PX13	Port x Bit 13 Polarity Invert Set. The PORT_POL_SET.PX13 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.
12 (R/W1S)	PX12	Port x Bit 12 Polarity Invert Set. The PORT_POL_SET.PX12 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.
11 (R/W1S)	PX11	Port x Bit 11 Polarity Invert Set. The PORT_POL_SET.PX11 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.
10 (R/W1S)	PX10	Port x Bit 10 Polarity Invert Set. The PORT_POL_SET.PX10 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.
9 (R/W1S)	PX9	Port x Bit 9 Polarity Invert Set. The PORT_POL_SET.PX9 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.
8 (R/W1S)	PX8	Port x Bit 8 Polarity Invert Set. The PORT_POL_SET.PX8 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.
7 (R/W1S)	PX7	Port x Bit 7 Polarity Invert Set. The PORT_POL_SET.PX7 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.

Table 13-29: PORT_POL_SET Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6 (R/W1S)	PX6	Port x Bit 6 Polarity Invert Set. The PORT_POL_SET.PX6 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.
5 (R/W1S)	PX5	Port x Bit 5 Polarity Invert Set. The PORT_POL_SET.PX5 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.
4 (R/W1S)	PX4	Port x Bit 4 Polarity Invert Set. The PORT_POL_SET.PX4 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.
3 (R/W1S)	PX3	Port x Bit 3 Polarity Invert Set. The PORT_POL_SET.PX3 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.
2 (R/W1S)	PX2	Port x Bit 2 Polarity Invert Set. The PORT_POL_SET.PX2 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.
1 (R/W1S)	PX1	Port x Bit 1 Polarity Invert Set. The PORT_POL_SET.PX1 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.
0 (R/W1S)	PX0	Port x Bit 0 Polarity Invert Set. The PORT_POL_SET.PX0 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.

Port x GPIO Trigger Toggle Register

The PORT_TRIG_TGL register permits toggling the state of output GPIO pins in response to a trigger from the TRU for the corresponding port. Setting bits in the PORT_TRIG_TGL register enables triggers to toggle the state of those specific pins without impacting other pins of the port.

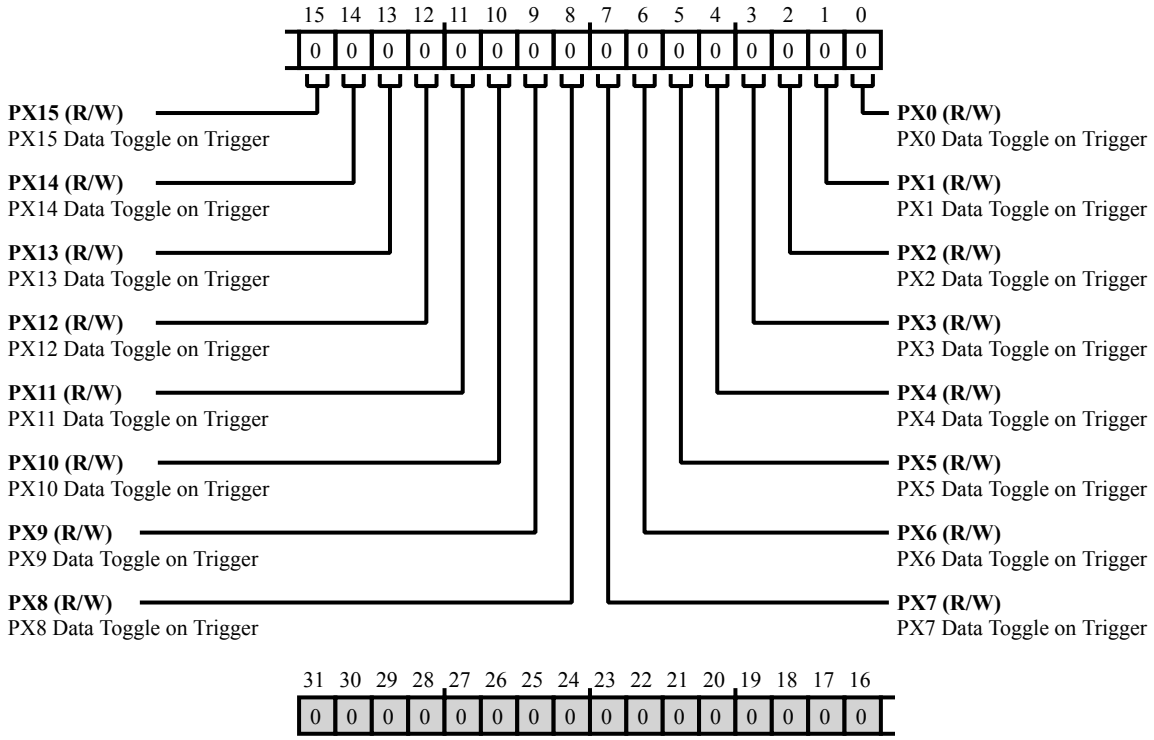

Figure 13-25: PORT_TRIG_TGL Register Diagram

Table 13-30: PORT_TRIG_TGL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W)	PX15	PX15 Data Toggle on Trigger. The PORT_TRIG_TGL.PX15 bit enables triggers to toggle the state of the pin.
14 (R/W)	PX14	PX14 Data Toggle on Trigger. The PORT_TRIG_TGL.PX14 bit enables triggers to toggle the state of the pin.
13 (R/W)	PX13	PX13 Data Toggle on Trigger. The PORT_TRIG_TGL.PX13 bit enables triggers to toggle the state of the pin.
12 (R/W)	PX12	PX12 Data Toggle on Trigger. The PORT_TRIG_TGL.PX12 bit enables triggers to toggle the state of the pin.
11 (R/W)	PX11	PX11 Data Toggle on Trigger. The PORT_TRIG_TGL.PX11 bit enables triggers to toggle the state of the pin.

Table 13-30: PORT_TRIG_TGL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
10 (R/W)	PX10	PX10 Data Toggle on Trigger. The PORT_TRIG_TGL.PX10 bit enables triggers to toggle the state of the pin.
9 (R/W)	PX9	PX9 Data Toggle on Trigger. The PORT_TRIG_TGL.PX9 bit enables triggers to toggle the state of the pin.
8 (R/W)	PX8	PX8 Data Toggle on Trigger. The PORT_TRIG_TGL.PX8 bit enables triggers to toggle the state of the pin.
7 (R/W)	PX7	PX7 Data Toggle on Trigger. The PORT_TRIG_TGL.PX7 bit enables triggers to toggle the state of the pin.
6 (R/W)	PX6	PX6 Data Toggle on Trigger. The PORT_TRIG_TGL.PX6 bit enables triggers to toggle the state of the pin.
5 (R/W)	PX5	PX5 Data Toggle on Trigger. The PORT_TRIG_TGL.PX5 bit enables triggers to toggle the state of the pin.
4 (R/W)	PX4	PX4 Data Toggle on Trigger. The PORT_TRIG_TGL.PX4 bit enables triggers to toggle the state of the pin.
3 (R/W)	PX3	PX3 Data Toggle on Trigger. The PORT_TRIG_TGL.PX3 bit enables triggers to toggle the state of the pin.
2 (R/W)	PX2	PX2 Data Toggle on Trigger. The PORT_TRIG_TGL.PX2 bit enables triggers to toggle the state of the pin.
1 (R/W)	PX1	PX1 Data Toggle on Trigger. The PORT_TRIG_TGL.PX1 bit enables triggers to toggle the state of the pin.
0 (R/W)	PX0	PX0 Data Toggle on Trigger. The PORT_TRIG_TGL.PX0 bit enables triggers to toggle the state of the pin.

ADSP-SC59x PINT Register Descriptions

The Pin Interrupt module (PINT) contains the following registers.

Table 13-31: ADSP-SC59x PINT Register List

Name	Description
PINT_ASSIGN	PINT Assign Register
PINT_EDGE_CLR	PINT Edge Clear Register
PINT_EDGE_SET	PINT Edge Set Register
PINT_INV_CLR	PINT Invert Clear Register

Table 13-31: ADSP-SC59x PINT Register List (Continued)

Name	Description
PINT_INV_SET	PINT Invert Set Register
PINT_LATCH	PINT Latch Register
PINT_MSK_CLR	PINT Mask Clear Register
PINT_MSK_SET	PINT Mask Set Register
PINT_PINSTATE	PINT Pin State Register
PINT_REQ	PINT Request Register

PINT Assign Register

The PINT_ASSIGN register controls the pin-to-interrupt request assignment in a byte-wide manner. This register consists of four control bytes that each function as a multiplexer control.

The PINT ports are subdivided into 8-bit half ports, resulting in lower and upper half 8-bit units. Using the multiplexers controlled by the PINT_ASSIGN register, the lower half units of eight pins can be forwarded to either byte 0 or byte 2 of either associated PINT block. The upper half units can be forwarded to either byte 1 or byte 3 of the PINT block, without further restrictions.

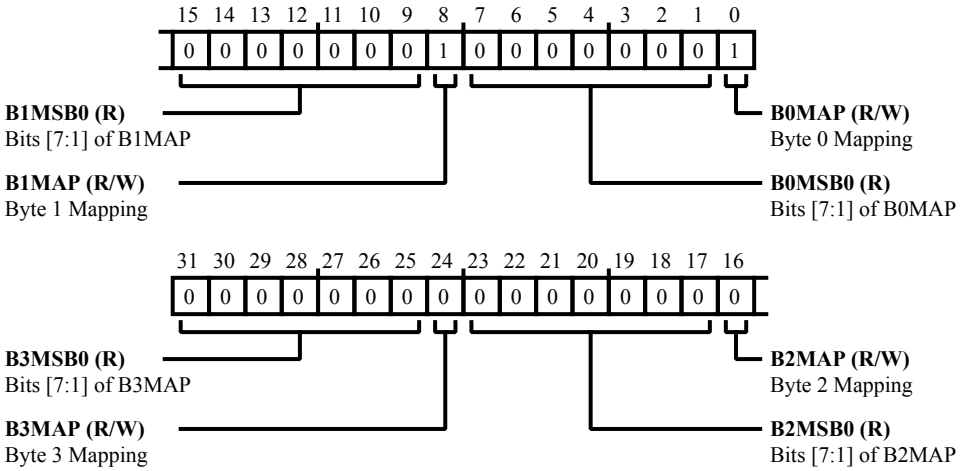

Figure 13-26: PINT_ASSIGN Register Diagram

Table 13-32: PINT_ASSIGN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:25 (R/NW)	B3MSB0	Bits [7:1] of B3MAP.	
24 (R/W)	B3MAP	Byte 3 Mapping.	
		0	B3MAP_PAH. Byte 3 = PA.H
		1	B3MAP_PBH. Byte 3 = PB.H
23:17 (R/NW)	B2MSB0	Bits [7:1] of B2MAP.	
16 (R/W)	B2MAP	Byte 2 Mapping.	
		0	B2MAP_PAL. Byte 2 = PA.L
		1	B2MAP_PBL. Byte 2 = PB.L
15:9 (R/NW)	B1MSB0	Bits [7:1] of B1MAP.	

Table 13-32: PINT_ASSIGN Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W)	B1MAP	Byte 1 Mapping.	
		0	B1MAP_PAH. Byte 1 = PA.H
		1	B1MAP_PBH. Byte 1 = PB.H
7:1 (R/NW)	B0MSB0	Bits [7:1] of B0MAP.	
0 (R/W)	B0MAP	Byte 0 Mapping.	
		0	B0MAP_PAL. Byte 0 = PA.L
		1	B0MAP_PBL. Byte 0 = PB.L

PINT Edge Clear Register

The PINT_EDGE_CLR register permits selecting level-sensitive interrupts. Writing 1 to a bit in PINT_EDGE_CLR enables level sensitivity for the corresponding pin interrupt.

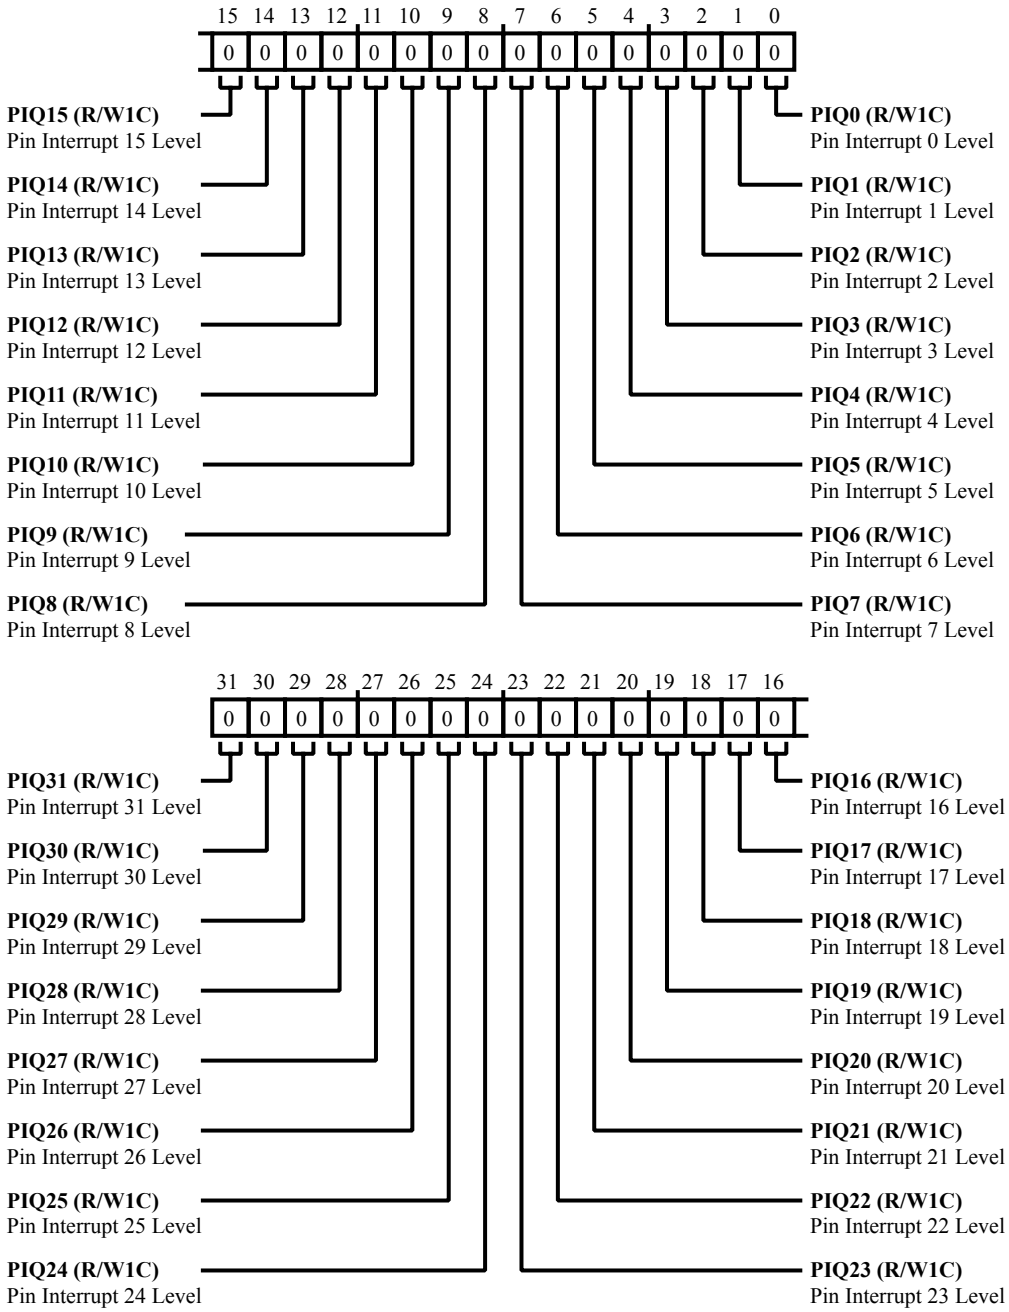

Figure 13-27: PINT_EDGE_CLR Register Diagram

Table 13-33: PINT_EDGE_CLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W1C)	PIQ31	Pin Interrupt 31 Level. Set the PINT_EDGE_CLR.PIQ31 bit to enable level sensitivity.
30 (R/W1C)	PIQ30	Pin Interrupt 30 Level. Set the PINT_EDGE_CLR.PIQ30 bit to enable level sensitivity.
29 (R/W1C)	PIQ29	Pin Interrupt 29 Level. Set the PINT_EDGE_CLR.PIQ29 bit to enable level sensitivity.
28 (R/W1C)	PIQ28	Pin Interrupt 28 Level. Set the PINT_EDGE_CLR.PIQ28 bit to enable level sensitivity.
27 (R/W1C)	PIQ27	Pin Interrupt 27 Level. Set the PINT_EDGE_CLR.PIQ27 bit to enable level sensitivity.
26 (R/W1C)	PIQ26	Pin Interrupt 26 Level. Set the PINT_EDGE_CLR.PIQ26 bit to enable level sensitivity.
25 (R/W1C)	PIQ25	Pin Interrupt 25 Level. Set the PINT_EDGE_CLR.PIQ25 bit to enable level sensitivity.
24 (R/W1C)	PIQ24	Pin Interrupt 24 Level. Set the PINT_EDGE_CLR.PIQ24 bit to enable level sensitivity.
23 (R/W1C)	PIQ23	Pin Interrupt 23 Level. Set the PINT_EDGE_CLR.PIQ23 bit to enable level sensitivity.
22 (R/W1C)	PIQ22	Pin Interrupt 22 Level. Set the PINT_EDGE_CLR.PIQ22 bit to enable level sensitivity.
21 (R/W1C)	PIQ21	Pin Interrupt 21 Level. Set the PINT_EDGE_CLR.PIQ21 bit to enable level sensitivity.
20 (R/W1C)	PIQ20	Pin Interrupt 20 Level. Set the PINT_EDGE_CLR.PIQ20 bit to enable level sensitivity.
19 (R/W1C)	PIQ19	Pin Interrupt 19 Level. Set the PINT_EDGE_CLR.PIQ19 bit to enable level sensitivity.
18 (R/W1C)	PIQ18	Pin Interrupt 18 Level. Set the PINT_EDGE_CLR.PIQ18 bit to enable level sensitivity.
17 (R/W1C)	PIQ17	Pin Interrupt 17 Level. Set the PINT_EDGE_CLR.PIQ17 bit to enable level sensitivity.
16 (R/W1C)	PIQ16	Pin Interrupt 16 Level. Set the PINT_EDGE_CLR.PIQ16 bit to enable level sensitivity.

Table 13-33: PINT_EDGE_CLR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W1C)	PIQ15	Pin Interrupt 15 Level. Set the PINT_EDGE_CLR.PIQ15 bit to enable level sensitivity.
14 (R/W1C)	PIQ14	Pin Interrupt 14 Level. Set the PINT_EDGE_CLR.PIQ14 bit to enable level sensitivity.
13 (R/W1C)	PIQ13	Pin Interrupt 13 Level. Set the PINT_EDGE_CLR.PIQ13 bit to enable level sensitivity.
12 (R/W1C)	PIQ12	Pin Interrupt 12 Level. Set the PINT_EDGE_CLR.PIQ12 bit to enable level sensitivity.
11 (R/W1C)	PIQ11	Pin Interrupt 11 Level. Set the PINT_EDGE_CLR.PIQ11 bit to enable level sensitivity.
10 (R/W1C)	PIQ10	Pin Interrupt 10 Level. Set the PINT_EDGE_CLR.PIQ10 bit to enable level sensitivity.
9 (R/W1C)	PIQ9	Pin Interrupt 9 Level. Set the PINT_EDGE_CLR.PIQ9 bit to enable level sensitivity.
8 (R/W1C)	PIQ8	Pin Interrupt 8 Level. Set the PINT_EDGE_CLR.PIQ8 bit to enable level sensitivity.
7 (R/W1C)	PIQ7	Pin Interrupt 7 Level. Set the PINT_EDGE_CLR.PIQ7 bit to enable level sensitivity.
6 (R/W1C)	PIQ6	Pin Interrupt 6 Level. Set the PINT_EDGE_CLR.PIQ6 bit to enable level sensitivity.
5 (R/W1C)	PIQ5	Pin Interrupt 5 Level. Set the PINT_EDGE_CLR.PIQ5 bit to enable level sensitivity.
4 (R/W1C)	PIQ4	Pin Interrupt 4 Level. Set the PINT_EDGE_CLR.PIQ4 bit to enable level sensitivity.
3 (R/W1C)	PIQ3	Pin Interrupt 3 Level. Set the PINT_EDGE_CLR.PIQ3 bit to enable level sensitivity.
2 (R/W1C)	PIQ2	Pin Interrupt 2 Level. Set the PINT_EDGE_CLR.PIQ2 bit to enable level sensitivity.
1 (R/W1C)	PIQ1	Pin Interrupt 1 Level. Set the PINT_EDGE_CLR.PIQ1 bit to enable level sensitivity.
0 (R/W1C)	PIQ0	Pin Interrupt 0 Level. Set the PINT_EDGE_CLR.PIQ0 bit to enable level sensitivity.

PINT Edge Set Register

The PINT_EDGE_SET register permits selecting edge-sensitive interrupts. Writing 1 to a bit in PINT_EDGE_SET enables edge sensitivity for the corresponding pin interrupt.

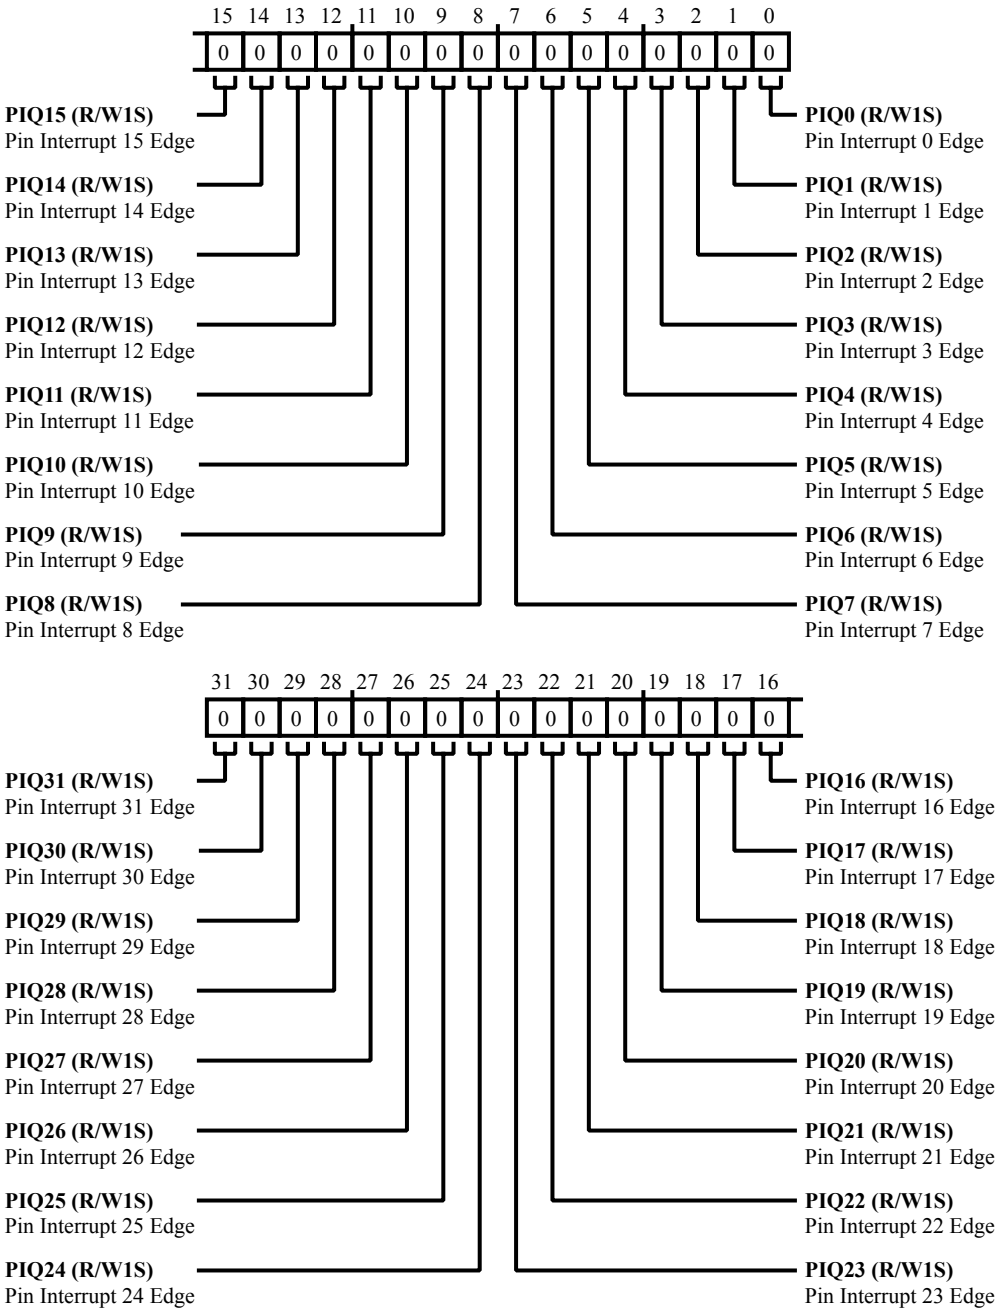

Figure 13-28: PINT_EDGE_SET Register Diagram

Table 13-34: PINT_EDGE_SET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W1S)	PIQ31	Pin Interrupt 31 Edge. Set the PINT_EDGE_SET.PIQ31 bit to enable edge sensitivity.
30 (R/W1S)	PIQ30	Pin Interrupt 30 Edge. Set the PINT_EDGE_SET.PIQ30 bit to enable edge sensitivity.
29 (R/W1S)	PIQ29	Pin Interrupt 29 Edge. Set the PINT_EDGE_SET.PIQ29 bit to enable edge sensitivity.
28 (R/W1S)	PIQ28	Pin Interrupt 28 Edge. Set the PINT_EDGE_SET.PIQ28 bit to enable edge sensitivity.
27 (R/W1S)	PIQ27	Pin Interrupt 27 Edge. Set the PINT_EDGE_SET.PIQ27 bit to enable edge sensitivity.
26 (R/W1S)	PIQ26	Pin Interrupt 26 Edge. Set the PINT_EDGE_SET.PIQ26 bit to enable edge sensitivity.
25 (R/W1S)	PIQ25	Pin Interrupt 25 Edge. Set the PINT_EDGE_SET.PIQ25 bit to enable edge sensitivity.
24 (R/W1S)	PIQ24	Pin Interrupt 24 Edge. Set the PINT_EDGE_SET.PIQ24 bit to enable edge sensitivity.
23 (R/W1S)	PIQ23	Pin Interrupt 23 Edge. Set the PINT_EDGE_SET.PIQ23 bit to enable edge sensitivity.
22 (R/W1S)	PIQ22	Pin Interrupt 22 Edge. Set the PINT_EDGE_SET.PIQ22 bit to enable edge sensitivity.
21 (R/W1S)	PIQ21	Pin Interrupt 21 Edge. Set the PINT_EDGE_SET.PIQ21 bit to enable edge sensitivity.
20 (R/W1S)	PIQ20	Pin Interrupt 20 Edge. Set the PINT_EDGE_SET.PIQ20 bit to enable edge sensitivity.
19 (R/W1S)	PIQ19	Pin Interrupt 19 Edge. Set the PINT_EDGE_SET.PIQ19 bit to enable edge sensitivity.
18 (R/W1S)	PIQ18	Pin Interrupt 18 Edge. Set the PINT_EDGE_SET.PIQ18 bit to enable edge sensitivity.
17 (R/W1S)	PIQ17	Pin Interrupt 17 Edge. Set the PINT_EDGE_SET.PIQ17 bit to enable edge sensitivity.
16 (R/W1S)	PIQ16	Pin Interrupt 16 Edge. Set the PINT_EDGE_SET.PIQ16 bit to enable edge sensitivity.

Table 13-34: PINT_EDGE_SET Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W1S)	PIQ15	Pin Interrupt 15 Edge. Set the PINT_EDGE_SET.PIQ15 bit to enable edge sensitivity.
14 (R/W1S)	PIQ14	Pin Interrupt 14 Edge. Set the PINT_EDGE_SET.PIQ14 bit to enable edge sensitivity.
13 (R/W1S)	PIQ13	Pin Interrupt 13 Edge. Set the PINT_EDGE_SET.PIQ13 bit to enable edge sensitivity.
12 (R/W1S)	PIQ12	Pin Interrupt 12 Edge. Set the PINT_EDGE_SET.PIQ12 bit to enable edge sensitivity.
11 (R/W1S)	PIQ11	Pin Interrupt 11 Edge. Set the PINT_EDGE_SET.PIQ11 bit to enable edge sensitivity.
10 (R/W1S)	PIQ10	Pin Interrupt 10 Edge. Set the PINT_EDGE_SET.PIQ10 bit to enable edge sensitivity.
9 (R/W1S)	PIQ9	Pin Interrupt 9 Edge. Set the PINT_EDGE_SET.PIQ9 bit to enable edge sensitivity.
8 (R/W1S)	PIQ8	Pin Interrupt 8 Edge. Set the PINT_EDGE_SET.PIQ8 bit to enable edge sensitivity.
7 (R/W1S)	PIQ7	Pin Interrupt 7 Edge. Set the PINT_EDGE_SET.PIQ7 bit to enable edge sensitivity.
6 (R/W1S)	PIQ6	Pin Interrupt 6 Edge. Set the PINT_EDGE_SET.PIQ6 bit to enable edge sensitivity.
5 (R/W1S)	PIQ5	Pin Interrupt 5 Edge. Set the PINT_EDGE_SET.PIQ5 bit to enable edge sensitivity.
4 (R/W1S)	PIQ4	Pin Interrupt 4 Edge. Set the PINT_EDGE_SET.PIQ4 bit to enable edge sensitivity.
3 (R/W1S)	PIQ3	Pin Interrupt 3 Edge. Set the PINT_EDGE_SET.PIQ3 bit to enable edge sensitivity.
2 (R/W1S)	PIQ2	Pin Interrupt 2 Edge. Set the PINT_EDGE_SET.PIQ2 bit to enable edge sensitivity.
1 (R/W1S)	PIQ1	Pin Interrupt 1 Edge. Set the PINT_EDGE_SET.PIQ1 bit to enable edge sensitivity.
0 (R/W1S)	PIQ0	Pin Interrupt 0 Edge. Set the PINT_EDGE_SET.PIQ0 bit to enable edge sensitivity.

PINT Invert Clear Register

The PINT_INV_CLR register disables inverting input polarity. Writing 1 to a bit in PINT_INV_CLR disables an inverter for input on the corresponding pin.

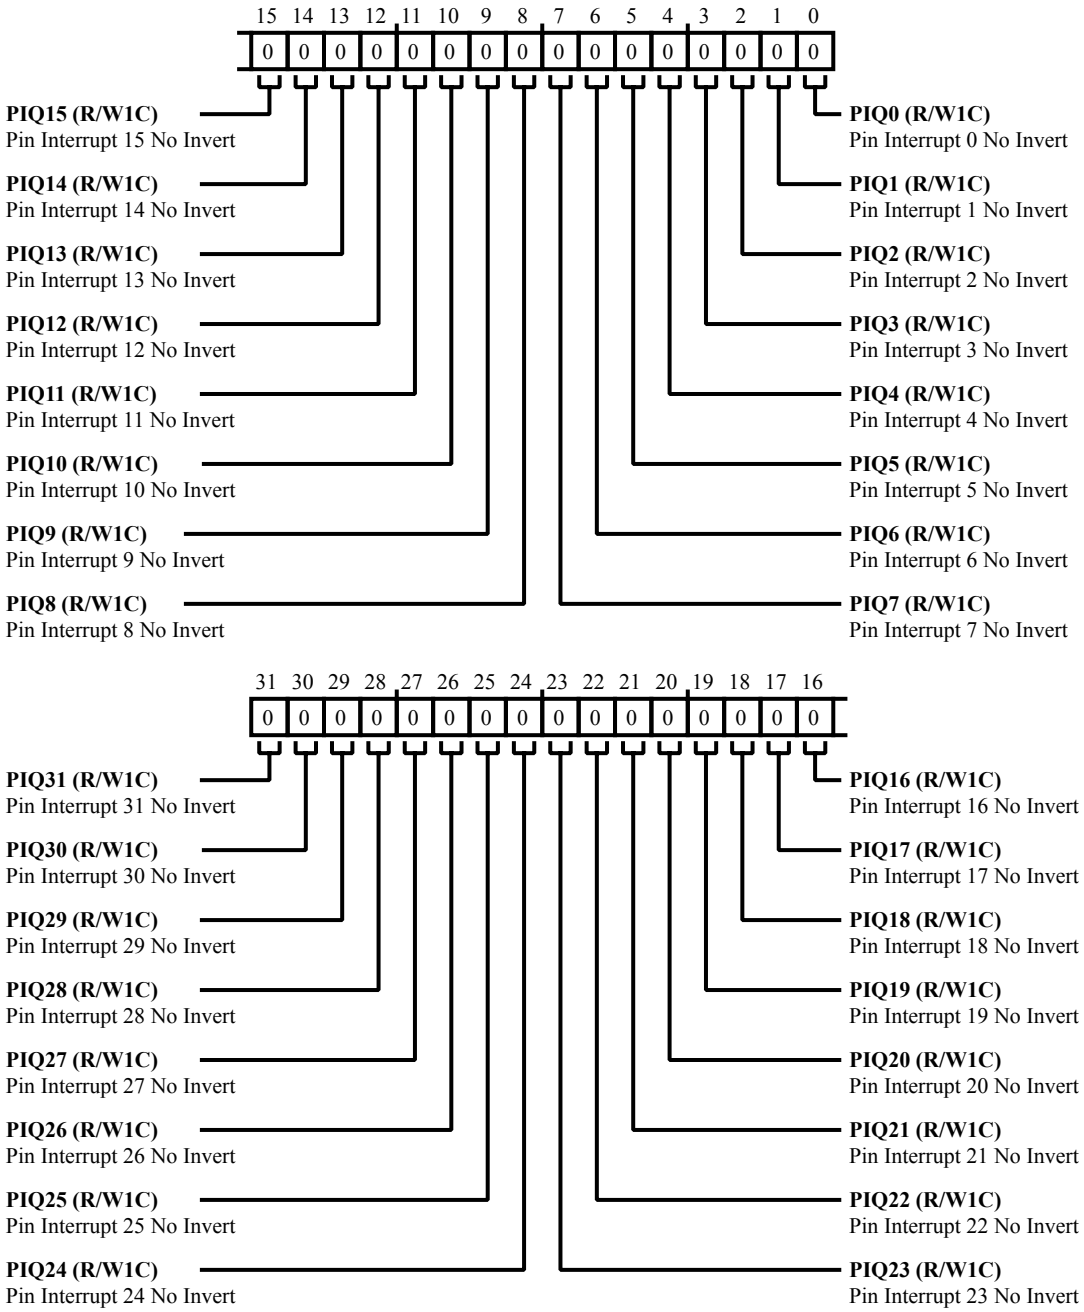

Figure 13-29: PINT_INV_CLR Register Diagram

Table 13-35: PINT_INV_CLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W1C)	PIQ31	Pin Interrupt 31 No Invert. Set the PINT_INV_CLR.PIQ31 bit to disable inverted input.
30 (R/W1C)	PIQ30	Pin Interrupt 30 No Invert. Set the PINT_INV_CLR.PIQ30 bit to disable inverted input.
29 (R/W1C)	PIQ29	Pin Interrupt 29 No Invert. Set the PINT_INV_CLR.PIQ29 bit to disable inverted input.
28 (R/W1C)	PIQ28	Pin Interrupt 28 No Invert. Set the PINT_INV_CLR.PIQ28 bit to disable inverted input.
27 (R/W1C)	PIQ27	Pin Interrupt 27 No Invert. Set the PINT_INV_CLR.PIQ27 bit to disable inverted input.
26 (R/W1C)	PIQ26	Pin Interrupt 26 No Invert. Set the PINT_INV_CLR.PIQ26 bit to disable inverted input.
25 (R/W1C)	PIQ25	Pin Interrupt 25 No Invert. Set the PINT_INV_CLR.PIQ25 bit to disable inverted input.
24 (R/W1C)	PIQ24	Pin Interrupt 24 No Invert. Set the PINT_INV_CLR.PIQ24 bit to disable inverted input.
23 (R/W1C)	PIQ23	Pin Interrupt 23 No Invert. Set the PINT_INV_CLR.PIQ23 bit to disable inverted input.
22 (R/W1C)	PIQ22	Pin Interrupt 22 No Invert. Set the PINT_INV_CLR.PIQ22 bit to disable inverted input.
21 (R/W1C)	PIQ21	Pin Interrupt 21 No Invert. Set the PINT_INV_CLR.PIQ21 bit to disable inverted input.
20 (R/W1C)	PIQ20	Pin Interrupt 20 No Invert. Set the PINT_INV_CLR.PIQ20 bit to disable inverted input.
19 (R/W1C)	PIQ19	Pin Interrupt 19 No Invert. Set the PINT_INV_CLR.PIQ19 bit to disable inverted input.
18 (R/W1C)	PIQ18	Pin Interrupt 18 No Invert. Set the PINT_INV_CLR.PIQ18 bit to disable inverted input.
17 (R/W1C)	PIQ17	Pin Interrupt 17 No Invert. Set the PINT_INV_CLR.PIQ17 bit to disable inverted input.
16 (R/W1C)	PIQ16	Pin Interrupt 16 No Invert. Set the PINT_INV_CLR.PIQ16 bit to disable inverted input.

Table 13-35: PINT_INV_CLR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W1C)	PIQ15	Pin Interrupt 15 No Invert. Set the PINT_INV_CLR.PIQ15 bit to disable inverted input.
14 (R/W1C)	PIQ14	Pin Interrupt 14 No Invert. Set the PINT_INV_CLR.PIQ14 bit to disable inverted input.
13 (R/W1C)	PIQ13	Pin Interrupt 13 No Invert. Set the PINT_INV_CLR.PIQ13 bit to disable inverted input.
12 (R/W1C)	PIQ12	Pin Interrupt 12 No Invert. Set the PINT_INV_CLR.PIQ12 bit to disable inverted input.
11 (R/W1C)	PIQ11	Pin Interrupt 11 No Invert. Set the PINT_INV_CLR.PIQ11 bit to disable inverted input.
10 (R/W1C)	PIQ10	Pin Interrupt 10 No Invert. Set the PINT_INV_CLR.PIQ10 bit to disable inverted input.
9 (R/W1C)	PIQ9	Pin Interrupt 9 No Invert. Set the PINT_INV_CLR.PIQ9 bit to disable inverted input.
8 (R/W1C)	PIQ8	Pin Interrupt 8 No Invert. Set the PINT_INV_CLR.PIQ8 bit to disable inverted input.
7 (R/W1C)	PIQ7	Pin Interrupt 7 No Invert. Set the PINT_INV_CLR.PIQ7 bit to disable inverted input.
6 (R/W1C)	PIQ6	Pin Interrupt 6 No Invert. Set the PINT_INV_CLR.PIQ6 bit to disable inverted input.
5 (R/W1C)	PIQ5	Pin Interrupt 5 No Invert. Set the PINT_INV_CLR.PIQ5 bit to disable inverted input.
4 (R/W1C)	PIQ4	Pin Interrupt 4 No Invert. Set the PINT_INV_CLR.PIQ4 bit to disable inverted input.
3 (R/W1C)	PIQ3	Pin Interrupt 3 No Invert. Set the PINT_INV_CLR.PIQ3 bit to disable inverted input.
2 (R/W1C)	PIQ2	Pin Interrupt 2 No Invert. Set the PINT_INV_CLR.PIQ2 bit to disable inverted input.
1 (R/W1C)	PIQ1	Pin Interrupt 1 No Invert. Set the PINT_INV_CLR.PIQ1 bit to disable inverted input.
0 (R/W1C)	PIQ0	Pin Interrupt 0 No Invert. Set the PINT_INV_CLR.PIQ0 bit to disable inverted input.

PINT Invert Set Register

The PINT_INV_SET register enables inverting input polarity. Writing 1 to a bit in PINT_INV_SET enables an inverter for input on the corresponding pin.

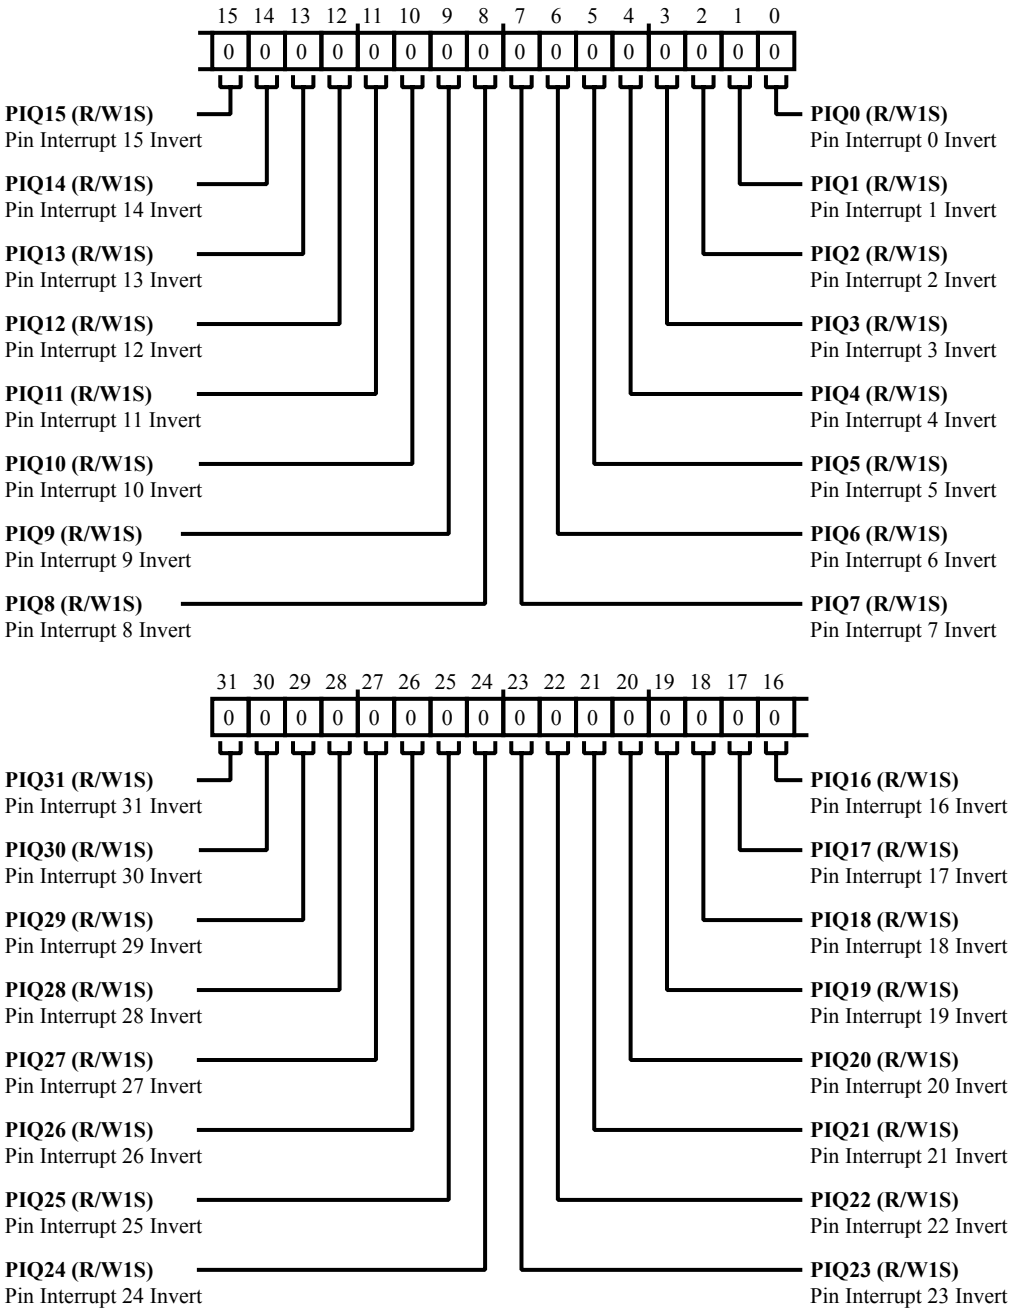

Figure 13-30: PINT_INV_SET Register Diagram

Table 13-36: PINT_INV_SET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W1S)	PIQ31	Pin Interrupt 31 Invert. Set the PINT_INV_SET.PIQ31 bit to enable inverted input.
30 (R/W1S)	PIQ30	Pin Interrupt 30 Invert. Set the PINT_INV_SET.PIQ30 bit to enable inverted input.
29 (R/W1S)	PIQ29	Pin Interrupt 29 Invert. Set the PINT_INV_SET.PIQ29 bit to enable inverted input.
28 (R/W1S)	PIQ28	Pin Interrupt 28 Invert. Set the PINT_INV_SET.PIQ28 bit to enable inverted input.
27 (R/W1S)	PIQ27	Pin Interrupt 27 Invert. Set the PINT_INV_SET.PIQ27 bit to enable inverted input.
26 (R/W1S)	PIQ26	Pin Interrupt 26 Invert. Set the PINT_INV_SET.PIQ26 bit to enable inverted input.
25 (R/W1S)	PIQ25	Pin Interrupt 25 Invert. Set the PINT_INV_SET.PIQ25 bit to enable inverted input.
24 (R/W1S)	PIQ24	Pin Interrupt 24 Invert. Set the PINT_INV_SET.PIQ24 bit to enable inverted input.
23 (R/W1S)	PIQ23	Pin Interrupt 23 Invert. Set the PINT_INV_SET.PIQ23 bit to enable inverted input.
22 (R/W1S)	PIQ22	Pin Interrupt 22 Invert. Set the PINT_INV_SET.PIQ22 bit to enable inverted input.
21 (R/W1S)	PIQ21	Pin Interrupt 21 Invert. Set the PINT_INV_SET.PIQ21 bit to enable inverted input.
20 (R/W1S)	PIQ20	Pin Interrupt 20 Invert. Set the PINT_INV_SET.PIQ20 bit to enable inverted input.
19 (R/W1S)	PIQ19	Pin Interrupt 19 Invert. Set the PINT_INV_SET.PIQ19 bit to enable inverted input.
18 (R/W1S)	PIQ18	Pin Interrupt 18 Invert. Set the PINT_INV_SET.PIQ18 bit to enable inverted input.
17 (R/W1S)	PIQ17	Pin Interrupt 17 Invert. Set the PINT_INV_SET.PIQ17 bit to enable inverted input.
16 (R/W1S)	PIQ16	Pin Interrupt 16 Invert. Set the PINT_INV_SET.PIQ16 bit to enable inverted input.

Table 13-36: PINT_INV_SET Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W1S)	PIQ15	Pin Interrupt 15 Invert. Set the PINT_INV_SET.PIQ15 bit to enable inverted input.
14 (R/W1S)	PIQ14	Pin Interrupt 14 Invert. Set the PINT_INV_SET.PIQ14 bit to enable inverted input.
13 (R/W1S)	PIQ13	Pin Interrupt 13 Invert. Set the PINT_INV_SET.PIQ13 bit to enable inverted input.
12 (R/W1S)	PIQ12	Pin Interrupt 12 Invert. Set the PINT_INV_SET.PIQ12 bit to enable inverted input.
11 (R/W1S)	PIQ11	Pin Interrupt 11 Invert. Set the PINT_INV_SET.PIQ11 bit to enable inverted input.
10 (R/W1S)	PIQ10	Pin Interrupt 10 Invert. Set the PINT_INV_SET.PIQ10 bit to enable inverted input.
9 (R/W1S)	PIQ9	Pin Interrupt 9 Invert. Set the PINT_INV_SET.PIQ9 bit to enable inverted input.
8 (R/W1S)	PIQ8	Pin Interrupt 8 Invert. Set the PINT_INV_SET.PIQ8 bit to enable inverted input.
7 (R/W1S)	PIQ7	Pin Interrupt 7 Invert. Set the PINT_INV_SET.PIQ7 bit to enable inverted input.
6 (R/W1S)	PIQ6	Pin Interrupt 6 Invert. Set the PINT_INV_SET.PIQ6 bit to enable inverted input.
5 (R/W1S)	PIQ5	Pin Interrupt 5 Invert. Set the PINT_INV_SET.PIQ5 bit to enable inverted input.
4 (R/W1S)	PIQ4	Pin Interrupt 4 Invert. Set the PINT_INV_SET.PIQ4 bit to enable inverted input.
3 (R/W1S)	PIQ3	Pin Interrupt 3 Invert. Set the PINT_INV_SET.PIQ3 bit to enable inverted input.
2 (R/W1S)	PIQ2	Pin Interrupt 2 Invert. Set the PINT_INV_SET.PIQ2 bit to enable inverted input.
1 (R/W1S)	PIQ1	Pin Interrupt 1 Invert. Set the PINT_INV_SET.PIQ1 bit to enable inverted input.
0 (R/W1S)	PIQ0	Pin Interrupt 0 Invert. Set the PINT_INV_SET.PIQ0 bit to enable inverted input.

PINT Latch Register

The PINT_LATCH register indicates the interrupt latch status for pin interrupts. When set, an interrupt request is latched. When cleared, there is no interrupt request latched.

Both the PINT_REQ and PINT_LATCH registers indicate whether an interrupt request is latched on the respective pin. The PINT_LATCH register is a latch that operates regardless of the interrupt masks. Bits of the PINT_REQ register depend on the mask register. The PINT_REQ register is a logical AND of the PINT_LATCH register and the interrupt mask.

Having two separate registers here enables the user to interrogate certain pins in polling mode while others work in interrupt mode. The PINT_LATCH registers can be used for edge detection or pin activity detection.

Both registers have W1C behavior. Writing a 1 to either register clears the respective bits in both registers. For interrupt operation, the user may prefer to W1C the PINT_REQ register (address still loaded in Px pointer). In polling mode, it might be cleaner to W1C the PINT_LATCH register.

Whether in edge-sensitive mode or level-sensitive mode, PINT_LATCH bits are never cleared by hardware except at system reset. Even in level-sensitive mode, the PINT_LATCH register functions as latch.

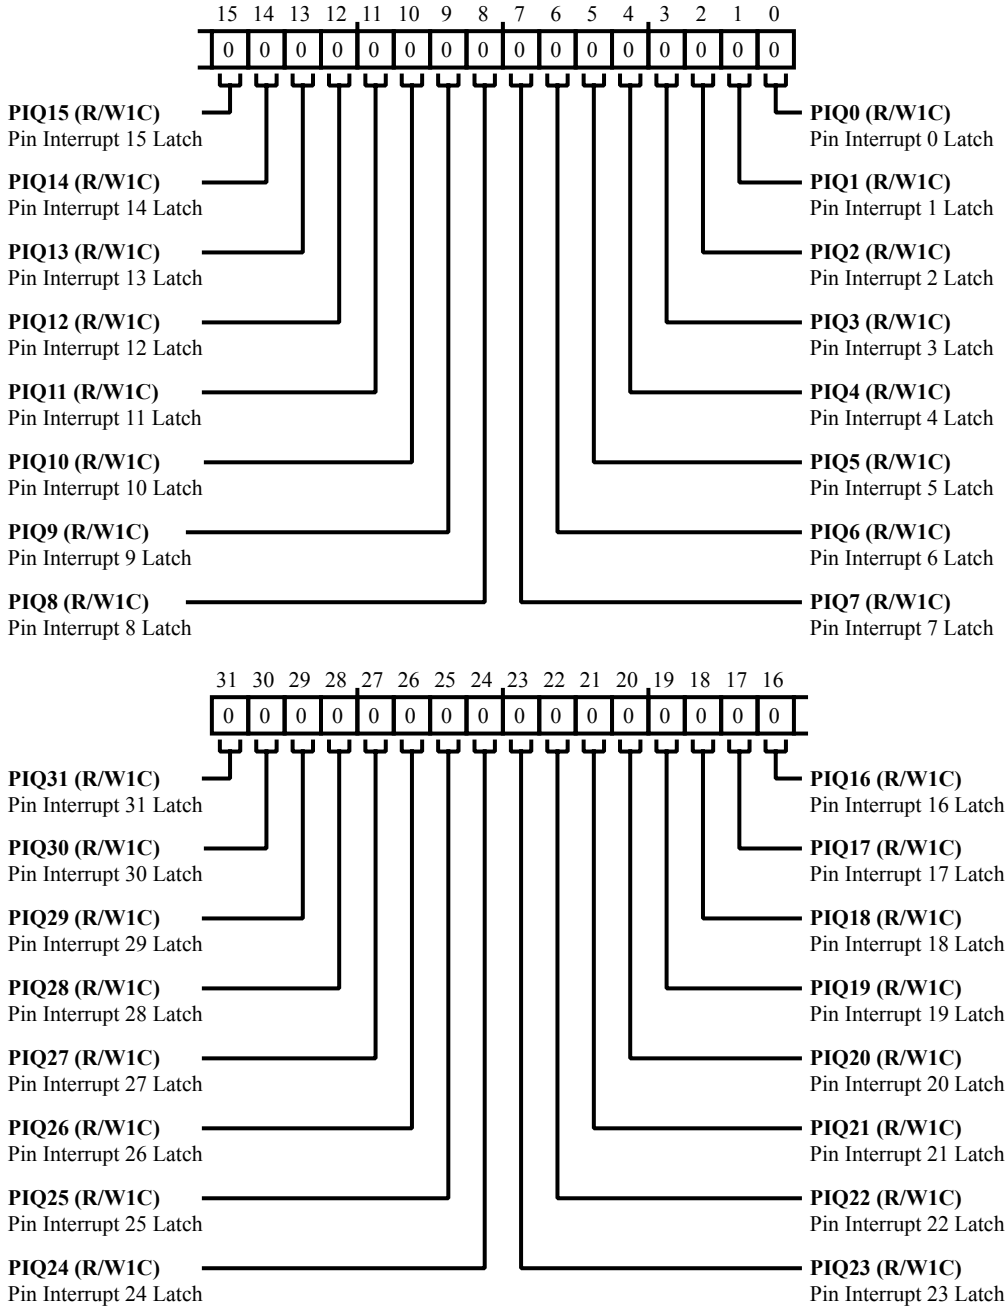

Figure 13-31: PINT_LATCH Register Diagram

Table 13-37: PINT_LATCH Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W1C)	PIQ31	Pin Interrupt 31 Latch. If the `PINT_LATCH.PIQ31` bit is set, the request is latched.

Table 13-37: PINT_LATCH Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
30 (R/W1C)	PIQ30	Pin Interrupt 30 Latch. If the `PINT_LATCH.PIQ30` bit is set, the request is latched.
29 (R/W1C)	PIQ29	Pin Interrupt 29 Latch. If the `PINT_LATCH.PIQ29` bit is set, the request is latched.
28 (R/W1C)	PIQ28	Pin Interrupt 28 Latch. If the `PINT_LATCH.PIQ28` bit is set, the request is latched.
27 (R/W1C)	PIQ27	Pin Interrupt 27 Latch. If the `PINT_LATCH.PIQ27` bit is set, the request is latched.
26 (R/W1C)	PIQ26	Pin Interrupt 26 Latch. If the `PINT_LATCH.PIQ26` bit is set, the request is latched.
25 (R/W1C)	PIQ25	Pin Interrupt 25 Latch. If the `PINT_LATCH.PIQ25` bit is set, the request is latched.
24 (R/W1C)	PIQ24	Pin Interrupt 24 Latch. If the `PINT_LATCH.PIQ24` bit is set, the request is latched.
23 (R/W1C)	PIQ23	Pin Interrupt 23 Latch. If the `PINT_LATCH.PIQ23` bit is set, the request is latched.
22 (R/W1C)	PIQ22	Pin Interrupt 22 Latch. If the `PINT_LATCH.PIQ22` bit is set, the request is latched.
21 (R/W1C)	PIQ21	Pin Interrupt 21 Latch. If the `PINT_LATCH.PIQ21` bit is set, the request is latched.
20 (R/W1C)	PIQ20	Pin Interrupt 20 Latch. If the `PINT_LATCH.PIQ20` bit is set, the request is latched.
19 (R/W1C)	PIQ19	Pin Interrupt 19 Latch. If the `PINT_LATCH.PIQ19` bit is set, the request is latched.
18 (R/W1C)	PIQ18	Pin Interrupt 18 Latch. If the `PINT_LATCH.PIQ18` bit is set, the request is latched.
17 (R/W1C)	PIQ17	Pin Interrupt 17 Latch. If the `PINT_LATCH.PIQ17` bit is set, the request is latched.
16 (R/W1C)	PIQ16	Pin Interrupt 16 Latch. If the `PINT_LATCH.PIQ16` bit is set, the request is latched.
15 (R/W1C)	PIQ15	Pin Interrupt 15 Latch. If the `PINT_LATCH.PIQ15` bit is set, the request is latched.

Table 13-37: PINT_LATCH Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
14 (R/W1C)	PIQ14	Pin Interrupt 14 Latch. If the `PINT_LATCH.PIQ14` bit is set, the request is latched.
13 (R/W1C)	PIQ13	Pin Interrupt 13 Latch. If the `PINT_LATCH.PIQ13` bit is set, the request is latched.
12 (R/W1C)	PIQ12	Pin Interrupt 12 Latch. If the `PINT_LATCH.PIQ12` bit is set, the request is latched.
11 (R/W1C)	PIQ11	Pin Interrupt 11 Latch. If the `PINT_LATCH.PIQ11` bit is set, the request is latched.
10 (R/W1C)	PIQ10	Pin Interrupt 10 Latch. If the `PINT_LATCH.PIQ10` bit is set, the request is latched.
9 (R/W1C)	PIQ9	Pin Interrupt 9 Latch. If the `PINT_LATCH.PIQ9` bit is set, the request is latched.
8 (R/W1C)	PIQ8	Pin Interrupt 8 Latch. If the `PINT_LATCH.PIQ8` bit is set, the request is latched.
7 (R/W1C)	PIQ7	Pin Interrupt 7 Latch. If the `PINT_LATCH.PIQ7` bit is set, the request is latched.
6 (R/W1C)	PIQ6	Pin Interrupt 6 Latch. If the `PINT_LATCH.PIQ6` bit is set, the request is latched.
5 (R/W1C)	PIQ5	Pin Interrupt 5 Latch. If the `PINT_LATCH.PIQ5` bit is set, the request is latched.
4 (R/W1C)	PIQ4	Pin Interrupt 4 Latch. If the `PINT_LATCH.PIQ4` bit is set, the request is latched.
3 (R/W1C)	PIQ3	Pin Interrupt 3 Latch. If the `PINT_LATCH.PIQ3` bit is set, the request is latched.
2 (R/W1C)	PIQ2	Pin Interrupt 2 Latch. If the `PINT_LATCH.PIQ2` bit is set, the request is latched.
1 (R/W1C)	PIQ1	Pin Interrupt 1 Latch. If the `PINT_LATCH.PIQ1` bit is set, the request is latched.
0 (R/W1C)	PIQ0	Pin Interrupt 0 Latch. If the `PINT_LATCH.PIQ0` bit is set, the request is latched.

PINT Mask Clear Register

The PINT_MSK_CLR register permits masking (disabling) of interrupt requests. Writing 1 to a bit in PINT_MSK_CLR masks the corresponding pin interrupt.

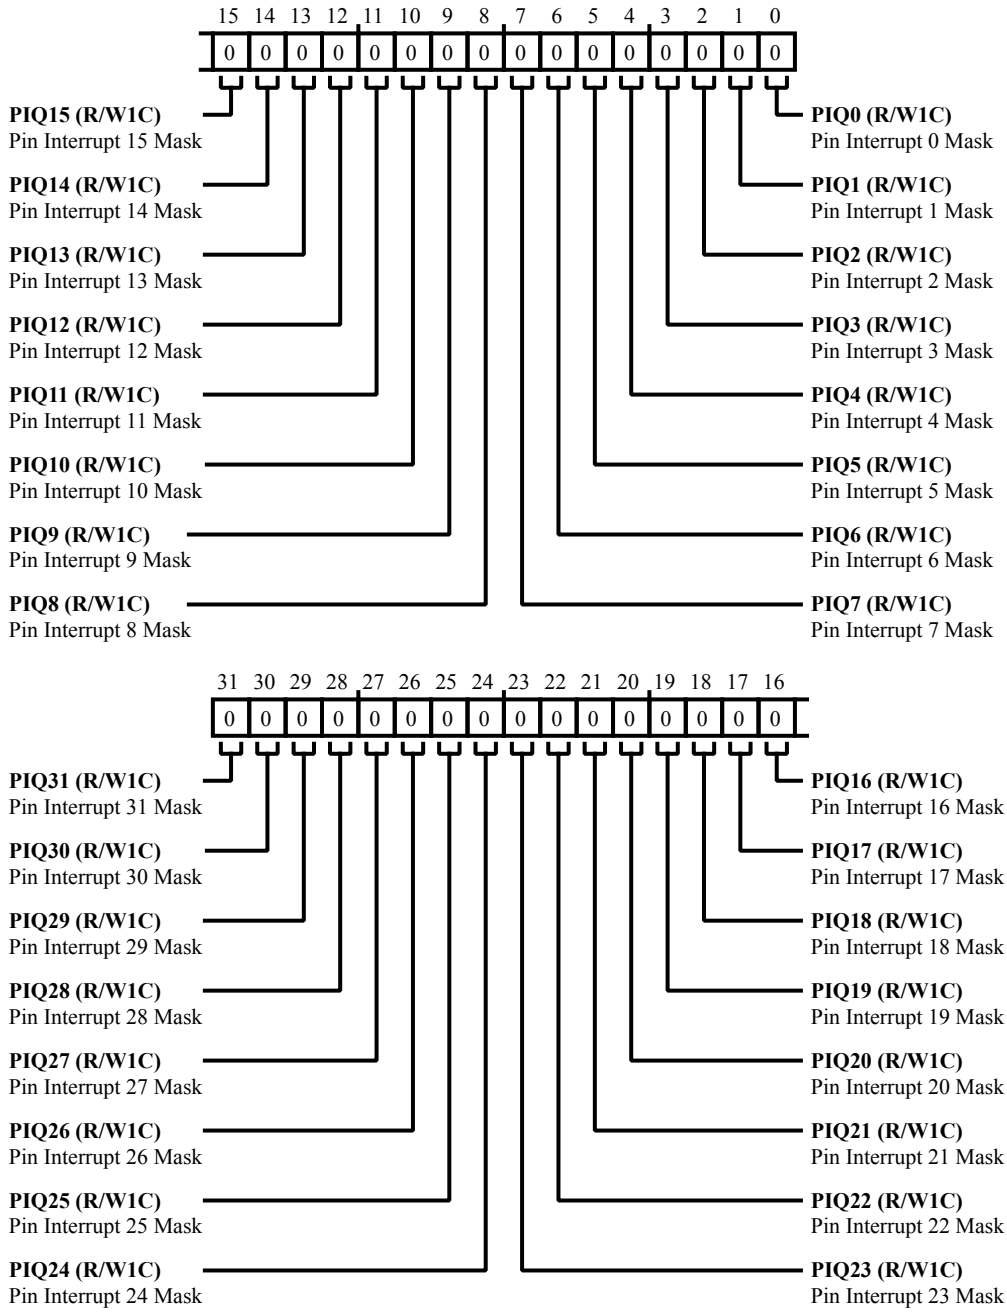

Figure 13-32: PINT_MSK_CLR Register Diagram

Table 13-38: PINT_MSK_CLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W1C)	PIQ31	Pin Interrupt 31 Mask. Set the PINT_MSK_CLR.PIQ31 bit to disable the interrupt.
30 (R/W1C)	PIQ30	Pin Interrupt 30 Mask. Set the PINT_MSK_CLR.PIQ30 bit to disable the interrupt.
29 (R/W1C)	PIQ29	Pin Interrupt 29 Mask. Set the PINT_MSK_CLR.PIQ29 bit to disable the interrupt.
28 (R/W1C)	PIQ28	Pin Interrupt 28 Mask. Set the PINT_MSK_CLR.PIQ28 bit to disable the interrupt.
27 (R/W1C)	PIQ27	Pin Interrupt 27 Mask. Set the PINT_MSK_CLR.PIQ27 bit to disable the interrupt.
26 (R/W1C)	PIQ26	Pin Interrupt 26 Mask. Set the PINT_MSK_CLR.PIQ26 bit to disable the interrupt.
25 (R/W1C)	PIQ25	Pin Interrupt 25 Mask. Set the PINT_MSK_CLR.PIQ25 bit to disable the interrupt.
24 (R/W1C)	PIQ24	Pin Interrupt 24 Mask. Set the PINT_MSK_CLR.PIQ24 bit to disable the interrupt.
23 (R/W1C)	PIQ23	Pin Interrupt 23 Mask. Set the PINT_MSK_CLR.PIQ23 bit to disable the interrupt.
22 (R/W1C)	PIQ22	Pin Interrupt 22 Mask. Set the PINT_MSK_CLR.PIQ22 bit to disable the interrupt.
21 (R/W1C)	PIQ21	Pin Interrupt 21 Mask. Set the PINT_MSK_CLR.PIQ21 bit to disable the interrupt.
20 (R/W1C)	PIQ20	Pin Interrupt 20 Mask. Set the PINT_MSK_CLR.PIQ20 bit to disable the interrupt.
19 (R/W1C)	PIQ19	Pin Interrupt 19 Mask. Set the PINT_MSK_CLR.PIQ19 bit to disable the interrupt.
18 (R/W1C)	PIQ18	Pin Interrupt 18 Mask. Set the PINT_MSK_CLR.PIQ18 bit to disable the interrupt.
17 (R/W1C)	PIQ17	Pin Interrupt 17 Mask. Set the PINT_MSK_CLR.PIQ17 bit to disable the interrupt.
16 (R/W1C)	PIQ16	Pin Interrupt 16 Mask. Set the PINT_MSK_CLR.PIQ16 bit to disable the interrupt.

Table 13-38: PINT_MSK_CLR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W1C)	PIQ15	Pin Interrupt 15 Mask. Set the PINT_MSK_CLR.PIQ15 bit to disable the interrupt.
14 (R/W1C)	PIQ14	Pin Interrupt 14 Mask. Set the PINT_MSK_CLR.PIQ14 bit to disable the interrupt.
13 (R/W1C)	PIQ13	Pin Interrupt 13 Mask. Set the PINT_MSK_CLR.PIQ13 bit to disable the interrupt.
12 (R/W1C)	PIQ12	Pin Interrupt 12 Mask. Set the PINT_MSK_CLR.PIQ12 bit to disable the interrupt.
11 (R/W1C)	PIQ11	Pin Interrupt 11 Mask. Set the PINT_MSK_CLR.PIQ11 bit to disable the interrupt.
10 (R/W1C)	PIQ10	Pin Interrupt 10 Mask. Set the PINT_MSK_CLR.PIQ10 bit to disable the interrupt.
9 (R/W1C)	PIQ9	Pin Interrupt 9 Mask. Set the PINT_MSK_CLR.PIQ9 bit to disable the interrupt.
8 (R/W1C)	PIQ8	Pin Interrupt 8 Mask. Set the PINT_MSK_CLR.PIQ8 bit to disable the interrupt.
7 (R/W1C)	PIQ7	Pin Interrupt 7 Mask. Set the PINT_MSK_CLR.PIQ7 bit to disable the interrupt.
6 (R/W1C)	PIQ6	Pin Interrupt 6 Mask. Set the PINT_MSK_CLR.PIQ6 bit to disable the interrupt.
5 (R/W1C)	PIQ5	Pin Interrupt 5 Mask. Set the PINT_MSK_CLR.PIQ5 bit to disable the interrupt.
4 (R/W1C)	PIQ4	Pin Interrupt 4 Mask. Set the PINT_MSK_CLR.PIQ4 bit to disable the interrupt.
3 (R/W1C)	PIQ3	Pin Interrupt 3 Mask. Set the PINT_MSK_CLR.PIQ3 bit to disable the interrupt.
2 (R/W1C)	PIQ2	Pin Interrupt 2 Mask. Set the PINT_MSK_CLR.PIQ2 bit to disable the interrupt.
1 (R/W1C)	PIQ1	Pin Interrupt 1 Mask. Set the PINT_MSK_CLR.PIQ1 bit to disable the interrupt.
0 (R/W1C)	PIQ0	Pin Interrupt 0 Mask. Set the PINT_MSK_CLR.PIQ0 bit to disable the interrupt.

PINT Mask Set Register

The PINT_MSK_SET register permits unmasking (enabling) of interrupt requests. Writing 1 to a bit in PINT_MSK_SET unmasks the corresponding pin interrupt.

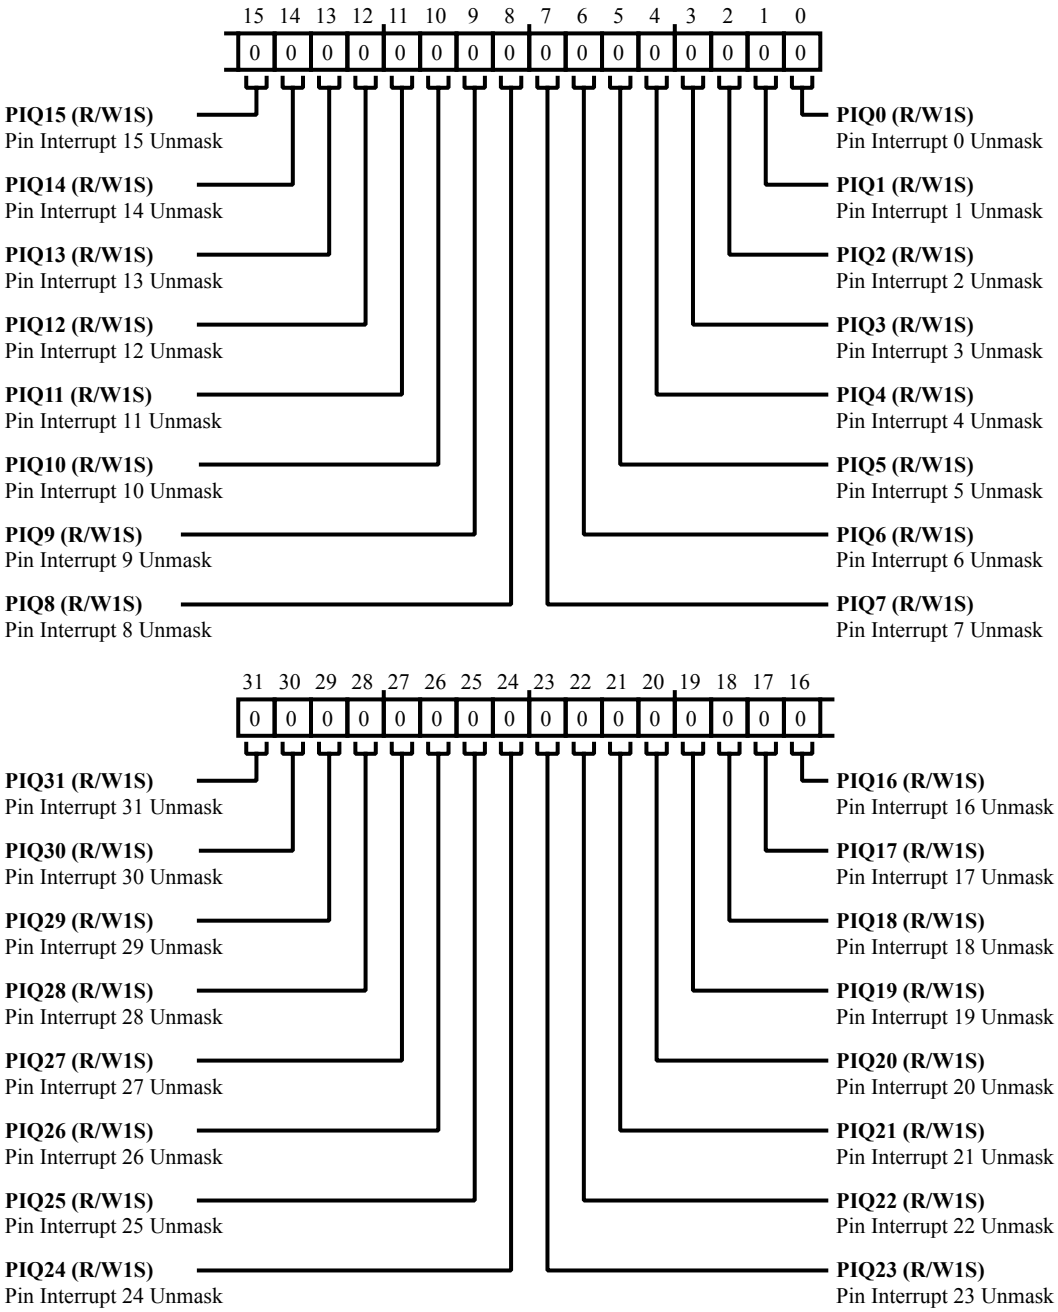

Figure 13-33: PINT_MSK_SET Register Diagram

Table 13-39: PINT_MSK_SET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W1S)	PIQ31	Pin Interrupt 31 Unmask. Set the PINT_MSK_SET.PIQ31 bit to enable the interrupt.
30 (R/W1S)	PIQ30	Pin Interrupt 30 Unmask. Set the PINT_MSK_SET.PIQ30 bit to enable the interrupt.
29 (R/W1S)	PIQ29	Pin Interrupt 29 Unmask. Set the PINT_MSK_SET.PIQ29 bit to enable the interrupt.
28 (R/W1S)	PIQ28	Pin Interrupt 28 Unmask. Set the PINT_MSK_SET.PIQ28 bit to enable the interrupt.
27 (R/W1S)	PIQ27	Pin Interrupt 27 Unmask. Set the PINT_MSK_SET.PIQ27 bit to enable the interrupt.
26 (R/W1S)	PIQ26	Pin Interrupt 26 Unmask. Set the PINT_MSK_SET.PIQ26 bit to enable the interrupt.
25 (R/W1S)	PIQ25	Pin Interrupt 25 Unmask. Set the PINT_MSK_SET.PIQ25 bit to enable the interrupt.
24 (R/W1S)	PIQ24	Pin Interrupt 24 Unmask. Set the PINT_MSK_SET.PIQ24 bit to enable the interrupt.
23 (R/W1S)	PIQ23	Pin Interrupt 23 Unmask. Set the PINT_MSK_SET.PIQ23 bit to enable the interrupt.
22 (R/W1S)	PIQ22	Pin Interrupt 22 Unmask. Set the PINT_MSK_SET.PIQ22 bit to enable the interrupt.
21 (R/W1S)	PIQ21	Pin Interrupt 21 Unmask. Set the PINT_MSK_SET.PIQ21 bit to enable the interrupt.
20 (R/W1S)	PIQ20	Pin Interrupt 20 Unmask. Set the PINT_MSK_SET.PIQ20 bit to enable the interrupt.
19 (R/W1S)	PIQ19	Pin Interrupt 19 Unmask. Set the PINT_MSK_SET.PIQ19 bit to enable the interrupt.
18 (R/W1S)	PIQ18	Pin Interrupt 18 Unmask. Set the PINT_MSK_SET.PIQ18 bit to enable the interrupt.
17 (R/W1S)	PIQ17	Pin Interrupt 17 Unmask. Set the PINT_MSK_SET.PIQ17 bit to enable the interrupt.
16 (R/W1S)	PIQ16	Pin Interrupt 16 Unmask. Set the PINT_MSK_SET.PIQ16 bit to enable the interrupt.

Table 13-39: PINT_MSK_SET Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W1S)	PIQ15	Pin Interrupt 15 Unmask. Set the PINT_MSK_SET.PIQ15 bit to enable the interrupt.
14 (R/W1S)	PIQ14	Pin Interrupt 14 Unmask. Set the PINT_MSK_SET.PIQ14 bit to enable the interrupt.
13 (R/W1S)	PIQ13	Pin Interrupt 13 Unmask. Set the PINT_MSK_SET.PIQ13 bit to enable the interrupt.
12 (R/W1S)	PIQ12	Pin Interrupt 12 Unmask. Set the PINT_MSK_SET.PIQ12 bit to enable the interrupt.
11 (R/W1S)	PIQ11	Pin Interrupt 11 Unmask. Set the PINT_MSK_SET.PIQ11 bit to enable the interrupt.
10 (R/W1S)	PIQ10	Pin Interrupt 10 Unmask. Set the PINT_MSK_SET.PIQ10 bit to enable the interrupt.
9 (R/W1S)	PIQ9	Pin Interrupt 9 Unmask. Set the PINT_MSK_SET.PIQ9 bit to enable the interrupt.
8 (R/W1S)	PIQ8	Pin Interrupt 8 Unmask. Set the PINT_MSK_SET.PIQ8 bit to enable the interrupt.
7 (R/W1S)	PIQ7	Pin Interrupt 7 Unmask. Set the PINT_MSK_SET.PIQ7 bit to enable the interrupt.
6 (R/W1S)	PIQ6	Pin Interrupt 6 Unmask. Set the PINT_MSK_SET.PIQ6 bit to enable the interrupt.
5 (R/W1S)	PIQ5	Pin Interrupt 5 Unmask. Set the PINT_MSK_SET.PIQ5 bit to enable the interrupt.
4 (R/W1S)	PIQ4	Pin Interrupt 4 Unmask. Set the PINT_MSK_SET.PIQ4 bit to enable the interrupt.
3 (R/W1S)	PIQ3	Pin Interrupt 3 Unmask. Set the PINT_MSK_SET.PIQ3 bit to enable the interrupt.
2 (R/W1S)	PIQ2	Pin Interrupt 2 Unmask. Set the PINT_MSK_SET.PIQ2 bit to enable the interrupt.
1 (R/W1S)	PIQ1	Pin Interrupt 1 Unmask. Set the PINT_MSK_SET.PIQ1 bit to enable the interrupt.
0 (R/W1S)	PIQ0	Pin Interrupt 0 Unmask. Set the PINT_MSK_SET.PIQ0 bit to enable the interrupt.

PINT Pin State Register

When a half port is assigned to a byte in any PINT block, the state of the eight pins (regardless of GPIO or function, input or output) can be seen in the PINT_PINSTATE register. While neither input nor output drivers of the pin are enabled, reads of the pin state in PINT_PINSTATE return zero. The PINT_PINSTATE register reports the inverted state of the pin if the signal inverter is activated by the PINT_INV_SET register. The inverter can be enabled on an individual bit-by-bit basis. Every bit in the PINT_INV_SET and PINT_INV_CLR register pair represents a pin signal.

The pin interrupt pin state registers enable the service routine to read the current state of the pin without reading from GPIO space. If there was an edge-sensitive interrupt, the service routine can check whether the state of the pin is still high or turned low.

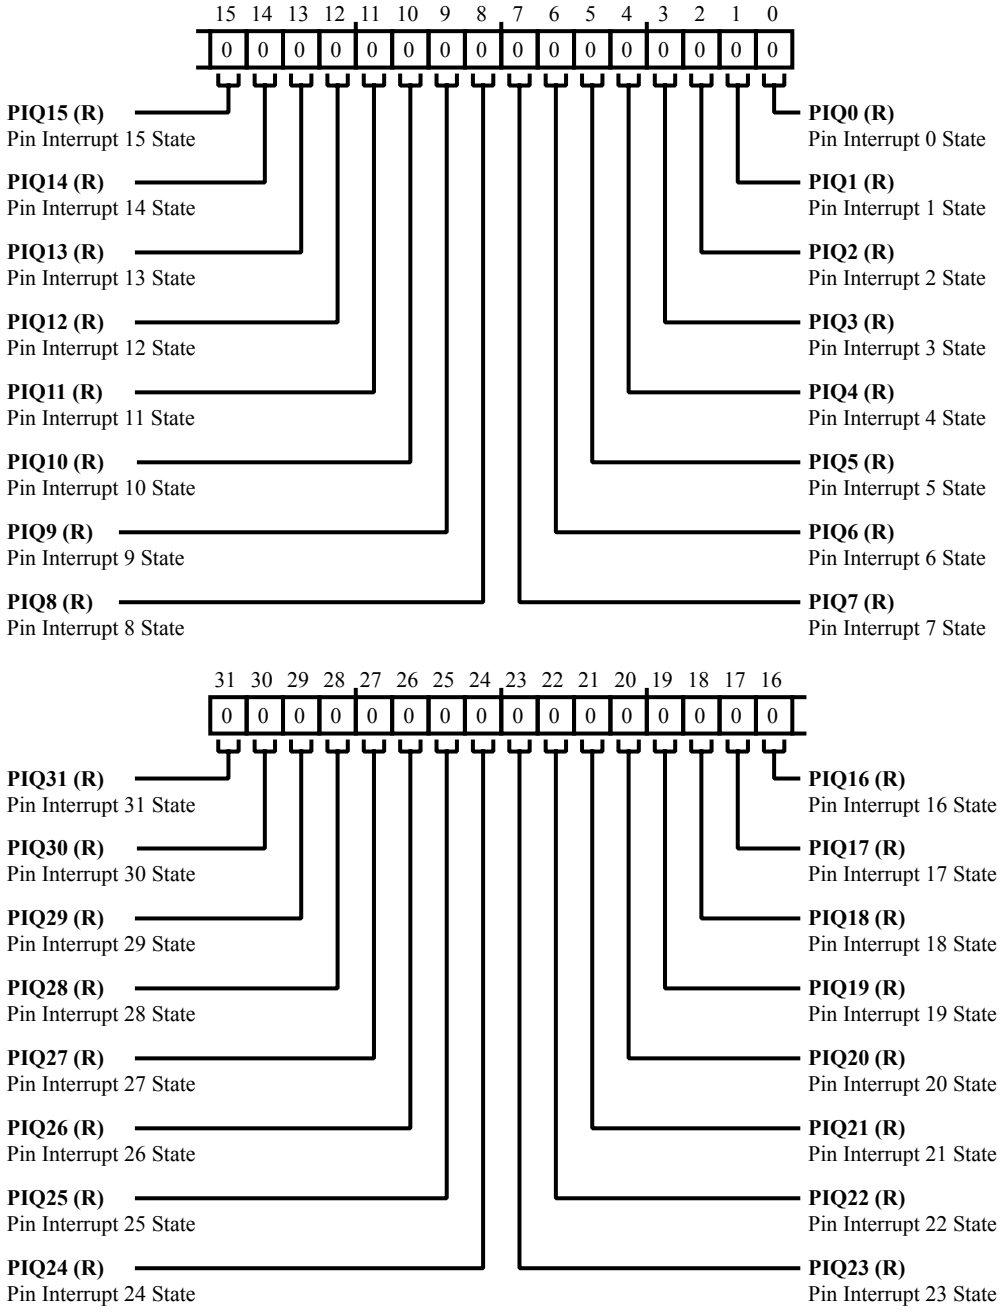

Figure 13-34: PINT_PINSTATE Register Diagram

Table 13-40: PINT_PINSTATE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/NW)	PIQ31	Pin Interrupt 31 State. A read of the `PINT_PINSTATE.PIQ31` bit returns the pin state.

Table 13-40: PINT_PINSTATE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
30 (R/NW)	PIQ30	Pin Interrupt 30 State. A read of the PINT_PINSTATE.PIQ30 bit returns the pin state.
29 (R/NW)	PIQ29	Pin Interrupt 29 State. A read of the PINT_PINSTATE.PIQ29 bit returns the pin state.
28 (R/NW)	PIQ28	Pin Interrupt 28 State. A read of the PINT_PINSTATE.PIQ28 bit returns the pin state.
27 (R/NW)	PIQ27	Pin Interrupt 27 State. A read of the PINT_PINSTATE.PIQ27 bit returns the pin state.
26 (R/NW)	PIQ26	Pin Interrupt 26 State. A read of the PINT_PINSTATE.PIQ26 bit returns the pin state.
25 (R/NW)	PIQ25	Pin Interrupt 25 State. A read of the PINT_PINSTATE.PIQ25 bit returns the pin state.
24 (R/NW)	PIQ24	Pin Interrupt 24 State. A read of the PINT_PINSTATE.PIQ24 bit returns the pin state.
23 (R/NW)	PIQ23	Pin Interrupt 23 State. A read of the PINT_PINSTATE.PIQ23 bit returns the pin state.
22 (R/NW)	PIQ22	Pin Interrupt 22 State. A read of the PINT_PINSTATE.PIQ22 bit returns the pin state.
21 (R/NW)	PIQ21	Pin Interrupt 21 State. A read of the PINT_PINSTATE.PIQ21 bit returns the pin state.
20 (R/NW)	PIQ20	Pin Interrupt 20 State. A read of the PINT_PINSTATE.PIQ20 bit returns the pin state.
19 (R/NW)	PIQ19	Pin Interrupt 19 State. A read of the PINT_PINSTATE.PIQ19 bit returns the pin state.
18 (R/NW)	PIQ18	Pin Interrupt 18 State. A read of the PINT_PINSTATE.PIQ18 bit returns the pin state.
17 (R/NW)	PIQ17	Pin Interrupt 17 State. A read of the PINT_PINSTATE.PIQ17 bit returns the pin state.
16 (R/NW)	PIQ16	Pin Interrupt 16 State. A read of the PINT_PINSTATE.PIQ16 bit returns the pin state.
15 (R/NW)	PIQ15	Pin Interrupt 15 State. A read of the PINT_PINSTATE.PIQ15 bit returns the pin state.

Table 13-40: PINT_PINSTATE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
14 (R/NW)	PIQ14	Pin Interrupt 14 State. A read of the PINT_PINSTATE.PIQ14 bit returns the pin state.
13 (R/NW)	PIQ13	Pin Interrupt 13 State. A read of the PINT_PINSTATE.PIQ13 bit returns the pin state.
12 (R/NW)	PIQ12	Pin Interrupt 12 State. A read of the PINT_PINSTATE.PIQ12 bit returns the pin state.
11 (R/NW)	PIQ11	Pin Interrupt 11 State. A read of the PINT_PINSTATE.PIQ11 bit returns the pin state.
10 (R/NW)	PIQ10	Pin Interrupt 10 State. A read of the PINT_PINSTATE.PIQ10 bit returns the pin state.
9 (R/NW)	PIQ9	Pin Interrupt 9 State. A read of the PINT_PINSTATE.PIQ9 bit returns the pin state.
8 (R/NW)	PIQ8	Pin Interrupt 8 State. A read of the PINT_PINSTATE.PIQ8 bit returns the pin state.
7 (R/NW)	PIQ7	Pin Interrupt 7 State. A read of the PINT_PINSTATE.PIQ7 bit returns the pin state.
6 (R/NW)	PIQ6	Pin Interrupt 6 State. A read of the PINT_PINSTATE.PIQ6 bit returns the pin state.
5 (R/NW)	PIQ5	Pin Interrupt 5 State. A read of the PINT_PINSTATE.PIQ5 bit returns the pin state.
4 (R/NW)	PIQ4	Pin Interrupt 4 State. A read of the PINT_PINSTATE.PIQ4 bit returns the pin state.
3 (R/NW)	PIQ3	Pin Interrupt 3 State. A read of the PINT_PINSTATE.PIQ3 bit returns the pin state.
2 (R/NW)	PIQ2	Pin Interrupt 2 State. A read of the PINT_PINSTATE.PIQ2 bit returns the pin state.
1 (R/NW)	PIQ1	Pin Interrupt 1 State. A read of the PINT_PINSTATE.PIQ1 bit returns the pin state.
0 (R/NW)	PIQ0	Pin Interrupt 0 State. A read of the PINT_PINSTATE.PIQ0 bit returns the pin state.

PINT Request Register

The PINT_REQ register indicates the interrupt request status for pin interrupts. When set, an interrupt request is pending. When cleared, there is no interrupt request pending.

Both the PINT_REQ and PINT_LATCH registers indicate whether an interrupt request is latched on the respective pin. The PINT_LATCH register is a latch that operates regardless of the interrupt masks. Bits of the PINT_REQ register depend on the mask register. The PINT_REQ register is a logical AND of the PINT_LATCH register and the interrupt mask.

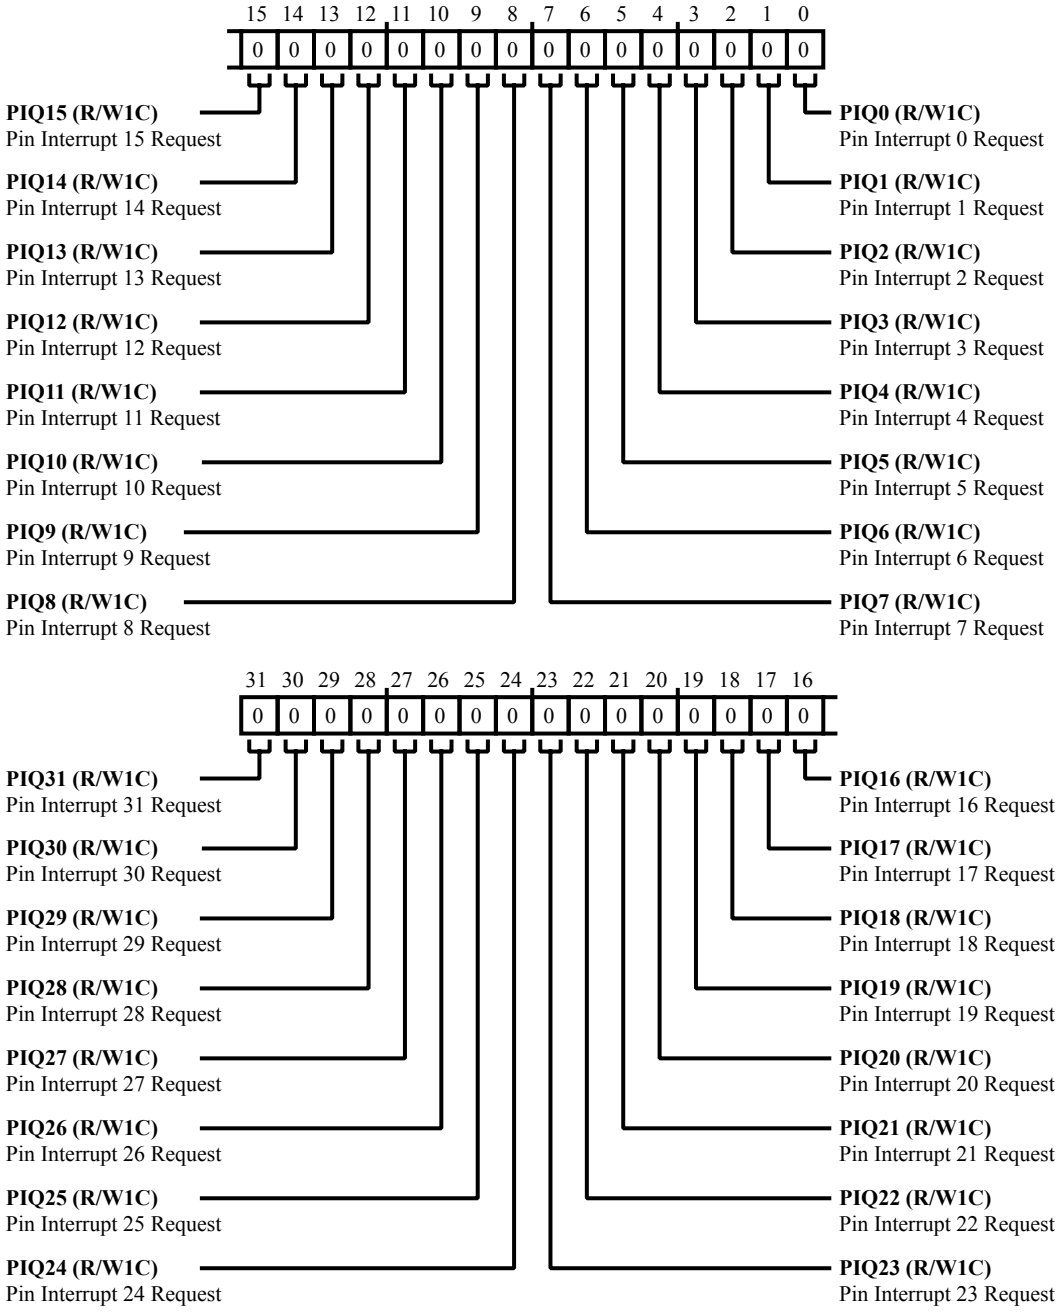

Figure 13-35: PINT_REQ Register Diagram

Table 13-41: PINT_REQ Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W1C)	PIQ31	Pin Interrupt 31 Request. If the `PINT_REQ.PIQ31` bit is set, a request is pending.

Table 13-41: PINT_REQ Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
30 (R/W1C)	PIQ30	Pin Interrupt 30 Request. If the `PINT_REQ.PIQ30` bit is set, a request is pending.
29 (R/W1C)	PIQ29	Pin Interrupt 29 Request. If the `PINT_REQ.PIQ29` bit is set, a request is pending.
28 (R/W1C)	PIQ28	Pin Interrupt 28 Request. If the `PINT_REQ.PIQ28` bit is set, a request is pending.
27 (R/W1C)	PIQ27	Pin Interrupt 27 Request. If the `PINT_REQ.PIQ27` bit is set, a request is pending.
26 (R/W1C)	PIQ26	Pin Interrupt 26 Request. If the `PINT_REQ.PIQ26` bit is set, a request is pending.
25 (R/W1C)	PIQ25	Pin Interrupt 25 Request. If the `PINT_REQ.PIQ25` bit is set, a request is pending.
24 (R/W1C)	PIQ24	Pin Interrupt 24 Request. If the `PINT_REQ.PIQ24` bit is set, a request is pending.
23 (R/W1C)	PIQ23	Pin Interrupt 23 Request. If the `PINT_REQ.PIQ23` bit is set, a request is pending.
22 (R/W1C)	PIQ22	Pin Interrupt 22 Request. If the `PINT_REQ.PIQ22` bit is set, a request is pending.
21 (R/W1C)	PIQ21	Pin Interrupt 21 Request. If the `PINT_REQ.PIQ21` bit is set, a request is pending.
20 (R/W1C)	PIQ20	Pin Interrupt 20 Request. If the `PINT_REQ.PIQ20` bit is set, a request is pending.
19 (R/W1C)	PIQ19	Pin Interrupt 19 Request. If the `PINT_REQ.PIQ19` bit is set, a request is pending.
18 (R/W1C)	PIQ18	Pin Interrupt 18 Request. If the `PINT_REQ.PIQ18` bit is set, a request is pending.
17 (R/W1C)	PIQ17	Pin Interrupt 17 Request. If the `PINT_REQ.PIQ17` bit is set, a request is pending.
16 (R/W1C)	PIQ16	Pin Interrupt 16 Request. If the `PINT_REQ.PIQ16` bit is set, a request is pending.
15 (R/W1C)	PIQ15	Pin Interrupt 15 Request. If the `PINT_REQ.PIQ15` bit is set, a request is pending.

Table 13-41: PINT_REQ Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
14 (R/W1C)	PIQ14	Pin Interrupt 14 Request. If the `PINT_REQ.PIQ14` bit is set, a request is pending.
13 (R/W1C)	PIQ13	Pin Interrupt 13 Request. If the `PINT_REQ.PIQ13` bit is set, a request is pending.
12 (R/W1C)	PIQ12	Pin Interrupt 12 Request. If the `PINT_REQ.PIQ12` bit is set, a request is pending.
11 (R/W1C)	PIQ11	Pin Interrupt 11 Request. If the `PINT_REQ.PIQ11` bit is set, a request is pending.
10 (R/W1C)	PIQ10	Pin Interrupt 10 Request. If the `PINT_REQ.PIQ10` bit is set, a request is pending.
9 (R/W1C)	PIQ9	Pin Interrupt 9 Request. If the `PINT_REQ.PIQ9` bit is set, a request is pending.
8 (R/W1C)	PIQ8	Pin Interrupt 8 Request. If the `PINT_REQ.PIQ8` bit is set, a request is pending.
7 (R/W1C)	PIQ7	Pin Interrupt 7 Request. If the `PINT_REQ.PIQ7` bit is set, a request is pending.
6 (R/W1C)	PIQ6	Pin Interrupt 6 Request. If the `PINT_REQ.PIQ6` bit is set, a request is pending.
5 (R/W1C)	PIQ5	Pin Interrupt 5 Request. If the `PINT_REQ.PIQ5` bit is set, a request is pending.
4 (R/W1C)	PIQ4	Pin Interrupt 4 Request. If the `PINT_REQ.PIQ4` bit is set, a request is pending.
3 (R/W1C)	PIQ3	Pin Interrupt 3 Request. If the `PINT_REQ.PIQ3` bit is set, a request is pending.
2 (R/W1C)	PIQ2	Pin Interrupt 2 Request. If the `PINT_REQ.PIQ2` bit is set, a request is pending.
1 (R/W1C)	PIQ1	Pin Interrupt 1 Request. If the `PINT_REQ.PIQ1` bit is set, a request is pending.
0 (R/W1C)	PIQ0	Pin Interrupt 0 Request. If the `PINT_REQ.PIQ0` bit is set, a request is pending.

ADSP-SC59x PADS Register Descriptions

Pads Controller (PADS) contains the following registers.

Table 13-42: ADSP-SC59x PADS Register List

Name	Description
PADS_DAI0_0_DS	DAI0 1 to 10 pins DS control
PADS_DAI0_1_DS	DAI0 11 to 20 pins DS control
PADS_DAI0_IE	DAI0 Port Input Enable Control Register
PADS_DAI1_0_DS	DAI1 1 to 10 pins DS control
PADS_DAI1_1_DS	DAI1 11 to 20 pins DS control
PADS_DAI1_IE	DAI1 Port Input Enable Control Register
PADS_DAI[n]_PDE	DAI[n] Pull-Down Enable
PADS_DAI[n]_PUE	DAI[n] Pull-Up Enable
PADS_NONPORTS_DS	Non-GPIO Drive Strength Register
PADS_PCFG0	Peripheral PAD Configuration0 Register
PADS_PCFG1	Peripheral Configuration1 Register
PADS_PORTA0_DS	PORTA 0 to 7 pins DS control
PADS_PORTA1_DS	PORTA 8 - 15 pins DS control
PADS_PORTB0_DS	PORTB 0 to 7 pins DS control
PADS_PORTB1_DS	PORTB 8 - 15 pins DS control
PADS_PORTC0_DS	PORTC 0 to 7 pins DS control
PADS_PORTC1_DS	PORTC 8 - 15 pins DS control
PADS_PORTD0_DS	PORTD 0 to 7 pins DS control
PADS_PORTD1_DS	PORTD 8 to 15 pins DS control
PADS_PORTE0_DS	PORTE 0 to 7 pins DS control
PADS_PORTE1_DS	PORTE 8 to 15 pins DS control
PADS_PORTF0_DS	PORTF 0 to 7 pins DS control
PADS_PORTF1_DS	PORTF 8 to 15 pins DS control
PADS_PORTG0_DS	PORTG 0 to 7 pins DS control
PADS_PORTG1_DS	PORTG 8 to 15 pins DS control
PADS_PORTH0_DS	PORTH 0 to 7 pins DS control
PADS_PORTH1_DS	PORTH 8 to 15 pins DS control
PADS_PORTI0_DS	PORTI 0 to 7 pins DS control
PADS_PORT[n]_PDE	PORT[n] Pull-Down Enable

Table 13-42: ADSP-SC59x PADS Register List (Continued)

Name	Description
PADS_PORT[n]_PUE	PORT[n] Pull-Up Enable

DAI0 1 to 10 pins DS control

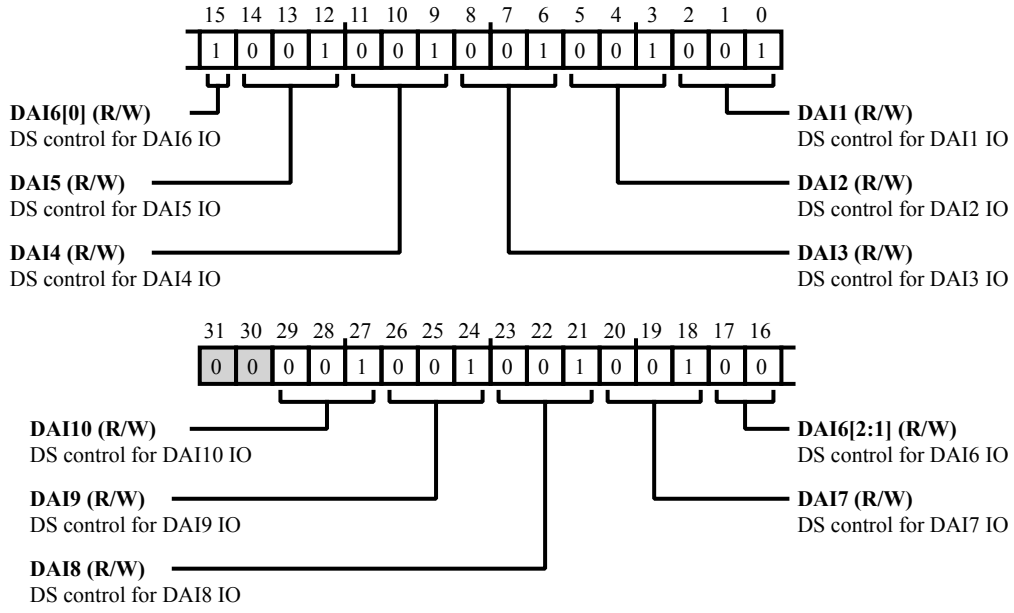

Figure 13-36: PADS_DAI0_0_DS Register Diagram

Table 13-43: PADS_DAI0_0_DS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
29:27 (R/W)	DAI10	DS control for DAI10 IO.	
		1	Drive strength 001. To be used for operating frequency less than or equal to 62.5MHz. Drive Strength 000/1xx are invalid
		2	Drive strength 010. To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid
26:24 (R/W)	DAI9	DS control for DAI9 IO.	
		1	Drive strength 001. To be used for operating frequency less than or equal to 62.5MHz. Drive Strength 000/1xx are invalid
		2	Drive strength 010.To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid

Table 13-43: PADS_DAI0_0_DS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
23:21 (R/W)	DAI8	DS control for DAI8 IO.	
		1	Drive strength 001. To be used for operating frequency less than or equal to 62.5MHz. Drive Strength 000/1xx are invalid
		2	Drive strength 010.To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid
20:18 (R/W)	DAI7	DS control for DAI7 IO.	
		1	Drive strength 001. To be used for operating frequency less than or equal to 62.5MHz. Drive Strength 000/1xx are invalid
		2	Drive strength 010.To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid
17:15 (R/W)	DAI6	DS control for DAI6 IO.	
		1	Drive strength 001. To be used for operating frequency less than or equal to 62.5MHz. Drive Strength 000/1xx are invalid
		2	Drive strength 010.To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid
14:12 (R/W)	DAI5	DS control for DAI5 IO.	
		1	Drive strength 001. To be used for operating frequency less than or equal to 62.5MHz. Drive Strength 000/1xx are invalid
		2	Drive strength 010.To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid
11:9 (R/W)	DAI4	DS control for DAI4 IO.	
		1	Drive strength 001. To be used for operating frequency less than or equal to 62.5MHz. Drive Strength 000/1xx are invalid
		2	Drive strength 010.To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid

Table 13-43: PADS_DAI0_0_DS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8:6 (R/W)	DAI3	DS control for DAI3 IO.	
		1	Drive strength 001. To be used for operating frequency less than or equal to 62.5MHz. Drive Strength 000/1xx are invalid
		2	Drive strength 010.To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid
5:3 (R/W)	DAI2	DS control for DAI2 IO.	
		1	Drive strength 001. To be used for operating frequency less than or equal to 62.5MHz. Drive Strength 000/1xx are invalid
		2	Drive strength 010.To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid
2:0 (R/W)	DAI1	DS control for DAI1 IO.	
		1	Drive strength 001. To be used for operating frequency less than or equal to 62.5MHz. Drive Strength 000/1xx are invalid
		2	Drive strength 010.To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid

		1	Drive strength 001. To be used for operating frequency less than or equal to 62.5MHz. Drive Strength 000/1xx are invalid
		2	Drive strength 010.To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid
20:18 (R/W)	DAI17	DS control for DAI17 IO.	
		1	Drive strength 001. To be used for operating frequency less than or equal to 62.5MHz. Drive Strength 000/1xx are invalid
		2	Drive strength 010.To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid
17:15 (R/W)	DAI16	DS control for DAI16 IO.	
		1	Drive strength 001. To be used for operating frequency less than or equal to 62.5MHz. Drive Strength 000/1xx are invalid
		2	Drive strength 010.To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid
14:12 (R/W)	DAI15	DS control for DAI15 IO.	
		1	Drive strength 001. To be used for operating frequency less than or equal to 62.5MHz. Drive Strength 000/1xx are invalid
		2	Drive strength 010.To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid
11:9 (R/W)	DAI14	DS control for DAI14 IO.	
		1	Drive strength 001. To be used for operating frequency less than or equal to 62.5MHz. Drive Strength 000/1xx are invalid
		2	Drive strength 010.To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid

Table 13-44: PADS_DAI0_1_DS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8:6 (R/W)	DAI13	DS control for DAI13 IO.	
		1	Drive strength 001. To be used for operating frequency less than or equal to 62.5MHz. Drive Strength 000/1xx are invalid
		2	Drive strength 010.To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid
5:3 (R/W)	DAI12	DS control for DAI12 IO.	
		1	Drive strength 001. To be used for operating frequency less than or equal to 62.5MHz. Drive Strength 000/1xx are invalid
		2	Drive strength 010.To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid
2:0 (R/W)	DAI11	DS control for DAI11 IO.	
		1	Drive strength 001. To be used for operating frequency less than or equal to 62.5MHz. Drive Strength 000/1xx are invalid
		2	Drive strength 010.To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid

DAI0 Port Input Enable Control Register

The PADS_DAI0_IE register configures input enable control of the DAI0 (20 pins) pads. If =0 implies input buffer disable and if =1 implies enable.

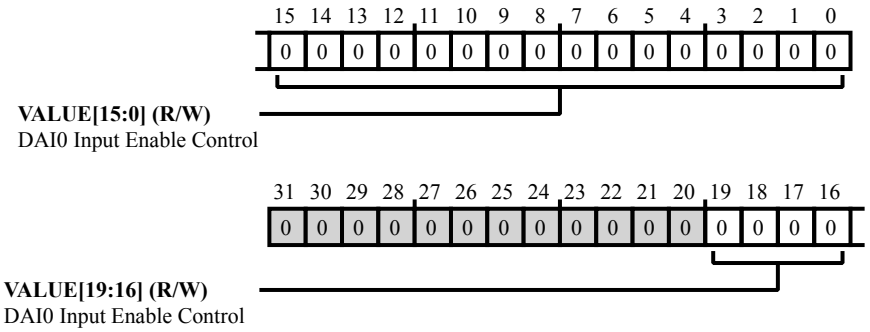

Figure 13-38: PADS_DAI0_IE Register Diagram

Table 13-45: PADS_DAI0_IE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
19:0 (R/W)	VALUE	DAI0 Input Enable Control.

DAI1 1 to 10 pins DS control

		2	Drive strength 010.To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid
5:3 (R/W)	DAI12	DS control for DAI12 IO.	
		1	Drive strength 001. To be used for operating frequency less than or equal to 62.5MHz. Drive Strength 000/1xx are invalid
		2	Drive strength 010.To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid
2:0 (R/W)	DAI11	DS control for DAI11 IO.	
		1	Drive strength 001. To be used for operating frequency less than or equal to 62.5MHz. Drive Strength 000/1xx are invalid
		2	Drive strength 010.To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid

DAI1 Port Input Enable Control Register

The PADS_DAI1_IE register configures input enable control of the DAI1 (20 pins) pads. If =0 implies input buffer disable and if =1 implies enable.

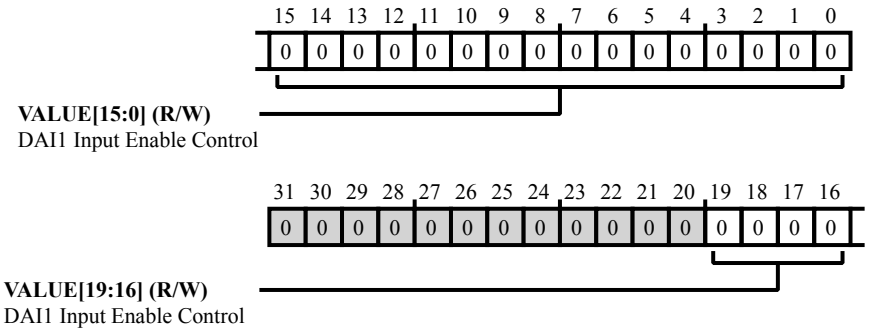

Figure 13-41: PADS_DAI1_IE Register Diagram

Table 13-48: PADS_DAI1_IE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
19:0 (R/W)	VALUE	DAI1 Input Enable Control.

DAI[n] Pull-Down Enable

Each bit of the PADS_DAI[n]_PDE register is mapped to a corresponding DAI pin pull-down enable.

Do not enable both the pull-up and pull-down at the same time for any pad. Check the Pull-Up Enable register to make sure there is no conflict.

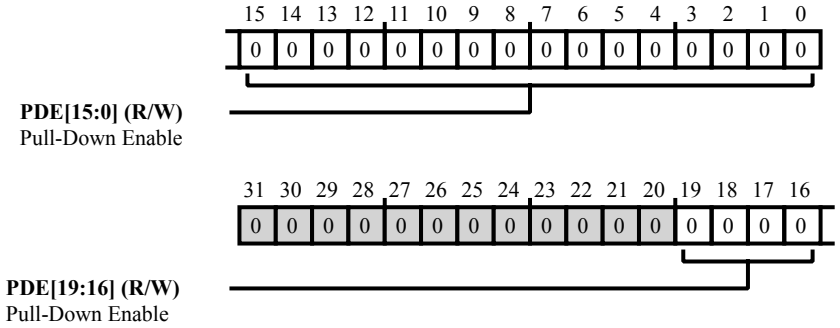

Figure 13-42: PADS_DAI[n]_PDE Register Diagram

Table 13-49: PADS_DAI[n]_PDE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
19:0 (R/W)	PDE	Pull-Down Enable. Set (=1) the PADS_DAI[n]_PDE.PDE bit to enable the pull-down. Clear (=0) the PADS_DAI[n]_PDE.PDE bit to disable the pull-down.

DAI[n] Pull-Up Enable

The PADS_DAI[n]_PUE register enables the pull-up resistor for DAI pins. Each bit of the PADS_DAI[n]_PUE register is mapped to the corresponding DAI pin pull-up enable.

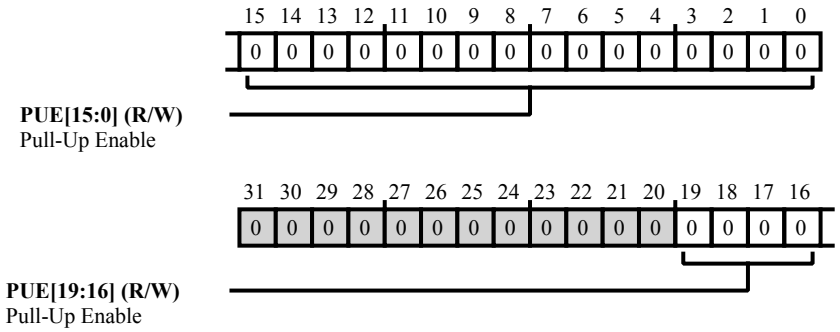

Figure 13-43: PADS_DAI[n]_PUE Register Diagram

Table 13-50: PADS_DAI[n]_PUE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
19:0 (R/W)	PUE	Pull-Up Enable. Set (=1) the PADS_DAI[n]_PUE.PUE bit to enable the pull-up. Clear (=0) the PADS_DAI[n]_PUE.PUE bit to disable the pull-up.

Non-GPIO Drive Strength Register

The PADS_NONPORTS_DS register sets the drive strength and tolerance for the non-GPIO pins. The drive strength is only controlled for pin groups classified by the interface type.

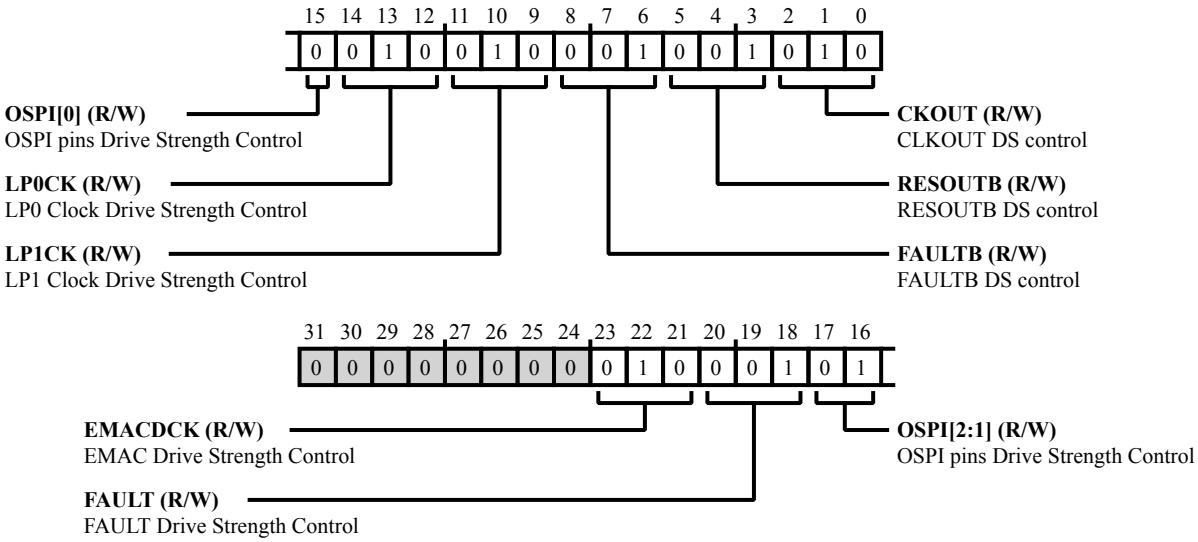

Figure 13-44: PADS_NONPORTS_DS Register Diagram

Table 13-51: PADS_NONPORTS_DS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
23:21 (R/W)	EMACDCK	EMAC Drive Strength Control.	
		1	Drive Strength 001 For an operating frequency less than or equal to 62.5MHz. A drive strength of 000/1xx is invalid.
		2	Drive Strength 010 For an operating frequency more than 62.5MHz. A drive strength of 000/1xx is invalid.
20:18 (R/W)	FAULT	FAULT Drive Strength Control.	
		1	Drive Strength 001 For an operating frequency less than or equal to 62.5MHz. A drive strength of 000/1xx is invalid.
		2	Drive Strength 010 For an operating frequency more than 62.5MHz. A drive strength of 000/1xx is invalid.

Table 13-51: PADS_NONPORTS_DS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
17:15 (R/W)	OSPI	OSPI pins Drive Strength Control.	
		1	Drive Strength 001 For an operating frequency less than or equal to 62.5MHz. A drive strength of 000/1xx is invalid.
		2	Drive Strength 010 For an operating frequency more than 62.5MHz. A drive strength of 000/1xx is invalid.
14:12 (R/W)	LP0CK	LP0 Clock Drive Strength Control.	
		1	Drive strength 001. To be used for operating frequency less than or equal to 62.5MHz. Drive Strength 000/1xx are invalid
		2	Drive strength 010.To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid
11:9 (R/W)	LP1CK	LP1 Clock Drive Strength Control.	
		1	Drive strength 001. To be used for operating frequency less than or equal to 62.5MHz. Drive Strength 000/1xx are invalid
		2	Drive strength 010.To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid
8:6 (R/W)	FAULTB	FAULTB DS control.	
		1	Drive strength 001. To be used for operating frequency less than or equal to 62.5MHz. Drive Strength 000/1xx are invalid
		2	Drive strength 010.To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid
5:3 (R/W)	RESOUTB	RESOUTB DS control.	
		1	Drive strength 001. To be used for operating frequency less than or equal to 62.5MHz. Drive Strength 000/1xx are invalid
		2	Drive strength 010.To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid

Table 13-51: PADS_NONPORTS_DS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2:0 (R/W)	CKOUT	CLKOUT DS control.	
		1	Drive strength 001. To be used for operating frequency less than or equal to 62.5MHz. Drive Strength 000/1xx are invalid
		2	Drive strength 010.To be used for operating frequency more than 62.5MHz. Drive Strength 000/1xx are invalid

Peripheral PAD Configuration0 Register

The PADS_PCFG0 register provides several configuration options for the pads and multiplexing for peripherals.

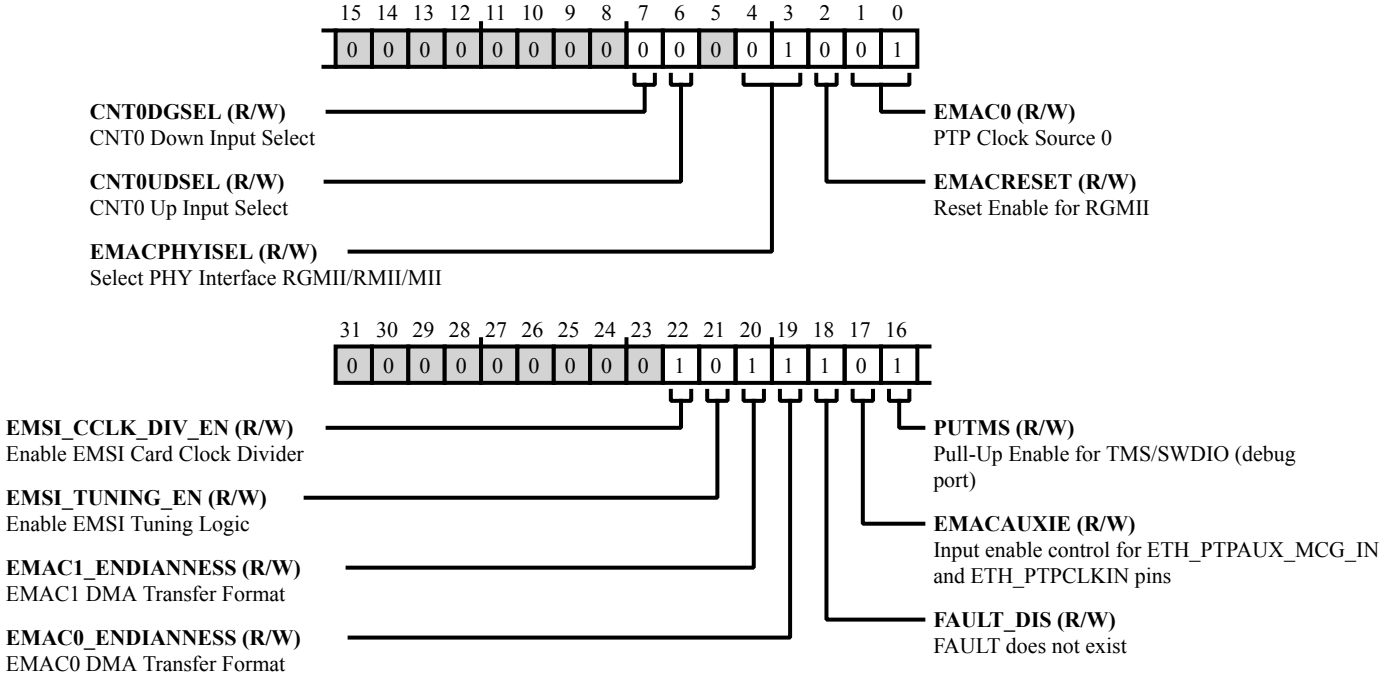

Figure 13-45: PADS_PCFG0 Register Diagram

Table 13-52: PADS_PCFG0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
22 (R/W)	EMSI_CCLK_DIV_EN	Enable EMSI Card Clock Divider.	
21 (R/W)	EMSI_TUNING_EN	Enable EMSI Tuning Logic.	
20 (R/W)	EMAC1_ENDIANNESS	EMAC1 DMA Transfer Format. Configure the PADS_PCFG0.EMAC1_ENDIANNESS bit field to set the EMAC1 DMA transfers to use big-endian or little-endian format.	
		0	Little-Endian
		1	Big-Endian

Table 13-52: PADS_PCFG0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
19 (R/W)	EMAC0_ENDIANNESS	EMAC0 DMA Transfer Format. Configure the `PADS_PCFG0.EMAC0_ENDIANNESS` bit field to set the EMAC0 DMA transfers to use big-endian or little-endian format.	
		0	Little-Endian
		1	Big-Endian
18 (R/W)	FAULT_DIS	FAULT does not exist.	
		0	Disable input
		1	Enable input
17 (R/W)	EMACAUXIE	Input enable control for ETH_PTPAUX_MCG_IN and ETH_PTPCLKIN pins.	
		0	Disable input
		1	Enable input
16 (R/W)	PUTMS	Pull-Up Enable for TMS/SWDIO (debug port).	
		0	Disable pull-up
		1	Enable pull-up
7 (R/W)	CNT0DGSEL	CNT0 Down Input Select. The `PADS_PCFG0` bit selects the input for the CNT0 counter down and gate.	
		0	GPIO port pins
		1	Trigger connection
6 (R/W)	CNT0UDSEL	CNT0 Up Input Select. The `PADS_PCFG0` bit selects the input for the CNT0 counter up and direction.	
		0	GPIO port pins
		1	Trigger connection
4:3 (R/W)	EMACPHYISEL	Select PHY Interface RGMII/RMII/MII.	
		0	MII Interface Selects PHY Interface MII
		1	RGMII Interface Selects PHY Interface RGMII
		2	RMII Interface Selects PHY Interface RMII
		3	Reserved

Table 13-52: PADS_PCFG0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W)	EMACRESET	Reset Enable for RGMII. The `PADS_PCFG0.EMACRESET` bit asserts the reset on the RGMII interface. To select the PHY interface (RGMII or RMII), set the EMACPHYISEL bit as required and then set `PADS_PCFG0.EMACRESET`.	
		0	RGMII reset is asserted
		1	RGMII reset reset is deasserted
1:0 (R/W)	EMAC0	PTP Clock Source 0. The `PADS_PCFG0.EMAC0` selects the clock source for the PTP Block in EMAC0.	
		0	REFCLK (MII or RMII) or CLKO7 (RGMII)
		1	SCLK0
		2	External PTP clock
		3	SCLK0

Peripheral Configuration1 Register

The PADS_PCFG1 register provides bits to configure PWM secondary inputs to timers and enable inputs from the TRU.

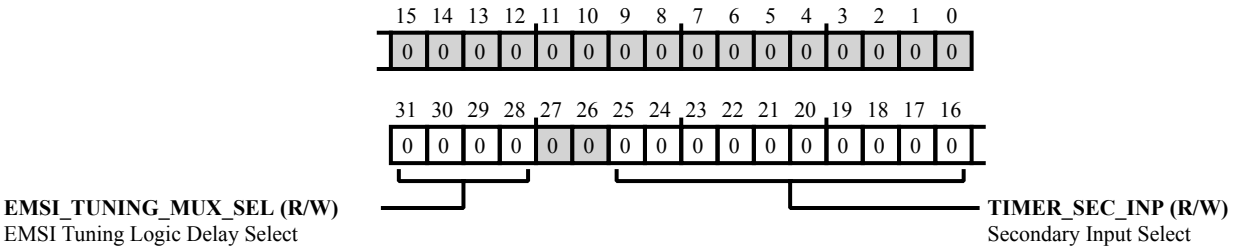

Figure 13-46: PADS_PCFG1 Register Diagram

Table 13-53: PADS_PCFG1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:28 (R/W)	EMSI_TUNING_MUX_SEL	EMSI Tuning Logic Delay Select. Delay Select for EMSI Tuning Logic to Generate Rx Clock.	
		0-3	Reserved
		4-7	Invert cclk_rx
		8	Reserved
		9	Reserved
		10	Reserved
		11	Reserved
		12	Reserved
		13	Reserved
		14	Reserved
		15	Reserved
25:16 (R/W)	TIMER_SEC_INP	Secondary Input Select. The PADS_PCFG1.TIMER_SEC_INP field selects secondary inputs to timers. The enumerated bits below define the source for the timer.	
		1	TIMER0_CLK The TIMER0_CLK source is PB_01 when bit[0] is cleared (=0) The TIMER0_CLK source is PF_05 when this bit is set (=1)

Table 13-53: PADS_PCFG1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		2	TIMER0_ACI0 The TIMER0_ACI0 source is PA_07 when bit[1] is cleared (=0) The TIMER0_ACI0 source is PD_08 when this bit is set (=1)
		4	TIMER0_ACI1 The TIMER0_ACI1 source is PA_14 when bit[2] is cleared (=0) The TIMER0_ACI1 source is PD_04 when this bit is set (=1)
		8	TIMER0_ACI2 The TIMER0_ACI2 source is PB_11 when bit[3] is cleared (=0) The TIMER0_ACI2 source is PD_10 when this bit is set (=1)
		16	TIMER0_ACI3 The TIMER0_ACI3 source is PB_00 when bit[4] is cleared (=0) The TIMER0_ACI3 source is PG_04 when this bit is set (=1)
		32	TIMER0_ACI4 The TIMER0_ACI4 source is PA_11 when bit[5] is cleared (=0) The TIMER0_ACI4 source is PF_15 when this bit is set (=1)
		64	TIMER0_ACLK1 The TIMER0_ACLK1 source is PA_06 when bit[6] is cleared (=0) The TIMER0_ACLK1 source is PG_09 when this bit is set (=1)
		128	TIMER0_ACLK2 The TIMER0_ACLK2 source is PA_08 when bit[7] is cleared (=0) The TIMER0_ACLK2 source is PI_05 when this bit is set (=1)

Table 13-53: PADS_PCFG1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		256	TIMER0_ACLK3 The TIMER0_ACLK3 source is PA_02 when bit[8] is cleared (=0) The TIMER0_ACLK3 source is PG_10 when this bit is set (=1)
		512	TIMER0_ACLK4 The TIMER0_ACLK4 source is PB_02 when bit[9] is cleared (=0) The TIMER0_ACLK4 source is PE_03 when this bit is set (=1)

14 Thermal Monitoring Unit (TMU)

The TMU provides on-chip temperature measurement which is important in applications that have substantial power consumption. The TMU is integrated into the processor die and digital infrastructure using an MMR-based system access to measure the die temperature variations in real-time.

TMU Features

The TMU supports the following features:

- On-chip temperature sensing
- Programmable over-temperature and under-temperature limits
- Programmable conversion rate
- Averaging feature available
- Temperature gain and offset correction options
- Uses dedicated channel of HADC for conversion
- Programmable blanking and refresh period for TMU conversion

TMU Functional Description

Following sections provide the functional description of TMU.

TMU Definitions

The following definitions are helpful when using the TMU module.

Thermal Diode

A special type of diode whose electrical properties change with the temperature in a defined way.

DTM

Dynamic thermal management is a set of techniques that adapt the run-time behavior of a processor to achieve the highest performance under thermal constraints.

TMU Block Diagram

The ***Thermal Monitoring Unit Block Diagram*** shows the main block inside TMU.

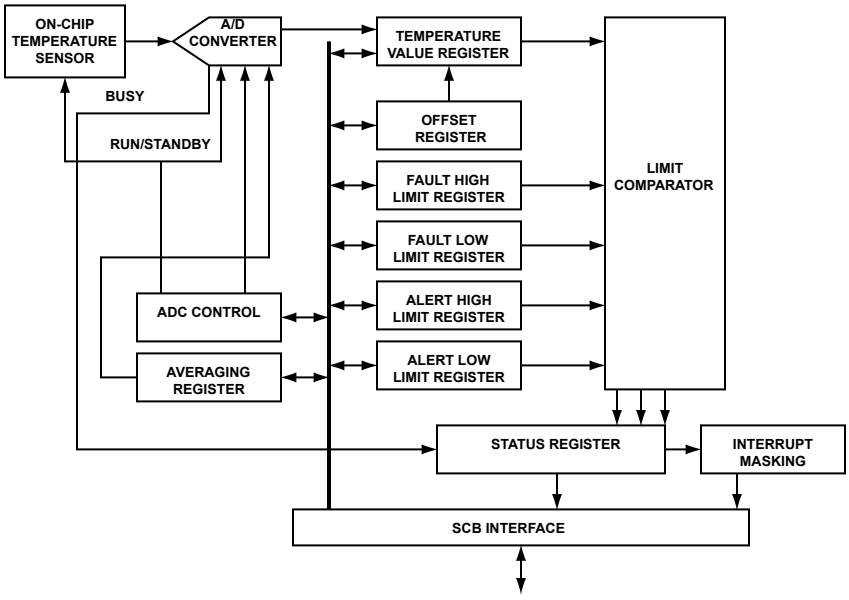

Figure 14-1: Thermal Monitoring Unit Block Diagram

TMU Architectural Concepts

The following sections provide information on the architecture and system integration of the TMU.

System Integration

Dynamic thermal management (DTM) techniques adapt the run-time behavior of a processor to achieve the highest performance under thermal constraints. One of the most important aspects of DTM is to capture the run-time variations in the temperature caused by power consumption variations due to workload changes.

The accuracy of thermal measurements directly affects the efficiency of thermal management as well as the performance of the processor. Temperature estimations lower or higher than the actual temperature may cause late or early activation of DTM techniques.

- Late activation of DTM can result in degraded reliability because the temperature may exceed the designated thresholds.
- Early activation of DTM can have significant impact on performance.

The TMU is an analog thermal sensor that consists of a temperature-sensing diode, a calibrated reference current source, and a current comparator. The sensor placement error is one of the most important sources of inaccuracy in values obtained from thermal sensors.

The TMU module provides the temperature monitoring capability to the chip and implements thermal management in the end system. It provides many features which ensure the minimum load on the software and also minimal or no external components for a flexible temperature monitoring system.

Digital Thermometer

The TMU functions as a digital thermometer with an MMR-based system access. The on-die temperature value is measured and digitized through an A/D converter. The temperature value is stored and updated periodically in an MMR register. The TMU can be configured to generate an interrupt as it crosses the upper temperature limit (`TMU_FLT_LIM_HI` register). A thermal event is also routed to the interrupt port of the sensor. The event is then routed to the SEC, to ensure that core intervention is not required in the event of overheating.

Temperature Sensor Averaging

The temperature sensor averaging feature enhances the accuracy of the temperature measurements. To enable this feature, the `TMU_AVG` bits must be enabled in the control register after power-up. In this mode, the averaging reduces the effect of noise on the temperature result. The temperature is measured each time a conversion is performed. A moving average method is used to determine the result in the temperature value register. The total time to measure a temperature channel is typically 1 ms.

TMU and HADC

The TMU modules uses one of the ADC channels to digitize the temperature reading. Therefore, the HADC module is shared by the TMU. If the TMU is not enabled, the HADC operates at its full throughput. TMU can be enabled periodically or permanently. In periodic enable mode, it is enabled once in a specific refresh period. After enabling, the TMU measures the temperature for a specific blanking period. During the blanking period, the TMU uses the ADC for temperature measurement, so that the ADC is not available for data conversion.

The typical value of blanking period is 21×10^4 system clock (SCLK0) cycles

The typical value of refresh period is 21×10^6 SCLK0 cycles

So, for every 21×10^6 cycles, 21×10^4 cycles are used for temperature measurement. Program these values for blanking period and refresh period through the TMU registers.

When TMU is enabled, the HADC modules is not available for external input conversion. This state is indicated by the `HADC_STAT.TMUHADC_BUSY` status bit. All the requests for HADC conversion are ignored when `HADC_STAT.TMUHADC_BUSY` bit is high.

In the periodic enable mode, the ongoing HADC conversion is completed activating the TMU to measure temperature as shown. If HADC is in autoscan mode, the TMU is activated after completing the ongoing sequence. If HADC is in fixed-conversion mode, all the fixed conversions are completed and followed by TMU activation.

TMU Event Control

The TMU generates different events depending on the state of the TMU temperature measurement and the different thresholds set in thresh hold registers. These events are reported in the TMU_STAT register as shown below. It can generate an event for each of following conditions.

- The fault high limit is configured in the TMU_FLT_LIM_HI register. The interrupt is generated when the temperature value is greater than or equal to this value.
- The alert high limit is configured in the TMU_ALRT_LIM_HI register. The interrupt is generated when the temperature value is greater than or equal to this value.
- The fault low limit is configured in the TMU_FLT_LIM_LO register. The TMU_STAT.FLTLO status bit is set when the temperature value is less than or equal to this value.
- The alert low limit is configured in the TMU_ALRT_LIM_LO register. The TMU_STAT.FLTLO status bit is set when the temperature value is less than or equal to this value.

Interrupts and status conditions can be masked (disabled) or unmasked (enabled) by setting and clearing bits in the TMU_IMSK register.

NOTE: Only TMU_FLT_LIM_HI and TMU_ALRT_LIM_HI generate an interrupt to core. Other events only result in status change in the TMU_STAT register.

Status and Error Signals

When the measured temperature value exceeds the high or low limits that are configured in the TMU_FLT_LIM_HI/TMU_FLT_LIM_LO and the TMU_ALRT_LIM_HI/TMU_ALRT_LIM_LO registers, corresponding thermal events are triggered.

The fault and alert events are sent to the core through the status register (TMU_STAT). Both the TMU_STAT.FLTHI and TMU_STAT.ALRTHI bits are sticky bits and are cleared by a W1C operation by the core.

The alert and fault registers can be programmed through the MMR bus interface as shown in the TMU block diagram. A write into the TMU_FLT_LIM_HI/TMU_FLT_LIM_LO and TMU_ALRT_LIM_HI/TMU_ALRT_LIM_LO registers or the TMU_TEMP register is not allowed when the events are being triggered.

TMU Programming Guidelines

The following section provides basic programming information for the TMU module.

To get the best performance and accuracy from the TMU, initialize the TMU_GAIN, TMU_OFFSET and TMU_AVG registers before enabling the module.

After these registers are programmed, the rest of the TMU initialization can take place. This includes setting up the fault and alert limits and then enabling the TMU.

TMU Calibration

Calibration settings are comprised of gain and offset settings. These settings must be programmed into the corresponding device registers before the temperature is read from the TMU temperature value register. The calibration setting ensures that the reported temperature approximates the actual die temperature (within the error specified in the data sheet). The specified accuracy of the reported temperature cannot be met if gain and offset settings are not used.

The TMU configuration software programs gain and offset values as part of the TMU initialization process. The gain value is programmed in the TMU_GAIN.VALUE field. The offset value is programmed in the TMU_OFFSET.VALUE bit field. The *TMU Calibration Settings* table provides the calibration setting for the processor.

Table 14-5: TMU Calibration Settings

Bit Field	Programmed Value
TMU_GAIN.VALUE	0x004
TMU_OFFSET.VALUE	0x7D40

NOTE: Refer to the product data sheet for the expected TMU accuracy achieved using the settings.

NOTE: The calibration settings provide expected TMU performance at temperatures above room temperature. The accuracy is not guaranteed for temperatures below room temperature.

ADSP-SC59x TMU Register Descriptions

Thermal monitoring unit (TMU) contains the following registers.

Table 14-6: ADSP-SC59x TMU Register List

Name	Description
TMU_ALRT_LIM_HI	Alert High Limit Register
TMU_ALRT_LIM_LO	Alert Low Limit Register
TMU_AVG	Averaging Register
TMU_CNV_BLANK	Temperature Conversion Blank Register
TMU_CTL	TMU Control Register
TMU_FLT_LIM_HI	Fault High Limit Register

Table 14-6: ADSP-SC59x TMU Register List (Continued)

Name	Description
TMU_FLT_LIM_LO	Fault Low Limit Register
TMU_GAIN	Gain Value Register
TMU_IMSK	Interrupt Mask Register
TMU_OFFSET	Offset Register
TMU_REFR_CNTR	Temperature Refresh Counter
TMU_STAT	Status Register
TMU_TEMP	Temperature Value Register

Alert High Limit Register

The TMU_ALRT_LIM_HI register sets the temperature alert high limit as an integer value. The value is stored in two's complement format. Asserts TMU_STAT.ALRTHI if the TMU_TEMP value is greater than or equal to TMU_ALRT_LIM_HI. The TMU_ALRT_LIM_HI value should be programmed for value greater than 8'h3C (60 degC).

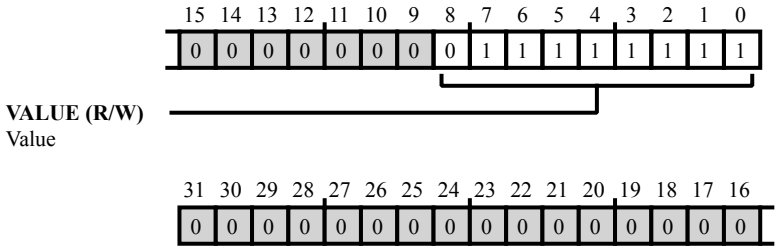

Figure 14-2: TMU_ALRT_LIM_HI Register Diagram

Table 14-7: TMU_ALRT_LIM_HI Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
8:0 (R/W)	VALUE	Value. The TMU_ALRT_LIM_HI.VALUE bit field configures the alert temperature high limit as an integer value stored in two's complement format. If the temperature value is greater than or equal to the high-limit the TMU_STAT.ALRTHI bit is set.

Alert Low Limit Register

The TMU_ALRT_LIM_LO register configures the alert temperature low limit.

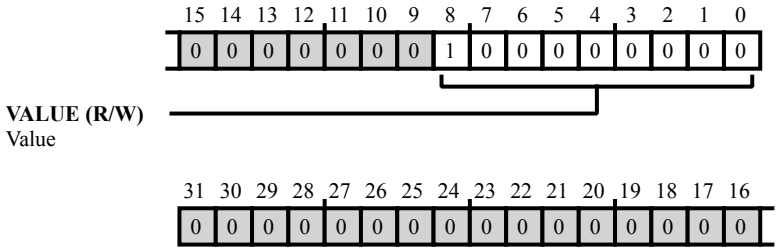

Figure 14-3: TMU_ALRT_LIM_LO Register Diagram

Table 14-8: TMU_ALRT_LIM_LO Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
8:0 (R/W)	VALUE	Value. The TMU_ALRT_LIM_LO.VALUE bit field configures the alert temperature low limit as an integer value stored in two's complement format. If the temperature value is less than or equal to the low-limit the TMU_STAT.ALRTLO bit is set.

Averaging Register

The TMU_AVG register enables averaging on the TMU.

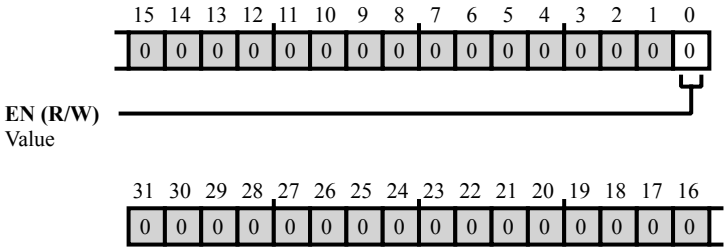

Figure 14-4: TMU_AVG Register Diagram

Table 14-9: TMU_AVG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	EN	Value. The TMU_AVG.EN bit enables averaging on the TMU. Averaging is done using the formula (7 x previous_avg_value + current_value)/8. Initially the current_value is taken as previous_avg_value.	
		0	No averaging
		1	Enable averaging

Temperature Conversion Blank Register

The TMU_CNV_BLANK register specifies blanking period in which TMU utilizes HADC for temperature conversion.

The conversion time is calculated as: (VALUE+1)*50k SCLK cycles. So, the minimum conversion time is 50k SCLK cycles. Default conversion time is 200k SCLK cycles. For this duration, the system cannot use HADC for data conversion and HADC does take input for data-conversion. The status is indicated by TMUHADC_BUSY bit of the HADC block.

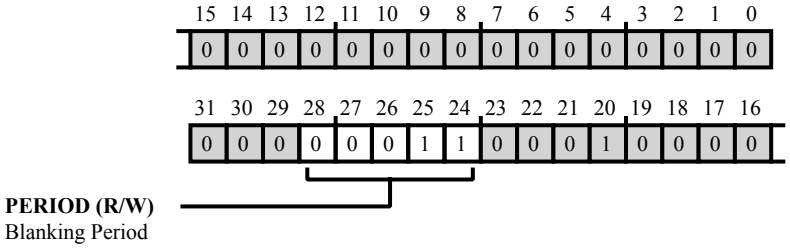

Figure 14-5: TMU_CNV_BLANK Register Diagram

Table 14-10: TMU_CNV_BLANK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
28:24 (R/W)	PERIOD	Blanking Period.

TMU Control Register

The TMU_CTL register contains bits that allow programs to configure and enable the TMU.

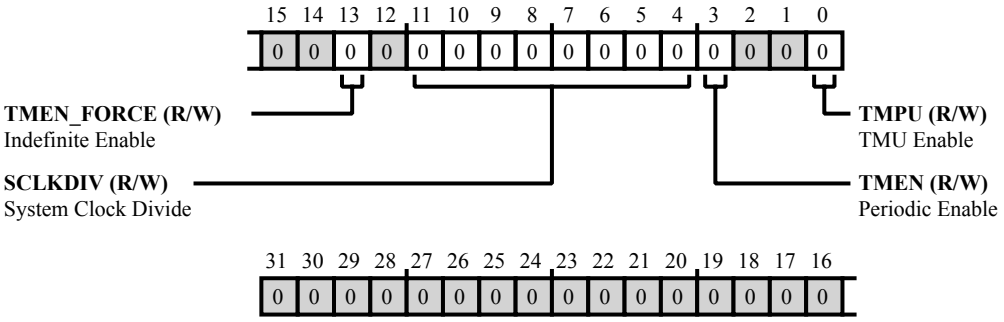

Figure 14-6: TMU_CTL Register Diagram

Table 14-11: TMU_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
13 (R/W)	TMEN_FORCE	Indefinite Enable. Asserting the TMU_CTL.TMEN_FORCE bit enables the TMU indefinitely. HADC is always used by the TMU, so the HADC cannot be used to convert channel inputs.	
11:4 (R/W)	SCLKDIV	System Clock Divide. The TMU_CTL.SCLKDIV bit selects the division ratio for the system clock (SCLK). SCLK is divided by (21+4*SCLKDIV). Thus, by default the SCLK is divided by 21.	
3 (R/W)	TMEN	Periodic Enable. Asserting the TMU_CTL.TMEN bit enables the TMU periodically. TMU is enabled once in every refresh period defined by the TMU_REFR_CNTR register. And in each refresh period, TMU measures temperature for the blanking period (Tblank). It is defined by CNV_BLANK bit.	
		0	Disable TMU
		1	Enable TMU periodically
0 (R/W)	TMPU	TMU Enable. The TMU_CTL.TMPU bit enables the TMU. By default, the module is in power-down mode. The peripheral interface is active even in power-down mode (the TMU registers can be read/written).	
		0	Power Down the analog circuitry of TMU
		1	Power Up the analog circuitry of TMU

Fault High Limit Register

The TMU_FLT_LIM_HI register sets the temperature fault high limit as an integer value. The value is stored in two's complement format. Asserts TMU_STAT.FLTHI if the TMU_TEMP value is greater than or equal to TMU_FLT_LIM_HI. The TMU_FLT_LIM_HI value should be programmed for value greater than 8'h3C (60 degC).

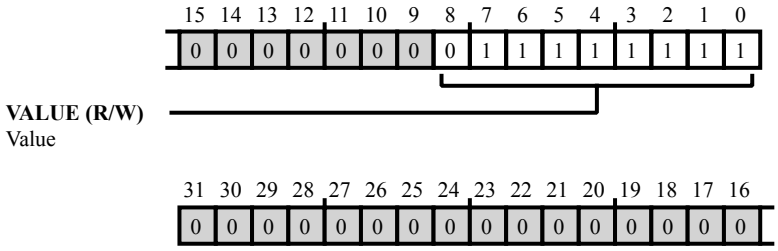

Figure 14-7: TMU_FLT_LIM_HI Register Diagram

Table 14-12: TMU_FLT_LIM_HI Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
8:0 (R/W)	VALUE	Value. The TMU_FLT_LIM_HI.VALUE bit field sets the temperature high limit as an integer in two's complement format. If the limit value is greater than or equal to the high-limit the TMU_STAT.FLTHI bit is set.

Fault Low Limit Register

The TMU_FLT_LIM_LO register configures the fault temperature low limit.

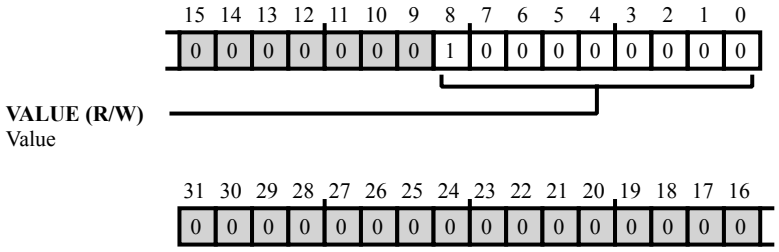

Figure 14-8: TMU_FLT_LIM_LO Register Diagram

Table 14-13: TMU_FLT_LIM_LO Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
8:0 (R/W)	VALUE	Value. The TMU_FLT_LIM_LO.VALUE bit field configures the fault temperature low limit as an integer which is stored in two's complement format. If the temperature value is less than or equal to the low-limit, the TMU_STAT.FLTLO bit is set.

Gain Value Register

The TMU_GAIN register is used to configure the gain value in two's complement format. This value is used to correct the gain error in the TMU_TEMP register.

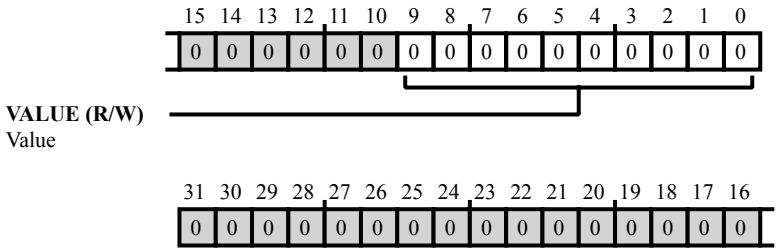

Figure 14-9: TMU_GAIN Register Diagram

Table 14-14: TMU_GAIN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
9:0 (R/W)	VALUE	Value. The TMU_GAIN.VALUE bit field configures the gain value in two's complement format. This value is used to correct the gain error in the TMU_TEMP register.

Interrupt Mask Register

The TMU_IMSK register provides bits that are used to mask and unmask the interrupts associated with the TMU module.

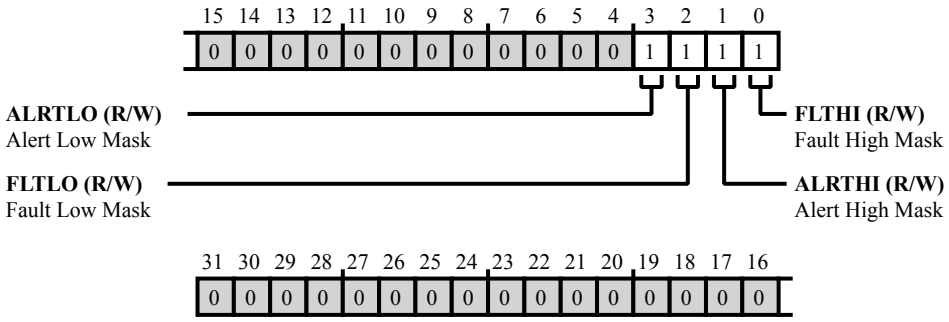

Figure 14-10: TMU_IMSK Register Diagram

Table 14-15: TMU_IMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	ALRTLO	Alert Low Mask. The TMU_IMSK.ALRTLO bit masks or unmasks the alert low status change (TMU_STAT.ALRTLO).	
		0	Unmask alert low status change
		1	Mask alert low status change
2 (R/W)	FLTLO	Fault Low Mask. The TMU_IMSK.FLTLO bit masks or unmasks the fault low status change (TMU_STAT.FLTLO).	
		0	Unmask fault low status change
		1	Mask fault low status change
1 (R/W)	ALRTHI	Alert High Mask. The TMU_IMSK.ALRTHI bit masks or unmasks the alert high status change (TMU_STAT.ALRTHI).	
		0	Unmask alert high status change
		1	Mask alert high status change
0 (R/W)	FLTHI	Fault High Mask. The TMU_IMSK.FLTHI bit masks or unmasks the fault high interrupt (TMU_STAT.FLTHI).	
		0	Unmask fault high interrupt
		1	Mask fault high interrupt

Offset Register

The value programmed in the TMU_OFFSET register is used to correct the offset error in TMU_TEMP register.

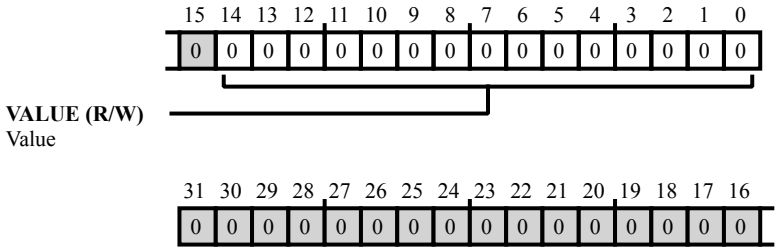

Figure 14-11: TMU_OFFSET Register Diagram

Table 14-16: TMU_OFFSET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
14:0 (R/W)	VALUE	Value. The TMU_OFFSET.VALUE bit field provides the offset value which is used to correct the offset error in the TMU_TEMP register. This value is in a two's complement fixed point Q7.7 format i.e 8 MSB's represent integer part in 2's complement format. and remaining 7 LSB's represent decimal part. Offset will be applied after multiplying gain.

Temperature Refresh Counter

The TMU_REFR_CNTR register defines the refresh-period to refresh temperature value.

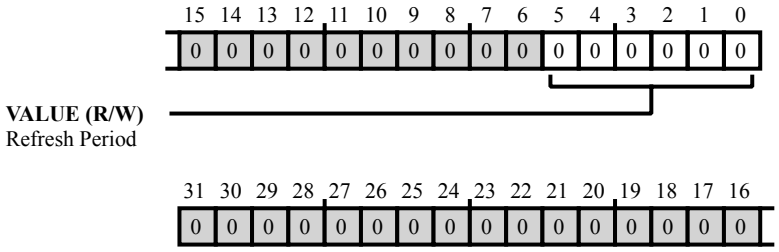

Figure 14-12: TMU_REFR_CNTR Register Diagram

Table 14-17: TMU_REFR_CNTR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
5:0 (R/W)	VALUE	Refresh Period. The TMU_REFR_CNTR.VALUE bit field defines the period to refresh the temperature value. Temperature is refreshed for every (VALUE+1)*(21+4*SCLKDIV)*1M system-clock cycles. SCLKDIV is defined in TMU_CTL register. So, by default, the period is 21 million system-clock cycles.

Status Register

The TMU_STAT register bits indicate when an error or fault is detected.

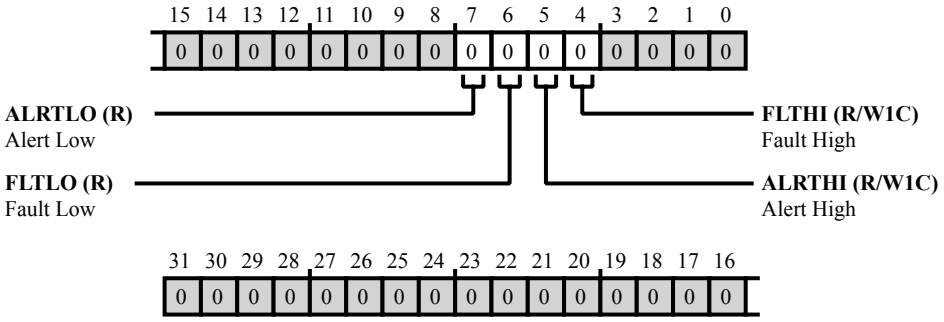

Figure 14-13: TMU_STAT Register Diagram

Table 14-18: TMU_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7 (R/NW)	ALRTLO	Alert Low. The TMU_STAT.ALRTLO bit is set when the temperature value is less than or equal to the setting in the TMU_ALRT_LIM_LO register. The bit assertion is masked if TMU_IMSK.ALRTLO is HIGH.
6 (R/NW)	FLTLO	Fault Low. The TMU_STAT.FLTLO bit is set when the temperature value is less than or equal to the setting in the TMU_FLT_LIM_LO register. The bit assertion is masked if TMU_IMSK.FLTLO is HIGH.
5 (R/W1C)	ALRTHI	Alert High. The TMU_STAT.ALRTHI bit is set when the temperature value is greater than or equal to the setting in the TMU_ALRT_LIM_HI register. The temperature value register is set to 16'h0D80 (effective temperature value of 27degrees C) when a W1C operation is done on this bit. The bit assertion is masked if TMU_IMSK.ALRTHI is HIGH.
4 (R/W1C)	FLTHI	Fault High. The TMU_STAT.FLTHI bit is set when the temperature value is greater than or equal to the setting in the TMU_FLT_LIM_HI register. The temperature value register is set to 16'h0D80 (effective temperature value of 27 degrees C) when a W1C is done on this bit. The bit assertion is masked if TMU_IMSK.FLTHI is HIGH.

Temperature Value Register

The TMU_TEMP register provides the temperature value from the A/D converter and the status.

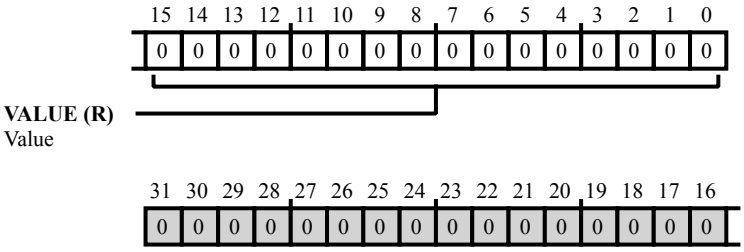

Figure 14-14: TMU_TEMP Register Diagram

Table 14-19: TMU_TEMP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	VALUE	Value. The TMU_TEMP.VALUE bit field is the temperature value from A/D converter. This value is stored in two's complement fixed point Q8.7 format where the 9 MSB's represent the integer part in 2's complement, and the remaining 7 LSB's represent the decimal part.

15 Housekeeping ADC (HADC)

The Housekeeping ADC is a 12-bit (with 10-bit accuracy), successive approximation ADC. It operates from single supply and features throughput rates up to 1 MSPS. The HADC can be used for the collection of housekeeping parameters like voltages, temperatures in the system or for any general-purpose use as well.

NOTE: HADC is used by the TMU for temperature monitor, so it may be unavailable during temperature conversion. For details, refer to the TMU and HADC section.

HADC Features

The HADC supports following features:

- 12-bit ADC core with built-in sample and hold
- ENOB = 10 bit
- 8 input channels which can be extended to 15 channels by putting an external channel multiplexer
- Throughput rates up to 1 MSPS
- Single ended operation
- External reference nominal at 1.8 V
- Analog input 0 V to 1.8 V.
- Selectable ADC clock frequency through a pre-scaler
- Conversion type adaptable to each application–allows single or continuous conversion with option of auto-scan
- Auto sequencing capability provides up to 8 *auto-conversions* in a single session. Each conversion can be programmed to select any of the available input channels.

HADC Functional Description

The HADC provides the analog to digital conversion capability for general-purpose housekeeping tasks, such as voltage and temperature monitoring. The core of HADC is a 12-bit SAR ADC, providing multiple analog input channels.

The HADC has the following functionality:

Fixed and continuous conversion modes

ADC converts the input channel sequence for a fixed number of times or continuously converts an input channel sequence.

Auto scanning

All the input channels can be sampled in a sequential manner.

Channel sequence programming

The sequence of a channel can be selected by programming the channel mask register. If the bit corresponding to the channel is programmed to zero, that channel is included in the auto-scan chain.

ADSP-SC59x HADC Register List

The Housekeeping ADC (HADC) provides a general purpose, multi-channel successive approximation A-to-D converter. A set of registers governs HADC operations. For more information on HADC functionality, see the HADC register descriptions.

Table 15-1: ADSP-SC59x HADC Register List

HADC Definitions

The following definitions are helpful when using the HADC module.

Auto-scan

Auto-scan is a feature which allows the multiple channels to be scanned and converted in sequence one after the other.

HADC Wakeup Time

It is the time required by the module after coming out of power down before it can start converting.

Signal-to-Noise and Distortion Ratio (SINAD)

The measured ratio of signal-to-noise and distortion at the output of the ADC. The signal is the rms amplitude of the fundamental. Noise is the sum of all non-fundamental signals up to half the sampling frequency ($f_S/2$), excluding dc. The ratio depends on the number of quantization levels in the digitization process; the more levels, the smaller the quantization noise. The theoretical signal-to-noise and distortion ratio for an ideal N-bit converter with a sine wave input is given by:

Signal-to-(Noise + Distortion) = (6.02 N + 1.76) dB

Total Harmonic Distortion (THD)

The ratio of the rms sum to the harmonics to the fundamental.

Peak Harmonic or Spurious Noise

The ratio of the rms value of the next largest component in the ADC output spectrum (up to $f_S/2$ and excluding dc) to the rms value of the fundamental. Typically, the value of this specification is determined by the largest harmonic in the spectrum, but for ADCs where the harmonics are buried in the noise floor, it is a noise peak.

Integral Nonlinearity

The maximum deviation from a straight line passing through the endpoints of the ADC transfer function. The endpoints are zero scale, a point 1 LSB below the first code transition, and full scale, a point 1 LSB above the last code transition.

Differential Nonlinearity

The difference between the measured and the ideal 1 LSB change between any two adjacent codes in the ADC.

Offset Error

The deviation of the first code transition (00...000) to (00...001) from the ideal—that is, GND1 + 1 LSB.

Offset Error Match

The difference in offset error between any two channels.

Gain Error

The deviation of the last code transition (111...110) to (111...111) from the ideal (that is, REFIN – 1 LSB) after the offset error has been adjusted out.

Gain Error Matching

The difference in gain error between any two channels.

Power Supply Rejection Ratio (PSRR)

PSRR is defined as the ratio of the power in the ADC output at full-scale frequency, f, to the power of a 100 mV p-p sine wave applied to the ADC VDD supply of frequency, f_S. The frequency of the input varies from 5 kHz to 25 MHz. PSRR (dB) = 10 log(Pf/Pf_S) where: Pf is the power at frequency, f, in the ADC output. Pf_S is the power at frequency, f_S, in the ADC output.

HADC Block Diagram

The ***HADC Block Diagram*** figure shows the functional blocks within the HADC and the interface to the processor core and the peripherals. The HADC has an internal channel multiplexer that is controlled by a programmable sequencer which selects the desired channel or sequence of channels.

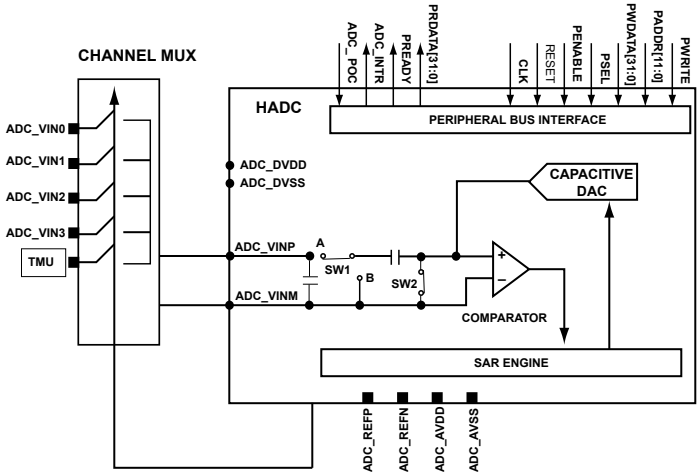

Figure 15-1: HADC Block Diagram

HADC Signal Descriptions

The ***HADC Signal Descriptions*** table provides descriptions of the signals used by the HADC.

Table 15-5: HADC Signal Descriptions

Signal Name	Signal Description
AVDD	ADC I/O supply
AVSS	I/O ground for analog blocks - shorted with other ground pins within the package
VREFP	External reference for ADC
VREFN	Ground reference for ADC
VINn	Analog input at channel n

HADC Architectural Concepts

The HADC is based on a 12-bit SAR ADC that provides a simple register-based access model to obtain the results of conversion. The digital front end of the HADC provides a set of registers to configure the mode of operation, sampling frequency, and input channel selection control. The ADC supports multiple input analog channels which can be individually selected or deselected for conversion. The results of each analog channel are stored in a register. The core can access the register to read the conversion results once the conversion is complete. The HADC also provides the interrupts on completion of each channel conversion to avoid polling by the core. The following sections provide more details about the architecture of the HADC.

Converter Operation

The housekeeping ADC is a 12-bit successive approximation ADC based around a capacitive DAC. The ***ADC Acquisition Phase*** figure and the ***ADC Conversion Phase*** figure show simplified schematics of the ADC. The ADC is comprised of control logic, SAR, and a capacitive DAC. The components are used to add and subtract fixed amounts of charge from the sampling capacitor to bring the comparator back into a balanced condition. The ***ADC Conversion Phase*** figure shows the ADC during its acquisition phase. SW2 is closed and SW1 is in Position A. The

comparator is held in a balanced condition and the sampling capacitor acquires the signal on the selected V_{IN} channel.

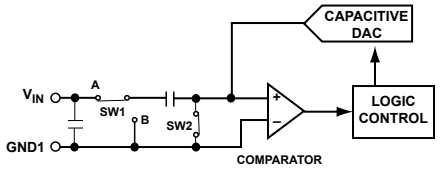

Figure 15-2: ADC Acquisition Phase

When the ADC starts a conversion (see the ***ADC Conversion Phase*** figure), SW2 opens and SW1 moves to Position B, causing the comparator to become unbalanced. The control logic and the capacitive DAC are used to add and subtract fixed amounts of charge to bring the comparator back into a balanced condition. When the comparator is rebalanced, the conversion is complete. The control logic generates the ADC output code.

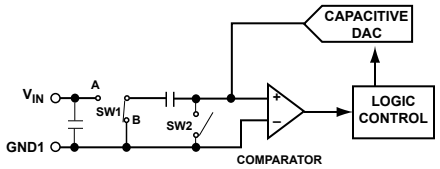

Figure 15-3: ADC Conversion Phase

Auto-Scan

The HADC features auto-scan mode where all the input channels can be sampled in a sequential manner. The number of channels enabled in auto-scan mode can be selected by programming the HADC_CHAN_MSK register. If the bit corresponding to the channel is set high, that particular channel is masked, and is not included in the auto-scan chain. In this way programs can sample all, none, or a selected set of channels by writing a high or a low for the individual channel. Auto sequencing allows the system to convert the same channel multiple times, allowing programs to perform oversampling algorithms.

For example, if the HADC_CHAN_MSK register bits [3:0] are set to 1101, then channel 0, channel 2 and channel 3 are not included in the auto-scan chain. Whether the conversion is a single or fixed number or continuous depends on the status of HADC_CTL.CONT bit. If this bit is low, the HADC_CTL.FIXEDCNV bits determine the number of sequence conversions.

The maximum number of fixed sequence conversions is 15. By default, the first eight channels of the HADC are enabled and extended channels are masked. An extended channel is the increased number of channels when a single channel of ADC is externally multiplexed, effectively increasing the total number of available channels. The total number of channels supported is 15. The program must configure the HADC_CHAN_MSK register to enable any desired channel.

Channel Sequence Programming

The sequence of a channel can be selected by programming the HADC_CHAN_MSK register. If the bit corresponding to the channel is programmed to zero, that channel is included in the auto-scan chain. If the program must get the conversion results from a particular channel, then the bit corresponding to that channel should be zero.

Channels 8-15 are virtual channels; in that they can connect an external multiplexer and increase the effective number of channels. As the output of the external multiplexer is routed to channel 7, this channel is not available (or converted) separately when the virtual channels are not masked in the HADC_CHAN_MSK register. The auto-scan section has more details.

ADC Transfer Function

The output coding is straight binary for the analog input channel conversion. The designed code transitions occur at successive LSB values (that is, 1 LSB, 2 LSBs, and so forth). The LSB size is $V_{REF}/4096$ for the HADC. The *ADC Transfer Function* figure shows the ideal transfer characteristic for straight binary coding.

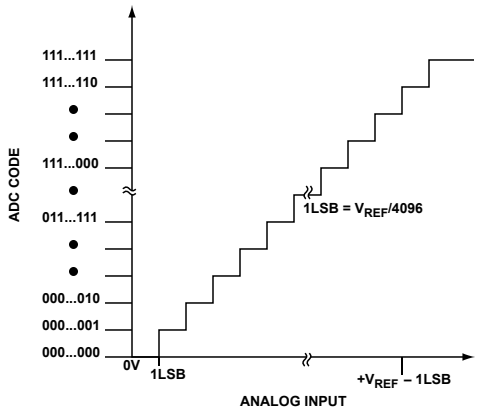

Figure 15-4: ADC Transfer Function

Results

The HADC takes 20 cycles of f_{SAMPLE} for one channel conversion. (The value of the HADC_CTL.FDIV bit field determines f_{SAMPLE}). The time taken to complete one sequence depends on the number of channels in the auto-scan chain. There is a latency of 1 cycle from the time the channel is selected internally to sample to the time the data is ready. After the end of each channel conversion, the data is written into the corresponding data register. An interrupt is generated (if the interrupt mask is not enabled) to signal that the data is ready for that particular channel.

HADC Operating Modes

The HADC has two modes of operation described in the following sections.

Fixed Conversion Mode

In this mode, the ADC converts the input channel sequence for a fixed number of times. The frequency is configured in the HADC_CTL.FIXEDCNV bit field. To use this mode, clear the HADC_CTL.CONT bit.

Continuous Conversion Mode

In this mode ADC continuously converts an input channel sequence, when the HADC_CTL.STARTCNV bit is held high. To use this mode, set the HADC_CTL.CONT bit.

HADC Event Control

The HADC generates different events depending on the state of the ADC and the status of channel conversions. It can generate an event for each of the following conditions:

- When ADC is ready for conversion
- At the end of sequence conversion
- At the end of each individual channel conversion

Each of these events can generate an interrupt. To generate an interrupt on any desired event, clear the respective bit in the HADC_IMSK register.

HADC Programming Model

Following sections provide some guidelines for HADC programming.

Powering Up the HADC

To power-up the HADC, program the following bits in the HADC_CTL register.

- Deassert the HADC_CTL.PD bit (HADC power down)
- Set the HADC_CTL.NRST bit (Reset)
- Set the HADC_CTL.ENLS bit (Enable level shifters)

After deasserting HADC_CTL.PD, the HADC requires a finite wake-up time (t_{WAKEUP}) before it can start converting. The HADC requires only two f_{SAMPLE} clocks from the assertion of the HADC_CTL.NRST bit before the module is ready to convert. (HADC_CTL.PD is low). Poll the HADC_STAT.RDY bit. A 1 on this bit indicates that the HADC is ready to convert data.

Enabling the HADC

Setting the HADC_CTL.STARTCNV bit enables the HADC. When this bit is kept high, the HADC can work in either continuous or fixed conversion mode. After the HADC_CTL.STARTCNV bit is set =1, the HADC_CHAN_MSK can still be re-programmed, but the new sequence only comes into effect after the current sequence conversion is complete.

ADSP-SC59x HADC Register Descriptions

Housekeeping ADC (HADC) contains the following registers.

Table 15-6: ADSP-SC59x HADC Register List

Name	Description
HADC_CHAN_MSK	Channel Mask Register

Table 15-6: ADSP-SC59x HADC Register List (Continued)

Name	Description
HADC_CTL	Control Register
HADC_DATA[nn]	Channel Data Registers
HADC_IMSK	Interrupt Mask Register
HADC_STAT	Status Register

Channel Mask Register

The HADC_CHAN_MSK register provides bits that mask each channel. The LSB corresponds to channel 0 , the second LSB to channel 1 and so on. If a mask bit is set, the corresponding channel is not converted. By default, channels 0-7 are not masked and the extended channels 8-15 are masked.

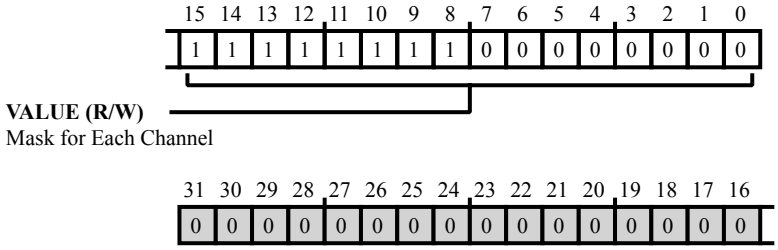

Figure 15-5: HADC_CHAN_MSK Register Diagram

Table 15-7: HADC_CHAN_MSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Mask for Each Channel. The HADC_CHAN_MSK.VALUE bit field is the mask bit for each channel. The first MSB corresponds to channel 15, the second MSB to channel 14 and so on. If the mask is set for a particular channel, that channel is not converted. By default, channels 0-7 are not masked and the extended channels 8-15 are masked. The first MSB corresponds to channel 7, the second MSB to channel 6 and so on. If the mask is set for a particular channel, that channel is not converted. By default, channels 0-7 are not masked.

Control Register

The HADC_CTL register contains control bits that configure various module settings start or reset the module.

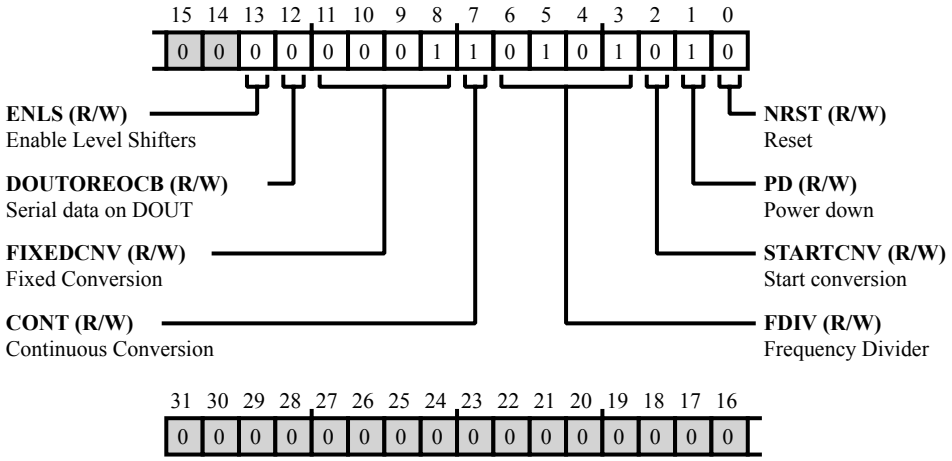

Figure 15-6: HADC_CTL Register Diagram

Table 15-8: HADC_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
13 (R/W)	ENLS	Enable Level Shifters. Setting the HADC_CTL.ENLS bit enables the level shifters, allowing the HADC analog side (which works in the VDD_EXT domain) to work with the digital core and interface is (in the VDD_INT domain).	
		0	Disable down level shifters
		1	Enable down level shifters
12 (R/W)	DOUTOREOCB	Serial data on DOUT. If the HADC_CTL.DOUTOREOCB bit =1, serial data arrives on the EOC_DOUT pin. If this bit =0 (default) it acts as an EOC only if the external multiplexer is connected.	
		0	Reserved
		1	Reserved
11:8 (R/W)	FIXEDCNV	Fixed Conversion. The HADC_CTL.FIXEDCNV bit configures the number of conversions = FIXEDCNV. This value determines how many times a sequence is converted when the HADC is in fixed conversion mode. This only applies when the HADC_CTL.CONT bit =0. Before changing the HADC_CTL.FIXEDCNV bit, clear the HADC_CTL.NRST bit (=0).	

Table 15-8: HADC_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	CONT	Continuous Conversion. When the HADC_CTL.CONT bit =0, the ADC converts a sequence for a fixed number of times. This number is configured using the HADC_CTL.FIXEDCNV bit field. When the HADC_CTL.CONT bit =1, the ADC continuously converts a given sequence, provided the HADC_CTL.STARTCNV is held high.	
		0	ADC converts sequence for fixed number of times
		1	ADC continuously converts given sequence
6:3 (R/W)	FDIV	Frequency Divider. The HADC_CTL.FDIV bit field configures the f_SAMPLE=f_CLK/(FDIV+1). Select f_CLK and HADC_CTL.FDIV values so that f_SAMPLE is in range of 50 kHz to 22.5 MHz. The minimum value for HADC_CTL.FDIV is 1. Before changing the HADC_CTL.FDIV bits, clear the HADC_CTL.NRST bit.	
2 (R/W)	STARTCNV	Start conversion. The HADC_CTL.STARTCNV bit needs to be set for the ADC to start converting data. If the ADC is running in non continuous mode, it is reset by hardware after the desired number of conversions is completed.	
		0	No action
		1	Start converting
1 (R/W)	PD	Power down. The HADC_CTL.PD bit powers down the analog circuitry of the ADC. After this bit returns to 0 a finite power-up time is required before the ADC can start converting data.	
		0	No action
		1	Power down the analog circuitry of the ADC
0 (R/W)	NRST	Reset. The HADC_CTL.NRST bit resets the ADC.	
		0	Reset the ADC
		1	No action

Channel Data Registers

The `HADC_DATA[nn]` registers NN ranges from 0-14. Each corresponding to an ADC channel. ADC_DATA_0 corresponds to channel 0, ADC_DATA_1 to channel 1 and so on.

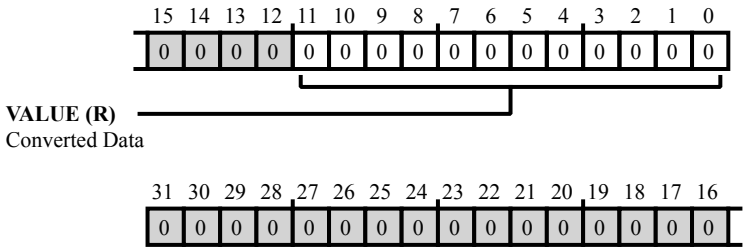

Figure 15-7: HADC_DATA[nn] Register Diagram

Table 15-9: HADC_DATA[nn] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
11:0 (R/NW)	VALUE	Converted Data. The `HADC_DATA[nn].VALUE` bit field contains the digital code for the sampled analog value. Each channel has its own data register.

Interrupt Mask Register

The HADC_IMSK register masks (disables) or unmasks (enables) the interrupts as programmed.

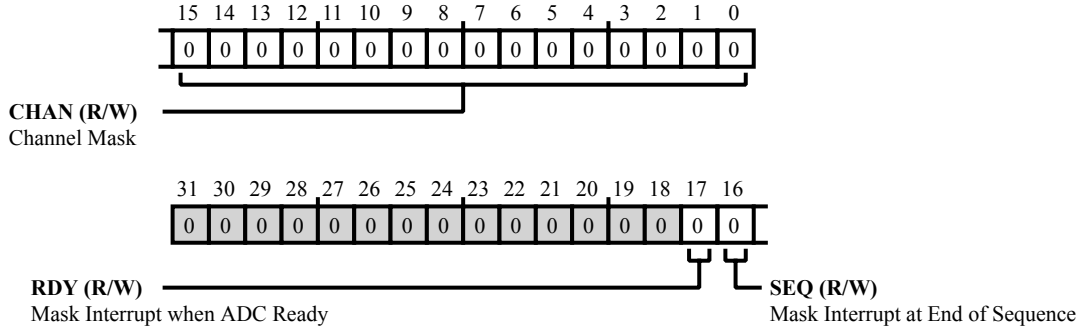

Figure 15-8: HADC_IMSK Register Diagram

Table 15-10: HADC_IMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/W)	RDY	Mask Interrupt when ADC Ready. The HADC_IMSK.RDY bit masks the interrupt generated when ADC is ready to convert.	
16 (R/W)	SEQ	Mask Interrupt at End of Sequence. The HADC_IMSK.SEQ bit masks the interrupt which is generated at the end of sequence completion.	
		0	Interrupt is unmasked
		1	Interrupt is masked
15:0 (R/W)	CHAN	Channel Mask. The HADC_IMSK.CHAN bit field provides the interrupt mask bit for each channel. N ranges from 0-15. The MSB corresponds to channel 15, the second MSB to channel 14 and so on. If the bit is SET, interrupt is masked for corresponding channel.	

Status Register

The HADC_STAT register contains bits that provide status information on the HADC module.

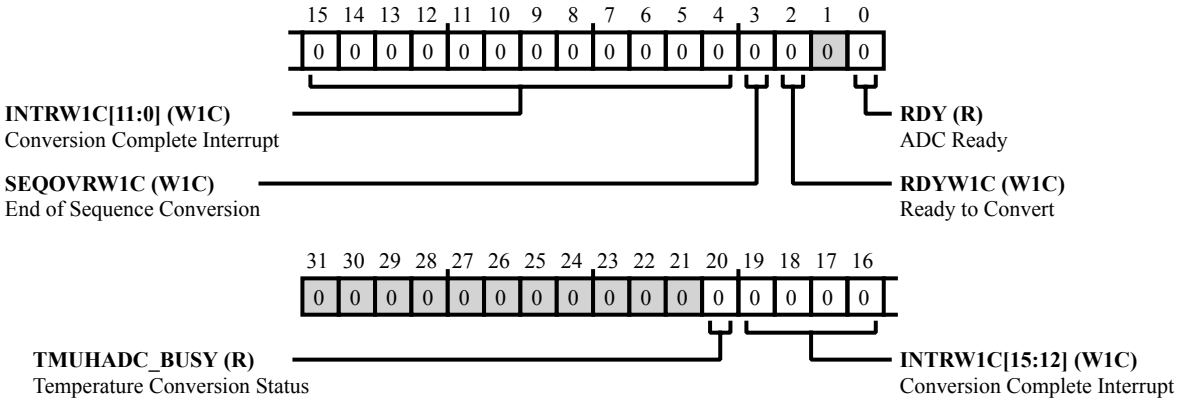

Figure 15-9: HADC_STAT Register Diagram

Table 15-11: HADC_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
20 (R/NW)	TMUHADC_BUSY	Temperature Conversion Status. The HADC_STAT.TMUHADC_BUSY bit, if high, indicates to the system that temperature conversion is ongoing. All ADC conversion requests are ignored.
19:4 (RX/W1C)	INTRW1C	Conversion Complete Interrupt. The HADC_STAT.INTRW1C bit field indicates when the corresponding ADC channel completes conversion. N ranges from 0-15 and the MSB corresponds to channel 15, the second MSB to channel 14 and so on. N ranges from 0-7 and the MSB corresponds to channel 7, the second MSB to channel 6 and so on. These bits are sticky and are W1C.
3 (RX/W1C)	SEQOVRW1C	End of Sequence Conversion. The HADC_STAT.SEQOVRW1C bit indicates the end of a sequence conversion and is a sticky status bit which is W1C.
2 (RX/W1C)	RDYW1C	Ready to Convert. The HADC_STAT.RDYW1C bit is the stick version of the HADC_STAT.RDY bit.
0 (R/NW)	RDY	ADC Ready. The HADC_STAT.RDY bit is set (=1) when the ADC is ready to convert data.

16 Controller Area Network Flexible Data Rate (CANFD)

The controller area network (CAN) protocol is primarily for use as a vehicle serial data bus. It meets the specific requirements of this field, including real-time processing, reliable operation in the EMI environment of a vehicle, cost-effectiveness, and required bandwidth.

The CANFD module is a full implementation of the CAN protocol specification, the CAN with flexible data rate (CAN FD) protocol, and the CAN 2.0 Part B protocol. It supports both standard and extended message frames and long payloads up to 64 bytes, transferred at rates up to 8 Mbps. The message buffers are stored in an embedded RAM dedicated to the CANFD module.

NOTE: This document assumes familiarity with the CAN standard. For more information, refer to Version 2.0 of the CAN specification from Robert Bosch GmbH.

CANFD Features

Key features of the CANFD module include:

- Full implementation of the CAN FD protocol and the CAN specification 2.0 (Part B) including:
  - Standard data frames
  - Extended data frames
  - Zero to sixty-four bytes data length
  - Programmable bit rate
  - Content-related addressing
- ISO 11898-1 standard compliance
- Flexible mailboxes
  - Configurable data lengths from 0 to 64 bytes
  - Configurable as receive or transmit, supporting standard and extended messages
  - Individual Rx mask registers per mailbox

- Full-featured Rx FIFO
  - Storage capacity for up to six frames
  - Automatic internal pointer handling with DMA support
- Transmission abort capability
- 28 message buffers of 8 bytes data length each, configurable as Rx or Tx
- Listen-Only mode capability
- Programmable Loop-Back mode supporting self-test operation
- Programmable transmission priority scheme: lowest ID, lowest buffer number, or highest priority
- Time stamp based on 16-bit free-running timer
- Global network time, synchronized by a specific message
- Independence from the transmission medium (an external transceiver is required)
- Low-power modes, with programmable wakeup on bus activity or matching with received frames (Pretended Networking)
- Transceiver Delay Compensation feature when transmitting CAN FD messages at faster data rates
- Remote request frames may be handled automatically or by software
- Identifier Acceptance Filter Hit Indicator (IDHIT) register for received frames
- Status of synchronization with CAN bus
- CRC status for transmitted message
- Rx FIFO Global Mask register
- Selectable priority between mailboxes and Rx FIFO during matching process
- Rx FIFO ID filtering, matching incoming IDs against 128 extended, 256 standard, or 512 partial (8 bit) IDs
  - Up to 32 ID filter table elements
- Detection and correction of memory read access errors, with five parity bits for each byte of CANFD memory
- Pretended networking functionality in low-power doze mode

CANFD Functional Description

The CANFD module is a CAN protocol engine with a very flexible mailbox system for transmitting and receiving CAN frames. The mailbox system consists of a set of message buffers (MBs) that store configuration and control data, time stamp, message ID, and data. The memory corresponding to the first 38 MBs is configurable to support a FIFO reception scheme with a powerful ID filtering mechanism. The ID filtering mechanism is capable of checking

incoming frames against a table of IDs (up to 128 extended IDs, 256 standard IDs, or 512 8-bit ID slices), with an individual mask register for up to 32 ID filter table elements.

Classical CAN frames support simultaneous reception through a FIFO and mailboxes. CAN FD frames support reception only through mailboxes. For mailbox reception, there is a matching algorithm to store received frames into the MBs that have the same ID programmed in the ID field. There is a masking scheme to match the ID programmed on the MB with a range of IDs on received CAN frames. For transmission, an arbitration algorithm decides the prioritization of MBs to be transmitted based on the message ID (optionally augmented by 3 local priority bits) or the MB ordering.

The CANFD module can also receive and transmit messages in CAN FD format. The MBs are sized to store the quantity of data bytes selected in the MBDSRn fields of the CANFD_FD_CTL register.

The following sections provides listings of the CANFD registers, interrupts, and triggers. It section also provides information on the architectural concepts and functional operation of the CANFD module.

ADSP-SC59x CANFD Register List

CANFD module is a communication controller implementing the CAN protocol according to the CAN 2.0B protocol specification. Features : Flexible DataRate, PretendedNetwork, DMA support, ECC for RAM.

Table 16-1: ADSP-SC59x CANFD Register List

Name	Description
CANFD_TIMING	Can Bit Timing Register
CANFD_CRC	CRC Register

CANFD Architectural Concepts

The following sections provide information about the CANFD architecture.

Block Diagram

The *CANFD Block Diagram* figure shows a block diagram of the CANFD module.

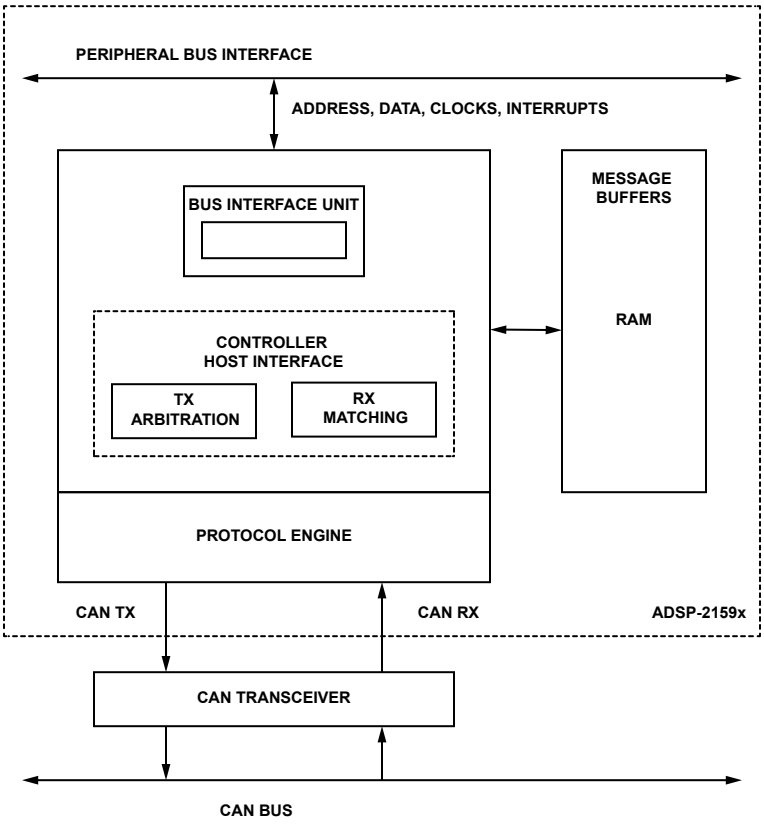

Figure 16-1: CANFD Controller Block Diagram

The CANFD module has the following three submodules and message buffers in an embedded RAM:

Protocol Engine (PE)

The PE submodule manages the serial communication on the CAN bus. It requests RAM access for receiving and transmitting message frames, validates received messages, preforms error handling, and detects CAN FD messages.

Controller Host Interface (CHI)

The CHI submodule handles message buffer selection for reception and transmission, including arbitration, and ID matching algorithms for both flexible data rate (FD) and non-FD message formats.

Bus Interface Unit (BIU)

The BIU submodule controls the access to and from the internal interface bus to establish connection to the CPU and to other blocks. Clocks, address and data buses, interrupt outputs, DMA, and test signals are accessed through the BIU.

Message Buffer (MB)

The CANFD module uses a message buffer structure that represents both extended (29-bit identifier) and standard (11-bit identifier) frames from the CAN specification (Version 2.0, Part B).

Each individual message buffer is 16, 24, 40, or 72 bytes, depending on the quantity of data bytes allocated for the message payload: 8, 16, 32, or 64 data bytes, respectively.

The memory area for mailboxes is from address offset 0x80 to 0x47F. When CAN FD is enabled, the exact address for each memory byte depends on the size of the payload.

The *Message Buffer Structure 64-Byte Payload* figure shows an example of the message buffer structure with a 64-byte payload.

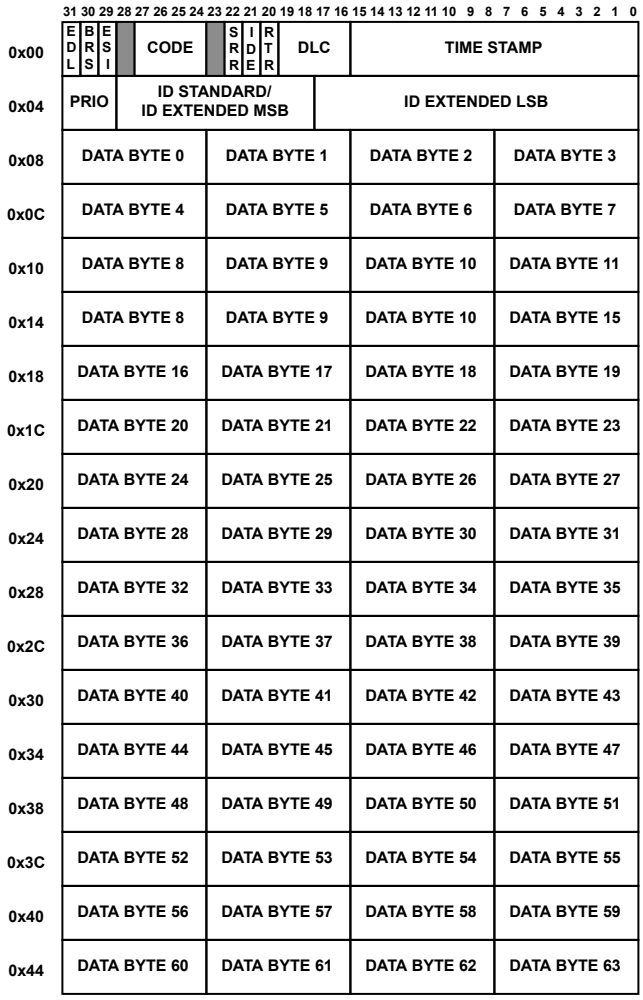

Figure 16-2: Message Buffer Structure 64-Byte Payload

In the example, the first eight bytes of the message buffer is control information associated with the data, followed by the bytes of data in the payload. The control information is defined in the following sections:

Extended Data Length (EDL)

The EDL bit distinguishes between CAN and CAN FD format frames. Do not set EDL when message buffers are configured to RANSWER with code field 0b1010.

Bit Rate Switch (BRS)

The BRS bit defines whether the bit rate is switched inside a CAN FD format frame.

Error State Indicator (ESI)

The ESI bit indicates if the transmitting node is error active or error passive.

Message Buffer Code (CODE)

The CODE field is accessible (read or write) to the processor and the CANFD module, as part of the message buffer matching and arbitration process. The *Message Buffer Code – Rx Buffer* and *Message Buffer Code – Tx Buffer* tables show the encoding.

Table 16-5: Message Buffer Code – Rx Buffer

CODE Description	Rx Code Before New Frame	SRV[*1]	Rx Code After Successful Reception [*2]	RRS [*3]	Comment
0000: INACTIVE – MB is not active.	INACTIVE	N/A	N/A	N/A	MB does not participate in the matching process.
0100: EMPTY – MB is active and empty	EMPTY	N/A	FULL	N/A	When a frame is received successfully, the CODE field is automatically updated to FULL.
0010: FULL – MB is full.	FULL	Yes	FULL	N/A	The act of reading the C/S word followed by unlocking the MB (SRV) does not make the code return to EMPTY. It remains FULL. If a new frame is moved to the MB after the MB was serviced, the code still remains FULL. See Matching Process.
		No	OVERRUN	N/A	If the MB is FULL and a new frame is moved to this MB before the CPU services it, the CODE field is automatically updated to OVERRUN. See Matching Process.
0110: OVERRUN – MB is being overwritten into a full buffer.	OVERRUN	Yes	FULL	N/A	If the CODE field indicates OVERRUN and CPU has serviced the MB, when a new frame is moved to the MB, the code returns to FULL.
		No	OVERRUN	N/A	If the CODE field already indicates OVERRUN, and another new frame must be moved, the MB will be overwritten again, and the code will remain OVERRUN. See Matching Process.

Table 16-5: Message Buffer Code – Rx Buffer (Continued)

CODE Description	Rx Code Before New Frame	SRV*1	Rx Code After Successful Reception *2	RRS *3	Comment
1010: RANSWER*4 – A frame was configured to recognize a remote request frame and transmit a response frame in return.	RANSWER	N/A	TANSWER(1110)	0	A Remote Answer was configured to recognize a remote request frame received. After that, an MB is set to transmit a response frame. The code is automatically changed to TANSWER (1110). See Matching Process. If the CANFD_CTL2.RRS bit is negated, transmit a response frame whenever a remote request frame with the same ID is received.
		N/A	N/A	1	This code is ignored during matching and arbitration process.
CODE[0]=1; BUSY – CANFD is updating the contents of the MB. The CPU must not access the MB.	BUSY*5	N/A	FULL	N/A	Indicates that the MB is being updated. It will be negated automatically and does not interfere with the next CODE.
		N/A	OVERRUN	N/A	

*1 Serviced MB. The MB has been read and unlocked by reading the CANFD_TMR register or other MB.

*2 A frame has a successful reception after it is moved to an MB. See Move Process.

*3 Remote Request Stored bit, see the CANFD_CTL2 register.

*4 Code 1010 is not considered Tx and an MB with this code should not be aborted.

*5 6. For Tx MBs, the BUSY bit is ignored upon read, except when the CANFD_CFG.ABORTEN bit is set. If this bit is asserted, the corresponding MB does not participate in the matching process.

Table 16-6: Buffer Message Code – Tx Buffer

CODE Description	Tx Code Before Tx Frame	MB RTR	Tx Code After Successful Transmission	Comment
1000: INACTIVE – MB is not active.	INACTIVE	N/A	N/A	MB does not participate in arbitration process.
1001: ABORT – MB is aborted.	ABORT	N/A	N/A	MB does not participate in arbitration process.
1100: DATA – MB is a Tx Data Frame (MB RTR must be 0).	DATA	0	INACTIVE	Transmit data frame unconditionally once. After transmission, the MB automatically returns to the INACTIVE state.

Table 16-6: Buffer Message Code – Tx Buffer (Continued)

CODE Description	Tx Code Before Tx Frame	MB RTR	Tx Code After Successful Transmission	Comment
1100: REMOTE – MB is a Tx Remote Request Frame (MB RTR must be 1).	REMOTE	1	EMPTY	Transmit remote request frame unconditionally once. After transmission, the MB automatically becomes an Rx Empty MB with the same ID.
1110: TANSWER – MB is a Tx Response Frame from an incoming Remote Request Frame.	TANSWER	N/A	RANSWER	This is an intermediate code that is automatically written to the MB by the CHI as a result of a match to a remote request frame. The remote response frame will be transmitted unconditionally once, and then the code will automatically return to RANSWER (1010). The CPU can also write this code with the same effect. The remote response frame can be either a data frame or another remote request frame depending on the RTR bit value. See Matching Process and Arbitration Process.

Substitute Remote Request (SRR)

SRR is a fixed recessive bit, only for the extended format. The SRR bit is set to one for transmission (Tx buffers) and is stored with the value received on the CAN bus for Rx receiving buffers. It is received as either recessive or dominant. If the CANFD module receives this bit as dominant, then it is interpreted as an arbitration loss.

When the bit is set, the recessive value is compulsory for transmission in extended format frames. When it is clear, dominant is not a valid value for transmission in extended format frames.

ID Extended Bit (IDE)

IDE identifies whether the frame format is standard or extended.

When the bit is set, the frame format is extended. When the bit is clear, the frame format is standard.

Remote Transmission Request (RTR)

The RTR bit affects the behavior of remote frames and is part of the reception filter:

When the bit is set, the current MB may have a remote request frame to be transmitted if MB is Tx. If the MB is Rx, then incoming remote request frames may be stored. When the RTR bit is clear, the current MB has a data frame to be transmitted. In an Rx MB, it may be considered in matching processes.

See the *Message Buffer Code – Rx Buffer* table, the *Message Buffer Code – Tx Buffer* table, and the description of the `CANFD_CTL2.RRS` bit for additional details.

If the CANFD module transmits RTR as 1 (recessive) and receives it as 0 (dominant), it is interpreted as an arbitration loss. If RTR is transmitted as 0 (dominant) and received as 1 (recessive), the CANFD treats it as a bit error. If the value received matches the value transmitted, it is considered a successful bit transmission.

NOTE: When configuring CAN FD frames, the RTR bit must be negated.

Length of Data in Bytes (DLC)

The 4-bit DLC field is the length (in bytes) of the Rx or Tx data, which is located in offset 0x8 through 0xF of the MB space. In reception, DLC is written by the CANFD module, copied from the DLC (Data Length Code) field of the received frame. In transmission, DLC is written by the processor and corresponds to the DLC field value of the frame to be transmitted. When RTR = 1, the frame to be transmitted is a remote frame and does not include the data field, regardless of the DLC field. See the *Data Byte Validity* table.

Free-Running Counter Time Stamp (TIME STAMP)

The 16-bit TIME STAMP field is a copy of the free-running timer, captured for Tx and Rx frames when the beginning of the identifier field appears on the CAN bus.

Local Priority (PRIO)

The 3-bit PRIO field is used only when the CANFD_CFG.LPRIO_EN bit is set and only makes sense for Tx mailboxes. The PRIO field is not transmitted. It is appended to the regular ID to define the transmission priority. See the Arbitration Process section.

Frame Identifier (ID)

In standard frame format, only the 11 most significant bits (28 to 18) are used for frame identification for both receive and transmit, and the 18 least significant bits are ignored. In extended frame format, all bits are used for frame identification for both receive and transmit.

Data Field (DATA BYTE 0 to 63)

Up to 64 bytes can be used for a data frame, depending on the size of payload selected for the Message Buffers.

For Rx frames, the data is stored as it is received from the CAN bus. DATA BYTE(n) is valid only if n is less than DLC as shown in the *Data Byte Validity* table.

Table 16-7: Data Byte Validity

DLC	Valid Data Bytes
0	None
1	Data Byte 0

Table 16-7: Data Byte Validity (Continued)

Memory Partition

When CAN FD is enabled, the CANFD RAM can be partitioned in two blocks of 512 bytes. Each block can accommodate a number of message buffers. This depends on the configuration of the size control bit fields in the `CANFD_FD_CTL` register as shown in the *RAM Partition* table.

Table 16-12: RAM Partition

RAM Block	Number of MBs with 8 Bytes*1	Size Control Bit Field	Number of MBs of Different Sizes, per Block
0	0 to 31	`CANFD_FD_CTL.MBDSIZR0`	MBDSIZR0=00, 32 MBs with 8 bytes payload MBDSIZR0=01, 21 MBs with 16 bytes payload MBDSIZR0=10, 12 MBs with 32 bytes payload, MBDSIZR0=11, 7 MBs with 64 bytes payload
1	32 to 63	`CANFD_FD_CTL.MBDSIZR1`	MBDSIZR1=00, 32 MBs with 8 bytes payload MBDSIZR1=01, 21 MBs with 16 bytes payload MBDSIZR1=10, 12 MBs with 32 bytes payload MBDSIZR1=11, 7 MBs with 64 bytes payload

*1 default range

When payload sizes of 16, 32, or 64 bytes are configured in some or all RAM blocks, the total number of MBs, and the respective number order may differ from the default configuration of 8 bytes. For example, if Block 0 is configured to 8 bytes payload, Block 1 to 16 bytes, the following table indicates how the message buffers are arranged into RAM.

Table 16-13: RAM Partition Example

RAM Block	Payload Size	Number of MBs in the RAM Block	MB Range
0	CANFD_FD_CTL[MBDSIZR0]=00, 8 bytes payload	32	0 to 31
1	CANFD_FD_CTL[MBDSIZR1]=01, 16 bytes payload	21	32 to 52

Rx FIFO Structure

When the `CANFD_CFG.RFEN` bit is set, the memory area from 0x80 to 0xDC (which is normally occupied by MBs 0-5) is used by the Rx FIFO engine.

The region 0x80 to 0x8C contains the output of the FIFO, which must be read by the processor as a message buffer. The FIFO output contains the oldest message that has been received but not yet read. The region 0x90–0xDC is reserved for internal use of the FIFO engine.

An additional memory area, which starts at 0xE0 and may extend up to 0x2DC (normally occupied by MBs 6 to 37) depending on the `CANFD_CTL2.RFFNUM` bit field setting, contains the ID filter table (configurable from 8 to 128 table elements), which specifies filtering criteria for accepting frames into the FIFO. Out of reset, the ID filter table flexible memory area defaults to 0xE0 and extends only to 0xFC, which corresponds to MBs 6 to 7 for the `CANFD_CTL2.RFFNUM` bit field setting equal to zero.

The *Rx FIFO Structure* figure shows the Rx FIFO data structure.

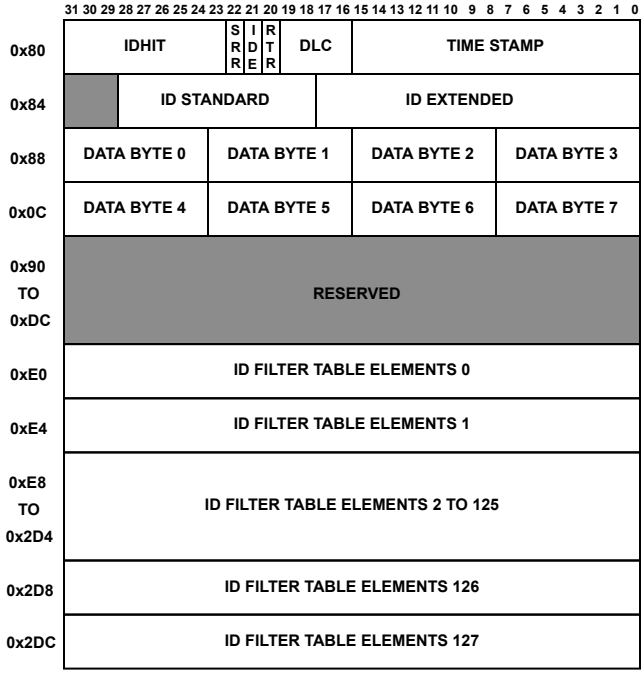

Figure 16-3: Rx FIFO Structure

Each ID filter table element occupies an entire 32-bit word and can be compounded by one, two, or four Identifier Acceptance Filters (IDAF) depending on the `CANFD_CFG.IDAM` bit field setting.

The *ID Filter Table Structure* figure shows the three different formats of the ID table elements. All elements of the table must have the same format, as selected by the `CANFD_CFG.IDAM` bit field.

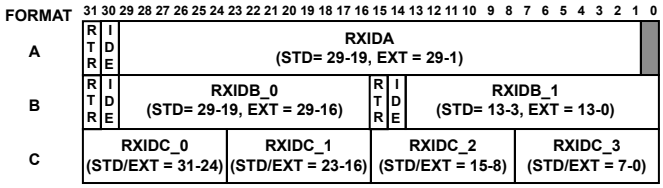

Figure 16-4: ID Filter Table Structure

The *Rx FIFO Filters* table shows the number of Rx FIFO filters configured with the `CANFD_CTL2.RFFNUM` bit field setting.

Table 16-14: Rx FIFO Filters

`CANFD_CTL2.RFFNUM`	**Number of Rx FIFO Filter Elements**	**Message Buffers Occupied by Rx FIFO and ID filter table**	**Remaining Mailboxes**	**Rx FIFO ID Filter Table Elements Affected by Rx Individual Masks**	**Rx FIFO ID filter table elements affected by Rx FIFO global mask**
0x0	8	MB 0 to 7	MB 8 to 63	Elements 0 to 7	None
0x1	16	MB 0 to 9	MB 10 to 63	Elements 0 to 9	Elements 10 to 15
0x2	24	MB 0 to 11	MB 12 to 63	Elements 0 to 11	Elements 12 to 23

Table 16-14: Rx FIFO Filters (Continued)

CANFD_CTL2.RFFNUM	Number of Rx FIFO Filter Elements	Message Buffers Occupied by Rx FIFO and ID filter table	Remaining Mailboxes	Rx FIFO ID Filter Table Elements Affected by Rx Individual Masks	Rx FIFO ID filter table elements affected by Rx FIFO global mask
0x3	32	MB 0 to 13	MB 14 to 63	Elements 0 to 13	Elements 14 to 31

0xD	112	MB 0 to 33	MB 34 to 63	Elements 0 to 31	Elements 32 to 111
0xE	120	MB 0 to 35	MB 36 to 63	Elements 0 to 31	Elements 32 to 119
0xF	128	MB 0 to 37	MB 38 to 63	Elements 0 to 31	Elements 32 to 127

Remote Frame (RTR)

The RTR bit specifies if remote frames are accepted into the FIFO if they match the target ID. If the bit is set, remote frames are accepted and data frames are rejected. If the bit is clear, remote frames are rejected and data frames are accepted.

Extended Frame (IDE)

The IDE bit specifies whether extended or standard frames are accepted into the FIFO if they match the target ID. If the bit is set, extended frames are accepted and standard frames are rejected. If the bit is clear, extended frames are rejected and standard frames are accepted.

Rx Frame Identifier Format A (RXIDA)

Specifies the ID for as acceptance criteria for the FIFO. In the standard frame format, only the 11 most significant bits (29 to 19) are used for frame identification. In the extended frame format, all bits are used.

Rx Frame Identifier Format B (RXIDB_0, RXIDB_1)

Specifies an ID to be used as acceptance criteria for the FIFO. In the standard frame format, the 11 most significant bits (a full standard ID) (29 to 19 and 13 to 3) are used for frame identification. In the extended frame format, all 14 bits of the field are compared to the 14 most significant bits of the received ID.

Rx Frame Identifier Format C (RXIDC_1, RXIDC_2, RXIDC_3)

Specifies an ID to be used as acceptance criteria for the FIFO. In both standard and extended frame formats, all 8 bits of the field are compared to the 8 most significant bits of the received ID.

Identifier Acceptance Filter Hit Indicator (IDHIT)

The 9-bit IDHIT field indicates which identifier acceptance filter is hit by the received message that is in the output of the Rx FIFO. See the Rx FIFO section for more information.

CANFD Processes

The following sections describe the how to transmit and receive CAN and CAN FD frames using the mailbox system.

Transmit Process

To transmit a CAN frame, the processor must prepare a message buffer for transmission by executing the following procedure:

1. Check if the respective interrupt bit is set and clear it.
2. If the MB is active (transmission pending), write the ABORT code (1001) to the CODE field of the control and status (C/S) word to request an abortion of the transmission. Wait for the corresponding IFLAG bit to be asserted by polling the `CANFD_IFLG1` or `CANFD_IFLG2` register or by the interrupt request if enabled in the respective IMASK bit in the `CANFD_IMSK1` or `CANFD_IMSK2` register. Then, read back the CODE field to check if the transmission was aborted or transmitted (see the Transmission Abort Mechanism section).
3. Write the ID word.
4. Write the data bytes.
5. Write the DLC, Control, and CODE fields of the C/S word to activate the MB. When `CANFD_CFG.FDEN` is set, also write the EDL, BRS and ESI bits.

When the MB is activated, it participates in the arbitration process and is eventually transmitted according to its priority. When the DLC value stored in the MB selected for transmission is larger than the respective MB payload size, the CANFD adds the necessary number of bytes with constant 0xCC pattern to complete the expected DLC.

At the end of the successful transmission, the value of the `CANFD_TMR` register is written into the TIME STAMP field, the CODE field in the C/S word is updated, both `CANFD_CRC` and `CANFD_FD_CRC` registers are updated, a status flag is set in the `CANFD_IFLG1` or `CANFD_IFLG2` register, and an interrupt is generated if allowed by the corresponding CANFD_IFLAGn bit. The new CODE field after transmission depends on the code that was used to activate the MB. See the *Message Buffer Code – Rx Buffer* table.

When the Abort feature is enabled (`CANFD_CFG.ABORTEN` is asserted), after the interrupt flag is asserted for a mailbox configured as transmit buffer, the mailbox is blocked. Therefore, the processor is not able to update it until the interrupt flag is disabled by the processor. This means that the processor must clear the corresponding CANFD_IFLAGn bit before starting to prepare this MB for a new transmission or reception.

Arbitration Process

The arbitration process scans the mailboxes, searching for the Tx mailbox that holds the message to be sent in the next opportunity. This mailbox is called the arbitration winner.

The scan starts from the lowest number mailbox and runs toward the higher ones. The arbitration process is triggered in the following events:

- From the CRC field of the CAN frame. The start point depends on the `CANFD_CTL2.TXASDLY` field value.
- During the error delimiter field of a CAN frame.
- During the overload delimiter field of a CAN frame.
- When the winner is inactivated, and the CAN bus has still not reached the first bit of the intermission field.
- When there is a processor write to the C/S word of a winner MB and the CAN bus has still not reached the first bit of the intermission field.
- When CHI is in idle state and the processor writes to the C/S word of any MB.
- When CANFD module exits the bus off state.
- Upon leaving freeze mode or low power mode.

If the arbitration process does not manage to evaluate all mailboxes before the CAN bus has reached the first bit of the intermission field, the temporary arbitration winner is invalidated and the CANFD module does not compete for the CAN bus in the next opportunity.

The arbitration process selects the winner among the active Tx mailboxes at the end of the scan according to the `CANFD_CTL1.LBUF` and `CANFD_CFG.LPRIOEN` bit settings.

Lowest Number Mailbox First

If the `CANFD_CTL1.LBUF` bit is enabled, the first (lowest number) active Tx mailbox found is the arbitration winner. The `CANFD_CFG.LPRIOEN` bit has no effect when the `CANFD_CTL1.LBUF` bit is enabled.

Highest-Priority Mailbox First

If the `CANFD_CTL1.LBUF` bit is disabled, then the arbitration process searches the active Tx mailbox with the highest priority. This mailbox frame with the highest priority has a higher probability to win the arbitration on CAN bus when multiple external nodes compete for the bus at the same time.

The sequence of bits considered for this arbitration is called the arbitration value of the mailbox. The highest-priority Tx mailbox is the one that has the lowest arbitration value among all Tx mailboxes.

If two or more mailboxes have equivalent arbitration values, the mailbox with the lowest number is the arbitration winner.

The composition of the arbitration value depends on the `CANFD_CFG.LPRIOEN` bit.

Local Priority Disabled

When the CANFD_CFG.LPRIOEN is disabled, local priority is disabled, and the arbitration value is built in the exact sequence of bits transmitted in a CAN frame as shown in the *Arbitration Value Priority Disabled* table.

Table 16-15: Arbitration Value Priority Disabled

Format	Mailbox Arbitration Value (32 bits)				
Standard (IDE = 0)	Standard ID (11 bits)	RTR (1bit)	IDE (1 bit)	- (18 bits)	- (1 bit)
Extended (IDE = 1)	Extended ID[28:18] (11 bits)	SRR (1bit)	IDE (1 bit)	Extended ID[17:0] (11 bits)	RTR (1bit)

Local Priority Enabled

If the CANFD_CFG.LPRIOEN is enabled, local priority is enabled. In this case, the mailbox PRIO field is included at the very left of the arbitration value as shown in the *Arbitration Value Priority Enabled table.*

Table 16-16: Arbitration Value Priority Enabled

Format	Mailbox Arbitration Value (35 bits)					
Standard (IDE = 0)	PRIO (3 bits)	Standard ID (11 bits)	RTR (1bit)	IDE (1 bit)	- (18 bits)	- (1 bit)
Extended (IDE = 1)	PRIO (3 bits)	Extended ID[28:18] (11 bits)	SRR (1bit)	IDE (1 bit)	Extended ID[17:0] (11 bits)	RTR (1bit)

As the PRIO field is the most significant part of the arbitration value, mailboxes with low PRIO values have higher priority than mailboxes with high PRIO values, regardless of the rest of their arbitration values.

NOTE: The PRIO field is not part of the frame on the CAN bus and only affects the internal arbitration process.

Arbitration Completion

After the arbitration winner is found, its content is copied to a hidden auxiliary MB called Tx Serial Message Buffer (Tx SMB), which has the same structure as a normal MB but is not user accessible. This operation is called move-out and, after it is done, write access to the C/S word of the corresponding MB is blocked (if CANFD_CFG.ABORTEN is asserted). Write access is restored in the following events:

- After the MB is transmitted and the corresponding IFLAG bit is cleared by the processor.
- The CANFD module enters freeze mode or bus off.
- The CANFD module loses the bus arbitration or there is an error during the transmission.

At the first opportunity window on the CAN bus, the message on the Tx SMB is transmitted according to the CAN protocol rules.

Arbitration Start and Stop Conditions

The arbitration process is triggered in the following situations:

- During Rx and Tx frames from CAN CRC field to end of frame. The `CANFD_CTL2.TXASDLY` value may be changed to optimize the arbitration start point.
- During CAN bus off state from TX_ERR_CNT = 124 to 128. The `CANFD_CTL2.TXASDLY` value may be changed to optimize the arbitration start point.
- During C/S write by the processor in bus idle mode. The first C/S write starts the arbitration process and a second C/S write during this same arbitration restarts the process. If other C/S writes are performed, the Tx arbitration process is pending. If there is no arbitration winner after the arbitration process has finished, the TX arbitration machine begins a new arbitration process. If there is a pending arbitration and the bus idle state starts, an arbitration process is triggered. In this case, the first and second C/S write in the bus idle state do not restart the arbitration process. It is possible that there is not enough time to finish arbitration in the wait for bus idle state and the next state is idle. In this case, the scan is not interrupted, and it is completed during the bus idle state. During this arbitration, a C/S write does not cause an arbitration restart.
- Arbitration winner deactivation during a valid arbitration window.
- Upon exiting freeze mode (first bit of the wait for bus idle state). If there is a re- synchronization during wait for bus idle state, the arbitration process restarts.

Arbitration process stops in the following situations:

- All mailboxes were scanned.
- A Tx active mailbox is found when the lowest buffer feature is enabled.
- Arbitration winner inactivation or abort during any arbitration process.
- There was not enough time to finish the Tx arbitration process (for example, when a deactivation was performed near the end of frame). In this case, the arbitration process is pending.
- There is an error or overload flag in the bus.
- There is a low power or freeze mode request in the idle state.

Arbitration is considered pending as described below:

- It was not possible to finish the arbitration process in time.
- C/S write during arbitration if write is performed in a MB whose number is lower than the Tx arbitration pointer.
- Any C/S write if there is no Tx arbitration process in progress.
- Rx Match has just updated an Rx code to Tx code
- Entering the bus off state.

C/S write during arbitration has the following effect:

- If the C/S write is performed in the arbitration winner, a new process is restarted immediately.
- If the C/S write is performed in an MB whose number is higher than the Tx arbitration pointer, the ongoing arbitration process will scan this MB as normal.

Receive Process

To receive CAN frames into a mailbox, the processor must prepare the mailbox for reception by executing the following steps:

1. If the mailbox is active (either Tx or Rx), inactivate the mailbox (See Mailbox Inactivation), preferably with a safe inactivation (See Transmission Abort Mechanism).
2. Write the ID word.
3. Write the EMPTY code (0b0100) to the CODE field of the C/S word to activate the mailbox. No setup is required for the EDL, BRS, and ESI bits; they are overwritten by the respective bit fields in the received message.

After the MB is activated, it will be able to receive frames that match the programmed filter. At the end of a successful reception, the mailbox is updated by the move-in process (See Move-In) as follows:

1. The received data field (8 bytes at most for classical CAN message format and up to 64 bytes for the CAN FD message format) is stored.
2. The received ID field is stored.
3. The value of the `CANFD_TMR` register at the time of the second bit of the frame identifier field is written into the mailbox TIME STAMP field.
4. The received SRR, IDE, RTR, EDL, BRS, ESI, and DLC fields are stored.
5. The CODE field in the C/S word is updated according to the *Message Buffer Code – Rx Buffer* and *Message Buffer Code – Tx Buffer* tables.
6. A status flag is set in the `CANFD_IFLG1` or `CANFD_IFLG2` register and an interrupt is generated if allowed by the corresponding `CANFD_IMSK1` or `CANFD_IMSK2` register bit.

The recommended procedure for the processor to service (read) the frame received in a mailbox is:

The processor polls for frame reception by checking the status flag bit for the specific mailbox in the respective CANFD_IFLAGn register and not by polling the CODE field of that mailbox. Polling the CODE field does not work because, once a frame is received and the processor services the mailbox (by reading the C/S word followed by unlocking the mailbox), the CODE field does not return to EMPTY. It remains FULL, as explained in the *Message Buffer Code – Rx Buffer* table. If the processor tries to work around this behavior by writing to the C/S word to force an EMPTY code after reading the mailbox without a prior safe inactivation, a newly received frame matching the filter of that mailbox may be lost.

NOTE: Never poll by reading the C/S word directly from the mailboxes. Always read the `CANFD_IFLG1` or `CANFD_IFLG2` register.

The identifier field of the receive frame is always stored in the matching mailbox. Therefore, the contents of the ID field in a mailbox may change if the match was due to masking.

When the CANFD_CFG.SRXDIS bit is enabled, the CANFD module does not store frames transmitted by itself in any MB, even if it contains a matching Rx mailbox, and no interrupt flag or interrupt signal is generated. Otherwise, when the CANFD_CFG.SRXDIS bit is disabled, the CANFD module can receive frames transmitted by itself if there is a matching Rx mailbox.

To be able to receive CAN frames through the Rx FIFO, the processor must enable and configure the Rx FIFO during freeze mode (See Rx FIFO). Upon receiving the frames available in Rx FIFO interrupt (see the CANFD_IFLG1.MB05 bit description), the processor services the received frame using the following procedure:

1. Read the C/S word (optional: needed only if a mask was used for the IDE and RTR bits).
2. Read the ID field (optional: needed only if a mask was used).
3. Read the Data field.
4. Read the CANFD_RX_FIFO register (optional).
5. Clear the frames available in Rx FIFO interrupt by writing a one to the CANFD_IFLG1.MB05 bit to release the MB and allow the processor to read the next Rx FIFO entry.

When the CANFD_CFG.DMAEN bit is enabled, upon receiving a frame in the Rx FIFO, the CANFD_IFLG1.MB05 bit generates a DMA request and does not generate a processor interrupt (See Rx FIFO Under DMA Operation). The CANFD_IMSK1 bits in the Rx FIFO region are not used.

The DMA controller must service the received frame using the following procedure:

1. Read the C/S word (read 0x80 address, optional).
2. Read the ID field (read 0x84 address, optional).
3. Read all data bytes (start read at 0x88 address, optional).
4. Read the last data bytes (read 0x8C address is mandatory).

Matching Process

The matching process scans the MB memory looking for Rx MBs programmed with the same ID as the one received from the CAN bus. If the FIFO is enabled, the priority of scanning can be selected between mailboxes and FIFO filters. The matching starts from the lowest number MB toward the higher ones. When no match is found within the first structure, then the other is scanned subsequently. When the FIFO is full, the matching algorithm always looks for a matching MB outside the FIFO region.

As the frame is being received, it is stored in a hidden auxiliary MB called Rx Serial Message Buffer (Rx SMB).

The matching process start point depends on the following conditions:

- When the received frame is a remote frame, the start point is the CRC field of the frame.

- When the received frame is a data frame with DLC field equal to zero, the start point is the CRC field of the frame.
- When the received frame is a data frame with DLC field different than zero, the start point is the DATA field of the frame.

When a matching ID is found in the FIFO table or in one of the mailboxes, the contents of the Rx SMB are transferred to the FIFO or to the matched mailbox by the move-in process. When any CAN protocol error is detected, then no match results are transferred to the FIFO or to the matched mailbox at the end of reception.

The matching process scans all matching elements of both Rx FIFO (if enabled) and the active Rx mailboxes (CODE is EMPTY, FULL, OVERRUN, or RANSWER) in search of a successful comparison with the matching elements of the Rx SMB that is receiving the frame on the CAN bus. The Rx SMB has the same structure as a mailbox. The reception structures (Rx FIFO or mailboxes) associated with the matching elements that had a successful comparison are the matched structures. The matching winner is selected at the end of the scan among those matched structures and depends on conditions described below.

Table 16-17: Matching Architecture

Structure	SMB.RTR	CTRL2.RSS	CTRL2.EACEN	MB.IDE	MB.RTR	MB.ID*1	MB.CODE
Mailbox	0	N/A	0	cmp*2	no_cmp*3	cmp_msk*4	
Mailbox	0	N/A	1	cmp_msk	cmp_msk	cmp_msk	
Mailbox	1	0	N/A	cmp	no_cmp	cmp	
Mailbox	1	1	0	cmp	no_cmp	cmp_msk	
Mailbox	1	1	1	cmp_msk	cmp_msk	cmp_msk	
FIFO*5	N/A	N/A	N/A	cmp_msk	cmp_msk	cmp_msk	

*1 1. For mailbox structure, If SMB.IDE is asserted, the ID is 29 bits (ID Standard + ID Extended). If SMB.IDE is negated, the ID is only 11 bits (ID Standard). For FIFO structure, the ID depends on CANFD_CFG.IDAM.

*2 cmp: Compares the Rx SMB contents with the MB contents regardless the masks.

*3 no_cmp: The Rx SMB contents are not compared with the MB contents.

*4 cmp_msk: Compares the Rx SMB contents with MB contents taking into account the masks.

*5 SMB.IDE and SMB.RTR. are not considered when CANFD_CFG.IDAM is format C.

A reception structure is free-to-receive when any of the following conditions is satisfied:

- The CODE field of the mailbox is EMPTY.
- The CODE field of the mailbox is either FULL or OVERRUN and it has already been serviced (the C/S word was read by the processor and unlocked as described in the Mailbox Lock Mechanism section).
- The CODE field of the mailbox is either FULL or OVERRUN and an inactivation is performed. See the Mailbox Inactivation section.
- The Rx FIFO is not full.

The scan order for mailboxes and the Rx FIFO is from the matching element with lowest number to the higher ones.

The matching winner search for mailboxes is affected by the CANFD_CFG.IRMQEN bit. If the CANFD_CFG.IRMQEN bit is disabled, the matching winner is the first matched mailbox regardless if it is free-to-receive or not. If the CANFD_CFG.IRMQEN bit is enabled, the matching winner is selected according to the priority below:

1. The first free-to-receive matched mailbox.
2. The last non free-to-receive matched mailbox.

It is possible to select the priority of scan between mailboxes and the Rx FIFO by using theCANFD_CTL2.MRPRIO bit.

If the selected priority is Rx FIFO first:

- If the Rx FIFO is a matched structure and is free-to-receive, then the Rx FIFO is the matching winner regardless of the scan for mailboxes.
- Otherwise (the Rx FIFO is not a matched structure or is not free-to-receive), then the matching winner is searched for among mailboxes as described above.

If the selected priority is mailboxes first:

- If a free-to-receive matched mailbox is found, it is the matching winner regardless of the scan for the Rx FIFO.
- If no matched mailbox is found, then the matching winner is searched for in the scan for the Rx FIFO.

If both conditions above are not satisfied and a non free-to-receive matched mailbox is found, then the matching winner determination is conditioned by the CANFD_CFG.IRMQEN bit:

- If the CANFD_CFG.IRMQEN bit is disabled, the matching winner is the first matched mailbox.
- If the CANFD_CFG.IRMQEN bit is enabled, the matching winner is the Rx FIFO if it is a free-to- receive matched structure; otherwise, the matching winner is the last non free-to- receive matched mailbox.

See the *Matching Possibilities and Resulting Reception Structures* table for a summary of matching possibilities.

Table 16-18: Matching Possibilities and Resulting Reception Structures

RFEN	IRMQEN	MRPRIO	Matched in MB[*1]	Matched in FIFO[*2]	Reception Structure	Description
No FIFO, only MB, match is always MB first:						
0	0	X[*3]	None	_[*4]	None	Frame lost by no match
0	0	X	Free	–	FirstMB	
0	1	X	None	–	None	Frame lost by no match

Table 16-18: Matching Possibilities and Resulting Reception Structures (Continued)

RFEN	IRMQEN	MRPRIO	Matched in MB*1	Matched in FIFO*2	Reception Structure	Description
0	1	X	Free	–	FirstMB	
0	1	X	Not Free	–	LastMB	Overrun
FIFO enabled, no match in FIFO (as if FIFO does not exist):						
1	0	X	None	None	None	Frame lost by no match
1	0	X	Free	None	FirstMB	
1	1	X	None	None	None	Frame lost by no match
1	1	X	Free	None	FirstMB	
1	1	X	Not Free	None	LastMB	Overrun
FIFO enabled, queue disabled:						
1	0	0	X	NotFull	FIFO	
1	0	0	None	Full	None	Frame lost by FIFO full (FIFO overflow)
1	0	0	Free	Full	FirstMB	
1	0	0	Not Free	Full	FirstMB	
1	0	1	None	NotFull	FIFO	
1	0	1	None	Full	None	Frame lost by FIFO full (FIFO overflow)
1	0	1	Free	X	FirstMB	
1	0	1	Not Free	X	FirstMB	Overrun
FIFO enabled, queue enabled:						
1	1	0	X	NotFull	FIFO	
1	1	0	None	Full	None	Frame lost by FIFO full (FIFO overflow)
1	1	0	Free	Full	FirstMB	
1	1	0	Not Free	Full	LastMB	Overrun
1	1	1	None	NotFull	FIFO	
1	1	1	Free	X	FirstMB	
1	1	1	Not Free	NotFull	FIFO	

Table 16-18: Matching Possibilities and Resulting Reception Structures (Continued)

RFEN	IRMQEN	MRPRIO	Matched in MB*1	Matched in FIFO*2	Reception Structure	Description
1	1	1	Not Free	Full	LastMB	Overrun

*1 In the Matched in MB column, the term "None" means the frame has not matched an MB (free-to-receive or non-free-to receive). The term "Free" means the frame matched at least one MB free-to-receive regardless of whether it has matched MBs non-free-to-receive.

*2 In the Matched in FIFO column, the term "None" means the frame has not matched any filter for the Rx FIFO. It is as if the Rx FIFO does not exist (CANFD_CTL2.RFEN = 0). The term "NotFull" means that the frame has matched a FIFO filter and has empty slots to receive it. The term "Full" means that the frame has matched a FIFO filter, but the FIFO couldn't store it because the FIFO has no empty slots to receive it.

*3 The X denotes a don't-care condition.

*4 The – denotes a forbidden condition.

When a non-safe mailbox inactivation (See Mailbox Inactivation) occurs during the matching process and the mailbox inactivated is the temporary matching winner, then the temporary matching winner is invalidated. The matching elements scan is not stopped nor restarted; it continues normally. The consequence is that the current matching process works as if the matching elements compared before the inactivation did not exist, therefore a message may be lost.

Suppose, for example, that the Rx FIFO is disabled, the `CANFD_CFG.IRMQEN` is enabled, there are two MBs with the same ID, and the CANFD starts receiving messages with that ID. If the two MBs are the second and the fifth in the array, then when the first message arrives, the matching algorithm finds the first match in MB number 2. The code of this MB is EMPTY, so the message is stored there. When the second message arrives, the matching algorithm finds MB number 2 again, but it is not "free-to-receive," so it keeps looking, finds MB number 5 and stores the message there. If yet another message with the same ID arrives, the matching algorithm finds out that there are no matching MBs that are "free-to-receive," so it decides to overwrite the last matched MB, which is number 5. In doing so, it sets the CODE field of the MB to indicate OVERRUN.

The ability to match the same ID in more than one MB can be exploited to implement a reception queue (in addition to the full-featured FIFO) to allow more time for the processor to service the MBs. By programming more than one MB with the same ID, received messages are queued into the MBs. The CPU can examine the TIME STAMP field of the MBs to determine the order in which the messages arrived.

Matching to a range of IDs is possible by using ID acceptance masks. The CANFD module supports individual masking per MB. During the matching algorithm, if a mask bit is asserted, then the corresponding ID bit is compared. If the mask bit is negated, the corresponding ID bit is a "don't care." The `CANFD_IMSK1` and `CANFD_IMSK2` registers are implemented in RAM, so they are not initialized out of reset. Also, they can only be programmed while the CANFD module is in freeze mode; otherwise, they are blocked by hardware.

The CANFD also supports an alternate masking scheme with only four mask registers (`CANFD_RX_FIFO_GMSK`, `CANFD_RX_MB_GMSK`, `CANFD_RX_14_MSK`, and `CANFD_RX_15_MSK`) for backward compatibility with legacy applications. This alternate masking scheme is enabled when `CANFD_CFG.IRMQEN` is enabled.

Receive Process Pretending Network Mode

Pretended networking mode adds specific wake up functionality in low power modes (doze mode). When pretended network (PN) mode is enabled by asserting the CANFD_CFG.PNETEN bit, the CANFD module continues processing Rx CAN messages under low power mode, able to detect specific wake up messages by filtering them against ID and payload target values using preselected matching criteria. Wake up functionality is not available for messages in CAN FD format. While in pretended networking mode, CAN FD format messages are ignored.

PN registers are in the 0x0B00–0x0B7C address range and can only be written only in freeze mode. These registers are used for writing PN configuration (both control and target values) prior entering into pretended networking mode, and for reading wake up flags and the received message ID and data when returning to normal mode after waking. The processor waits for the CANFD_CFG.LPMACK bit to be disabled before performing any access to CANFD PN registers.

PN control registers are CANFD_PN_CTL1 and CANFD_PN_CTL2. The control bit fields that configure the filtering criteria are:

- CANFD_PN_CTL1.PLFSEL: Payload filtering selection.
- CANFD_PN_CTL1.IDFSEL: ID filtering selection.
- CANFD_PN_CTL1.FCSEL: Filtering combination selection.

PN target values are:

- CANFD_FLTR_ID1.IDE: IDE target value used to filter the incoming message by its format (standard or extended).
- CANFD_FLTR_ID1.RTR: RTR target value used to filter the incoming message by its type (data or remote frame).
- CANFD_FLTR_DLC.HI and CANFD_FLTR_DLC.LO: Target DLC range used to filter the size of payload part of an incoming message.
- CANFD_FLTR_ID1.VALUE: ID target value used to filter the incoming message ID (equal to, smaller than or equal, greater than or equal, or the lower limit value in an ID range).
- CANFD_FLTR_ID2_IDMSK: ID target value used as the upper limit in an ID range.
- PL1: Payload target value used to filter the incoming message payload (equal to, smaller than or equal, greater than or equal, or the lower limit value in a payload range).
- PL2: Payload target value used as the upper limit in a payload range.

The IDE, RTR, ID, and payload filters have their respective masks. These masks determine which bits are considered in equality comparisons (1 in certain mask positions) and which ones are don't care (0 in other mask positions). ID and payload masks are used only for exact ID and/or exact payload comparisons.

The ID of Rx incoming messages can be filtered based on the following criteria:

- A match with the exact ID value by detecting the equality between the ID field of the incoming message and the content of target CANFD_FLTR_ID1 register. The ID mask is used.
- A match with the maximum range of ID; in other words, any message with ID value smaller than or equal to the content of target CANFD_FLTR_ID11 register is accepted. The ID mask is not used.
- A match with the minimum range of ID; in other words, any message with ID value greater than or equal to the content of target CANFD_FLTR_ID1 register is accepted. The ID mask is not used.
- A match inside a range of IDs; in other words, any message with an ID value that is greater than or equal to the content of target CANFD_FLTR_ID1 register and smaller than or equal to the content of target CANFD_FLTR_ID2_IDMSK register is accepted. The ID mask is not used.

The above criteria for ID filtering must be coherent with CANFD_FLTR_ID1.IDE and CANFD_FLTR_ID1.RTR target values. Only Rx frames that match the respective IDE and RTR bits to the contents of FLT_IDE and FLT_RTR bit fields are compared. When range of IDs is selected (CANFD_PN_CTL1.IDFSEL = 11), both the CANFD_FLTR_ID1.VALUE field and the CANFD_FLTR_ID2_IDMSK register are referred to the same CANFD_FLTR_ID1.IDE and CANFD_FLTR_ID1.RTR bits.

The ID mask is applied only to the exact ID comparison filtering option (CANFD_PN_CTL1.IDFSEL = 00) to determine which bits are considered in the comparison. For the exact match option, the mask can select any bit within the ID field. For maximum range, minimum range and inside range comparisons, the ID mask is not considered.

The IDE and RTR masks are applied in both exact and range ID comparison filtering options to determine which bits are considered in comparison.

Similarly to the ID criteria, 64-bit data or payloads (PL) of Rx incoming messages can be filtered based on the following criteria:

- A match with the exact payload value by detecting the equality between the payload field of the incoming message and the content of PL1 register. The payload mask is used.
- A match with the maximum range of payload–in other words, any message with payload value smaller than or equal to the content of PL1 register is accepted. The payload mask is not used.
- A match with the minimum range of payload–in other words, any message with payload value greater than or equal to the content of PL1 register is accepted. The payload mask is not used.
- A match inside a range of payloads–in other words, any message with a payload value that is greater than or equal to the content of PL1 register and smaller than or equal to the content of PL2 register is accepted. The payload mask is not used.

The above criteria for payload filtering must be coherent with CANFD_FLTR_DLC.HI and CANFD_FLTR_DLC.LO limit values. The payload of a Rx incoming message is filtered in accordance with the selected criteria only when the DLC value of the Rx incoming message is inside a DLC range:

- Greater than or equal to the CANFD_FLTR_DLC.LO (lower limit) and

- Lower than or equal to the CANFD_FLTR_DLC.HI (upper limit)

Conversely, a DLC value out of the specified range results in mismatch. By making CANFD_FLTR_DLC.LO = CANFD_FLTR_DLC.HI, only payloads of specified quantity of bytes will be filtered. DLC is not maskable.

When the inside range of payloads option is selected (CANFD_PN_CTL1.PLFSEL = 11), both PL1 and PL2 are considered with the 8-byte data length. All the data bytes excluded by the DLC of the received message are considered with value zero.

Payload mask is only used in the exact match option (CANFD_PN_CTL1.PLFSEL = 00) to select which bits or bytes in the 8-byte data field of both Rx incoming message and the contents of PL1 register are selected for matching. Mask length must be in accordance with the expected range of DLC values. For maximum range, minimum range, and inside range comparisons, the payload mask is not considered.

When a remote frame is received by the CANFD module and the CANFD_PN_CTL1.FCSEL bit is configured to select the payload comparison, the payload filtering is not considered and the comparison results in a mismatch.

Rx incoming messages can also be filtered based upon the quantity and rate of message reception, specifically:

- Several messages that match the filtering criteria for ID or payload a predefined quantity of times. This quantity can be configured in the 1 to 255 range. See the CANFD_CTL1 register.
- No message matching the filtering criteria for ID or payload up to a timeout trigger.

  That is, non-reception of a matching message for a defined quantity of time. See the CANFD_CTL2 register.

The CANFD module can generate a wakeup timeout event from an internal timer with associated comparator circuitry capable of generating a timeout flag when the counting reaches the predefined timeout value, as specified in the CANFD_PN_CTL2.MATCHTO bit field.

The above filtering criteria can be used together as follows:

- Message ID filtering only.
- Message ID filtering and payload filtering.
- Message ID filtering only occurring N times.
- Message ID filtering and payload filtering occurring N times.

The timeout counter runs concurrently with the reception filtering process. Both engines, timeout counter and message filtering, are independent. If an incoming message matches the selected filter criteria, the timeout counter keeps counting until the processor wakes up.

Conversely, if the timeout counter reaches the target value, then the message filtering process continue to filter incoming messages until the processor wakes up. The CANFD_WUM.MCNT field reports the number of matched messages that occurred under pretended networking mode up to the moment the processor wakes up.

Under pretended networking mode, a wakeup event that occurs sets the respective wake up flag (see the CANFD_WUM register.

- In case of a successful match with the selected filtering criteria, the CANFD_WUM.WUMF bit field.

- In case of a timeout trigger, the CANFD_WUM.WTOF bit field.

Either of these flags generates an interrupt to the processor if the respective mask bit is asserted (CANFD_PN_CTL1.WUMFMSK or CANFD_PN_CTL1.WTOFMSK).

There are four wake up message buffers (WMBs) for storing incoming messages in pretended networking mode. Up to four messages can be stored per the CANFD_WMB[n]_ID register. When the CANFD_PN_CTL1.MATCHCNT value is one, just one message is received if matching the filtering criteria, and this message is stored in the CANFD_WMB0 register. If the CANFD_PN_CTL1.MATCHCNT value is between two and four, CANFD_WMB1, CANFD_WMB2, and CANFD_WMB3 are used to store the second, third, and fourth matching messages, respectively. If CANFD_PN_CTL1.MATCHCNT is greater than four, the last four matching messages are stored in the WMBs; respecting the WMB index to indicate the arrival order, the latest is stored in CANFD_WMB3. Only the valid data bytes of the incoming match message is stored in data field of WMBs. The non-valid data bytes are read as zero. In case the of DLC = 0 and RTR = 1, the data field is filled with zero. In any of the above cases, the wake up interrupt is generated just when the filtering criteria is completed and the CANFD_PN_CTL1.WUMFMSK bit is set.

When a non-match wakeup event occurs (timeout or external) and the CANFD_WUM.MCNT value is equal or greater than four, the message stored in WMB0 does not have a valid content. The CANFD_WMB0 is used as the buffer for the current message on the CAN bus. Messages received during pretended networking mode do not have timestamps and respective field in the WMB structure must be ignored.

Under low-power mode (doze or stop), all processes are shut down except for the PN functionality in the PE submodule, which is kept clocked by the oscillator clock. The CANFD continues to receive Rx incoming messages and just compares them against the predefined target values and according to the selected filtering criteria. The matching, arbitration, move-in, and move-out processes, normally available in normal mode, are not performed under pretended networking mode.

Under pretended networking, the CANFD reacts to messages on the CAN bus in the same manner as in normal mode (generates acknowledge bits, detects and counts errors, etc.).

Move Process

There are two types of move process: move-in and move-out.

Move-In

The move-in process is the copy of a message received by an Rx SMB to an Rx mailbox or FIFO that has matched it. If the move destination is the Rx FIFO, attributes of the message are also copied to the CANFD_RX_FIFO register. Each Rx SMB has its own move-in process, but only one is performed at a given time as described below. The move-in starts only when the message held by the Rx SMB has a corresponding matching winner (See Matching Process) and all of the following conditions are true:

- The CAN bus has reached or let past either of the following:
  - The second bit of the Intermission field next to the frame that carried the message that is in the Rx SMB
  - The first bit of an overload frame next to the frame that carried the message that is in the Rx SMB

- There is no ongoing matching process.
- The destination mailbox is not locked by the processor.
- There is no ongoing move-in process from another Rx SMB. If more than one move-in processes are to be started at the same time, both are performed and the newest substitutes the oldest.

The term pending *move-in* is used throughout the documentation and stands for a *move-to- be* that still does not satisfy all the previously mentioned conditions.

The move-in is canceled and the Rx SMB can receive another message when any of the following conditions is satisfied:

- The destination mailbox is inactivated after the CAN bus has reached the first bit of intermission field next to the frame that carried the message and its matching process has finished.
- There is a previous pending move-in to the same destination mailbox.
- The Rx SMB is receiving a frame transmitted by the CANFD itself and the self-reception is disabled (`CANFD_CFG.SRXDIS` bit is enabled)
- Any CAN protocol error is detected.

Note that the pending move-in is not canceled if the CANFD module enters freeze or low-power mode. The pending move-in stays on hold waiting for exit from Freeze or low-power mode and to be unlocked. If an MB is unlocked during freeze mode, the move-in happens immediately.

The move-in process is the execution by the CANFD module of the following steps:

1. Push `CANFD_RX_FIFO.IDHIT` into the `CANFD_RX_FIFO` FIFO if the message is destined to the Rx FIFO.
2. Read all data words from the Rx SMB according to the selected payload size for the Rx storage element.
3. Write all data words to the Rx mailbox according to the selected payload size for the Rx storage element. If the data size of the storage element is smaller than the original payload size described in the message DLC field, the payload is truncated and the high order bytes that do not fit the destination size are lost.
4. Read the C/S and ID words from the Rx SMB.
5. Write C/S and ID words to the Rx mailbox and update the CODE field.

The move-in process is not atomic, in such a way that it is immediately canceled by the inactivation of the destination mailbox (See Mailbox Inactivation). In this case, the mailbox may be left partially updated, thus incoherent. The exception is if the move-in destination is an Rx FIFO message buffer, in which case the process cannot be canceled.

The BUSY bit (least significant bit of the CODE field) of the destination message buffer is asserted while the move-in is being performed to alert the processor that the message buffer content is temporarily incoherent.

Move-Out

The move-out process is the copy of the content from a Tx mailbox to the Tx SMB when a message for transmission is available (See Arbitration Process). The move-out occurs in the following conditions:

- The first bit of intermission field.
- During the bus off state when TX error counter is in the 124 to 128 range.
- During bus idle state.
- During the wait for bus idle state.

The move-out process is not atomic. Only the processor has priority to access the memory concurrently out of bus idle state. In bus idle, the move-out has the lowest priority to the concurrent memory accesses.

Data Coherence

In order to maintain data coherency and proper operation of the CANFD module, the processor must obey the rules described in the Transmit Process and Receive Process sections.

Transmission Abort Mechanism

The abort mechanism provides a safe way to request the abortion of a pending transmission. A feedback mechanism is provided to inform the processor if the transmission was aborted or if the frame could not be aborted and was transmitted instead.

Two primary conditions must be fulfilled in order to abort a transmission:

- The `CANFD_CFG.ABORTEN` bit is enabled.
- The first processor action must be the writing of abort code (1001) into the CODE field of the C/S word.

Active MBs configured for transmission must be aborted first before they can be updated. If the abort code is written to a mailbox that is currently being transmitted or to a mailbox that was already loaded into the Tx SMB for transmission, the write operation is blocked, and the transmission is not disturbed. However, the abort request is captured and kept pending until one of the following conditions is satisfied:

- The CANFD module loses the bus arbitration.
- There is an error during the transmission.
- The CANFD module is put into freeze mode.
- The CANFD enters the bus off state.
- There is an overload frame.

When none of the conditions above are reached, the MB is transmitted correctly, the interrupt flag is set in the respective `CANFD_IFLG1` or `CANFD_IFLG2` register, and an interrupt to the processor is generated (if enabled). The abort request is automatically cleared when the interrupt flag is set. On the other hand, when one of the above conditions is reached, the frame is not transmitted; therefore, the abort code is written into the CODE field, the

interrupt flag is set in the respective CANFD_IFLG1 or CANFD_IFLG2 register, and an interrupt is (optionally) generated.

When the processor writes the abort code before the transmission begins internally, then the write operation is not blocked; therefore, the MB is updated, and the interrupt flag is set. The processor just needs to read the abort code to make sure the active MB was safely inactivated. Although the CANFD_CFG.ABORTEN bit is asserted and the processor wrote the abort code, in this case the MB is inactivated and not aborted, because the transmission did not start yet. One mailbox is only aborted when the abort request is captured and kept pending until one of the previous conditions are satisfied.

The abort procedure can be summarized as follows:

- The processor checks the corresponding IFLAG and clears it, if asserted.
- The processor writes 1001 into the CODE field of the C/S word.
- The processor waits for the corresponding IFLAG indicating that the frame was either transmitted or aborted.
- The processor reads the CODE field to check if the frame was either transmitted (CODE = 1000) or aborted (CODE = 1001).
- It is necessary to clear the corresponding IFLAG to allow the MB to be reconfigured.
- It is necessary to reconfigure the EDL, BRS, and ESI fields of the aborted MB before transmitting it again.

Mailbox Inactivation

Inactivation is a mechanism provided to protect the mailbox against updates by the CANFD internal processes, thus allowing the processor to rely on mailbox data coherence after having updated it, even in normal mode.

Inactivation of transmission mailboxes must be performed only when the CANFD_CFG.ABORTEN bit is deasserted.

If a mailbox is inactivated, it participates in neither the arbitration process nor the matching process until it is reactivated.

To inactivate a mailbox, the processor must update its CODE field to INACTIVE (either 0000 or 1000).

Because the processor is not able to synchronize the CODE field update with the CANFD internal processes, an inactivation has the following consequences:

- A frame on the bus that matches the filtering of the inactivated Rx mailbox may be lost without notice, even if there are other mailboxes with the same filter.
- A frame containing the message within the inactivated Tx mailbox may be transmitted without setting the respective IFLAG.

To perform a safe inactivation and avoid the above consequences for Tx mailboxes, the processor must use the transmission abort mechanism .

The inactivation automatically unlocks the mailbox (See Mailbox Lock Mechanism).

NOTE: Message buffers that are part of the Rx FIFO cannot be inactivated. There is no write protection on the FIFO region. The processor must maintain data coherency in the FIFO region when the CANFD_CFG.RFEN bit is enabled.

Mailbox Lock Mechanism

Other than mailbox inactivation, the CANFD module has another data coherence mechanism for the receive process. When the processor reads the C/S word of an Rx MB with codes FULL or OVERRUN, the CANFD assumes that the processor wants to read the whole MB in an atomic operation and therefore it sets an internal lock flag for that MB. The lock is released when the processor reads the CANFD_TIMING register (global unlock operation), or when it reads the C/S word of another MB regardless of its code. A processor write into the C/S word also unlocks the MB, but this procedure is not recommended for normal unlock use because it cancels a pending move and potentially may lose a received message. The MB locking prevents a new frame from being written into the MB while the processor is reading it.

NOTE: The locking mechanism applies only to Rx MBs that are not part of the FIFO and have a code other than INACTIVE (0000) or EMPTY (0100). Tx MBs can not be locked. When the CANFD_CFG.IRMQEN bit is disabled, reading the C/S word locked the MB even if it was EMPTY.

When the FIFO is disabled and the second and the fifth MBs of the array are programmed with the same ID, and the CANFD module has already received and stored messages into these two MBs. If the processor then attempts to read MB number five and at the same time another message with the same ID is arriving, then when the processor reads the C/S word of MB number five, this MB is locked. The new message arrives, and the matching algorithm finds out that there are no “free-to-receive” MBs, it decides to override MB number five. However, this MB is locked, so the new message cannot be written there. It remains in the Rx SMB waiting for the MB to be unlocked, and only then will be written to the MB.

When the MB is not unlocked in time and yet another new message with the same ID arrives, the new message overwrites the message in the Rx SMB and there is no indication of lost messages either in the CODE field of the MB or in the Error and Status Register.

While the message is being moved-in from the Rx SMB to the MB, the BUSY bit on the CODE field is enabled. If the processor reads the C/S word and finds out that the BUSY bit is set, it should defer accessing the MB until the BUSY bit is cleared.

NOTE: If the BUSY bit is enabled or if the MB is empty, then reading the C/S word does not lock the MB.

Inactivation takes precedence over locking. If the processor inactivates a locked Rx MB, then the lock status is negated and the MB is marked as invalid for the current matching round. Any pending message on the Rx SMB is transferred to the MB. An MB is unlocked when the processor reads the CANFD_TMR register, or the C/S word of another MB.

Lock and unlock mechanisms have the same functionality in both normal and freeze modes.

An unlock during normal or freeze mode results in the move-in of the pending message. However, the move-in is postponed if an unlock occurs during a low power mode, and it takes place only when the module resumes to normal or freeze mode.

Rx FIFO

The Rx FIFO is receive-only and is enabled by asserting the CANFD_CFG.RFEN bit. The reset value of this bit is zero to maintain software backward compatibility with previous versions of the CANFD module that did not have the FIFO feature.

NOTE: The Rx FIFO must not be enabled when the CAN FD feature is enabled.

The Rx FIFO is 6 messages deep. The memory region occupied by the FIFO structure (both message buffers and FIFO engine) is described in the Rx FIFO Structure section. The processor can read the received messages sequentially, in the order they were received, by repeatedly reading a message buffer structure at the output of the FIFO.

The frames available bit (CANFD_IFLG1.MB05)is enabled when there is at least one frame available to be read from the Rx FIFO. An interrupt is generated if it is enabled by the corresponding mask bit. Upon receiving the interrupt, the processor reads the message (accessing the output of the FIFO as a message buffer) and the CANFD_RX_FIFO register, then clears the interrupt. If there are more messages in the Rx FIFO, the act of clearing the interrupt updates the output of the FIFO with the next message and updates the CANFD_RX_FIFO register with the attributes of that message, reissuing the interrupt to the processor. Otherwise, the flag remains negated. The output of the Rx FIFO is only valid while the CANFD_IFLG1.MB05 bit enabled.

The Rx FIFO warning bit (CANFD_IFLG1.MB06) is enabled when the number of unread messages in the Rx FIFO is increased to five from four due to the reception of a new message, meaning that the Rx FIFO is almost full. The flag remains enabled until the processor clears it.

The Rx FIFO overflow bit (CANFD_IFLG1.MB07) is enabled when an incoming message is lost because the Rx FIFO is full. The CANFD_IFLG1.MB07 bit is not set when the Rx FIFO is full, and the message is captured by a mailbox. The CANFD_IFLG1.MB07 remains set until the processor clears it.

Clearing one of those three flags does not affect the state of the other two.

An interrupt is generated when an IFLAG bit asserts and the corresponding mask bit is enabled.

A powerful filtering scheme is provided to accept only frames intended for the target application, reducing the interrupt servicing workload. The filtering criteria is specified by programming a table of up to 128 32-bit registers, according to the CANFD_CTL2.RFFNUM bit setting, which is configurable to one of the following formats:

- Format A: 128 IDAFs (extended or standard IDs including IDE and RTR)
- Format B: 256 IDAFs (standard IDs or extended 14-bit ID slices including IDE and RTR)
- Format C: 512 IDAFs (standard or extended 8-bit ID slices)

NOTE: A chosen format is applied to all entries of the filter table. It is not possible to mix formats within the table.

Every frame available in the FIFO has a corresponding identifier acceptance filter hit indicator (IDHIT) that can read in the IDHIT field from C/S word. Another way the processor can obtain this information is by accessing the CANFD_RX_FIFO register. The CANFD_RX_FIFO.IDHIT field refers to the message at the output of the FIFO

and is valid while the CANFD_IFLG1.MB05 flag is enabled. The CANFD_RX_FIFO register must be read only before clearing the flag, to guarantee that the information refers to the correct frame within the FIFO.

Up to 32 elements of the filter table are individually affected by the individual mask registers (CANFD_IMSK1 and CANFD_IMSK2), according to the setting of the CANFD_CTL2.RFFNUM bit, allowing very powerful filtering criteria to be defined. If the CANFD_CFG.IRMQEN bit is disabled, then the FIFO filter table is affected by the CANFD_RX_FIFO_GMSK register value.

Rx FIFO Under DMA Operation

The Rx FIFO can support DMA. Using the Rx FIFO with the DMA feature is enabled by enabling both CANFD_CFG.RFEN and CANFD_CFG.DMAEN bits. The DMA controller reads the received message by reading a message buffer structure at the FIFO output port at the 0x80–0x8C address range.

The reset value of the CANFD_CFG.DMAEN bit is zero. When the CANFD_CFG.DMAEN is enabled, the processor must not access the FIFO output port address range. Before enabling the CANFD_CFG.DMAEN bit, the processor must service the IFLAGs asserted in the Rx FIFO region. Otherwise, these IFLAGs may show that the FIFO has data to be serviced, and mistakenly generate a DMA request. Before disabling the CANFD_CFG.DMAEN, the processor must perform a clear FIFO operation.

The Frames available in Rx FIFO bit (CANFD_IFLG1.MB05) is asserted when there is at least one frame available to be read from the FIFO; consequently, a DMA request is generated simultaneously. Upon receiving the request, the DMA controller reads the message (accessing the output of the FIFO as a message buffer). The DMA reading process must end by reading address 0x8C, which clears the CANFD_IFLG1.MB05 bit and updates both the FIFO output with the next message (if FIFO is not empty) and the CANFD_RX_FIFO register with the attributes of the new message. If there are more messages stored in the FIFO, the CANFD_IFLG1.MB05 bit is re-enabled, and another DMA request is issued.

NOTE: The CANFD_RX_FIFO register contents cannot be read after the DMA completes the FIFO read. The IDHIT information is also available in the C/S word at address 0x080.

The CANFD_IFLG1.MB06 and CANFD_IFLG1.MB07 flags are not used when the DMA feature is enabled.

When the CANFD module is working with DMA, the processor does not receive any Rx FIFO interrupts and must not clear the related IFLAGs. In addition, the related IMASKs are not used to mask the generation of DMA requests.

There is no dedicated DMA channel for reading the CANFD FIFO, however, the MDMA along with the TRU can read from the FIFO RAM. This works by configuring the CANFD module to generate a trigger whenever the CANFD_IFLG1.MB05 bit is set. The MDMA is configured to wait for the trigger from the CANFD module and on receiving the trigger, read from the CANFD FIFO start address at 0x80 offset. Once 16 bytes of FIFO data are read, the CANFD_IFLG1.MB05 bit is cleared.

Only MDMA2 and MDMA6 streams can access the CANFD FIFO.

Clear FIFO Operation

When the CANFD_CFG.RFEN is enabled, the clear FIFO operation empties the FIFO contents. With the CANFD_CFG.RFEN bit enabled, the clear FIFO occurs when the processor writes a one to the

CANFD_IFLG1.MB01 bit. This operation only can only occur in freeze mode and is blocked by hardware in other modes. This operation does not clear the FIFO IFLAGs; consequently, the processor must service all FIFO IFLAGs before executing the clear FIFO task.

When the Rx FIFO is working with DMA, the clear FIFO operation clears the CANFD_IFLG1.MB05 flag and the DMA request is canceled.

NOTE: The clear FIFO operation does not clear IFLAGs, except when the CANFD_CFG.DMAEN bit is enabled. When the CANFD_CFG.DMAEN bit is enabled, only the CANFD_IFLG1.MB05 flag is cleared.

CAN Protocol Features

This section describes the CAN protocol related features.

CAN FD Frames

The ISO 11898-1 standard specifies the classical Frame format compliant to ISO 11898-1 (2003) and introduces the CAN flexible data rate frame format. The classical frame format allows bit rates up to 1 Mbit/s and payloads up to 8 bytes per frame. The flexible data rate frame format allows bit rates higher than 1 Mbit/s and payloads longer than 8 bytes per frame. The CANFD module can receive and transmit CAN FD messages interleaved with classical CAN messages.

There are three additional control bits in the CAN FD frame:

- The extended data length (EDL) bit enables a longer data payload with different data length coding.
- The bit rate switch (BRS) bit decides whether the bit rate is switched inside a CAN FD format frame.
- The error state indicator (ESI) flag is transmitted dominant by error active nodes, and recessive by error passive nodes.

There are no remote frames in the CAN FD format. A message configured to transmit a remote frame is always sent out in the classical CAN format. When a FD frame is received and matches a mailbox, the RTR bit in the receiving message buffer is cleared. The RTR bit is considered in only in classical CAN frames.

CAN FD messages can be formatted as long frames, in which the data field exceeds 8 bytes and may range from 12 up to 64 bytes. CAN FD messages can also be configured to support bit rate switching, where the control field, the data field, and the CRC field of a CAN frame are transmitted with a higher bit rate than the beginning and the end of the frame.

Messages in the classical CAN format are limited to transport a maximum payload of 8 bytes at nominal rate. The *CAN Message Format* figure illustrates the message formats for classical and FD frames with either a standard or extended ID.

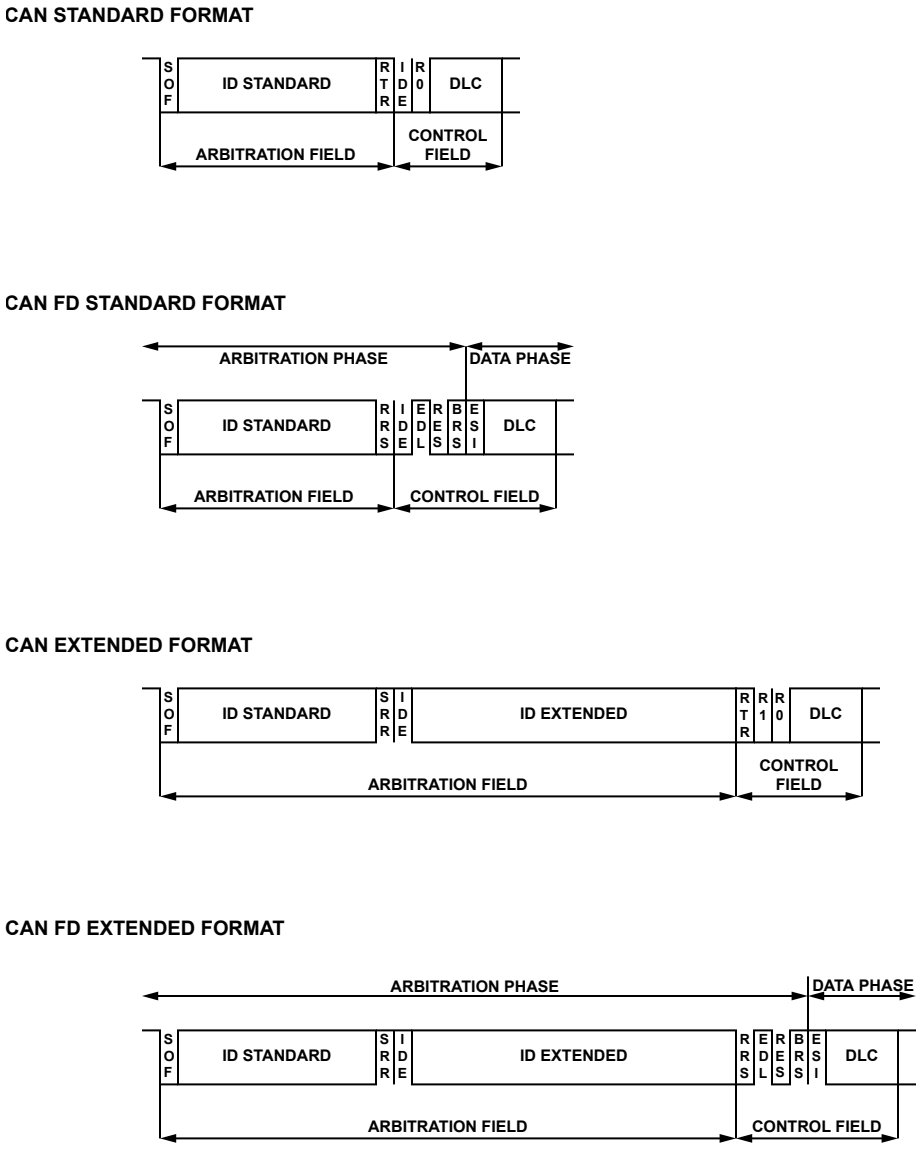

Figure 16-5: CAN Message Format

The ability to receive and transmit CAN FD messages is enabled by the `CANFD_CFG.FDEN` bit. Either a recessive R0 bit in CAN frames with 11-bit identifiers or a recessive R1 bit in CAN frames with 29-bit identifiers are decoded as an EDL bit (not a reserved one). A CAN FD frame is recognized by a recessive EDL bit, while a classical CAN frame is recognized by a dominant EDL bit. The BRS bit specifies whether this frame switches the bit rate in its data phase. A long frame is decoded according to the DLC field value.

CANFD messages can be transmitted with two different bit rates. The first part of a CAN FD frame, from the start of frame (SOF) bit until the bit rate switch (BRS) bit, also called the arbitration phase, is transmitted with the nominal bit rate based on a set of nominal CAN bit timing configuration values. The second part, from the BRS bit until the CRC delimiter bit, also named the data phase, is transmitted with the data bit rate defined by a second set of CAN data bit timing configuration values. Finally, from the CRC delimiter until the intermission bits, the transmission resumes to nominal bit rate. In CAN FD frames with bit rate switching, the bit timing is changed inside the frame at the sample point of the BRS bit if this bit is recessive. Before the BRS bit, in the CAN FD arbitration

phase, the nominal CAN bit timing defined by the CANFD_TIMING register and by the CANFD_CTL1 register for backward compatibility. Upon detecting a recessive BRS bit, the CAN data bit timing is used as defined by the CANFD_FD_TIMING register.

NOTE: If the length of the time quantum in the nominal bit timing and the length of the time quantum in the data bit timing are not identical, a quantization error of up to one time quantum of the arbitration phase may be present as a phase error. This situation can occur after the switch from arbitration to data phase and lasts until the next synchronization event. Thus, the length of the time quantum should be the same in nominal and data bit timing to minimize the chance of error frames on the CAN bus, and to optimize the clock tolerance in networks that use CAN FD frames.

The CANFD_FD_CTL.BRSEN bit enables the transmission of all frames with bit rate switching if the BRS bit in the selected Tx MB is set. When the bit is cleared, the transmission is performed at nominal rate regardless of the BRS bit value. The CANFD_FD_CTL.BRSEN bit can be written any time but takes effect only for the next message transmitted or received.

The nominal bit timing is resumed at either the sample point of the CRC delimiter bit or when an error is detected, whichever occurs first. The *CAN FD Message Bit Rate Switching* figure describes the mechanism for entering and leaving the data phase when the BRS bit is recessive.

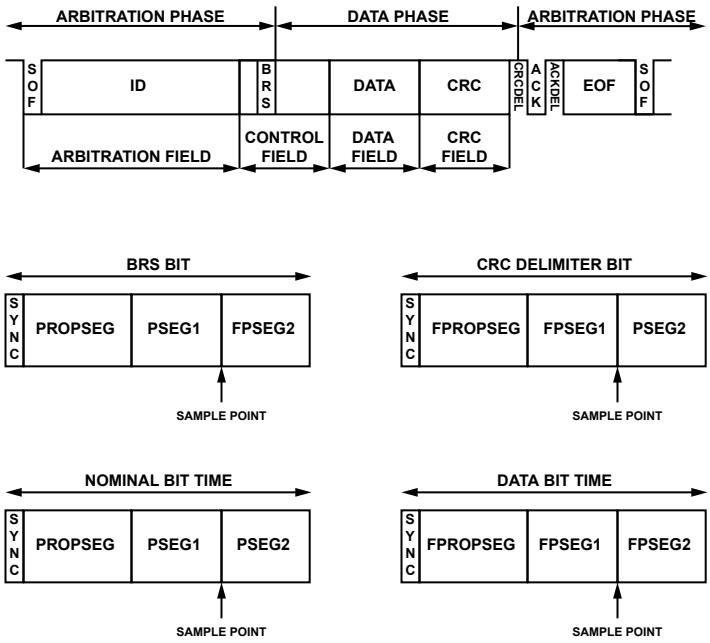

Figure 16-6: CAN FD Message Bit Rate Switching

NOTE: In classical CAN frames, the CRC delimiter is one single recessive bit. In CAN FD frames, the CRC delimiter may consist of one or two recessive bits. The CANFD module sends only one recessive bit as the CRC delimiter, but it accepts two recessive bits before the edge from recessive to dominant that starts the acknowledge slot. As a receiver, the CANFD module sends its acknowledge bit after the first CRC delimiter bit. In CAN FD frames, the CANFD module accepts a two-bit dominant ACK slot as a valid ACK to compensate for phase shifts between the receivers.

The value of the ESI bit is determined either by the error state of the transmitter at the start of the transmission, if the frame is originated in the CANFD node, or by the original transmitting node if the CANFD module is acting as a gateway for the message. If the transmitter is error passive, the ESI is transmitted recessive; otherwise, it is transmitted dominant.

There are different CRC polynomials for different CAN frame formats:

- The first polynomial, CRC_15, is for all frames in classical CAN format.
- The second, CRC_17, is for frames in CAN FD format with a data field up to 16 bytes long.
- The third, CRC_21, is for frames in CAN FD format with a data field longer than 16 bytes.

Each polynomial results in a hamming distance of 6. At the start of the frame, all three CRC polynomials are calculated concurrently. The CRC sequence to be transmitted is selected by the values of the EDL bit and the DLC bit field. When receiving a message, the CANFD module decodes the EDL and DLC bits to select the proper CRC polynomial to check for a CRC error.

In CAN FD format frames, stuff bits are included in the bit stream for CRC calculation. In classical CAN format frames, stuff bits are not included. After the transmission of the last bit relevant to the CRC calculation, the CANFD_FD_CRC register stores the calculated CRC for the transmitted message, with the adequate length for the type of message, for both CAN FD and non-FD messages. The CANFD_CRC register reports a valid CRC for classical CAN messages only.

In CAN FD format frames, the CAN bit stuffing method is changed for the CRC sequence so that the stuff bits are inserted at fixed positions. When the CANFD module is transmitting a CAN FD frame, a fixed stuff bit is inserted just before the first bit of the CRC sequence, even if the last bits of the preceding field do not fulfill the CAN stuff condition. Additional stuff bits are inserted after each fourth bit of the CRC sequence. The value of any fixed stuff bit is the inverse value of its preceding bit. When the CANFD module is receiving a CAN FD frame, it discards the fixed stuff bits from the bit stream for the CRC check. A stuff error is detected if the fixed stuff bit has the same value as its preceding bit.

The CANFD module detects errors in CAN FD frames the same way as in Classical CAN frames. The error counters CANFD_ECR.RXERRCNT and CANFD_ECR.TXERRCNT in the CANFD_ECR register accumulate the counts of Rx and Tx errors, respectively, for both FD and non-FD frames indistinctly. There are two extra error counters (CANFD_ECR.RXERRCNTF and CANFD_ECR.TXERRCNTF) that accumulate Rx and Tx errors occurring in the data phase of CAN FD frames with the BRS bit set. The rules for updating the error counters are the same for both CAN FD and non-FD frames.

The error flags CANFD_ESR1.B1ERR, CANFD_ESR1.B0ERR, CANFD_ESR1.ACKERR, CANFD_ESR1.CRCERR, CANFD_ESR1.FRMERR, and CANFD_ESR1.STFERR report errors in both CAN FD and non-FD frames. They also generate the ERRINT interrupt if the CANFD_CTL1.ERRMSK bit is enabled. The CANFD_ESR1 register has additional error flags (CANFD_ESR1.B1ERRF, CANFD_ESR1.B0ERRF, CANFD_ESR1.CRCERRF, CANFD_ESR1.FRMERRF, and CANFD_ESR1.STFERRF) to individually indicate the occurrence of errors in the data phase of CAN FD frames with the BRS bit set. There is no ACKERR detected in the data phase of a CAN FD frame. Fault confinement status reported with the CANFD_ESR1.FLTCONF bit is the same for both CAN FD and classical CAN frames, and is based on CANFD_ECR.RXERRCNT and

CANFD_ECR.TXERRCNT error counters only. Information contained in CANFD_ECR.RXERRCNTF and CANFD_ECR.TXERRCNTF counters may be considered as status to help detect the error nature related to the bit rate value. The *CANFD State Related Bit Encoding* table shows how the CANFD state is related to the CANFD_ESR1.SYNC, CANFD_ESR1.IDLE, CANFD_ESR1.TXINPROG, and CANFD_ESR1.RXINPROG bits.

Table 16-19: CANFD State Related Bit Encoding

SYNC	IDLE1	TXINPROG	RXINPROG	CANFD State
0	0	0	0	Not synchronized to CAN bus
1	1	x	x	Idle
1	0	1	0	Transmitting
1	0	0	1	Receiving

When the CANFD is in the data phase, either transmitting or receiving a CAN FD message, and detects an error, it immediately switches back to the arbitration phase and to the nominal rate to start an error flag

Resynchronization and hard synchronization occur in CAN FD frames in the same way as in classical CAN frames. A hard synchronization is also performed at the recessive-to-dominant edge from EDL to R0 in CAN FD format frames. The CANFD does not resynchronize while transmitting in the CAN FD data phase.

Transceiver Delay Compensation

The CAN FD protocol allows the transmission and reception of data at a higher bit rate than the nominal rate used in the arbitration phase when the BRS bit of the message is set. This feature enables the use of rates up to 8 Mbps.

During the data phase of a CAN FD frame, the transmitter detects a bit error if it cannot receive its own latest transmitted bit at the sample point of that bit. When bit rate switching is enabled, the length of the CAN bit time in the data phase can become shorter than the transceiver's loop delay, thus impeding the correct comparison between the transmitted bit and the received bit within the current CAN bit time interval.

The CANFD module supports an optional transceiver delay compensation (TDC) mechanism that defines a secondary sample point where the transmitted bit is correctly compared with the received bit to check for bit errors.

The TDC mechanism is enabled by the CANFD_FD_CTL.TDCOMPEN bit and is effective only during the data phase of CAN FD frames having the BRS bit set. It has no effect either on non-FD frames, or on FD frames transmitted at normal bit rate. The TDC mode is active from the sample point of the BRS bit until the sample point of the CRC delimiter bit, provided the respective message under transmission has the BRS bit set. When it is active, a comparison is done between the real received bit and the delayed transmitted bit, where the delay is calculated based on the measured transceiver loop delay.

NOTE: The actual value of the CRC delimiter bit is disregarded by transmitters using the TDC mechanism. A global error at the end of the CRC field will cause the receivers to send error frames that the transmitter will detect during an acknowledge or end of frame.

For every transmitted FD frame having the BRS bit set, the delay measurement is triggered by the transition from the recessive EDL bit to the dominant R0 bit, as shown in the *Transceiver Loop Delay Measurement* figure.

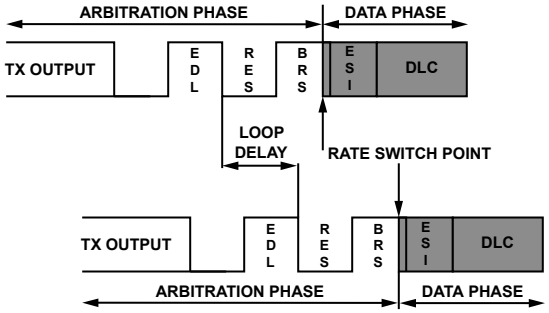

Figure 16-7: Transceiver Loop Delay Measurement

The loop delay is measured in PE clock periods (CANCLK) , from the transmitted EDL-R0 edge to the received EDL-R0 edge. The position of the secondary sample point is defined by the measured loop delay time added to an offset value specified with the `CANFD_FD_CTL.TDCOMPOFF` bit. The `CANFD_FD_CTL.TDCOMPVAL` bit field stores the result of this calculation. The `CANFD_FD_CTL.TDCOMPVAL` value saturates at the maximum value of 15 CANCLK when the delay measurement is too long.

The measured loop delay is not enough to be used to define the secondary sample point because it relates to the CAN bit edges. The transceiver delay compensation offset (`CANFD_FD_CTL.TDCOMPOFF`) shifts the secondary sample point from the edge to an intermediate point inside the bit time (for example, half of the bit time in the data phase), far away from its edges. Therefore, the `CANFD_FD_CTL.TDCOMPOFF` value cannot be larger than the CAN bit duration in the data phase.

During the data phase of CAN FD frames with bit rate switching enabled, at the onset of every Tx CAN bit, the transmitted Tx bit value is temporarily stored in a buffer and a time countdown based on the `CANFD_FD_CTL.TDCOMPVAL` value is started which ends with the comparison of the received Rx bit (delayed by the external loop delay plus the specified offset) with the stored Tx bit. If a bit error is detected at the secondary sample point, the CANFD module issues an error flag to the CAN bus at the next sample point.

During the arbitration phase, the delay compensation is always disabled. The maximum delay that can be compensated by the transceiver delay compensation during the data phase is 3 CAN bit times - 2 Tq. Beyond this limit, the `CANFD_FD_CTL.TDCOMPFAIL` flag is set to indicate when the TDC mechanism is out of range and unable to compensate the transceiver loop delay.

Remote Frames

A remote frame is a special kind of frame. The processor can program a mailbox to be a remote request frame by configuring the mailbox to transmit with the RTR bit set to one. After the remote request frame is transmitted successfully, the mailbox becomes a receive message buffer, with the same ID as before.

When a remote request frame is received by the CANFD module, it is treated in one of the following ways, depending on the `CANFD_CTL2.RRS` and `CANFD_CFG.RFEN` bits:

- When RRS is disabled, the frame ID is compared to the IDs of the transmit message buffers with the CODE field 1010. If there is a matching ID, then this mailbox frame is transmitted. Note that if the matching mailbox has the RTR bit set, then the CANFD module transmits a remote frame as a response. The received remote request frame is not stored in a receive buffer. It is only used to trigger a transmission of a frame in response. The mask registers are not used in remote frame matching, and all ID bits (except RTR) of the incoming received frame match. In the case that a remote request frame is received and matches a mailbox, this message buffer immediately enters the internal arbitration process, but is considered a normal Tx mailbox, with no higher priority. The data length of this frame is independent of the DLC field in the remote frame that initiated its transmission.
- When RRS is enabled, the frame ID is compared to the IDs of the receive mailboxes with the CODE field 0100, 0010, or 0110. If there is a matching ID, then this mailbox stores the remote frame in the same fashion of a data frame. No automatic remote response frame is generated. The mask registers are used in the matching process.
- When RFEN is asserted, the CANFD does not generate an automatic response for remote request frames that match the FIFO filtering criteria. If the remote frame matches one of the target IDs, it is stored in the FIFO and presented to the processor. Note that for filtering formats A and B, it is possible to select whether remote frames are accepted or not. For format C, remote frames are always accepted (if they match the ID). Remote request frames are considered normal frames,and generate a FIFO overflow when a successful reception occurs, and the FIFO is already full.

NOTE: There is no remote frame in the CAN FD format. The RTR bit is replaced by a fixed dominant RRS bit. The CANFD receives and transmits remote frames in the classical CAN format.

Overload Frames

The CANFD module transmits overload frames due to the detection of the following CAN bus conditions:

- Detection of a dominant bit in the first/second bit of intermission.
- Detection of a dominant bit at the 7th bit (last) of end of frame field (Rx frames).
- Detection of a dominant bit at the 8th bit (last) of error frame delimiter or overload frame delimiter.

Time Stamp

The value of the CANFD_TMR register is sampled at the beginning of the identifier field on the CAN bus and stored at the end of the move-in process in the TIME STAMP field, providing network behavior with respect to time. The free running timer is clocked by the CANFD bit-clock, which defines the baud rate on the CAN bus. During a message transmission or reception, it increments by one for each bit that is received or transmitted. When there is no message on the bus, it counts using the previously programmed baud rate.

The CANFD_TMR register is not incremented during module disable, doze, stop, and freeze modes. It can be reset upon a specific frame reception, enabling network time synchronization.

Protocol Timing

The *CAN Engine Clocking Scheme* figure shows the structure of the clock generation circuitry that prescales the CAND module clock to generate the Sclock.

Figure 16-8: CAN Engine Clocking Scheme

The CANFD module supports a variety of means to set up bit timing parameters that are required by the CAN protocol. The CANFD_CTL1 register has fields to control bit timing parameters: CANFD_CTL1.PRESDIV, CANFD_CTL1.PROPSEG, CANFD_CTL1.PSEG1, CANFD_CTL1.PSEG2, and CANFD_CTL1.RJW.

The CANFD_TIMING register extends the range of the CAN bit timing variables in the CANFD_CTL1 register. The CANFD_TIMING register provides a second set of CAN bit timing variables to be applied at the data phase of CAN FD frames with the BRS bit set.

NOTE: When the CAN FD feature is enabled, always set the CANFD_TIMING.BTF bit and configure the CAN bit timing variables in the CANFD_TIMING register.

The CANFD_CTL1.PRESDIV bit field (as well as the extended range CANFD_TIMING.EPRESDIV and CANFD_FD_TIMING.FPRESDIV for the data phase bits of CAN FD messages) defines the prescaler value that generates Sclock. The Sclock period defines the time quantum used to compose the CAN waveform. A time quantum (Tq) is the atomic unit of time handled by the CAN engine.

$Tq = (PRESDIV + 1) / f_{CANCLK}$

The bit rate, which defines the rate at which the CAN message is either received or transmitted, is given by the formula:

CAN Bit Time = (Number of Time Quanta in 1 bit time) * Tq

Bit Rate = 1/CAN Bit Time

A bit time is subdivided into three segments:

- SYNC_SEG – Has a fixed length of one time quantum. Signal edges are expected to occur within this segment.
- Time segment 1 – Includes the propagation segment and the phase segment 1 of the CAN standard. Time segment 1 is programmed by setting the CANFD_CTL1.PROPSEG and the CANFD_CTL1.PSEG1 fields so that their sum (plus 2) is in the range of 2 to 16 time quanta. When the CANFD_TIMING.BTF bit is enabled, the CANFD module uses the CANFD_TIMING.EPROPSEG and CANFD_TIMING.EPSEG1 bit fields so that their sum (plus 2) is in the range of 2 to 96 time quanta. For messages in CAN FD format with the BRS bit set, the CANFD uses CANFD_FD_TIMING.FPROPSEG and CANFD_FD_TIMING.FPSEG1 bit fields, so that their sum (plus 1) is in the range of 2 to 39 time quanta.
- Time Segment 2 – Represents the phase segment 2 of the CAN standard. It can be programmed by setting the CANFD_CTL1.PSEG2 bit field (plus 1) to be 2 to 8 time quanta long. When the CANFD_TIMING.BTF

bit is enabled, the CANFD module configures the CANFD_TIMING.EPSEG2 bit field with a value (plus 1) is in the range of 2 to 32 time quanta. For messages in CAN FD format with the BRS bit set, the CANFD uses the CANFD_FD_TIMING.FPSEG2 bit field instead, so that the value (plus 1) is in the range of 2 to 8 time quanta. The time segment 2 cannot be smaller than the information processing time (IPT), which is 2 time quanta.

See the *Bit Time Segment Example One* figure for an example using CANFD_CTL1 register bit timing variables for classical can format. See the *Bit Time Segment Example Two* figure for an example using CANFD_TIMING and CANFD_FD_TIMING register bit timing variables for CAN FD format. See the *Time Segment Syntax* table for syntax descriptions.

NOTE: For further explanation of the underlying concepts, see the ISO 11898-1 standard and the CAN 2.0A/B protocol specification for bit timing.

The bit time defined by the above time segments must not be smaller than 5 time quanta. For bit time calculations, use an IPT of 2, which is the value implemented in the CANFD module.

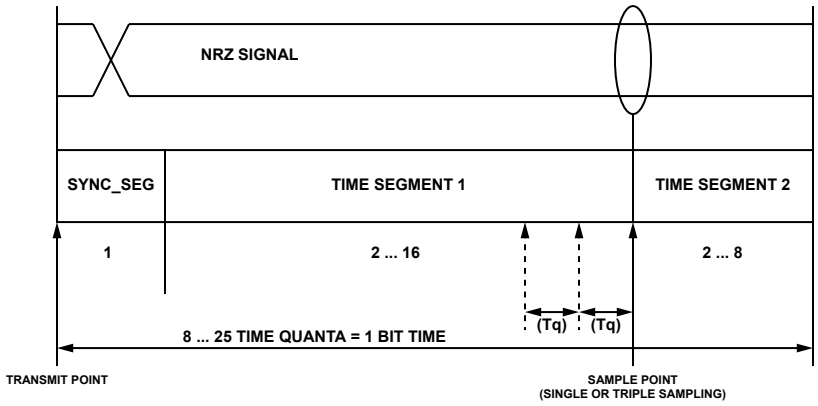

Figure 16-9: Bit Time Segment Example One

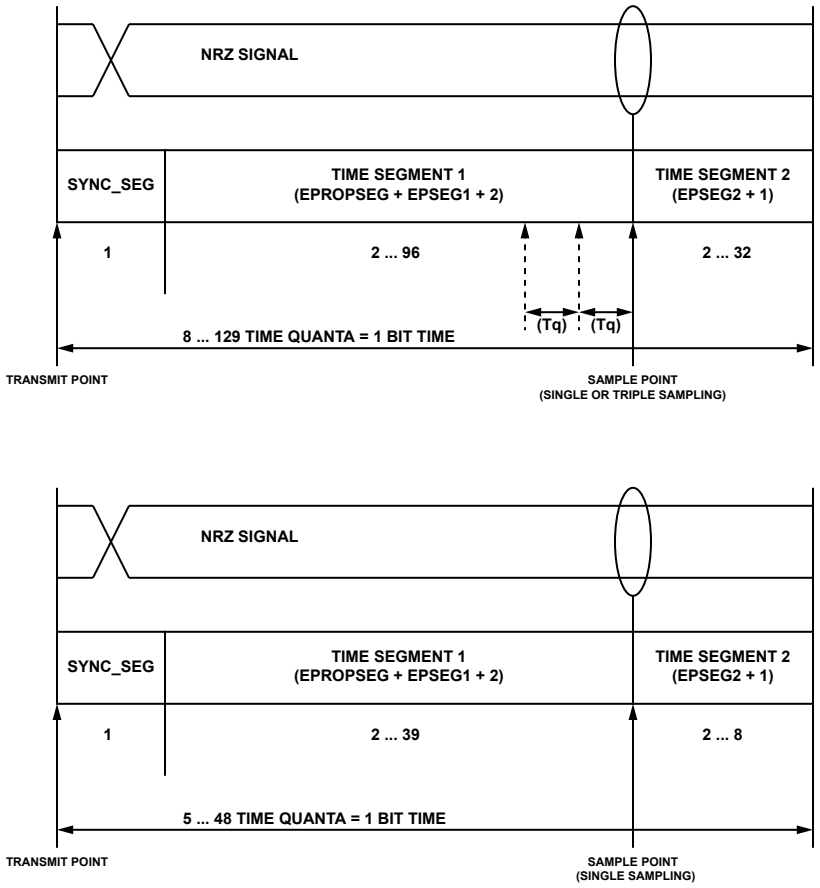

Figure 16-10: Bit Time Segment Example Two

Table 16-20: Time Segment Syntax

Syntax	Description
SYNC_SEG	System expects transitions to occur on the bus during this period.
TSEG1	Corresponds to the sum of PROPSEG and PSEG1.
TSEG2	Corresponds to the PSEG2 value.
Transmit Point	A node in transmit mode transfers a new value to the CAN bus at this point.
Sample Point	A node samples the bus at this point. If the three samples per bit option is selected, then this point marks the position of the third sample.

The *BOSCH CAN 2.0B Standard Compliant Bit Time Segment Settings* table gives some examples of the CAN compliant segment settings for classical CAN format (Bosch CAN 2.0B) (non-FD) messages.

Table 16-21: BOSCH CAN 2.0B Standard Compliant Bit Time Segment Settings

Time Segment 1	Time Segment 2	Resynchronization Jump Width
	2	1 .. 2

Table 16-21: BOSCH CAN 2.0B Standard Compliant Bit Time Segment Settings (Continued)

Time Segment 1	Time Segment 2	Resynchronization Jump Width
5 .. 10		
4 .. 11	3	1 .. 3
5 .. 12	4	1 .. 4
6 .. 13	5	1 .. 4
7 .. 14	6	1 .. 4
8 .. 15	7	1 .. 4
9 .. 16	8	1 .. 4

NOTE: Ensure the bit time settings comply with the CAN Protocol standard (ISO 11898-1).

Whenever a CAN bit is used as a measure of time duration (for example, estimating the occurrence of a CAN bit event in a message), the number of peripheral clocks in one CAN bit (NumClkBit) is calculated as NumClkBit = (f_{SYS}/f_{CANCLK}) x (PRESDIV + 1) x (PROPSEG + PSEG1 + PSEG2 + 4), where:

- NumClkBit is the number of peripheral clocks in one CAN bit.
- f_{CANCLK} is the PE clock in Hz
- f_{SYS} is the frequency of operation of the system CHI clock in Hz.
- PSEG1 is the `CANFD_CTL1.PSEG1` value.
- PSEG2 is the `CANFD_CTL1.PSEG2` value.
- PROPSEG is the `CANFD_CTL1.PROPSEG` value.
- PRESDIV is the `CANFD_CTL1.PRESDIV` value.

The formula above is also applicable to the alternative CAN bit timing variables described in the `CANFD_TIMING` register and the `CANFD_FD_TIMING` register. For example, 180 CAN bits = (180 x NumClkBit) peripheral clock periods.

Arbitration and Matching Timing

During normal reception and transmission, the matching, arbitration, move-in and move-out processes are executed during certain time windows inside the CAN frame, as shown in the following figures.

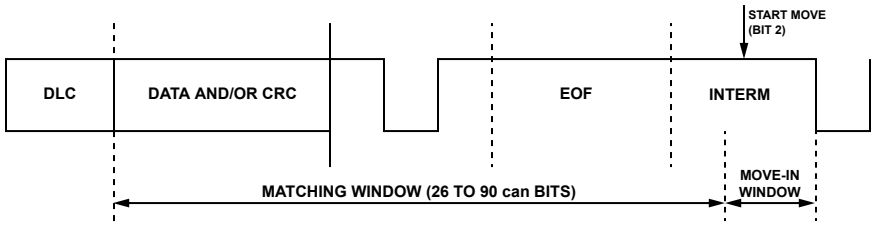

Figure 16-11: Matching and Move-In Time Windows

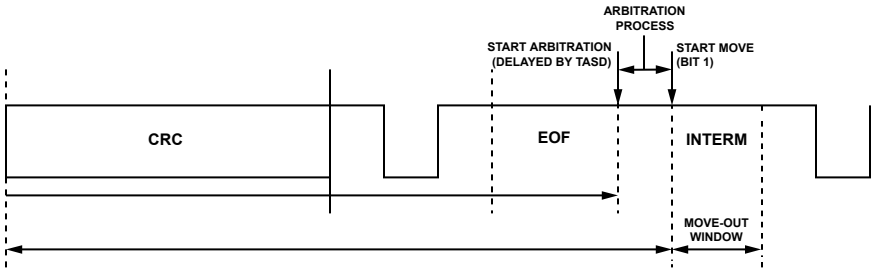

Figure 16-12: Arbitration And Move-out Time Windows

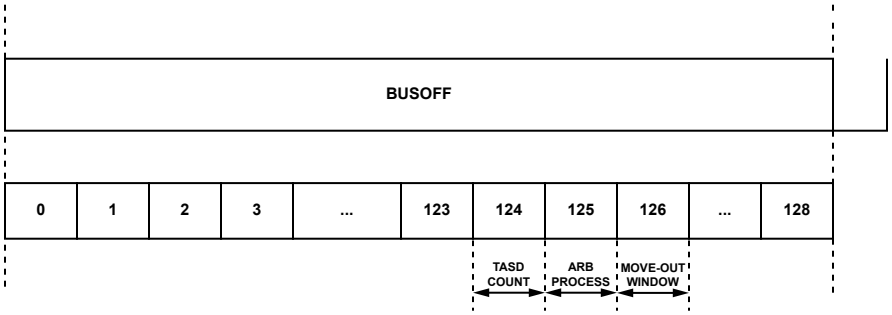

Figure 16-13: Arbitration At The End Of Bus Off And Move-out Time Windows

NOTE: In the previous figures, the matching and arbitration timing does not consider the delay caused by the concurrent memory access due to the processor or other internal CANFD submodules.

Tx Arbitration Start Delay

The Tx arbitration start delay (`CANFD_CTL2.TXASDLY` bit field) is a variable that indicates the number of CAN bits used by the CANFD to delay the Tx arbitration process start point from the first bit of the CRC field of the current frame.

The `CANFD_CTL2.TXASDLY` bit field can only be written only in freeze mode and is blocked by hardware in other modes.

The transmission performance is impacted by the ability of the processor to reconfigure MBs for transmission after the end of the internal arbitration process, in which the CANFD module finds the winner MB for transmission according to the standard arbitration process. If the arbitration ends before the first bit of the intermission field, then there is a chance the processor reconfigures some Tx MBs and the winner MB is no longer the best candidate to be transmitted.

The `CANFD_CTL2.TXASDLY` bit field is useful to optimize the transmission performance by defining the arbitration start point, as shown in the next figure, based on factors such as the CAN bit timing variables that determine the CAN bit rate and the number of MBs in use by the matching and arbitration processes.

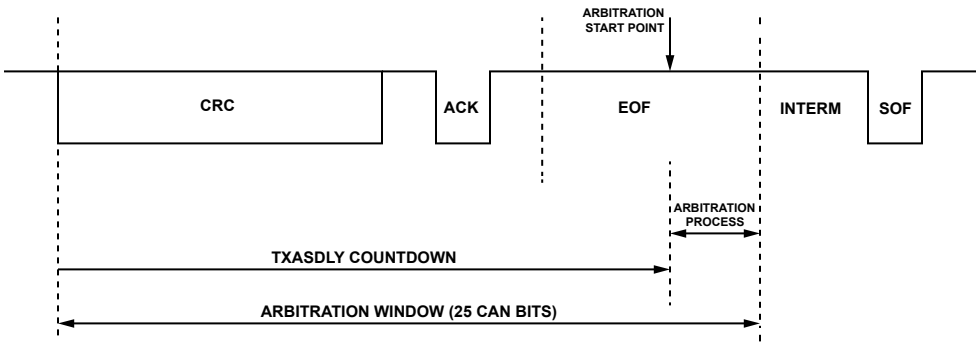

Figure 16-14: Optimal Tx Arbitration Start Point

The duration of an arbitration process, in terms of CAN bits, is directly proportional to the number of available MBs and to the CAN bit rate, and inversely proportional to the peripheral clock frequency.

The optimal arbitration timing is that in which the last MB is scanned right before the first bit of the intermission field of a CAN frame. For instance, if there are few MBs and the peripheral/oscillator clock ratio is high and the CAN baud rate is low, then the arbitration is placed closer to the frame's end, adding more delay to its start point, and vice-versa.

When the `CANFD_CTL2.TXASDLY` field is set to zero, the arbitration start is not delayed, and more time is reserved for arbitration. On the other hand, when the `CANFD_CTL2.TXASDLY` value is close to 24, then the processor can configure a Tx MB later and less time is reserved for arbitration. When too little time is reserved for arbitration, the CANFD module may not be able to find a winner MB in time to be transmitted with the best chance to win the bus arbitration against external nodes on the CAN bus.

The optimal `CANFD_CTL2.TXASDLY` value is calculated as follows:

For CAN FD frames and (MAXMB + 1) $\leq NMB_{END}$, TXASDLY = 31 – ((2*(MAXMB + 1) + 4)/$CPCB_N$)

For CAN FD frames and (MAXMB + 1) > NMB_{END}, TXASDLY = 22 – ((2*(MAXMB + 1) - NMB_{END})/ $CPCB_F$)

For non-FD frames, TXASDLY = 25 – (((2*(MAXMB + 1) + 4)) / CPCB) where:

NMB_{END} = ((9 * CPCBN) - 4) / 2

$BITRATE_N$= f_{CANCLK} / ([1 + (EPSEG1 + 1) + (EPSEG2 + 1) + (EPROPSEG + 1)] x (EPRESDIV + 1))

$BITRATE_F$= f_{CANCLK} / ([1 + (FPSEG1 + 1) + (FPSEG2 + 1) + FPROPSEG] x (FPRESDIV + 1))

$CPCB_N$ = f_{SYS} / $BITRATE_N$

$CPCB_F$ = f_{SYS} / $BITRATE_F$

CPCB = $CPCB_N$

- MAXMB is the `CANFD_CFG.MAXMB` value.

- NMBEND is the number of MBs that can be scanned by the arbitration process during the 9 last CAN bits at the end of a frame.
- BITRATEN is the CAN bit rate in bits per second calculated by the nominal CAN bit time variables.
- BITRATEF is the CAN bit rate in bits per second calculated by the data CAN bit time variables.
- CPCBN is the number of peripheral clocks per CAN bit in nominal bit rate for CAN FD frames.
- CPCBF is the number of peripheral clocks per CAN bit in data bit rate for CAN FD frames.
- CPCB is the number of peripheral clocks per CAN bit for non-FD frames.
- f_{CANCLK} is the oscillator clock, in Hz.
- f_{SYS} is the peripheral clock, in Hz.
- EPSEG1 is the `CANFD_TIMING.EPSEG1` or `CANFD_CTL1.PSEG1` value.
- EPSEG2 is the `CANFD_TIMING.EPSEG2` or `CANFD_CTL1.PSEG2` value.
- EPROPSEG is the `CANFD_TIMING.EPROPSEG` or `CANFD_CTL1.PROPSEG` value.
- EPRESDIV is the `CANFD_TIMING.EPRESDIV` or `CANFD_CTL1.PRESDIV` value.
- FPSEG1 is the `CANFD_FD_TIMING.FPSEG1` value.
- FPSEG2 is the `CANFD_FD_TIMING.FPSEG2` value.
- FPROPSEG is the `CANFD_FD_TIMING.FPROPSEG` value.
- FPRESDIV is the `CANFD_FD_TIMING.FPRESDIV` value.

NOTE: The f_{SYS} and f_{CANCLK} is same clocked from CDU CLKO4.

The following table give the TXASDLY value calculated for some configuration cases.

- f_{CANCLK} = 40 MHz
- Bit rate in arbitration phase = 1 Mbaud

Table 16-22: TXASDLY Values For Case Example

Number of MBs	TXASDLY Value	Maximum Bit Rate in Data Phase (Mbaud)
16	24	Invalid
32	23	6.67
54	22	5.0
64	21	3.33
96	20	1.6

CANFD Clock Domains and Restrictions

When doing matching and arbitration, the CANFD module needs to scan the entire MB memory during the time slot of one CAN frame, comprising a number of CAN bits. To have sufficient time to do that, there must be a minimum number of peripheral clocks per CAN bit, as specified in the *CAN Bit Minimum Peripheral Clock* table.

Table 16-23: CAN Bit Minimum Peripheral Clock

Number of Mailboxes	**CANFD_CFG.RFEN** Bit Value	Minimum Peripheral Clocks per CAN Bit
16	0	16
32	0	16
64	0	25
96	0	37
128	0	49
16	1	16
32	1	17
64	1	30

For the classical CAN frame format, the minimum number of peripheral clocks per CAN bit specified in the *TXASDLY Values For Case Example* table determines the minimum peripheral clock frequency for a given number of mailboxes and for an expected CAN bit rate. The CAN bit rate depends on the number of time quanta in a CAN bit, that can be defined by adjusting one or more of the bit timing values contained in either the CANFD_CTL1 register or the CANFD_TIMING register. The time quantum (Tq) is defined in the Protocol Timing section. The minimum number of time quanta per CAN bit must be 8, so the CAN clock frequency is at least 8 times the CAN bit rate.

For the CAN FD frame format, the number of peripheral clocks per CAN bit in nominal bit rate (NumClkNom-Bit) is calculated with the following equation:

NumClkNomBit =(fSYS/fCANCLK) X (PRESDIV + 1) X (PROPSEG + PSEG1 + PSEG2 + 4)

= fSYS/NomBitRate

where PRESDIV, PSEG1 and PSEG2 are CAN bit time values in the CANFD_CTL1 register. Alternatively, the EPRESDIV, EPSEG1 and EPSEG2 values in the CANFD_TIMING register can be used instead. NumClkNomBit is also calculated as a function of the expected nominal bit rate used in the arbitration phase (NomBitRate).

The number of CAN bits in the data phase of a FD frame with the BRS bit set depends on the number of data bytes in the payload. The number of fast CAN bits (NumOfFastBits) is determined as shown in the *CAN FD Frame Fast CAN Bits* table. The less the number of data bytes, the less the number of fast CAN bits, and less time is available for the CANFD module to scan the whole MB memory during the internal matching and arbitration processes.

Table 16-24: CAN FD Frame Fast CAN Bits

Minimum Data Bytes	DLC Field	Number of Fast Bits
0	0x0	21
1	0x1	29
2	0x2	37
3	0x3	45
4	0x4	53
5	0x5	61
6	0x6	69
7	0x7	77
8	0x8	85
12	0x9	117
16	0xA	149
20	0xB	186
24	0xC	218
32	0xD	282
48	0xE	410
64	0xF	538

The critical part of a CAN FD frame is during the data phase, where the CAN bit rate is faster than in the arbitration phase. The minimum number of peripheral clocks per fast CAN bit (MinNumClkFastBit) is calculated so that enough time is available for the CANFD module to scan the MB memory during reception and transmission. The equation below calculates this constraint:

MinNumClkFastBit = ((8.5 x MaxNumOfMb) + 64 - (9 x NumClkNomBit)) / NumOfFastBits

where MaxNumOfMb is the maximum number of available mailboxes defined in the `CANFD_CFG.MAXMB` bit field.

The clock domain crossing circuit between the CHI and PE submodules also imposes a minimum number of peripheral clocks per fast CAN bit for the handshake mechanism to work properly without losing status information through the interface, as shown in the following equation:

MinNumClkFastBit = 3 x (1 + (f_{SYS}/f_{CANCLK}))

Therefore, the minimum number of peripheral clocks per fast CAN bit (MinNumClkFastBit) is determined by the larger of the two values calculated above:

MinNumClkFastBit = Maximum (MinNumClkFastBit , MinNumClkFastBit)

Then, the maximum CAN bit rate in the data phase of CAN FD frames (DataBitRateMAX) is calculated as follows:

DataBitRate = f_{CANCLK} / (ROUNDUP ((MinNumClkFastBit x f_{CANCLK}) / f_{SYS}

The peripheral and oscillator clock frequencies, the maximum number of mailboxes, and the expected nominal bit rate affect the maximum data bit rate attainable by the CANFD module in CAN FD mode. In addition, the data bit rate depends on the minimum payload size of FD frames used in each application.

To illustrate how the CAN FD bit rate is affected by the configuration of CANFD variables, an consider an application example with the peripheral and oscillator clock frequencies set to 50 MHz.

1. Considering the nominal bit rate as 1 Mbps, the number of peripheral clocks per CAN bit in nominal bit rate is calculated as follows: NumClkNomBit = (50 x 10^6)/(1 x 10^6) = 50
2. The number of fast CAN bits (NumOfFastBits) is determined as shown in the *CAN FD Frames Maximum CAN Bit Rate In Data Phase* table. For example, if the minimum payload in FD frames is 8 bytes, then there are 85 CAN bits in the data phase.
3. Assuming the maximum number of mailboxes is 96, the minimum number of peripheral clocks per fast CAN bit (MinNumClkFastBit) can be calculated as follows:

   MinNumClkFastBit = ((8.5 X 96) + 64 - (9 X 50)) / 85 = 5.06

   MinNumClkFastBit = 3 x (1 + 50/50) = 6.0

   MinNumClkFastBit = Maximum (5.06 , 6.0) = 6.0

As demonstrated in this example, even though the oscillator clock frequency (50 MHz) is adequate to generate a data rate of 8 Mbps in CAN FD mode, the specific CANFD configuration limits this rate to 6.667 Mbps. This limitation is due to the low peripheral clock frequency that imposes the $MinNumClkFastBit_B$ limit.

The *CAN FD Frames Maximum CAN Bit Rate In Data Phase* table shows the maximum data rate for CAN FD according to the clock frequencies, payload size, and number of available mailboxes. As shown in the *CAN FD Frames Maximum CAN Bit Rate In Data Phase* table, for some cases, if the number of available mailboxes is reduced, the CANFD module achieves a data rate up to 8 Mbps.

Table 16-25: CAN FD Frames Maximum CAN Bit Rate In Data Phase

Peripheral Clock Frequency (MHz)	Payload Size	Number of Available Mailboxes	Maximum Data Rate (Mbps)
40	8	94	6.667
40	8	114	5.0
40	12	117	6.667
40	12	128	5.714
50	12 to 64	128	6.667
60	8	128	8.0
60	12	128	8.0

Table 16-25: CAN FD Frames Maximum CAN Bit Rate In Data Phase (Continued)

Peripheral Clock Frequency (MHz)	Payload Size	Number of Available Mailboxes	Maximum Data Rate (Mbps)
67	6	128	8.0
80	3	128	8.0
100	0	128	8.0

CANFD Operating Modes

The CANFD module has functional modes and low-power modes.

CAUTION: The CANFD does not support the permanent dominant failure on the CAN bus line. If a low-power request or freeze mode request is done during a permanent dominant, the corresponding acknowledge can never be asserted.

The CANDFD module has the following main functional modes:

- Normal Mode
- Freeze Mode
- Loop-Back Mode
- Listen-Only Mode
- CAN FD Active Mode

For low-power operation, the CANDFD module has the following modes:

- Module Disable Mode
- Doze Mode
- Stop Mode
- Pretended Network Mode

NOTE: The CANFD does not support the permanent dominant failure on the CAN bus line. If there is a low-power request or freeze mode request during a permanent dominant, the corresponding acknowledge will not be asserted.

Normal Mode

In normal mode, the CANFD module operates by receiving and transmitting message frames. In this mode, errors are handled normally, and all CAN protocol functions are enabled.

Freeze Mode

In freeze mode, there is no transmission or reception of frames and synchronicity to the CAN bus is lost. Freeze mode is enabled by setting the CANFD_CFG.FRZ bit.

Freeze mode is requested either by the processor by enabling the CANFD_CFG.HALT bit or when it is put into debug mode. In both cases, when the CANFD_CFG.FRZ bit is enabled, the CANFD module must not be in a low-power mode. Freeze mode is also requested through the automatic assertion of both the CANFD_CFG.HALT and CANFD_CFG.FRZACK bits when the CANFD_MEC.NCERRFRZEN bit is set and a non-correctable error is detected in a memory read access performed by CANFD internal processes. The acknowledgement is obtained through the assertion by the CANFD_CFG.FRZACK bit. The CANFD module is only in freeze mode when both the request and acknowledge conditions are satisfied.

In response to a freeze mode request, the CANFD module performs the following operations:

- Waits to be in either the intermission, passive error, bus off, or idle state.
- Waits for all internal activities like arbitration, matching, move-in, and move-out to finish. A pending move-in does not prevent going to freeze mode.
- Ignores the Rx input pin and drives the Tx pin as recessive.
- Stops the prescaler, thus halting all CAN protocol activities.
- Grants write access to the CANFD_ECR register, which is read-only in other modes.
- Sets the CANFD_CFG.NOTRDY and CANFD_CFG.FRZACK bits.

After requesting freeze mode, wait for the CANFD_CFG.FRZACK bit to be set before executing any other action, or the CANFD module will not operate properly.

To exit freeze mode, disable the CANFD_CFG.FRZ bit, remove the processor from debug mode, or disable the CANFD_CFG.HALT bit.

The CANFD_CFG.FRZACK bit is disabled after the PE recognizes the negation of the freeze request. Once out of freeze mode, the CANFD module tries to re-synchronize to the CAN bus by waiting for 11 consecutive recessive bits.

Loop-Back Mode

The CANFD module enters loop-back mode when the CANFD_CTL1.LBEN is set. In loop-back mode, the CANFD module performs an internal loop back for self-test operation. The bit stream output of the transmitter is internally fed back to the receiver input. The Rx CAN input pin is ignored and the Tx CAN output goes to the recessive state (logic ‘1’). The CANFD module behaves as it normally does when transmitting and treats its own transmitted message as a message received from a remote node. In loop-back mode, the CANFD ignores the bit sent during the ACK slot in the CAN frame acknowledge field to ensure proper reception of its own message. Both transmit and receive interrupts are generated.

Listen-Only Mode

The CANFD module enters listen-only mode when the CANFD_CTL1.LOMEN bit is enabled. In listen-only mode, transmission is disabled, all error counters are frozen, and the CANFD module operates in a CAN error passive mode. The module only receives messages acknowledged by another CAN station. If the CANFD detects a message that has not been acknowledged, it flags a BIT0 error (without changing the receive error counter), as if it were trying to acknowledge the message.

CAN FD Active Mode

In CAN FD active mode, the CANFD module can transmit and receive all messages formatted according to the CAN FD protocol and CAN 2.0 (protocol 2.0) in an interleaved fashion. The CANFD module is put into CAN FD active mode by setting the CANFD_CFG.FDEN bit when in freeze mode.

Module Disable Mode

The module disable mode is a low-power mode normally used to temporarily disable a complete CANFD block, with no power consumption. To enter module disable mode, enable the CANFD_CFG.DIS bit. Once the processor is in module disable mode, the CANFD_CFG.LPMACK bit is set.

Do not use module disable mode under pretended networking mode. Disable the CANFD_CFG.DIS bit and wait for CANFD_CFG.LPMACK bit to clear before enabling the CANFD_CFG.PNETEN bit.

If the CNAFD module is disabled during transmission or reception, it will perform the following operations:

- Waits to be in either the idle or bus off state, or else waits for the third bit of intermission and then checks it to be recessive.
- Waits for all internal activities like arbitration, matching, move-in, and move-out to finish. A pending move-in is not considered.
- Ignores its Rx input pin and drives its Tx pin as recessive.
- Shuts down the clocks to the PE and CHI submodules.
- Sets the CANFD_CFG.NOTRDY and CANFD_CFG.LPMACK bits.

The bus interface unit continues to operate, enabling the processor to access memory mapped registers, except the CANFD_RX_FIFO_GMSK, CANFD_RX_14_MSK, CANFD_RX_15_MSK, and CANFD_RX_FIFO_GMSK registers. The CANFD_RX_FIFO, the message buffers, the Rx individual mask registers, and the reserved words within RAM are not accessible when the CANFD module is in the module disable mode.

To exit module disable mode, disable the CANFD_CFG.DIS bit. If the CANFD module is disabled during freeze mode, it sends a requests to disable the clocks to the PE and CHI submodules, sets the CANFD_CFG.LPMACK bit, and clears the CANFD_CFG.FRZACK bit.

Doze Mode

The doze mode is a system low-power mode in which the processor bus is kept alive, and a global doze mode request is sent to all peripherals asking them to enter low-power mode. Before sending a global doze mode request, set the CANFD_CFG.DOZEN bit. The global doze request is set with the MISCREG_CAN_SYSCTL.CAN1_IPG_DOZE or MISCREG_CAN_SYSCTL.CAN0_IPG_DOZE bit. Once the processor requests the doze mode, the CANFD_CFG.LPMACK bit is set.

To exit doze mode, disable the CANFD_CFG.DOZEN bit or clear the IPG_DOZE bits in the MISCREG_CAN_SYSCTL register. The CANFD module also exits doze mode when activity is detected on the CAN bus and the self-wake up mechanism is enabled using the CANFD_CFG.SLFWAKEN bit.

If the doze mode is triggered during freeze mode, the CANFD module requests to disable the clocks to the PE and CHI submodules, sets the CANFD_CFG.LPMACK bit, and clears the CANFD_CFG.FRZACK bit.

If doze mode is triggered during transmission or reception, the CANFD module performs the following operations:

- Waits to be in either idle or bus off state, or else waits for the third bit of intermission and checks it to be recessive.
- Waits for all internal activities like arbitration, matching, move-in, and move-out to finish. A pending move-in is not considered.
- Ignores its Rx input pin and drives its Tx pin as recessive.
- Shuts down the clocks to the PE and CHI submodules.
- Sets the CANFD_CFG.NOTRDY and CANFD_CFG.LPMACK bits.

The bus interface unit continues to operate, enabling the processor to access memory mapped registers, except the CANFD_RX_FIFO_GMSK, CANFD_RX_14_MSK, CANFD_RX_15_MSK, and CANFD_RX_FIFO_GMSK registers. The CANFD_RX_FIFO, the message buffers, the Rx individual mask registers, and the reserved words within RAM are not accessible when the CANFD module is in the doze mode.

Exiting Doze mode is done in one of the following ways:

- Disabling the doze mode request in the MISCREG_CAN_SYSCTL register.
- Disabling the CANFD_CFG.DOZEN bit.
- When the CANFD module detects activity on the CAN bus and the self-wake up mechanism is enabled using the CANFD_CFG.SLFWAKEN bit.

When the self-wake up mechanism is enabled at the time that the CANFD module entered doze mode, then upon detection of a recessive-to-dominant transition on the CAN bus, the CANFD module clears the CANFD_CFG.DOZEN bit, requests to resume clocks, and disables the CANFD_CFG.LPMACK bit after the CAN PE recognizes the doze mode is disabled.

The CANFD module also sets the CANFD_ESR1.WAKINT bit, so if the CANFD_CFG.WAKMSK bit is enabled, it generates a wake up interrupt to the processor. The CANFD module then waits for 11 consecutive recessive bits to

synchronize to the CAN bus. Consequently, the CANFD module does not receive the frame that woke it up. The *Wake Up From Doze Mode* table details the effect of the CANFD_CFG.SLFWAKEN and the CANFD_CFG.WAKMSK bits upon waking from the doze mode.

Table 16-26: Wake Up From Doze Mode

SLFWAKEN	WAKINT	WAKMSK	CANFD Clocks Enabled	Wakeup Interrupt Generated
0	N/A	N/A	No	No
0	N/A	N/A	No	No
1	0	0	No	No
1	0	1	No	No
1	1	0	Yes	No
1	1	1	Yes	Yes

Applying a low-pass filter function to the Rx CAN input line while in doze mode will modify sensitivity to CAN bus activity as described in the CANFD_CFG.WSFLTREN bit description. This feature also protects the CANFD module from waking up due to short glitches on the CAN bus lines that can result from electromagnetic interference in noisy environments.

Stop Mode

The stop mode is a system low-power mode in which all clocks are stopped for maximum power savings. A global stop request is set with the MISCREG_CAN_SYSCTL.CAN0_IPG_STOP or MISCREG_CAN_SYSCTL.CAN1_IPG_STOP bit. Once the processor is in the stop mode, the CANFD_CFG.LPMACK bit is set.

If the CANFD module receives a global stop mode request during freeze mode, it sets the CANFD_CFG.LPMACK bit, clears the CANFD_CFG.FRZACK bit, and then sends the stop acknowledge signal to the processor to shut down the clocks globally.

If stop mode is requested during transmission or reception, the CANFD module performs the following operations:

- Waits to be in either the idle or bus off state, or else waits for the third bit of intermission and checks it to be recessive.
- Waits for all internal activities like arbitration, matching, move-in, and move-out to finish. A pending move-in is not considered.
- Ignores its Rx input pin and drives its Tx pin as recessive.
- Sets the CANFD_CFG.NOTRDY and CANFD_CFG.LPMACK bits.
- Sends a stop acknowledge signal to the processor to shut down the clocks globally.

Stop mode is exited when the processor resumes the clocks and removes the stop mode request, or when activity is detected on the CAN bus and the self-wake up mechanism is enabled using the CANFD_CFG.SLFWAKEN bit.

When the self-wake up mechanism is enabled at the time that the CANFD module entered stop mode, then upon detection of a recessive-to-dominant transition on the CAN bus, the CANFD module sets the CANFD_ESR1.WAKINT bit, so if the CANFD_CFG.WAKMSK bit is enabled, it generates a wake up interrupt to the processor. Upon receiving the interrupt, the processor resumes the clocks and removes the stop mode request. The CANFD module then waits for 11 consecutive recessive bits to synchronize to the CAN bus. Consequently, the CANFD module does not receive the frame that woke it up. The *Wakeup From Stop Mode* table details the effect of the CANFD_CFG.SLFWAKEN and the CANFD_CFG.WAKMSK bits upon wakeup from the stop mode. Note that wakeup from the stop mode only works when both bits are asserted.

Table 16-27: Wakeup From Stop Mode

SLFWAKEN	WAKINT	WAKMSK	Chip Clocks Enabled	Wakeup Interrupt Generated
0	N/A	N/A	No	No
0	N/A	N/A	No	No
1	0	0	No	No
1	0	1	No	No
1	1	0	No	No
1	1	1	Yes	Yes

Applying a low-pass filter function to the Rx CAN input line while in stop mode will modify sensitivity to CAN bus activity as described in the CANFD_CFG.WSFLTREN bit description. This feature also protects the CANFD module from waking up due to short glitches on the CAN bus lines that can result from electromagnetic interference in noisy environments.

Pretended Network Mode

Pretended networking is a special low-power mode used to receive wake up messages with low power consumption. Pretended networking mode can be selected to operate together with stop or doze mode. Before entering low-power mode, the CANFD_CFG.PNETEN bit must be asserted. Once in low-power mode, the CHI submodule clocks are shut down and the PE submodule is kept clocked, so that the receive process is still active to filter incoming messages as defined by the configuration.

Upon detecting a wakeup event, a wake up interrupt is issued to the system. When the CANFD_CFG.PNETEN bit is enabled, the processor disables the self-wake up feature by disabling the CANFD_CFG.SLFWAKEN bit. Wake up from matched message or time-out in pretended networking modes happens only when pretended networking mode is used along with doze mode. Wakeup is not supported in stop mode.

To enter pretended networking mode, the CANFD must be in normal mode and not in freeze or module disable mode. Under pretended networking mode, the CANFD module stays synchronized with the CAN bus in doze or stop mode. When either doze or stop is requested, the CANFD module performs the following operations:

- Waits to be in the idle state, or else waits for the third bit of intermission, and then checks it to be recessive.
- Sets the CANFD_CFG.LPMACK bit.

- Requests the shutdown of the CHI submodule clock, while keeping the PE submodule clock active.

The CANFD module exits pretended networking mode in the following ways:

- The processor removes the doze mode request.
- The processor disables the CANFD_CFG.DOZEN bit.
- The CPU removes the stop mode request.

The CANFD will wait until bus idle or the third bit of the intermission state to disable the CANFD_CFG.LPMACK bit.

The above exit methods are triggered either by the CANFD module detecting a wake up event and issuing the respective interrupt, or by the processor itself upon being woken up. The CANFD will wait until the bus idle state or until the third bit of the intermission state to disable the CANFD_CFG.LPMACK bit and resume normal mode. This procedure ensures that the CANFD module is synchronized to the CAN bus after exiting pretended networking mode. The processor must wait for the CANFD_CFG.LPMACK bit to be disabled before performing any access to the CANFD.

CANFD Event Control

The following section describe how the CANFD module generates and controls events.

Interrupts

The CANFD module has many interrupt sources: interrupts due to MBs and interrupts due to the OR'd interrupts from MBs, bus off, bus off done, error, error fast (errors detected in the data phase of CAN FD format messages with the CANFD_FD_CTL.BRSEN bit set), wake up, wake up match, wake up timeout, Tx warning, and Rx warning states.

Each one of the MBs can be an interrupt source if the corresponding IMASK bit is set. There is no distinction between Tx and Rx interrupts for a particular buffer, under the assumption that the buffer is initialized for either transmission or reception. Each of the buffers has an assigned flag bit in the CANFD_IFLG1 and CANFD_IFLG2 registers. The bit is set when the corresponding buffer completes a successful transfer and is cleared when the processor writes it to 1 (unless another interrupt is generated at the same time).

NOTE: The processor must only clear the bit causing the current interrupt, so bit manipulation instructions (BSET) must not be used to clear interrupt flags. These instructions may cause the accidental clearing of interrupt flags which are set after entering the current interrupt service routine.

If the Rx FIFO is enabled (CANFD_CFG.RFEN = 1) and DMA is disabled (CANFD_CFG.DMAEN = 0), the interrupts corresponding to MBs 0 to 7 have different meanings:

- Bit 7 of the CANFD_IFLG1 register becomes the "FIFO Overflow" flag.
- Bit 6 of the CANFD_IFLG1 register becomes the "FIFO Warning" flag.

- Bit 5 of the CANFD_IFLG1 register becomes the “Frames Available in FIFO” flag.
- Bit 4-0 of the CANFD_IFLG1 register are unused.

If both Rx FIFO and DMA are enabled (CANFD_CFG.RFEN =1 and CANFD_CFG.DMAEN = 1), the CANFD does not generate any FIFO interrupt. Bit 5 of the CANFD_IFLG1 register still indicates “Frames Available in FIFO” and generates a DMA request. Bits 7, 6, and 4–0 are unused.

NOTE: The Rx FIFO cannot be enabled when the CAN FD feature is enabled.

For a combined interrupt where multiple MB interrupt sources are OR’d together, the interrupt is generated when any of the associated MBs (or FIFO, if applicable) generates an interrupt. In this case, the processor must read the CANFD_IFLG1 and CANFD_IFLG2 registers to determine which MB or FIFO source caused the interrupt.

The interrupt sources for bus off, bus off done, error, error fast, wake up, Tx warning ,and Rx warning generate interrupts like the MB interrupt sources, and are read from the CANFD_ESR1 register. The bus off, error, Tx warning, and Rx warning interrupt mask bits are located in the CANFD_CTL1 register; the wake up interrupt mask bit is located in CANFD_CFG register.

The interrupt sources for pretended networking (wake up by match flag and wake up by timeout flag) are read in the CANFD_WUM register and the respective interrupts masks bits are located in CANFD_PN_CTL1 register.

Bus Interface

The processor accesses to CANFD registers are subject to the following rules:

- Read and write accesses to reserved address space result in access errors.
- Write accesses to positions with bits that are all currently read-only results in access errors.

  If at least one of the bits is not read-only then no access error is issued. Write permission to positions or some of their bits can change depending on the mode of operation or transitory state. Refer to the register and bit descriptions for details.
- Read and write accesses to unimplemented address space results in access errors.
- Read and write accessed to RAM located positions during low-power modes results in access errors.
- If CANFD_CFG.MAXMB is programmed with a value smaller than the available number of MBs, then the unused memory space can be used as general purpose RAM space. Reserved words within RAM cannot be used.

  For example, suppose the CANFD RAM can support up to 16 MBs, the CANFD_CTL2.RFFNUM bit field is 0x0, and the CANFD_CFG.MAXMB bit field is programmed with zero. The maximum number of MBs in this case becomes one. The RAM starts at 0x0080, and the space from 0x0080 to 0x008F is used by the one MB. The memory space from 0x0090 to 0x017F is available. The space between 0x0180 and 0x087F is reserved. The space from 0x0880 to 0x0883 is used by the one individual mask and the available memory in the mask registers space is from 0x0884 to 0x08BF. From 0x08C0 through 0x09DF, there are reserved words for internal use which cannot be used as general purpose RAM. Generally, free memory space for general-purpose usage depends only on the CANFD_CFG.MAXMB bit field.

Detection and Correction of Memory Errors

The CANFD module supports detection and correction of errors in memory read accesses. Each byte of CANFD memory is associated with five parity bits, which ensures a Hamming distance of four. The error correction mechanism ensures that in this 13-bit word, errors in one bit can be corrected (correctable errors), and errors in 2 bits can be detected but not corrected (non-correctable errors). Errors in more than 2 bits may not be detected. In case of non-correctable errors, the corrupted data is not changed by the error correction logic. When a read access is performed, the parity bits are used to calculate a syndrome, which indicates the error in each byte.

The CANFD module detects a non-correctable error in the event either an all-zeros or an all-ones read occurs and updates the CANFD_ERR_RSYN register. The CANFD_ERR_RSYN register holds the syndrome detected in a memory read with an error. It reports the bytes that are read in the 32-bit read transaction.

The *Syndrome Definition* table shows the SYNDn field in the CANFD_ERR_RSYN register, indicates the type of error, and the bit in byte (n) affected by the error. Each BEn field in the CANFD_ERR_RSYN register indicates which byte in the 32-bit word reported was effectively read. The syndrome bits are calculated for all bytes, even for the non-read ones. Errors detected in non-read bytes are indicated and reported as described in the Error Indication and Error Reporting sections.

Table 16-28: Syndrome Definition

SYNDn	Type	Bit Affected
0x00	N/A	None (no error)
0x01	Code	0
0x02	Code	1
0x04	Code	2
0x07	Data	5
0x08	Code	3
0x0E	Data	7
0x10	Code	4
0x13	Data	2
0x15	Data	6
0x16	Data	1
0x19	Data	3
0x1A	Data	4
0x1C	Data	0
0x06	N/A	All-zeros non-correctable error
0x1F	N/A	All-ones non-correctable error
All others	N/A	Non-correctable error

Memory errors are indicated to the host through the CANFD_ERR_STAT register and bus transfer errors, and reported through the CANFD_ERR_RADDR,CANFD_ERR_RDAT, and CANFD_ERR_RSYN registers.

The error detection and correction mechanism is activated by the CANFD_MEC.ECCDIS bit. When error detection and correction is disabled, updates on indications and reporting registers are stopped, but the parity bits are still calculated and written along with data in memory write operations to ensure that memory has consistent parity bits associated to the data.

NOTE: All CANFD memory must be initialized before any operation for the parity bits in memory to properly update. The CANFD_CTL2.WRMFRZEN bit grants write access to all memory positions that require initialization, ranging from 0x080 to 0xADF (and from 0xF28 to 0xFFF when the CAN FD feature is enabled). The CANFD_RX_MB_GMSK, CANFD_RX_14_MSK, CANFD_RX_15_MSK, and CANFD_RX_FIFO_GMSK registers also need to be initialized. The CANFD_CFG.RFEN bit must not be set during memory initialization. The *Identifier Acceptance Filter Fields for Global Bits* table shows the configurations for the CANFD_RX_FIFO_GMSK register.

Table 16-29: Identifier Acceptance Filter Fields for Global Mask Bits

Rx FIFO ID Filter Table Element Format **CANFD_CFG.IDAM**	Identifier Acceptance Filter Fields **CANFD_RX_FIFO_GMSK.VALUE**					
RTR	IDE	RXIDA	RXIDB	RXIDC	Reserved	
A	VALUE[31]	VALUE[30]	VALUE[29:1]	N/A	N/A	VALUE[0]
B	VALUE[31], VALUE[15]	VALUE[30], VALUE[14]	N/A	VALUE[29:16], VALUE[13:0]	N/A	N/A
C	N/A	N/A	N/A	N/A	VALUE[31:24], VALUE[23:16], VALUE[15:8], VALUE[7:0]	N/A

To avoid accidentally changing the critical error correction configuration, use the following protocol to enable the CANFD_MEC register update:

1. By default, the CANFD_CTL2.ECRWREN bit is zero and the CANFD_MEC.ECRWRDIS bit is one.
2. Set the CANFD_CTL2.ECRWREN bit.
3. Clear the CANFD_MEC.ECRWRDIS bit.
4. All writes to the CANFD_MEC register must keep the CANFD_MEC.ECRWRDIS bit cleared.
5. After configuration is done, lock the CANFD_MEC register by either setting the CANFD_MEC.ECRWRDIS bit or clearing the CANFD_CTL2.ECRWREN bit.

Sources of Memory Access

The CANFD memory can be accessed by two major sources (or requesters):

- Host (processor): The largest word accessed is 32 bits wide.
- CANFD internals processes (Rx matching, Tx arbitration, move-in on reception, move-out on transmission): The largest word accessed is 64 bits wide.

The way that non-correctable errors are indicated and reported depends on the source of access.

Error Indication

Memory errors are indicated by the CANFD_ERR_STAT.HNCEI, CANFD_ERR_STAT.INCEI, and CANFD_ERR_STAT.CEI flag bits. Non-correctable errors detected in memory reads requested by the host are indicated separately from the errors detected in requests by CANFD internal processes. The CANFD makes no distinction of the source of the access when correctable errors are detected. There are three independent flags for these three cases, and each flag raises an interrupt unless it is masked in the CANFD_MEC register. If both non-correctable and correctable errors are found in different bytes of the same read operation, both flags are set.

A non-correctable error detected in host access is also indicated as a bus transfer error. A bus wait request asserts to extend the memory transaction to the moment the report registers are updated. This indication cannot be masked. If the CANFD_ERR_STAT.HNCEI bit is not masked, the same non-correctable error will raise a bus transfer error and an interrupt request.

Each indication flag has one overrun flag in the CANFD_ERR_STAT register. The overrun flags do not request interrupts. Overrun flags for non-correctable errors indicate that other errors of the same nature were detected after current error being treated, while overrun flags for correctable errors indicate that other errors of the same nature were detected before the current error being treated. The recommended handling sequence for error indication is as follows:

1. Get the error report information from the report registers CANFD_ERR_RADDR, CANFD_ERR_RDAT, and CANFD_ERR_RSYN.
2. Use the error report information to take proper measures in the application.
3. Clear the CANFD_ERR_STAT.HNCEI, CANFD_ERR_STAT.INCEI, CANFD_ERR_STAT.CEI flag bits.
4. If the overrun flag is active:
    a. Alert that application that at least one error could not be handled.
    b. Clear the overrun flag bit.

The CANFD internal processes can access memory in transactions larger than 32 bits. For the indication, this kind of access is considered a consecutive sequence of 32-bit accesses. If errors are found in 2 or more 32-bit words, the interrupt and overrun flags are set simultaneously.

Error Reporting

The report registers CANFD_ERR_RADDR, CANFD_ERR_RDAT, and CANFD_ERR_RSYN provide detailed information about the address read, raw data, and syndrome read with error and indicated by the flags.

The address, data, and syndrome registers are updated simultaneously along with the error flags, according to these rules:

1. If any of the two non-correctable error flags is currently set, the report registers are not updated (the previous non-correctable error reporting is preserved).
2. Otherwise (either no error flag is currently set or only the correctable error flag is currently set), the report registers are updated according to the new error, or according to the most severe of new errors if non-correctable and correctable errors are simultaneously detected.

Reporting of errors detected in accesses larger than 32 bits follows the rules described in the CANFD_ERR_RADDR register.

The address reported in the CANFD_ERR_RADDR register and defined in the CANFD_ERR_IADDR register are not the same as those listed in the module memory map. The relation between the reported addresses and the respective ones in the module memory map is shown in the Error Injection section.

Addresses reported when reading memory portions organized as FIFOs, such as the CANFD_RX_FIFO register, refer to the address of the specific entry accessed in the FIFO, not to the FIFO base address.

To ensure coherence of the error report registers, turn off the report update by setting the CANFD_MEC.RERDIS bit before reading the report registers.

Response to Errors

Correctable errors have no effect on CANFD operation because affected data is corrected before use by the host or CANFD internal processes.

For host-initiated reads, a non-correctable error affects the host, but does not affect CANFD operation.

Non-correctable errors detected on memory reads requested by the CANFD internal processes result in incorrect operation depending on the state of the CANFD_MEC.NCERRFRZEN bit, as follows:

- During reception (either matching or move-in processes), when a non-correctable error occurs, an incorrect destination is selected to store the incoming frame, a corrupted frame is stored in the correct destination, or both. If the CANFD_MEC.NCERRFRZEN is set, the CANFD module stops operation automatically and enters freeze mode to prevent corrupted data from being treated as valid by CANFD internal processes. If the CANFD_MEC.NCERRFRZEN bit is cleared, the CANFD continues working and a corrupted frame is received.
- During the arbitration process, when a non-correctable error occurs, either a non-highest priority Tx message buffer is mistakenly selected for transmission or the data is corrupted. If the CANFD_MEC.NCERRFRZEN bit is set, the CANFD module stops operation automatically and enters freeze mode before starting the move-out. If the CANFD_MEC.NCERRFRZEN bit is cleared, the CANFD proceeds to move-out with a corrupted frame that will transmit on the CAN bus.

- During the move-out process, when a non-correctable error occurs, a corrupted frame is copied from the selected Tx MB that won the arbitration to the Tx SMB for transmission. If the CANFD_MEC.NCERRFRZEN bit is set, the CANFD module stops operation automatically and enters freeze mode before starting the transmission. If the CANFD_MEC.NCERRFRZEN bit is cleared, the corrupted frame is transferred from the Tx SMB to the PE submodule and transmits on the CAN bus.
- A non-correctable error can be detected beyond the move-out process, when Tx data is read from the Tx SMB (buffer located in RAM) to be transferred to the PE submodule for transmission. In this case, a frame with corrupted ID and/or data is transmitted on the CAN bus. To prevent the frame from being successfully received by the external nodes, the CANFD module inverts all bits in the CRC field (CRC sequence plus CRC Delimiter) and transmits an error flag just after CRC delimiter because of a self-detecting bit1 error and a form error due to the CRC field inversion. When the CANFD_MEC.NCERRFRZEN bit is set, the CANFD module stops operation automatically and enters freeze mode just after the error frame. If the CANFD_MEC.NCERRFRZEN bit is negated, the CANFD module attempts to re-transmit the same frame, when no other higher priority Tx MB is subsequently configured for transmission. In the event the non-correctable error persists, the CANFD module eventually reaches the bus off state because of consecutive error detections. The CANFD_ECR.TXERRCNT field is updated every time the CANFD module inverts the CRC field causing errors as described above.

When the CANFD_MEC.NCERRFRZEN bit is set and the CANFD module enters freeze mode, only the host processor can cause then CANFD to exit freeze mode and resume normal mode. Assertion of the CANFD_MEC.NCERRFRZEN bit is the only way to prevent corrupted frames from transmitting on the CAN bus up to the move-out internal process.

The error report registers provide information to the application for customized handling of these situations.

Error Injection

The error injection registers CANFD_ERR_IADDR, CANFD_ERR_IDP, and CANFD_ERR_IPP are used to inject errors in memory reads in order to force errors and consequently update the indication and reporting registers.

The *Error Injection Address Mapping* table shows the relationship between the error injection addresses and the ones in the module memory map. Use this table to convert from the memory map address to the correct location in the physical CANFD RAM.

NOTE: Where pairs of values are provided in the table, the first is the address when the CANFD_CFG.FDEN bit is disabled and the second is when the CANFD_CFG.FDEN bit is enabled.

Table 16-30: Error Injection Address Mapping

RAM Contents	Injection Address	Memory Map
CANFD registers	Not mapped	N/A
MBs	0x0000	0x0080
Reserved	N/A	0x0480
RXIMRs	0x0400	0x0880

Table 16-30: Error Injection Address Mapping (Continued)

RAM Contents	Injection Address	Memory Map
Reserved	N/A	0x0980
RXFIR_0	0x0500	0x0A80
RXFIR_1	0x0504	0x0A84
RXFIR_2	0x0508	0x0A88
RXFIR_3	0x050C	0x0A8C
RXFIR_4	0x0510	0x0A90
RXFIR_5	0x0514	0x0A94
Reserved	N/A	0x0A98
CANFD_RX_MB_GMSK	0x0520	0x0010
CANFD_RX_FIFO_GMSK	0x0524	0x0048
CANFD_RX_14_MSK	0x0528	0x0014
CANFD_RX_15_MSK	0x052C	0x0018
Tx_SMB	0x0530	0x0AB0 / 0x0F28
Rx_SMB0	0x0540 / 0x0578	0x0AC0 / 0x0F70
Rx_SMB1	0x0550 / 0x05C0	0x0AD0 / 0x0FB8
ECC registers	Not mapped	0x0AE0
Pretended networking registers	Not mapped	0x0B00
CAN FD registers	Not mapped	0x0C00
Reserved	N/A	0x0C0C

The injection is done by flipping the data and parity bits corresponding to the bits set to 1 in the CANFD_ERR_IDP and CANFD_ERR_IPP registers. Injection can be selected specifically for memory accesses requested by host or by CANFD internal processes.

In case of accesses larger than 32 bits, the CANFD_MEC.EXTERRIEN bit extends the injection pattern, replicating it in 32-bit words to fill the width of the access.

NOTE: It is very unlikely, but error injection may correct a bit with an error. This will not raise the error flags and reports as expected.

To ensure coherence among error injection registers and avoid spurious error injections, the CANFD_MEC.HAERRIEN and CANFD_MEC.IAERRIEN bits must be cleared while configuring the memory injection.

CANFD Programming Model

Following sections provide some guidelines for CANFD programming.

Initialization

The CANFD module is reset in one of the following ways:

- A chip level hard reset that resets all memory mapped registers asynchronously.
- Setting the CANFD_CFG.SOFTRST bit , which resets some of the memory mapped registers synchronously. The *Register Reset States* table shows the registers affected by a soft reset.
- Chip level soft reset, which has the same effect as setting the CANFD_CFG.SOFTRST bit.

A soft reset is synchronous and must follow an internal request and acknowledge procedure across clock domains and takes time to fully propagate the effects. The CANFD_CFG.SOFTRST bit remains set while soft reset is pending, so software can poll this bit to know when the reset has completed. Also, soft reset cannot be applied while clocks are shut down in a low-power mode. Exit the low-power mode and resume the clocks before applying a soft reset.

Table 16-31: Register Reset States

Register	Affected by Hard Reset	Affected by Soft Reset
CANFD_TIMING	Yes	No
CANFD_CRC	Yes	Yes
CANFD_CTL1	Yes	No
CANFD_PN_CTL1	Yes	Yes
CANFD_CTL2	Yes	No
CANFD_PN_CTL2	Yes	Yes
CANFD_ECR	Yes	Yes
CANFD_ERR_IADDR	Yes	Yes
CANFD_ERR_IDP	Yes	Yes
CANFD_ERR_IPP	Yes	Yes
CANFD_ERR_STAT	Yes	Yes
CANFD_ESR1	Yes	Yes
CANFD_ESR2	Yes	Yes
CANFD_FD_TIMING	Yes	No
CANFD_FD_CRC	Yes	Yes
CANFD_FD_CTL	Yes	No
CANFD_FLTR_DLC	Yes	Yes
CANFD_FLTR_ID1	Yes	Yes
CANFD_FLTR_ID2_IDMSK	Yes	Yes

Table 16-31: Register Reset States (Continued)

Register	Affected by Hard Reset	Affected by Soft Reset
CANFD_IFLG1	Yes	Yes
CANFD_IFLG2	Yes	Yes
CANFD_IMSK1	Yes	Yes

Note that the MBs and the Rx individual mask registers are not affected by reset, so they are not automatically initialized.

CANFD Initialization Sequence

For any configuration change or initialization, the CANFD must be is put into freeze mode. The following steps are a generic initialization sequence applicable to the CANFD module:

1. Initialize the Module Configuration Register (CANFD_CFG):

- Enable the individual filtering per MB and reception queue features by setting the CANFD_CFG.IRMQEN bit.
- Enable the warning interrupts by setting the CANFD_CFG.WRNEN bit.
- Optionally disable frame self reception by setting the CANFD_CFG.SRXDIS bit.
- Enable the Rx FIFO by setting the CANFD_CFG.RFEN bit.
- If Rx FIFO is enabled and DMA is required, set the CANFD_CFG.DMAEN bit.
- If Pretended Networking mode is required, set the CANFD_CFG.PNETEN bit.
- Enable the abort mechanism by setting the CANFD_CFG.ABORTEN bit.
- Enable the local priority feature by setting the CANFD_CFG.LPRIOEN bit.

2. Initialize the Control 1 Register (CANFD_CTL1) and optionally the CAN Bit Timing Register (CANFD_TIMING). Also, initialize the CAN FD CAN Bit Timing Register (CANFD_FD_TIMING):
   - Determine the bit timing parameters: CANFD_CTL1.PROPSEG, CANFD_CTL1.PSEG1, CANFD_CTL1.PSEG2, CANFD_CTL1.RJW.
   - Optionally determine the extended bit timing parameters: CANFD_TIMING.EPROPSEG, CANFD_TIMING.EPSEG1, CANFD_TIMING.EPSEG2, CANFD_TIMING.ERJW.
   - Determine the CAN FD bit timing parameters: CANFD_FD_TIMING.FPROPSEG, CANFD_FD_TIMING.FPSEG1, CANFD_FD_TIMING.FPSEG2, CANFD_FD_TIMING.FRJW.
   - Determine the bit rate by programming the CANFD_CTL1.PRESDIV field and optionally the CANFD_TIMING.EPRESDIV field.
   - Determine the CAN FD bit rate by programming the CANFD_FD_TIMING.FPRESDIV field. Determine the internal arbitration mode (CANFD_CTL1.LBUF bit).
3. Initialize the Message Buffers:
   - Initialize the C/S word of all MBs.
   - If the Rx FIFO is enabled, initialize the ID filter table.
   - Initialize other entries in each MB.
4. Initialize the individual masks in the CANFD_IMSK1 and CANFD_IMSK2 registers.
5. Set required interrupt mask bits in the CANFD_IMSK1 and CANFD_IMSK2 registers (for all MB interrupts), in the CANFD_CFG register for the wake up interrupt, and in the CANFD_CTL1 and CANFD_CTL2 registers for the bus off and error interrupts.
6. If pretended networking mode is enabled, configure the necessary registers for selective wake up.
7. Disable the CANFD_CFG.HALT bit.

After the last step listed, the CANFD module attempts to synchronize to the CAN bus.

Pretended Network - Doze Mode

Complete the following sequence to enter the pretended networking mode in doze mode:

1. Set the CANFD_CFG.PNETEN bit to enable the controller to enter the pretended networking mode, when one of the low power modes is requested.
2. Clear the CANFD_PN_CTL1.WTOFMSK and CANFD_PN_CTL1.WUMFMSK bits.
3. Request the CANFD to enter Doze mode.
4. Wait for the CANFD to set the CANFD_CFG.LPMACK bit.
5. Clear the CANFD_WUM.WTOF and/or CANFD_WUM.WUMF bits (if either bit is set).
6. Set the CANFD_PN_CTL1.WTOFMSK and CANFD_PN_CTL1.WUMFMSK bits.

Pretended Network - Stop Mode

Complete the following sequence to enter the pretended networking mode in stop mode:

1. Set the CANFD_CFG.PNETEN bit to enable the controller to enter pretended networking mode, when one of the low power modes is requested.
2. Clear the CANFD_PN_CTL1.WTOFMSK and CANFD_PN_CTL1.WUMFMSK bits.
3. Request the CANFD to enter Stop mode. Keep CAN0_IPG_STOP_CLK_EXT/ CAN1_IPG_STOP_CLK_EXT bits set to keep the clock to register block running.
4. Wait for the CANFD to set the CANFD_CFG.LPMACK bit.
5. Clear the CANFD_WUM.WTOF and/or CANFD_WUM.WUMF bits (if either bit is set).
6. Set the CANFD_PN_CTL1.WTOFMSK and CANFD_PN_CTL1.WUMFMSK bits.
7. Disable CANFD register clocks by clearing bits CAN0_IPG_STOP_CLK_EXT/ CAN1_IPG_STOP_CLK_EXT for CANFD0/CANFD1 respectively.

ADSP-SC59x CANFD Register Descriptions

Controller Access Network with Flexible Data Rate (CANFD) (CANFD) contains the following registers.

Table 16-32: ADSP-SC59x CANFD Register List

Name	Description
CANFD_TIMING	Can Bit Timing Register
CANFD_CRC	CRC Register
CANFD_CTL1	Control 1 Register
CANFD_PN_CTL1	Pretended Networking Control1 Register

Table 16-32: ADSP-SC59x CANFD Register List (Continued)

Name	Description
CANFD_CTL2	Control 2 Register
CANFD_PN_CTL2	Pretended Networking Control2 Register
CANFD_ECR	Error Counter Register
CANFD_ERR_IADDR	Error Injection Address Register
CANFD_ERR_IDP	Error Injection Data Pattern Register
CANFD_ERR_IPP	Error Injection Parity Pattern Register
CANFD_ERR_STAT	Error Status Register
CANFD_ESR1	Error and Status 1 Register
CANFD_ESR2	Error and Status 2 Register
CANFD_FD_TIMING	CANFD Bit Timing Register
CANFD_FD_CRC	CANFD CRC Register
CANFD_FD_CTL	CANFD Control Register
CANFD_FLTR_DLC	Pretended Networking DLC Filter Register
CANFD_FLTR_ID1	Pretended Networking ID Filter1 Register
CANFD_FLTR_ID2_IDMSK	Pretended Networking ID Filter2 / IDMask Register
CANFD_IFLG1	Mailbox Interrupt Flag 1 Register
CANFD_IFLG2	Mailbox Interrupt Flag 2 Register
CANFD_IMSK1	Mailbox Interrupt Mask 1 Register
CANFD_IMSK2	Mailbox Interrupt Mask 2 Register
CANFD_CFG	Module Configuration Register
CANFD_MEC	Memory Error Control Register
CANFD_FLTR_DATA1_HI	Pretended Networking Payload Low Filter2 Register
CANFD_FLTR_DATA1_LO	Pretended Networking Payload Low Filter1 Register
CANFD_FLTR_DATA2_DMSK_HI	Pretended Networking Payload High Filter2 High Order Bits / Payload High Mask Register
CANFD_FLTR_DATA2_DMSK_LO	Pretended Networking Payload Low Filter2 / Payload Low Mask Register
CANFD_ERR_RADDR	Error Report Address Register
CANFD_ERR_RDAT	Error Report Data Register
CANFD_ERR_RSYN	Error Report Syndrome Register
CANFD_RX_14_MSK	Receive Mailbox14 Mask Register
CANFD_RX_15_MSK	Receive Mailbox15 Mask Register
CANFD_RX_FIFO_GMSK	Receive FIFO Global Mask Register

Table 16-32: ADSP-SC59x CANFD Register List (Continued)

Name	Description
CANFD_RX_FIFO	Receive FIFO Information Register
CANFD_RX_IMSK[n]	Receive Individual Mask Register
CANFD_RX_MB_GMSK	Receive Mailbox Global Mask Register
CANFD_TMR	Free Running Timer Register
CANFD_WMB[n]_DATA_HI	Wakeup Message Buffer Data 4-7 Register
CANFD_WMB[n]_DATA_LO	Wakeup Message Buffer Data 0-3 Register
CANFD_WMB[n]_ID	Wakeup Message ID Buffer Register
CANFD_WMB[n]_STAT	Wakeup Message Buffer Control/Status Register
CANFD_WUM	Pretended Networking Wakeup Match Register

Can Bit Timing Register

The CANFD_TIMING register is an alternative way to store the CAN bit timing variables described in the CANFD_CTL1 register. The CANFD_TIMING.EPRESDIV, CANFD_TIMING.EPROPSEG, CANFD_TIMING.EPSEG1, CANFD_TIMING.EPSEG2, and CANFD_TIMING.ERJW bit fields are extended versions of the CANFD_CTL1 register CANFD_CTL1.PRESDIV, CANFD_CTL1.PROPSEG, CANFD_CTL1.PSEG1, CANFD_CTL1.PSEG2 and CANFD_CTL1.RJW bit fields respectively.

The CANFD_TIMING.BTF bit selects the use of the timing variables defined in the CANFD_TIMING register. The contents of the CANFD_TIMING register are not affected by a soft reset.

NOTE: The CAN bit variables in the CANFD_CTL1 and CANFD_TIMING registers are stored in the same register.

NOTE: When the CAN FD feature is enabled (CANFD_CFG.FDEN is set), always set CANFD_TIMING.BTF.

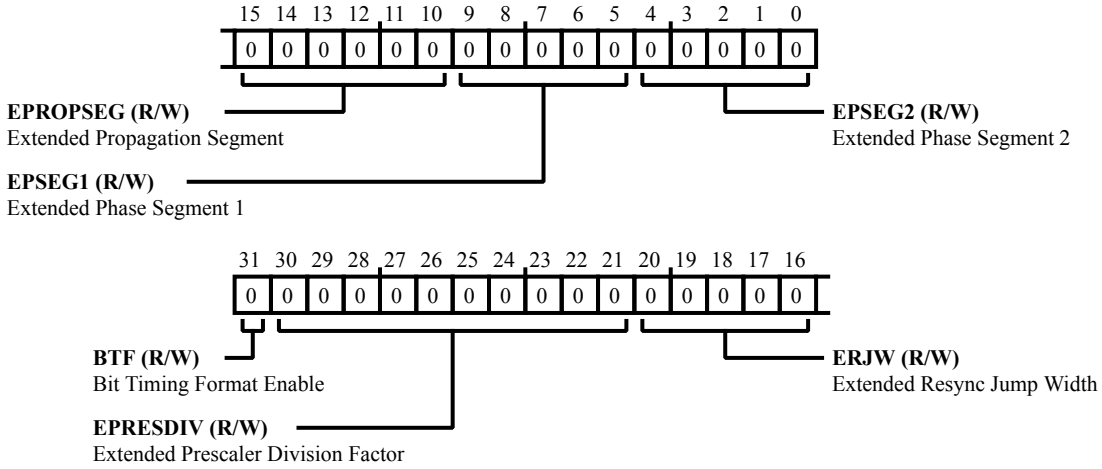

Figure 16-15: CANFD_TIMING Register Diagram

Table 16-33: CANFD_TIMING Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	BTF	Bit Timing Format Enable. The CANFD_TIMING.BTF bit enables the use of the extended CAN bit timing fields in the CANFD_TIMING register to replace the CAN bit time variables defined in the CANFD_CTL1 register. The CANFD_TIMING.BTF bit can only be written in freeze mode.	
		0	Disable
		1	Enable

Table 16-33: CANFD_TIMING Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
30:21 (R/W)	EPRESDIV	Extended Prescaler Division Factor. When the CANFD_TIMING.BTF bit is enabled, the CANFD_TIMING.EPRESDIV bit field defines the ratio between the PE clock frequency and the serial clock (Sclock) frequency. The CANFD_TIMING.EPRESDIV bit field extends the CANFD_CTL1.PRESDIV value range. Sclock frequency = PE clock frequency / (EPRESDIV + 1) The Sclock period defines the time quantum of the CAN protocol. For the reset value, the Sclock frequency is equal to the PE clock frequency. When the CANFD_TIMING.BTF bit is disabled, the CANFD_TIMING.EPRESDIV bit field has no effect. The CANFD_TIMING.EPRESDIV bit field can only be written in freeze mode and is blocked by hardware in other modes.
20:16 (R/W)	ERJW	Extended Resync Jump Width. When the CANFD_TIMING.BTF bit is enabled, the CANFD_TIMING.ERJW bit field defines the maximum number of time quanta that a bit time can be changed by one resynchronization. The CANFD_TIMING.ERJW bit field extends the CANFD_CTL1.RJW value range. Resync Jump Width = ERJW + 1 One time quantum is equal to the Sclock period. When the CANFD_TIMING.BTF bit is disabled, the CANFD_TIMING.ERJW bit field has no effect. The CANFD_TIMING.ERJW bit field can only be written in freeze mode and is blocked by hardware in other modes.
15:10 (R/W)	EPROPSEG	Extended Propagation Segment. When the CANFD_TIMING.BTF bit is enabled, the CANFD_TIMING.EPROPSEG bit field defines the length of the propagation segment in the bit time. The CANFD_TIMING.EPROPSEG bit field extends the CANFD_CTL1.PROPSEG value range. Propagation Segment Time = (EPROPSEG + 1) Time-Quanta One time quantum is equal to the Sclock period. When the CANFD_TIMING.BTF bit is disabled, the CANFD_TIMING.EPROPSEG bit field has no effect. The CANFD_TIMING.EPROPSEG bit field can only be written in freeze mode and is blocked by hardware in other modes.

Table 16-33: CANFD_TIMING Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
9:5 (R/W)	EPSEG1	Extended Phase Segment 1. When the CANFD_TIMING.BTF bit is enabled, the CANFD_TIMING.EPSEG1 bit field defines the length of phase segment 1 in the bit time. The CANFD_TIMING.EPSEG1 bit field extends the CANFD_CTL1.PSEG1 value range. Phase Buffer Segment 1 = (EPSEG1 + 1) Time-Quanta One time quantum is equal to the Sclock period. When the CANFD_TIMING.BTF bit is disabled, the CANFD_TIMING.EPSEG1 bit field has no effect. The CANFD_TIMING.EPSEG1 bit field can only be written in freeze mode and is blocked by hardware in other modes.
4:0 (R/W)	EPSEG2	Extended Phase Segment 2. When the CANFD_TIMING.BTF bit is enabled, the CANFD_TIMING.EPSEG2 bit field defines the length of phase segment 2 in the bit time. The CANFD_TIMING.EPSEG2 bit field extends the CANFD_CTL1.PSEG2 value range. Phase Buffer Segment 1 = (EPSEG1 + 1) Time-Quanta One time quantum is equal to the Sclock period. When the CANFD_TIMING.BTF bit is disabled, the CANFD_TIMING.EPSEG2 bit field has no effect. The CANFD_TIMING.EPSEG2 bit field can only be written in freeze mode and is blocked by hardware in other modes.

CRC Register

The CANFD_CRC register provides information about the CRC of transmitted messages for non-FD messages. For messages in CAN FD format that require either 17 or 21 bits, the CANFD_CRC register only reports the 15 low order bits of CRC calculations. For CAN FD format frames, the CANFD_FD_CRC register must be used. The CANFD_CRC register updates at the same time the Tx Interrupt Flag is set.

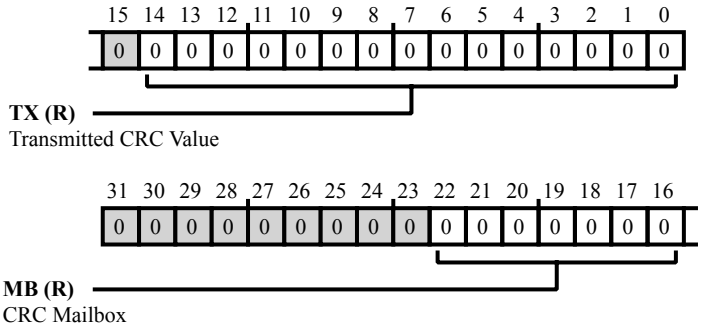

Figure 16-16: CANFD_CRC Register Diagram

Table 16-34: CANFD_CRC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
22:16 (R/NW)	MB	CRC Mailbox. The CANFD_CRC.MB bit field indicates the number of the mailbox corresponding to the value in the CANFD_CRC.TX field.
14:0 (R/NW)	TX	Transmitted CRC Value. The CANFD_CRC.TX bit field indicates the CRC value of the last transmitted message for non-FD frames. For CAN FD frames, the CRC value is reported in the CANFD_FD_CRC register.

Control 1 Register

The CANFD_CTL1 register is defined for specific CANFD control features related to the CAN bus, such as bit-rate, programmable sampling point within an Rx bit, loop-back mode, listen-only mode, bus off recovery behavior, and interrupt enabling (bus off, error, warning). It also determines the division factor for the clock prescaler.

The CAN bit timing variables (PRESDIV, PROPSEG, PSEG1, PSEG2, and RJW) are also configurable in the CANFD_TIMING register, which extends the range of all these variables. If the CANFD_TIMING.BTF bit is set, the PRESDIV, PROPSEG, PSEG1, PSEG2, and RJW fields of the CANFD_CTL1 register become read-only.

NOTE: When the CAN FD feature is enabled, do not use the CANFD_CTL1.PRESDIV, CANFD_CTL1.RJW, CANFD_CTL1.PSEG1, CANFD_CTL1.PSEG2, and CANFD_CTL1.PROPSEG fields of the CANFD_CTL1 register for CAN bit timing. Instead, use the CANFD_TIMING.EPRESDIV, CANFD_TIMING.ERJW, CANFD_TIMING.EPSEG1, CANFD_TIMING.EPSEG2, and CANFD_TIMING.EPROPSEG fields of the CANFD_TIMING register.

The contents of the CANFD_CTL1 register are not affected by a soft reset.

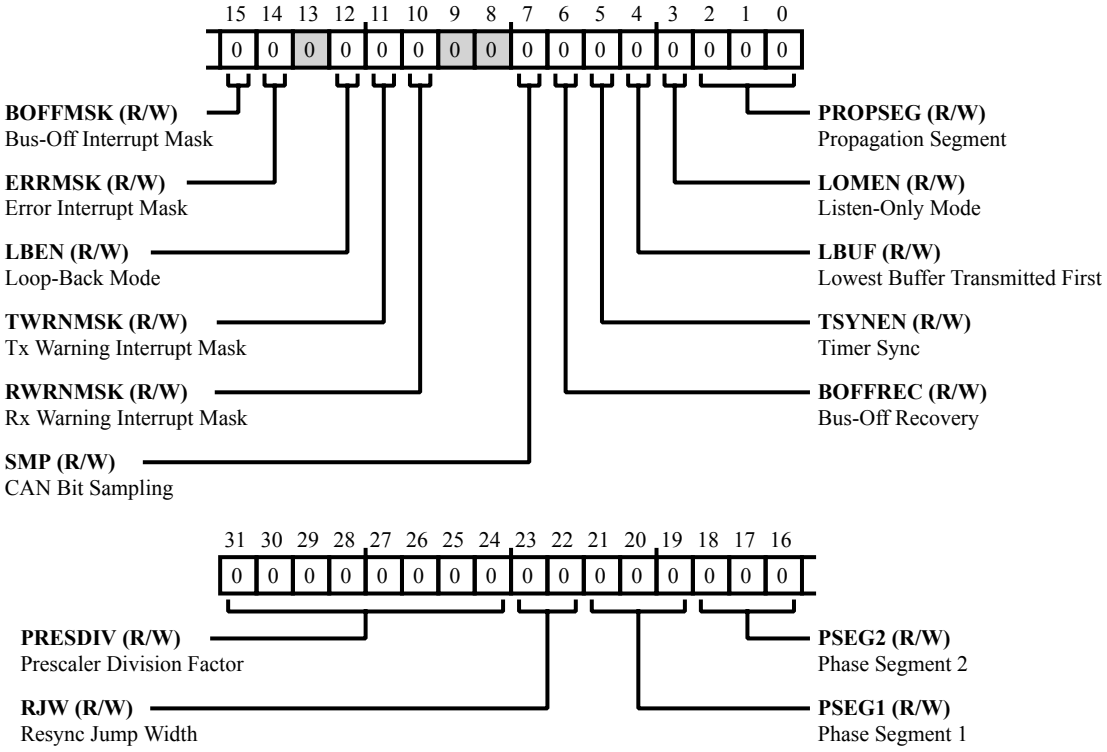

Figure 16-17: CANFD_CTL1 Register Diagram

Table 16-35: CANFD_CTL1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:24 (R/W)	PRESDIV	Prescaler Division Factor. The CANFD_CTL1.PRESDIV bit field defines the ratio between the PE clock frequency and the serial clock (SCLOCK) frequency. The SCLOCK period defines the time quantum of the CAN protocol. For the reset value, the SCLOCK frequency is equal to the PE clock frequency. The maximum value of PRESDIV is 0xFF, which gives a minimum SCLOCK frequency equal to the PE clock frequency divided by 256. The CANFD_CTL1.PRESDIV bit can only be written in freeze mode and is blocked by hardware in other modes. SCLOCK Frequency = PE Clock Frequency / (PRESDIV + 1)	
23:22 (R/W)	RJW	Resync Jump Width. The CANFD_CTL1.RJW bit field defines the maximum number of time quanta that a bit time can change with one re-synchronization. One time quantum is equal to the SCLOCK period. The valid programmable values for the CANFD_CTL1.RJW bits are 03. This bit field can only be written in freeze mode and is blocked by hardware in other modes. Resync Jump Width = RJW + 1	
21:19 (R/W)	PSEG1	Phase Segment 1. The CANFD_CTL1.PSEG1 bit field defines the length of the phase segment 1 of the bit time. The valid programmable values are 07. This bit field can only be written in freeze mode and is blocked by hardware in other modes. Phase Buffer Segment 1 = (PSEG1 + 1) Time-Quanta	
18:16 (R/W)	PSEG2	Phase Segment 2. The CANFD_CTL1.PSEG2 bit field defines the length of phase segment 2 of the bit time. The valid programmable values are 17. This bit field can only be written in freeze mode and is blocked by hardware in other modes. Phase Buffer Segment 2 = (PSEG2 + 1) Time-Quanta	
15 (R/W)	BOFFMSK	Bus-Off Interrupt Mask. The CANFD_CTL1.BOFFMSK bit provides a mask for the bus off interrupt (CANFD_ESR1.BOFFINT).	
		0	Disable
		1	Enable

Table 16-35: CANFD_CTL1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
14 (R/W)	ERRMSK	Error Interrupt Mask. The CANFD_CTL1.ERRMSK bit provides a mask for the error interrupt (CANFD_ESR1.ERRINT).	
		0	Disable
		1	Enable
12 (R/W)	LBEN	Loop-Back Mode. The CANFD_CTL1.LBEN bit configures the CANFD module to operate in loop-back mode. In loop-back mode, the CANFD modules performs an internal loop back to use for self-test operation. The bit stream output of the transmitter is fed back internally to the receiver input. The Rx CAN input pin is ignored and the Tx CAN output goes to the recessive state (logic 1). The CANFD module behaves as it normally does when transmitting, and treats its own transmitted message as a message received from a remote node. In loop-back mode, the CANFD module ignores the bit sent during the ACK slot in the CAN frame acknowledge field, generating an internal acknowledge bit to ensure proper reception of its own message. Both transmit and receive interrupts are generated. The CANFD_CTL1.LBEN bit can only be written in freeze mode and is blocked by hardware in other modes. Note that in loop-back mode, the CANFD_CFG.SRXDIS bit cannot be asserted, because it impedes the self reception of a transmitted message. Also, note that the CANFD_FD_CTL.TDCOMPEN bit must be 0 (transceiver delay compensation feature disabled) when the CANFD_CTL1.LBEN bit is asserted.	
11 (R/W)	TWRNMSK	Tx Warning Interrupt Mask. The CANFD_CTL1.TWRNMSK bit provides a mask for the Tx warning interrupt (CANFD_ESR1.TXWRNINT) The CANFD_CTL1.TWRNMSK bit is read as zero when CAN_MCR.WRNEN is negated. The CANFD_CTL1.TWRNMSK bit can only be written when the CANFD_CFG.WRNEN bit is enabled.	
		0	Tx Warning Interrupt Disabled
		1	Tx Warning Interrupt Enabled

Table 16-35: CANFD_CTL1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
10 (R/W)	RWRNMSK	Rx Warning Interrupt Mask. The CANFD_CTL1.RWRNMSK bit provides a mask for the Rx warning interrupt (CANFD_ESR1.RXWRNINT) The CANFD_CTL1.RWRNMSK bit is read as zero when the CANFD_CFG.WRNEN bit is negated. It can only be written only if the CANFD_CFG.WRNEN bit is enabled.	
		0	Rx Warning Interrupt Disabled
		1	Rx Warning Interrupt Enabled
7 (R/W)	SMP	CAN Bit Sampling. The CANFD_CTL1.SMP bit defines the sampling mode of CAN bits at the Rx input. When the CANFD_CTL1.SMP bit is disabled, one sample determines the bit value. When it is enabled three samples determine the value of the received bit: the regular sample (sample point) and the two preceding samples; a majority rule is used. The CANFD_CTL1.SMP bit can only be written in freeze mode and is blocked by hardware in other modes. Note that for proper operation, when enabling CAN bit sampling, guarantee a minimum value of 2 time quanta in the CANFD_CTL1.PSEG1 (or CANFD_TIMING.EPSEG1) bit field. SMP cannot be asserted when CAN FD is enabled (CANFD_CFG.FDEN = 1).	
		0	Disable
		1	Enable

Table 16-35: CANFD_CTL1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6 (R/W)	BOFFREC	Bus-Off Recovery. The CANFD_CTL1.BOFFREC bit defines how the CANFD module recovers from bus off state. When the CANFD_CTL1.BOFFREC bit is enabled, automatic recovering from the bus off state occurs according to the CAN Specification 2.0B. When the CANFD_CTL1.BOFFREC bit is disabled, automatic recovering from the bus off state is disabled and the CANFD module remains in the bus off state until the CANFD_CTL1.BOFFREC bit is enabled by software. If this occurs before 128 sequences of 11 recessive bits are detected on the CAN bus, then the bus off recovery happens as if the CANFD_CTL1.BOFFREC bit was never disabled. If the bit is enabled after 128 sequences of 11 recessive bits occurred, then the CANFD module will re-synchronize to the bus by waiting for 11 recessive bits before joining the bus. After being enabled, the CANFD_CTL1.BOFFREC bit can be disabled again during the bus off state, but it will be effective only the next time the CANFD module enters the bus off state. If CANFD_CTL1.BOFFREC bit was enabled when the CANFD module entered the bus off state, disabling the CANFD_CTL1.BOFFREC bit during the bus off state will not be effective for the current bus off recovery.	
		0	Enable
		1	Disable
5 (R/W)	TSYNEN	Timer Sync. The CANFD_CTL1.TSYNEN bit enables a mechanism that resets the free-running timer each time a message is received in message buffer 0. The timer sync feature provides a means to synchronize multiple CANFD stations with a special SYNC message (global network time). If the CANFD_CFG.RFEN bit is set (Rx FIFO enabled), the first available mailbox, according to the CANFD_CTL2.RFFNUM setting, is used for timer synchronization instead of MB0. The CANFD_CTL1.TSYNEN bit can only be written in freeze mode and is blocked by hardware in other modes.	
		0	Disable
		1	Enable

Table 16-35: CANFD_CTL1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/W)	LBUF	Lowest Buffer Transmitted First. The CANFD_CTL1.LBUF bit defines the ordering mechanism for message buffer transmission. When the CANFD_CTL1.LBUF bit is enabled, the lowest number buffer is transmitted first and when it is disabled the buffer with highest priority is transmitted first. When the CANFD_CTL1.LBUF bit is enabled, the CANFD_CFG.LPRIOEN bit does not affect the arbitration priority. The CANFD_CTL1.LBUF bit can only be written in freeze mode and is blocked by hardware in other modes.	
		0	Disable
		1	Enable
3 (R/W)	LOMEN	Listen-Only Mode. The CANFD_CTL1.LOMEN bit configures the CANFD module to operate in listen-only mode. When the CANFD_CTL1.LOMEN is enabled to be in listen-only mode, transmission is disabled, all error counters in the CANFD_ECR register are frozen, and the CANFD module operates in the CAN error passive mode. Only messages acknowledged by another CAN station will be received. If the CANFD module detects a message that has not been acknowledged, it flags a BIT0 error without changing the receive error counter (CANFD_ECR.RXERRCNT), as if it were trying to acknowledge the message. Listen-Only mode is acknowledged by the state of the CANFD_ESR1.FLTCONF bit field indicating a passive error. There can be some delay between the Listen-Only mode request and acknowledge. The CANFD_CTL1.LOMEN bit can only be written in freeze mode and is blocked by hardware in other modes.	
		0	Disable
		1	Enable
2:0 (R/W)	PROPSEG	Propagation Segment. The CANFD_CTL1.PROPSEG bit field defines the length of the propagation segment in the bit time. The valid programmable values are 07. The CANFD_CTL1.PROPSEG bit can only be written in freeze mode and is blocked by hardware in other modes. Propagation Segment Time = (PROPSEG + 1) Time-Quanta. Time-Quantum = One SCLOCK Period.	

Pretended Networking Control1 Register

The CANFD_PN_CTL1 register contains control bits for pretended networking mode filtering selection. Configure this register with the filter criteria to receive wakeup messages. Bits other than CANFD_PN_CTL1.WTOFMSK and CANFD_PN_CTL1.WUMFMSK can only be written in freeze mode.

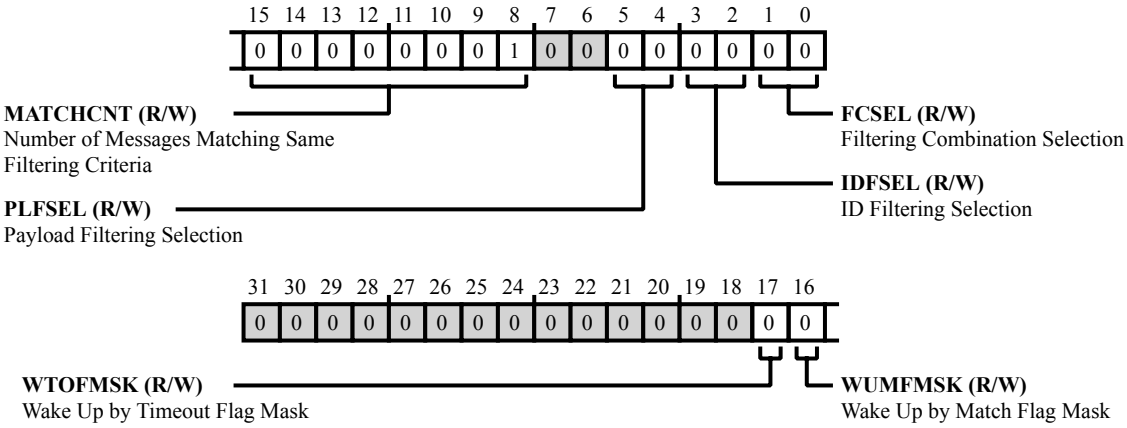

Figure 16-18: CANFD_PN_CTL1 Register Diagram

Table 16-36: CANFD_PN_CTL1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/W)	WTOFMSK	Wake Up by Timeout Flag Mask. The CANFD_PN_CTL1.WTOFMSK bit masks the generation of a wakeup event originated by a timeout:	
		0	Timeout Event Disabled
		1	Timeout Event Enabled
16 (R/W)	WUMFMSK	Wake Up by Match Flag Mask. The CANFD_PN_CTL1.WUMFMSK bit masks the generation of a wakeup event originated by a successfully filtered Rx message.	
		0	Wakeup match disabled
		1	Wakeup match enabled

Table 16-36: CANFD_PN_CTL1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
15:8 (R/W)	MATCHCNT	Number of Messages Matching Same Filtering Criteria. The CANFD_PN_CTL1.MATCHCNT bit field defines the number of times a given message must match the predefined filtering criteria for ID and/or PL before generating a wakeup event. This quantity is configured in the 1 to 255 range. For example, if the received message must match the predefined filtering criteria for ID and/or PL once before generating a wakeup event, the CANFD_PN_CTL1.MATCHCNT bit field value is 0x01; if it must match twice before generating a wakeup event, the bit field value is 0x02; and if it must match 255 times generating a wakeup event, the CANFD_PN_CTL1.MATCHCNT bit field value is 0xFF.	
5:4 (R/W)	PLFSEL	Payload Filtering Selection. The CANFD_PN_CTL1.PLFSEL bit field selects the level of payload filtering to be applied when the CANFD module is under pretended networking mode. Filtering does not accept remote messages (RTR=1) when payload filtering is active.	
		0	Match the payload contents against an exact target value
		1	Match if a payload value is greater than or equal to a specific target value
		2	Match if a payload value is less than or equal to a specific target value
		3	Match if a payload value is inside a range, greater than or equal to a specified lower limit and smaller than or equal a specified upper limit
3:2 (R/W)	IDFSEL	ID Filtering Selection. The CANFD_PN_CTL1.IDFSEL bit field selects the level of ID filtering to be applied when the CANFD module is under pretended networking mode. In ID filtering, if the CANFD_FLTR_ID2_IDMSK.IDE and CANFD_FLTR_ID2_IDMSK.RTR bits are set, the IDE and RTR bits are also considered part of the reception filter.	
		0	Match the ID contents against an exact target value
		1	Match if the ID value is greater than or equal to a specific target value
		2	Match if the ID value is less than or equal to a specific target value
		3	Match if the ID value is inside a range, greater than or equal to a specified lower limit and smaller than or equal a specified upper limit

Table 16-36: CANFD_PN_CTL1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1:0 (R/W)	FCSEL	Filtering Combination Selection. The `CANFD_PN_CTL1.FCSEL` bit field selects elects the filtering criteria to be applied when the CANFD module is in pretended networking mode.	
		0	Message ID filtering only
		1	Message ID filtering and payload filtering
		2	Message ID filtering occurring a specified number of times
		3	Message ID filtering and payload filtering a specified number of times

Control 2 Register

The CANFD_CTL2 register complements CANFD_CTL1, providing control bits for memory write accesses in freeze mode, for extending FIFO filter quantity, and for adjusting the operation of internal CANFD processes like matching and arbitration.

The contents of the CANFD_CTL2 register are not affected by soft reset.

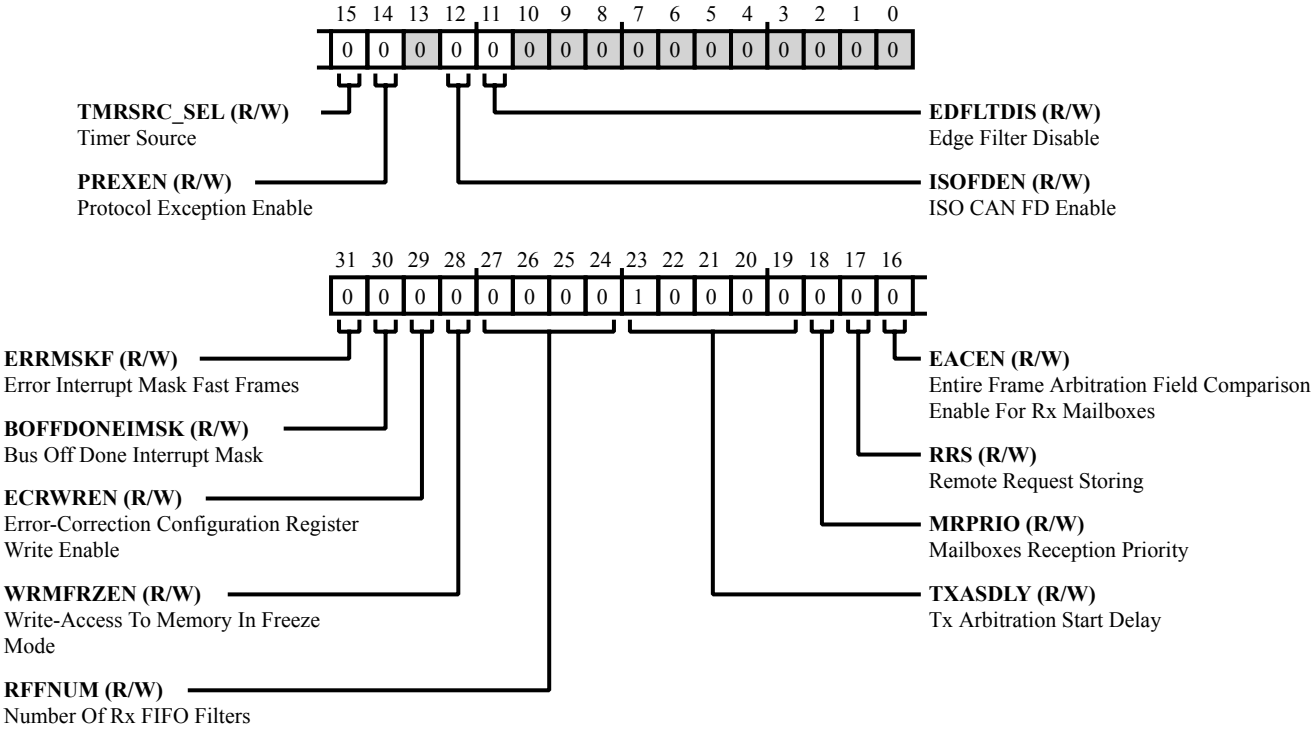

Figure 16-19: CANFD_CTL2 Register Diagram

Table 16-37: CANFD_CTL2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	ERRMSKF	Error Interrupt Mask Fast Frames. The CANFD_CTL2.ERRMSKF bit is the error interrupt mask for errors detected in the data phase of fast CAN FD frames. It provides a mask for the CANFD_ESR1.ERRINTF interrupt. When the CANFD_CTL2.ERRMSKF bit is set, the error interrupt is enabled. When the bit is cleared the error interrupt is disabled.

Table 16-37: CANFD_CTL2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
30 (R/W)	BOFFDONEIMSK	Bus Off Done Interrupt Mask. The CANFD_CTL2.BOFFDONEIMSK bit provides a mask for the bus off done interrupt in the CANFD_ESR1 register. When the CANFD_CTL2.BOFFDONEIMSK bit is set, the bus off done interrupt is enabled. When the bit is cleared the bus off done interrupt is disabled.
29 (R/W)	ECRWREN	Error-Correction Configuration Register Write Enable. The CANFD_CTL2.ECRWREN bit enables the MECR register to be updated. Setting the CANFD_CTL2.ECRWREN bit is set, enables updates. Clearing the bit disables updates. The CANFD_CTL2.ECRWREN bit is automatically set to zero if the protocol described in the Detection and Correction of Memory Errors section of the CANFD chapter is not followed.
28 (R/W)	WRMFRZEN	Write-Access To Memory In Freeze Mode. The CANFD_CTL2.WRMFRZEN bit enables unrestricted write access to the CANFD memory in freeze mode. Clear the CANFD_CTL2.WRMFRZEN bit to maintain the write access restrictions. Set the CANFD_CTL2.WRMFRZEN bit to enable unrestricted write access to the CANFD memory. The CANFD_CTL2.WRMFRZEN bit can only be written in freeze mode and has no effect out of freeze mode. The CANFD_CFG.RFEN bit must not be set during CANFD memory initialization.

Table 16-37: CANFD_CTL2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
27:24 (R/W)	RFFNUM	Number Of Rx FIFO Filters. The CANFD_CTL2.RFFNUM bit field defines the number of Rx FIFO filters. For more details, see the Number of Rx FIFO Filters table in the CANFD chapter. The maximum selectable number of filters is a function of configuration parameter NUMBER_OF_MB. Do not program the CANFD_CTL2.RFFNUM bit field with values that make the number of message buffers occupied by the Rx FIFO and ID Filter exceed the number of mailboxes present, defined by the CANFD_CFG.MAXMB bit field. Each group of eight filters occupies a memory space equivalent to two message buffers, which means that as more filters are implemented fewer mailboxes are available. Considering that the Rx FIFO occupies the memory space originally reserved for MB05, program the CANFD_CTL2.RFFNUM bit with a value corresponding to a number of filters not greater than the number of available memory words. Calculate this as follows: (SETUP_MB - 6) 4 where SETUP_MB is the lower value between parameter NUMBER_OF_MB and register field CANFD_CFG.MAXMB. The number of remaining mailboxes available is (SETUP_MB - 8) - (RFFN 2) If the number of Rx FIFO filters programmed through the CANFD_CTL2.RFFNUM bit field exceeds the SETUP_MB value (memory space available), the exceeding ones are not functional. Note that the number of the last remaining available mailbox is defined by the least value between (NUMBER_OF_MB - 1) and the CANFD_CFG.MAXMB field. If the individual Rx mask registers are not enabled, all Rx FIFO filters are affected by the Rx FIFO global mask. The CANFD_CTL2.RFFNUM bit field can only be written in freeze mode as it is blocked by hardware in other modes.
23:19 (R/W)	TXASDLY	Tx Arbitration Start Delay. The CANFD_CTL2.TXASDLY bit field indicates how many CAN bits the Tx arbitration process start point can be delayed from the first bit of CRC field on the CAN bus. The CANFD_CTL2.TXASDLY bit field can only be written in freeze mode and it is blocked by hardware in other modes.
18 (R/W)	MRPRIO	Mailboxes Reception Priority. The CANFD_CTL2.MRPRIO bit defines the mailboxes reception priority. If the CANFD_CTL2.MRPRIO bit is set, the matching process starts from the mailboxes and if no match occurs the matching continues on the Rx FIFO. If the bit is cleared, matching starts from Rx FIFO and continues on mailboxes. The CANFD_CTL2.MRPRIO bit can only be written only in freeze mode and it is blocked by hardware in other modes.

Table 16-37: CANFD_CTL2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/W)	RRS	Remote Request Storing. If the CANFD_CTL2.RRS bit is set, a remote request frame is submitted to a matching process and stored in the corresponding message buffer in the same fashion of a data frame. No automatic remote response frame is generated. If the CANFD_CTL2.RRS bit is cleared, the remote request frame is submitted to a matching process and an automatic remote response frame is generated if a message buffer with CODE=0b1010 is found with the same ID. The CANFD_CTL2.RRS bit can only be written in freeze mode and it is blocked by hardware in other modes.	
16 (R/W)	EACEN	Entire Frame Arbitration Field Comparison Enable For Rx Mailboxes. The CANFD_CTL2.EACEN bit controls the comparison of IDE and RTR bits within Rx mailboxes filters with their corresponding bits in the incoming frame by the matching process. The CANFD_CTL2.EACEN bit does not affect matching for the Rx FIFO. When the CANFD_CTL2.EACEN bit is set it enables the comparison of both the IDE and RTR bits of an Rx mailbox filter with the corresponding bits of the incoming frame. Mask bits do apply. When the CANFD_CTL2.EACEN bit is cleared the IDE bit of the Rx mailbox filter is always compared and RTR is never compared, regardless of mask bits. EACEN can be only written only in freeze mode and it is blocked by hardware in other modes.	
15 (R/W)	TMRSRC_SEL	Timer Source. The CANFD_CTL2.TMRSRC_SEL bit selects the time tick source used for incrementing the free running timer counter. When the CANFD_CTL2.TMRSRC_SEL bit is set, the free running timer is clocked by an external time tick. The period can be either adjusted to be equal to the baud rate on the CAN bus or a different value as required. When the CANFD_CTL2.TMRSRC_SEL bit is cleared, the free running timer is clocked by the CAN bit clock, which defines the baud rate on the CAN bus. The CANFD_CTL2.TMRSRC_SEL bit can only be written in freeze mode.	
14 (R/W)	PREXEN	Protocol Exception Enable. The CANFD_CTL2.PREXEN bit enables the protocol exception feature. The CANFD_CTL2.PREXEN bit can only be written in freeze mode.	
		0	Disable
		1	Enable

Table 16-37: CANFD_CTL2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W)	ISOFDEN	ISO CAN FD Enable. The `CANFD_CTL2.ISOFDEN` bit controls ISO CAN FD compliant operation. Setting the bit enables ISO CAN FD compliant operation by enabling the following features, which are part of the ISO 11898 standard and not included in the original (Bosch) CAN FD protocol specification: The count of variable stuff bits inserted from the Start of Frame bit to the last bit of Data field. Also, the modulo 8 count of variable stuff bits plus the respective parity bit (even parity calculated over the 3-bit modulo 8 count) are combined as the 4-bit Stuff Count field and inserted before the CRC sequence field. CRC calculation extends beyond the end of data field and takes the stuff count field bits into account. Clearing the `CANFD_CTL2.ISOFDEN` bit disables ISO CAN FD specific features (non-ISO CAN FD operation). The `CANFD_CTL2.ISOFDEN` bit is only writable in freeze mode.	
11 (R/W)	EDFLTDIS	Edge Filter Disable. The `CANFD_CTL2.EDFLTDIS` bit controls the edge filter used during the bus integration state. When the edge filter is enabled, two consecutive nominal time quanta with dominant bus state are required to detect an edge that causes synchronization. When synchronization occurs, the counting of the sequence of eleven consecutive recessive bits is restarted. The edge filter prevents the dominant pulses that are shorter than a nominal bit time (present during the data phase of an FD frame) from being mistaken for an idle condition. The `CANFD_CTL2.EDFLTDIS` bit is only writable in freeze mode.	
		0	Enable
		1	Disable

Pretended Networking Control2 Register

The CANFD_PN_CTL2 register contains configuration bits for the timeout value under pretended networking mode. Only write to this register in freeze mode.

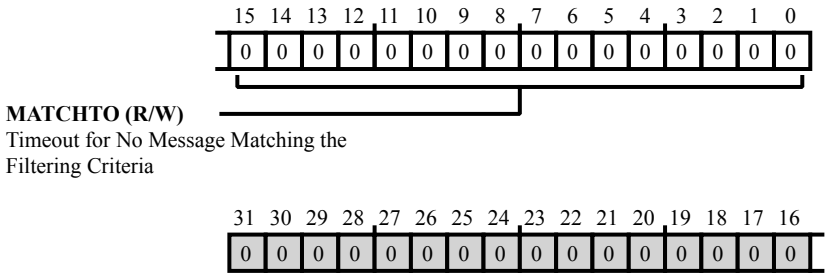

Figure 16-20: CANFD_PN_CTL2 Register Diagram

Table 16-38: CANFD_PN_CTL2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	MATCHTO	Timeout for No Message Matching the Filtering Criteria. The CANFD_PN_CTL2.MATCHTO bit field defines a timeout value that generates a wakeup event when the CANFD_CFG.PNETEN bit is enabled. If the timeout counter reaches the target value when the CANFD module is in pretended networking mode, a wakeup event is generated. The timeout limit value is configured from 1 to 65535 to control an internal 16-bit up-count timer to produce a trigger upon reaching this configured value. The internal timer is incremented based on periodic time ticks, with a period 64 times the CAN bit time unit. When the CANFD_PN_CTL2.MATCHTO bit field is 0x0000, the timeout is disabled.

Error Counter Register

The CANFD_ECR register has four 8-bit fields reflecting the value of the CANFD error counters:

• Transmit error counter (CANFD_ECR.TXERRCNT field)

• Receive error counter (CANFD_ECR.RXERRCNT field)

• Transmit error counter for errors detected in the data phase of CAN FD messages with the BRS bit set (CANFD_ECR.TXERRCNTF field)

• Receive error counter for errors detected in the data phase of CAN FD messages with the BRS bit set (CANFD_ECR.RXERRCNTF field)

The TXERRCNT and RXERRCNT counters take into account all errors in both CAN FD and non-FD message formats. The TXERRCNTF and RXERRCNT_FAST counters only count the errors that occur in the data phase of CAN FD frames with the BRS bit set.

The fault confinement state (CANFD_ESR1.FLTCONF) is only updated based on the TXERRCNT and RXERRCNT counters. The TXERRCNT and RXERRCNT counters can only be written in freeze mode. The TXERRCNTF and RXERRCNT_FAST counters are read-only except in freeze mode, where the processor can write a zero value. The rules for incrementing and decrementing these counters are described in the CAN protocol and are completely implemented in the CANFD module.

The basic rules for the CANFD bus state transitions are as follows:

• If the value of TXERRCNT or RXERRCNT increases to be greater than or equal to 128, the CANFD_ESR1.FLTCONF field updates to reflect the error passive state.

• If the CANFD state is error passive, and either TXERRCNT or RXERRCNT decrements to a value less than or equal to 127 while the other already satisfies this condition, the CANFD_ESR1.FLTCONF field updates to reflect the error active state.

• If the value of TXERRCNT increases to be greater than 255, the CANFD_ESR1.FLTCONF field updates to reflect the bus off state and an interrupt may be issued. The value of TXERRCNT is then reset to zero.

• If the CANFD is in the bus off state, then TXERRCNT is cascaded together with another internal counter to count the 128 occurrences of 11 consecutive recessive bits on the bus. Hence, TXERRCNT is reset to zero and counts in a manner where the internal counter counts 11 such bits and then wraps around while incrementing TXERRCNT. When TXERRCNT reaches the value of 128, the CANFD_ESR1.FLTCONF field is updated to be error active and both error counters are reset to zero. At any instance of dominant bit following a stream of less than 11 consecutive recessive bits, the internal counter resets itself to zero without affecting the TXERRCNT value. The TXERRCNTF counter is frozen during bus off.

• If during system start-up, only one node is operating, then its TXERRCNT increases in each message it is trying to transmit, as a result of acknowledge errors (indicated by the CANFD_ESR1.ACKERR bit). After the transition to the error passive state, TXERRCNT is no longer incremented by acknowledge errors. Therefore, the device never goes to the bus off state.

• If RXERRCNT increases to a value greater than 127, it is not incremented further, even if more errors are detected while being a receiver. At the next successful message reception, the counter is set to a value between 119 and 127 to resume to the error active state.

• The TXERRCNTF and RXERRCNT_FAST error counters values increment and decrement based on errors detected only in the data phase of CAN FD frames with the BRS bit set, following the same increment and decrement rules as the TXERRCNT and RXERRCNT counters. These counters do not wrap around and get stuck at their maximum value (255). They stop counting and keep their values frozen while the CANFD is in the bus off state. They are reset when the CANFD leaves the bus off state and restart counting once the CANFD resumes to the error active state.

• When the CANFD module is in pretended networking mode, RXERRCNT and RXERRCNT_FAST keep counting errors and error flags are stored. TXERRCNT and TXERRCNTF preserve their values and do not change since no transmission occurs under pretended networking mode. Error counters and error flags that changed values while in pretended networking mode are updated in the CANFD_ECR and CANFD_ESR1 registers when the CANFD module resumes normal mode. The FAST error flags in the CANFD_ESR1 register are not set if the CANFD is in pretended networking mode.

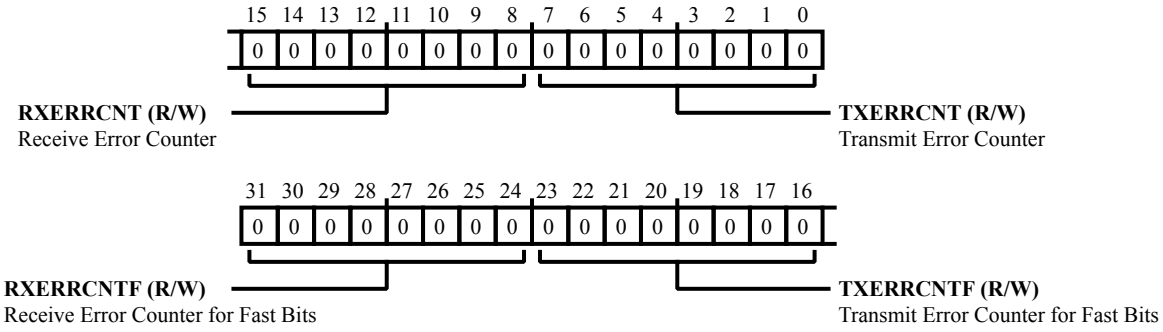

Figure 16-21: CANFD_ECR Register Diagram

Table 16-39: CANFD_ECR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	RXERRCNTF	Receive Error Counter for Fast Bits. The CANFD_ECR.RXERRCNTF bit field is for errors detected in the data phase of received CAN FD messages with the BRS bit set. The CANFD_ECR.RXERRCNTF bit field is read-only except in freeze mode. In freeze mode the processor can only write a 8-bit zero value.
23:16 (R/W)	TXERRCNTF	Transmit Error Counter for Fast Bits. The CANFD_ECR.TXERRCNTF bit field is for errors detected in the data phase of received CAN FD messages with the BRS bit set. The CANFD_ECR.TXERRCNTF bit field is read-only except in freeze mode. In freeze mode the processor can only write a 8-bit zero value.

Table 16-39: CANFD_ECR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15:8 (R/W)	RXERRCNT	Receive Error Counter. The `CANFD_ECR.RXERRCNT` bit field is for all errors detected in received messages. The `CANFD_ECR.RXERRCNT` bit field is read-only except in freeze mode, where the processor can write it.
7:0 (R/W)	TXERRCNT	Transmit Error Counter. The `CANFD_ECR.TXERRCNT` bit field is for all errors detected in transmitted messages. The `CANFD_ECR.TXERRCNT` bit field is read-only except in freeze mode, where the processor can write it.

Error Injection Address Register

The CANFD_ERR_IADDR register holds the address where a memory read error is injected.

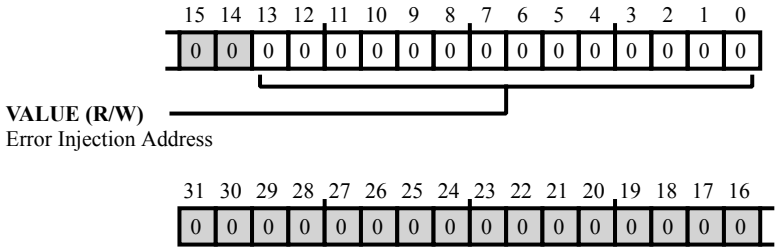

Figure 16-22: CANFD_ERR_IADDR Register Diagram

Table 16-40: CANFD_ERR_IADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
13:0 (R/W)	VALUE	Error Injection Address. The CANFD_ERR_IADDR.VALUE bit field defines the physical RAM address where a memory read error is to be injected. See the Error Injection Address Mapping table in the CANFD chapter for more details. Note that the two least significant bits are always read as zero.

Error Injection Data Pattern Register

The CANFD_ERR_IDP register holds the error pattern injected in the data word that is read from memory.

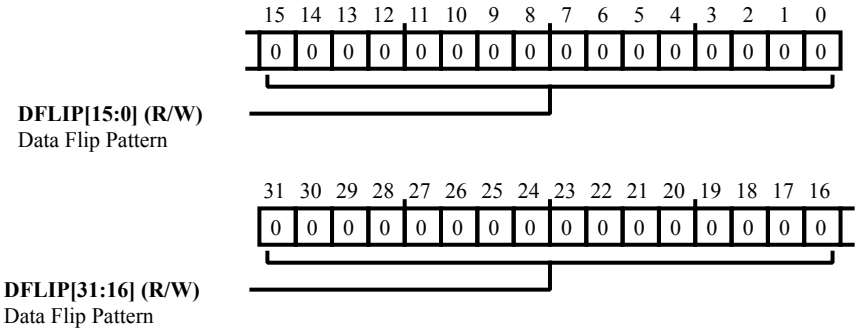

Figure 16-23: CANFD_ERR_IDP Register Diagram

Table 16-41: CANFD_ERR_IDP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	DFLIP	Data Flip Pattern. The CANFD_ERR_IDP.DFLIP bit field determines the data flip pattern. Bits set to one in the flip pattern cause the corresponding data bit in the word read from memory to invert.

Error Injection Parity Pattern Register

The CANFD_ERR_IPP register holds the error pattern that is injected in the parity bits read from memory along with data word. Bits set to one in the flip pattern cause the corresponding parity bit, in the word read from memory, to invert.

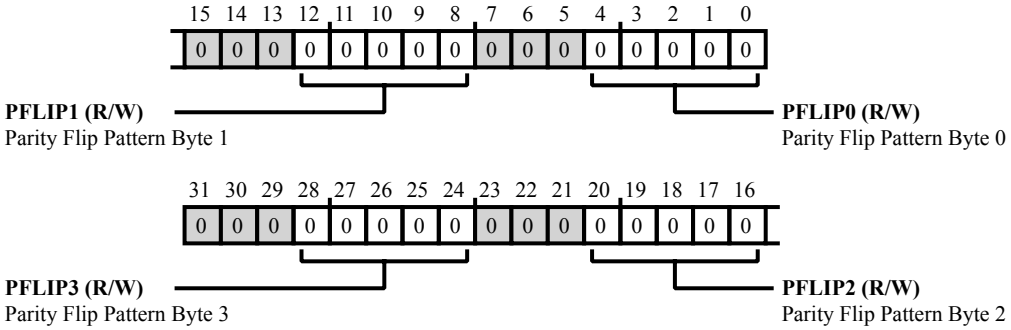

Figure 16-24: CANFD_ERR_IPP Register Diagram

Table 16-42: CANFD_ERR_IPP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
28:24 (R/W)	PFLIP3	Parity Flip Pattern Byte 3. The CANFD_ERR_IPP.PFLIP3 bit field is for the parity flip pattern for byte 3 (most significant).
20:16 (R/W)	PFLIP2	Parity Flip Pattern Byte 2. The CANFD_ERR_IPP.PFLIP2 bit field is for the parity flip pattern for byte 2.
12:8 (R/W)	PFLIP1	Parity Flip Pattern Byte 1. The CANFD_ERR_IPP.PFLIP1 bit field is for the parity flip pattern for byte 1.
4:0 (R/W)	PFLIP0	Parity Flip Pattern Byte 0. The CANFD_ERR_IPP.PFLIP0 bit field is for the parity flip pattern for byte 0 (least significant).

Error Status Register

The CANFD_ERR_STAT register holds the status bits of the error correction and detection operations. Clear these flags by writing them with a one. Writing a zero to the flags has no effect.

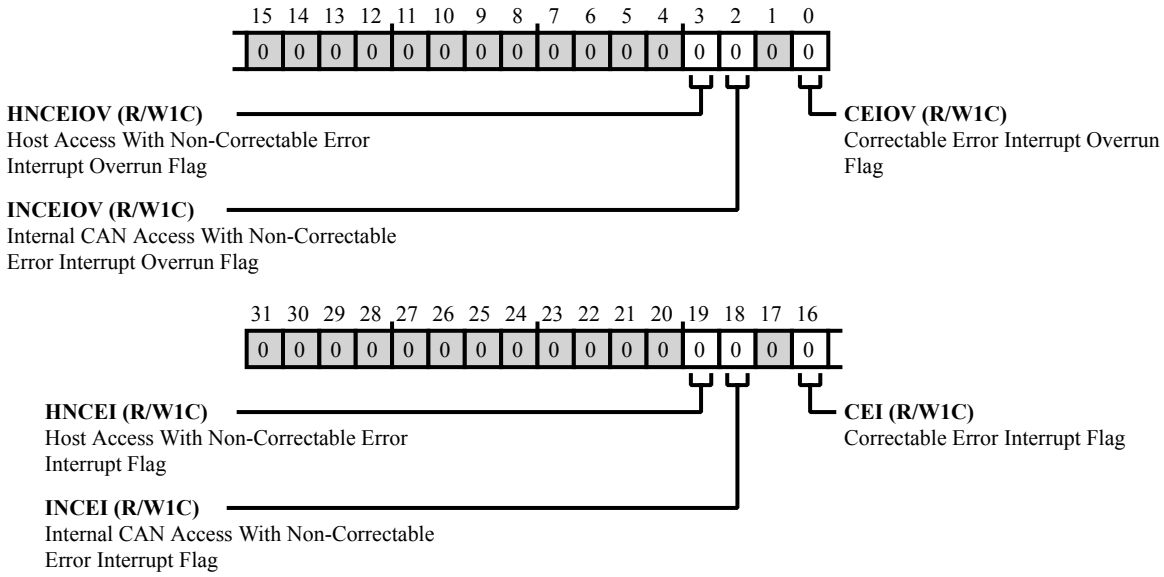

Figure 16-25: CANFD_ERR_STAT Register Diagram

Table 16-43: CANFD_ERR_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
19 (R/W1C)	HNCEI	Host Access With Non-Correctable Error Interrupt Flag. The CANFD_ERR_STAT.HNCEI bit indicates if a non-correctable error is detected in a host access. If the CANFD_ERR_STAT.HNCEI bit is set, a non-correctable error was detected in a memory read initiated by the host. A bus transfer error is asserted for that access. If the CANFD_MEC.HNCIMSK bit is set, the interrupt is asserted. If the CANFD_ERR_STAT.HNCEI bit is cleared, no non-correctable errors were detected in host accesses so far.	
		0	No Non-Correctable Error Detected
		1	Non-Correctable Error Detected

Table 16-43: CANFD_ERR_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
18 (R/W1C)	INCEI	Internal CAN Access With Non-Correctable Error Interrupt Flag. The CANFD_ERR_STAT.INCEI bit indicates if a non-correctable error is detected in a CAN access. If the CANFD_ERR_STAT.INCEI bit is set, a non-correctable error was detected in a memory read initiated by a CANFD internal process. A bus transfer error is asserted for that access. If the CANFD_MEC.INCEMSK bit is set, the interrupt is asserted. If the CANFD_ERR_STAT.INCEI bit is cleared, no non-correctable errors were detected in CAN accesses so far.	
		0	No Non-Correctable Error Detected
		1	Non-Correctable Error Detected
16 (R/W1C)	CEI	Correctable Error Interrupt Flag. The CANFD_ERR_STAT.CEI bit indicates if a correctable error is detected. If the CANFD_ERR_STAT.CEI bit is set, a correctable error was detected in a memory read. If the CANFD_MEC.CEIMSK bit is set, the interrupt is asserted. If the CANFD_ERR_STAT.CEI bit is cleared, no correctable errors were detected so far.	
		0	No Correctable Error Detected
		1	Correctable Error Detected
3 (R/W1C)	HNCEIOV	Host Access With Non-Correctable Error Interrupt Overrun Flag. The CANFD_ERR_STAT.HNCEIOV bit indicates if an overrun on non-correctable error is detected in a host access. If the CANFD_ERR_STAT.HNCEIOV bit is set, a non-correctable error was detected in a memory read initiated by the host when the CANFD_ERR_STAT.HNCEI bit is set. No interrupt is associated with this flag. If the CANFD_ERR_STAT.HNCEIOV bit is cleared, no overrun on non-correctable errors were detected in a host access.	
		0	No Overrun Detected
		1	Overrun Detected

Table 16-43: CANFD_ERR_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W1C)	INCEIOV	Internal CAN Access With Non-Correctable Error Interrupt Overrun Flag. The `CANFD_ERR_STAT.INCEIOV` bit indicates if an overrun on non-correctable error is detected in a CAN access. If the `CANFD_ERR_STAT.INCEIOV` bit is set, a non-correctable error was detected in a memory read initiated by a CANFD internal process when the `CANFD_ERR_STAT.INCEI` bit is set. No interrupt is associated with this flag. If the `CANFD_ERR_STAT.INCEIOV` bit is cleared, no overrun on non-correctable errors were detected in a CAN access.	
		0	No Overrun Detected
		1	Overrun Detected
0 (R/W1C)	CEIOV	Correctable Error Interrupt Overrun Flag. The `CANFD_ERR_STAT.CEIOV` bit indicates if an overrun on correctable errors is detected. If the `CANFD_ERR_STAT.CEIOV` bit is set, a overrun on a correctable error was detected in a memory read while the `CANFD_ERR_STAT.CEI` bit was set. No interrupt is associated with this flag. If the `CANFD_ERR_STAT.CEIOV` bit is cleared, no overrun on correctable errors were detected.	
		0	No Overrun Detected
		1	Overrun Detected

Error and Status 1 Register

The CANFD_ESR1 register reports various error conditions detected in the reception and transmission of a CAN frame, some general status of the device, and is the source of some interrupts to the processor.

The reported error conditions are:

• CANFD_ESR1.B1ERR, CANFD_ESR1.B0ERR, CANFD_ESR1.ACKERR, CANFD_ESR1.CRCERR, CANFD_ESR1.FRMERR, and CANFD_ESR1.STFERR, for errors detected in CAN frames of any format.

• CANFD_ESR1.B1ERRF, CANFD_ESR1.B0ERRF, CANFD_ESR1.CRCERRF, CANFD_ESR1.FRMERRF, and CANFD_ESR1.STFERRF for errors detected in the data phase of CAN FD frames with the BRS bit set.

An error detected in a single CAN frame is reported by one or more error flags. Error reporting is cumulative in case additional error events occur in subsequent frames before the processor reads the CANFD_ESR1 register.

CANFD_ESR1.TXWRN, CANFD_ESR1.RXWRN, CANFD_ESR1.IDLE, CANFD_ESR1.TXINPROG, CANFD_ESR1.FLTCONF, CANFD_ESR1.RXINPROG, and CANFD_ESR1.SYNC are status bits.

CANFD_ESR1.BOFFINT, CANFD_ESR1.BOFFDONEINT, CANFD_ESR1.ERRINT, CANFD_ESR1.ERRINTF, CANFD_ESR1.WAKINT,CANFD_ESR1.TXWRNINT, and CANFD_ESR1.RXWRNINT are interrupt bits. When servicing interrupt requests generated by these bits use the following procedure:

• Read the CANFD_ESR1 register to capture all error condition and status bits. This action clears the respective bits set since the last read access.

• Write 1 to clear the interrupt bit that triggered the interrupt request.

• Write 1 to clear the CANFD_ESR1.ERROVR bit if it is set.

Starting from all error flags cleared, a first error event sets either the CANFD_ESR1.ERRINT or the CANFD_ESR1.ERRINTF bits (provided the corresponding mask bit is asserted). If other error events in subsequent frames occur before the processor services the interrupt request, the CANFD_ESR1.ERROVR bit is set to indicate that errors from different frames have accumulated.

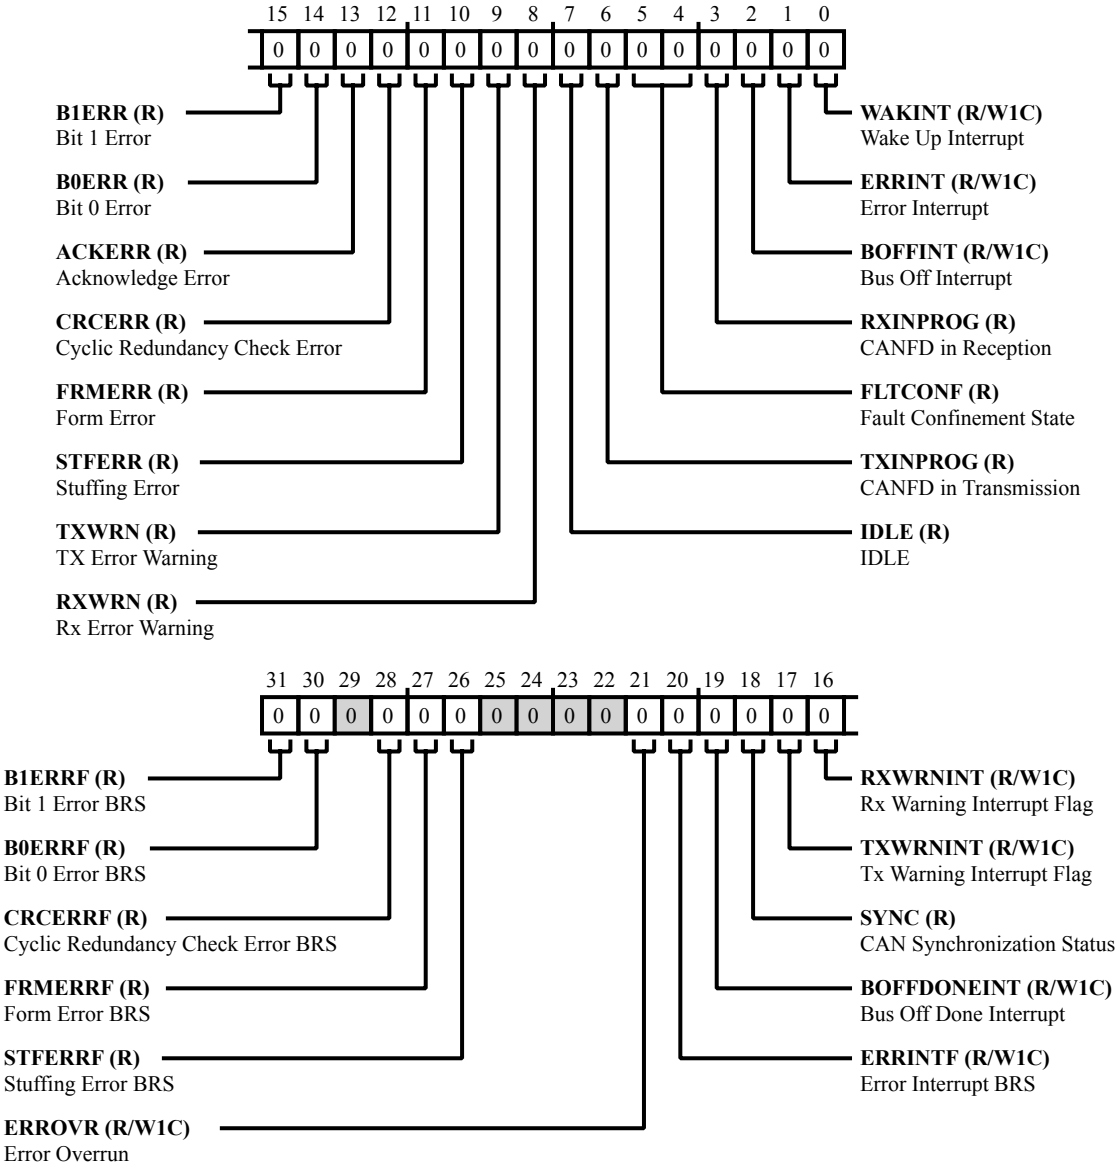

Figure 16-26: CANFD_ESR1 Register Diagram

Table 16-44: CANFD_ESR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/NW)	B1ERRF	Bit 1 Error BRS. The CANFD_ESR1.B1ERRF bit indicates when an inconsistency occurs between the transmitted and the received bit in the data phase of CAN FD frames with the BRS bit set. When the CANFD_ESR1.B1ERRF bit is enabled, at least one bit sent as recessive is received as dominant. When the bit is disabled, there is no such occurrence.	
		0	Disable
		1	Enable
30 (R/NW)	B0ERRF	Bit 0 Error BRS. The CANFD_ESR1.B0ERRF bit indicates when an inconsistency occurs between the transmitted and the received bit in the data phase of CAN FD frames with the BRS bit set. When the CANFD_ESR1.B0ERRF bit is enabled, at least one bit sent as recessive is received as dominant. When the bit is disabled, there is no such occurrence.	
		0	Disable
		1	Enable
28 (R/NW)	CRCERRF	Cyclic Redundancy Check Error BRS. The CANFD_ESR1.CRCERRF bit indicates if a CRC error is detected by the receiver node in the CRC field of CAN FD frames with the BRS bit set. The calculated CRC is different from the received CRC. When the CANFD_ESR1.CRCERRF bit is enabled, a CRC error occurred since the last read of the register. When the bit is disabled, there is no such occurrence.	
		0	Disable
		1	Enable
27 (R/NW)	FRMERRF	Form Error BRS. The CANFD_ESR1.FRMERRF bit indicates that a form error is detected by the receiver node in the data phase of CAN FD frames with the BRS bit set. A fixed-form bit field contains at least one illegal bit. When the CANFD_ESR1.FRMERRF bit is enabled, a form error occurred since the last read of the register. When the bit is disabled, there is no such occurrence.	
		0	Disable
		1	Enable

Table 16-44: CANFD_ESR1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
26 (R/NW)	STFERRF	Stuffing Error BRS. The CANFD_ESR1.STFERRF bit indicates that a stuffing error is detected in the data phase of CAN FD frames with the BRS bit set. When the CANFD_ESR1.STFERRF bit is enabled, a stuffing error occurred since the last read of the register. When the bit is disabled, there is no such occurrence.	
		0	Disable
		1	Enable
21 (R/W1C)	ERROVR	Error Overrun. The CANFD_ESR1.ERROVR bit indicates that an error condition occurred when any error flag is already set. When the CANFD_ESR1.ERROVR bit is enabled an overrun has occurred. When it is disabled, an overrun has not occurred. Clear the CANFD_ESR1.ERROVR bit by writing a one to it.	
		0	Disable
		1	Enable
20 (R/W1C)	ERRINTF	Error Interrupt BRS. The CANFD_ESR1.ERRINTF bit indicates an error interrupt is detected in the data phase of CAN FD frames with the BRS bit set. When the CANFD_ESR1.ERRINTF bit is enabled it indicates setting the of any error bit detected in the data phase of CAN FD frames with the BRS bit set. When it is disabled, there is no such occurrence. The CANFD_ESR1.ERRINTF bit indicates that at least one of the error bits detected in the data phase of CAN FD frames with the BRS bit set (CANFD_ESR1.B1ERRF, CANFD_ESR1.B0ERRF, CANFD_ESR1.CRCERRF, CANFD_ESR1.FRMERRF, or CANFD_ESR1.STFERRF) is set. If the CANFD_CTL2.ERRMSKF is set, an interrupt is generated to the processor. Clear the CANFD_ESR1.ERRINTF bit by writing a one to it. Writing a zero has no effect.	
		0	Disable
		1	Enable

Table 16-44: CANFD_ESR1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
19 (R/W1C)	BOFFDONEINT	Bus Off Done Interrupt. When the CANFD_ESR1.BOFFDONEINT bit is enabled it indicates the CANFD module has completed the bus off process. When it is disabled, there is no such occurrence. The CANFD_ESR1.BOFFDONEINT bit is set when the Tx Error Counter (CANFD_ECR.TXERRCNT) finishes counting 128 occurrences of 11 consecutive recessive bits on the CAN bus and is ready to leave bus off mode. If the CANFD_CTL2.BOFFDONEIMSK is set, an interrupt is generated to the processor. Clear the CANFD_ESR1.BOFFDONEINT bit by writing a one to it. Writing a zero has no effect.	
		0	Disable
		1	Enable
18 (R/NW)	SYNC	CAN Synchronization Status. The CANFD_ESR1.SYNC bit is a read-only flag that indicates whether the CANFD module is synchronized to the CAN bus and able to participate in the communication process. It is set and cleared by the CANFD module. When the CANFD_ESR1.SYNC bit is enabled, the CANFD module is synchronized to the CAN bus. When it is disabled, the CANFD module is not synchronized to the CAN bus.	
		0	Disable
		1	Enable

Table 16-44: CANFD_ESR1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/W1C)	TXWRNINT	Tx Warning Interrupt Flag. When the CANFD_ESR1.TXWRNINT bit is enabled, the Tx error counter transitioned from less than 96 to greater than or equal to 96. When the bit is disabled, there is no such occurrence. If the CANFD_CFG.WRNEN bit is enabled, the CANFD_ESR1.TXWRNINT bit is set when the CANFD_ESR1.TXWRN bit transitions from 0 to 1, meaning that the Tx error counter reached 96. If the CANFD_CTL1.TWRNMSK bit is set, an interrupt is generated to the processor. The CANFD_ESR1.TXWRNINT bit is cleared by writing a one to it. Writing a zero has no effect. When the CANFD_CFG.WRNEN bit is disabled, the CANFD_ESR1.TXWRNINT flag is masked. The processor must clear the CANFD_ESR1.TXWRNINT flag before disabling the CANFD_CFG.WRNEN bit or the CANFD_ESR1.TXWRNINT bit will be set when the CANFD_CFG.WRNEN bit is enabled again. The CANFD_ESR1.TXWRNINT bit is not generated during the bus off state and is not updated during freeze mode. When the CANFD module returns to normal mode from pretended networking mode, the CANFD_ESR1.TXWRNINT bit does not update.	
		0	Disable
		1	Enable
16 (R/W1C)	RXWRNINT	Rx Warning Interrupt Flag. When the CANFD_ESR1.RXWRNINT bit is enabled, it indicates that the Rx error counter transitioned from less than 96 to greater than or equal to 96. When the bit is disabled, there is no such occurrence. If the CANFD_CFG.WRNEN bit is enabled, the CANFD_ESR1.RXWRNINT bit is set when the CANFD_ESR1.RXWRN bit transitions from 0 to 1, meaning that the Rx error counter reached 96. If the CANFD_CTL1.RWRNMSK bit is set, an interrupt is generated to the processor. The CANFD_ESR1.RXWRNINT bit is cleared by writing a one to it. Writing a zero has no effect. When the CANFD_CFG.WRNEN bit is disabled, the CANFD_ESR1.RXWRNINT flag is masked. The processor must clear the CANFD_ESR1.RXWRNINT flag before disabling the CANFD_CFG.WRNEN bit or the CANFD_ESR1.RXWRNINT bit will be set when the CANFD_CFG.WRNEN bit is enabled again. The CANFD_ESR1.RXWRNINT bit is not updated during freeze mode. When the CANFD module returns to normal mode from pretended networking mode, the CANFD_ESR1.RXWRNINT bit does not update to reflect the Rx error counter state.	
		0	Disable
		1	Enable

Table 16-44: CANFD_ESR1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/NW)	B1ERR	Bit 1 Error. The CANFD_ESR1.B1ERR bit indicates when an inconsistency occurs between the transmitted and the received bit in a non-CAN FD message or in the arbitration or data phase of a CAN FD message. When the CANFD_ESR1.B1ERR bit is enabled, at least one bit sent as recessive is received as dominant. When the bit is disabled, there is no such occurrence. The CANFD_ESR1.B1ERR bit updates when the CANFD module returns to normal mode from pretended networking mode. Note that the CANFD_ESR1.B1ERR bit is not set by a transmitter in case of arbitration field or ACK slot, or in case of a node sending a passive error flag that detects dominant bits.	
		0	Disable
		1	Enable
14 (R/NW)	B0ERR	Bit 0 Error. The CANFD_ESR1.B0ERR bit indicates when an inconsistency occurs between the transmitted and the received bit in a non-CAN FD message or in the arbitration or data phase of a CAN FD message. When the CANFD_ESR1.B0ERR bit is enabled, at least one bit sent as recessive is received as dominant. When the bit is disabled, there is no such occurrence. The CANFD_ESR1.B0ERR bit updates when the CANFD module returns to normal mode from pretended networking mode.	
		0	Disable
		1	Enable
13 (R/NW)	ACKERR	Acknowledge Error. The CANFD_ESR1.ACKERR bit indicates an acknowledge error is detected by the transmitter node (a dominant bit detected during the ACK SLOT) When the CANFD_ESR1.ACKERR bit is enabled an ACK error occurred since the last read of this register.When the bit is disabled, there is no such occurrence. The CANFD_ESR1.ACKERR bit updates when the CANFD module returns to normal mode from pretended networking mode.	
		0	Disable
		1	Enable

Table 16-44: CANFD_ESR1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/NW)	CRCERR	Cyclic Redundancy Check Error. The CANFD_ESR1.CRCERR bit indicates if a CRC error is detected by the receiver node in a non-FD message or in the arbitration or data phase of a frame in CAN FD format (the calculated CRC is different from the received CRC) When the CANFD_ESR1.CRCERR bit is enabled, a CRC error occurred since the last read of the register. When the bit is disabled, there is no such occurrence. The CANFD_ESR1.CRCERR bit updates when the CANFD module returns to normal mode from pretended networking mode.	
		0	Disable
		1	Enable
11 (R/NW)	FRMERR	Form Error. The CANFD_ESR1.FRMERR bit indicates that a form error is detected by the receiver node in a non-FD message or in a CAN FD message in the arbitration or data phase. A fixed-form bit field contains at least one illegal bit. When the CANFD_ESR1.FRMERR bit is enabled, a form error occurred since the last read of the register. When the bit is disabled, there is no such occurrence. The CANFD_ESR1.FRMERR bit updates when the CANFD module returns to normal mode from pretended networking mode.	
		0	Disable
		1	Enable
10 (R/NW)	STFERR	Stuffing Error. The CANFD_ESR1.STFERR bit indicates that a stuffing error is detected by the receiver node in a non-FD message or in a CAN FD message in the arbitration or data phase. When the CANFD_ESR1.STFERR bit is enabled, a stuffing error occurred since the last read of the register. When the bit is disabled, there is no such occurrence. The CANFD_ESR1.STFERR bit updates when the CANFD module returns to normal mode from pretended networking mode.	
		0	Disable
		1	Enable

Table 16-44: CANFD_ESR1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/NW)	TXWRN	TX Error Warning. The CANFD_ESR1.TXWRN bit indicates when repetitive errors are occurring during message transmission. When the CANFD_ESR1.TXWRN bit is enabled, the CANFD_ECR.TXERRCNT value is greater than or equal to 96. When it is disabled, there is no such occurrence. The CANFD_ESR1.TXWRN bit is only affected by the CANFD_ECR.TXERRCNT value. It does not update during freeze mode.	
		0	Disable
		1	Enable
8 (R/NW)	RXWRN	Rx Error Warning. The CANFD_ESR1.RXWRN bit indicates when repetitive errors are occurring during message transmission. When the CANFD_ESR1.RXWRN bit is enabled, the CANFD_ECR.TXERRCNT value is greater than or equal to 96. When it is disabled, there is no such occurrence. The CANFD_ESR1.RXWRN bit is only affected by the CANFD_ECR.RXERRCNT value. It does not update during freeze mode. It updates when the CANFD returns to normal mode from pretended networking mode.	
		0	Disable
		1	Enable
7 (R/NW)	IDLE	IDLE. The CANFD_ESR1.IDLE bit indicates when the CAN bus is in the IDLE state. When the CANFD_ESR1.IDLE bit is enabled, the CAN bus is IDLE. When it is disabled, there is no such occurrence.	
		0	Disable
		1	Enable
6 (R/NW)	TXINPROG	CANFD in Transmission. The CANFD_ESR1.TXINPROG bit indicates if the CANFD module is transmitting a message. When the CANFD_ESR1.TXINPROG bit is enabled, the CANFD module is transmitting a message. When it is disabled, the CANFD module is not transmitting a message.	
		0	Disable
		1	Enable

Table 16-44: CANFD_ESR1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5:4 (R/NW)	FLTCONF	Fault Confinement State. The CANFD_ESR1.FLTCONF bit field indicates the fault confinement state of the CANFD module. If the CANFD_CTL1.LOMEN bit is enabled, after some delay that depends on the CAN bit timing, the CANFD_ESR1.FLTCONF bit field will indicate the error passive state. The same delay affects how the CANFD_ESR1.FLTCONF bit field reflects an update to the CANFD_ECR register by the processor. It may take up to one CAN bit time to get them coherent again. The CANFD_ESR1.FLTCONF bit field is affected by soft reset. However, if the CANFD_CTL1.LOMEN bit is enabled, the CANFD_ESR1.FLTCONF reset value lasts just one CAN bit. After this time, the CANFD_ESR1.FLTCONF bit field indicates the error passive state.	
		0	Error Active
		1	Error Passive
		2	Bus Off
		3	Bus Off
3 (R/NW)	RXINPROG	CANFD in Reception. The CANFD_ESR1.RXINPROG bit indicates if the CANFD module is receiving a message. When the CANFD_ESR1.RXINPROG bit is enabled the CANFD module is receiving a message and when it is disabled the CANFD module is not receiving a message.	
		0	Disable
		1	Enable
2 (R/W1C)	BOFFINT	Bus Off Interrupt. The CANFD_ESR1.BOFFINT bit is enabled when the CANFD module enters the bus off state. If the corresponding mask bit (CAN_CTRL1.BOFFMSK) is set, an interrupt is generated to the processor. When the CANFD_ESR1.BOFFINT bit is disabled, there is no such occurrence. The CANFD_ESR1.BOFFINT bit is cleared by writing one to it. Writing zero has no effect.	
		0	Disable
		1	Enable

Table 16-44: CANFD_ESR1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W1C)	ERRINT	Error Interrupt. The CANFD_ESR1.ERRINT bit indicates that at least one of the error bits (CANFD_ESR1.B1ERR, CANFD_ESR1.B0ERR, CANFD_ESR1.CRCERR, CANFD_ESR1.FRMERR, or CANFD_ESR1.STFERR) is set. If the corresponding mask bit (CANFD_CTL1.ERRMSK) is set, an interrupt is generated to the processor. The CANFD_ESR1.ERRINT bit is cleared by writing a one to it. Writing a zero has no effect.	
		0	Disable
		1	Enable
0 (R/W1C)	WAKINT	Wake Up Interrupt. The CANFD_ESR1.WAKINT bit applies when the CANFD module is in low-power mode under a self wake up mechanism (doze or stop mode). When the CANFD_ESR1.WAKINT bit is enabled it indicates a recessive-to-dominant transition was received on the CAN bus. When a recessive-to-dominant transition is detected on the CAN bus and the CANFD_CFG.WAKMSK bit is set, an interrupt is generated to the processor. This bit is cleared by writing it to one. When the bit is disabled, there is no such occurrence. When the CANFD_CFG.SLFWAKEN bit is disabled, the CANFD_ESR1.WAKINT flag is masked. The processor must clear the CANFD_ESR1.WAKINT flag before disabling the CANFD_CFG.SLFWAKEN bit. Otherwise, he CANFD_ESR1.WAKINT is set when the CANFD_CFG.SLFWAKEN bit is set again. Writing zero has no effect. The CANFD_ESR1.WAKINT bit is cleared by writing one to it. Writing zero has no effect.	
		0	Disable
		1	Enable

Error and Status 2 Register

The CANFD_ESR2 register reports general status information.

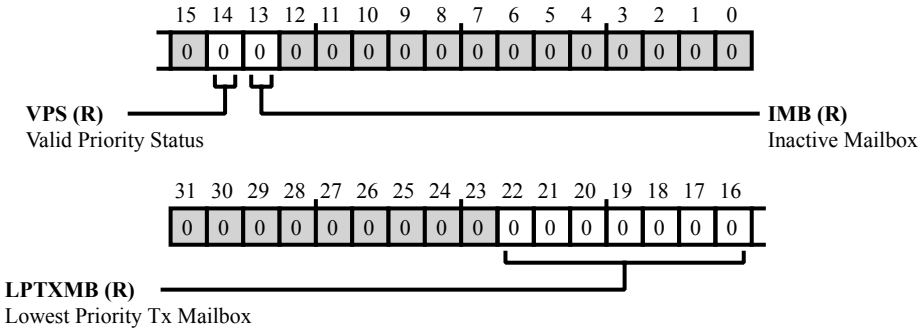

Figure 16-27: CANFD_ESR2 Register Diagram

Table 16-45: CANFD_ESR2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
22:16 (R/NW)	LPTXMB	Lowest Priority Tx Mailbox. If the CANFD_ESR2.VPS bit is set, the CANFD_ESR2.LPTXMB bit field indicates the lowest number inactive mailbox, per the CANFD_ESR2.IMB bit. If there is no inactive mailbox, then the mailbox indicated depends on the CANFD_CTL1.LBUF bit value. If the CANFD_CTL1.LBUF bit bit is cleared, the mailbox indicated is the one that has the greatest arbitration value. If the CANFD_CTL1.LBUF bit bit is set, the mailbox indicated is the highest number active Tx mailbox. If a Tx mailbox is being transmitted, it is not considered in the CANFD_ESR2.LPTXMB bit field calculation. If the CANFD_ESR2.IMB bit is not set and a frame is transmitted successfully, the CANFD_ESR2.LPTXMB bit field is updated with the mailbox number.

Table 16-45: CANFD_ESR2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
14 (R/NW)	VPS	Valid Priority Status. The CANFD_ESR2.VPS bit indicates whether the CANFD_ESR2.IMB and CANFD_ESR2.LPTXMB contents are currently valid. If the CANFD_ESR2.VPS bit is set, the contents of the CANFD_ESR2.IMB and CANFD_ESR2.LPTXMB bits are valid. If the bit is cleared, the contents of the CANFD_ESR2.IMB and CANFD_ESR2.LPTXMB bits are invalid. The CANFD_ESR2.VPS bit is set upon every complete Tx arbitration process unless the processor writes to the C/S word of a mailbox that has already been scanned (is behind Tx Arbitration Pointer during the Tx arbitration process). If there is no inactive mailbox and only one Tx mailbox that is being transmitted, then the CANFD_ESR2.VPS bit is not set. The CANFD_ESR2.VPS bit is cleared upon the start of every Tx arbitration process or upon a write to the C/S word of any mailbox. Note that the CANFD_ESR2.VPS bit is not affected by any processor write into the C/S of a MB that is blocked by the abort mechanism. When the CANFD_CFG.ABORTEN bit is set, the abort code write into the C/S of an MB that is being transmitted (pending abort), or any write attempt into a Tx MB with the interrupt flag set is blocked.
13 (R/NW)	IMB	Inactive Mailbox. If the CANFD_ESR2.VPS bit is set, the CANFD_ESR2.IMB bit indicates whether there is any inactive mailbox (CODE field is either 0b1000 or 0b0000). If the CANFD_ESR2.IMB bit is set and the CANFD_ESR2.VPS bit is set and there is at least one inactive mailbox. The CANFD_ESR2.LPTXMB bit field content is the number of the first one. If the CANFD_ESR2.IMB bit is cleared and the CANFD_ESR2.VPS bit is set, the CANFD_ESR2.LPTXMB bit field is not an inactive mailbox. The CANFD_ESR2.IMB bit is set during arbitration, if a CANFD_ESR2.LPTXMB value is found and it is inactive. The CANFD_ESR2.IMB bit is also set if CAN_ESR2.MB is not set and a frame is transmitted successfully. The CANFD_ESR2.IMB bit is cleared at the start of arbitration. Note that if an MB is successfully transmitted and The CANFD_ESR2.IMB bit is zero (no inactive mailbox), then the CANFD_ESR2.VPS and CANFD_ESR2.IMB bits are set and the index related to the MB just transmitted is loaded into the CANFD_ESR2.LPTXMB bit field.

CANFD Bit Timing Register

The CANFD_FD_TIMING register stores the CAN bit timing variables for use in the data phase of CAN FD messages when the CANFD_FD_CTL.BRSEN bit is set, compatible with CAN FD specification. The CANFD_FD_TIMING.FPRESDIV, CANFD_FD_TIMING.FPROPSEG, CANFD_FD_TIMING.FPSEG1, CANFD_FD_TIMING.FPSEG2, and CANFD_FD_TIMING.FRJW bit fields define the time quantum duration, the number of time quanta per CAN bit, and the sample point position for the data bit rate portion of a CAN FD message with the BRS bit set.

The contents of the CANFD_FD_TIMING register are not affected by soft reset.

Note that the sum of values in the CANFD_FD_TIMING.FPROPSEG and CANFD_FD_TIMING.FPSEG1 bit fields must be at least two time quanta.

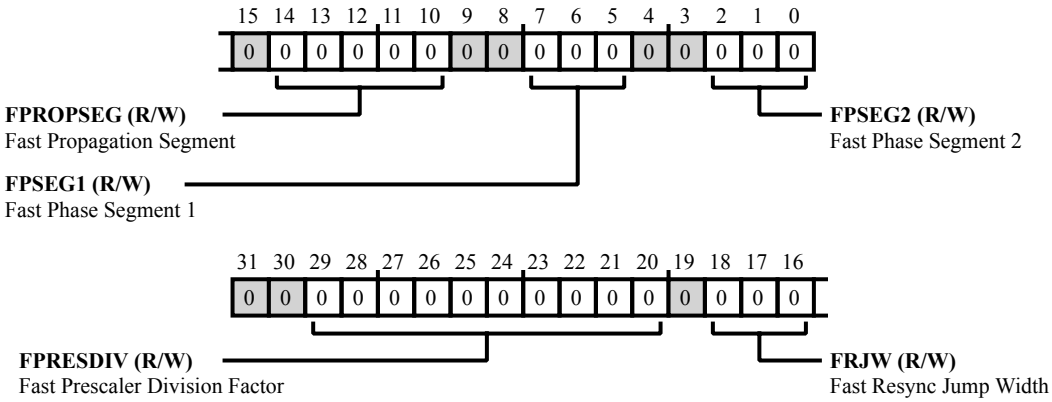

Figure 16-28: CANFD_FD_TIMING Register Diagram

Table 16-46: CANFD_FD_TIMING Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:20 (R/W)	FPRESDIV	Fast Prescaler Division Factor. The CANFD_FD_TIMING.FPRESDIV bit field defines the ratio between the PE clock frequency and the Serial Clock (Sclock) frequency. This is in the data bit rate portion of a CAN FD message with the BRS bit set. The Sclock period defines the time quantum of the CAN FD protocol for the data bit rate. Sclock frequency = PE clock frequency / (FPRESDIV + 1). To minimize errors when processing FD frames, use the same value for the CANFD_FD_TIMING.FPRESDIV and CANFD_CTL1.PRESDIV bit fields The CANFD_FD_TIMING.FPRESDIV bit field can only be written in freeze mode and is blocked by hardware in other modes.

Table 16-46: CANFD_FD_TIMING Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
18:16 (R/W)	FRJW	Fast Resync Jump Width. The `CANFD_FD_TIMING.FRJW` bit field defines the maximum number of time quanta that a bit time can be changed by one re-synchronization. This is in the data bit rate portion of a CAN FD message with the BRS bit set. Resync Jump Width = FSJW + 1. One time quantum is equal to the Sclock period. The `CANFD_FD_TIMING.FRJW` bit field can only be written in freeze mode and is blocked by hardware in other modes.
14:10 (R/W)	FPROPSEG	Fast Propagation Segment. The `CANFD_FD_TIMING.FPROPSEG` bit field defines the length of the propagation segment in the bit time. This is in the data bit rate portion of a CAN FD message with the BRS bit set. Propagation Segment Time = FPROPSEG Time-Quanta One time quantum is equal to the Sclock period. The `CANFD_FD_TIMING.FPROPSEG` bit field can only be written in freeze mode and is blocked by hardware in other modes.
7:5 (R/W)	FPSEG1	Fast Phase Segment 1. The `CANFD_FD_TIMING.FPSEG1` bit field defines the length of phase segment 1 in the bit time. This is in the data bit rate portion of a CAN FD message with the BRS bit set. Phase Segment 1 = (FPSEG1 + 1) Time-Quanta One time quantum is equal to the Sclock period. FPSEG1 can be written only in Freeze mode because it is blocked by hardware in other modes.
2:0 (R/W)	FPSEG2	Fast Phase Segment 2. The `CANFD_FD_TIMING.FPSEG2` bit field defines the length of phase segment 2. This is in the data bit rate portion of a CAN FD message with the BRS bit set. Phase Segment 2 = (FPSEG2 + 1) Time-Quanta One time quantum is equal to the Sclock period. FPSEG1 can be written only in Freeze mode because it is blocked by hardware in other modes.

CANFD CRC Register

The CANFD_FD_CRC register provides information about the CRC of transmitted messages. The CANFD module uses different CRC polynomials for different frame formats as follows:

- The CRC_15 polynomial is used for all frames in CAN format.
- The CRC_17 polynomial is used for frames in CAN FD format with a data field up to sixteen bytes.
- The CRC_21 polynomial is used for frames in CAN FD format with a data field longer than sixteen bytes.

Each polynomial shown below results in a Hamming distance of 6. The CANFD_FD_CRC register updates when the Tx interrupt flag is asserted.

CRC_15 = 0xC599:$(x^{15}+x^{14}+x^{10}+x^{8}+ x^{7}+x^{4}+x^{3}+1)$

CRC_17 = 0x3685B:$(x^{17}+x^{16}+x^{14}+x^{13}+x^{11}+x^{6}+x^{4}+x^{3}+x^{1}+1)$

CRC_21 = 0x302899:$(x^{21}+x^{20}+x^{13}+x^{11}+x^{7}+x^{4}+x^{3}+1)$

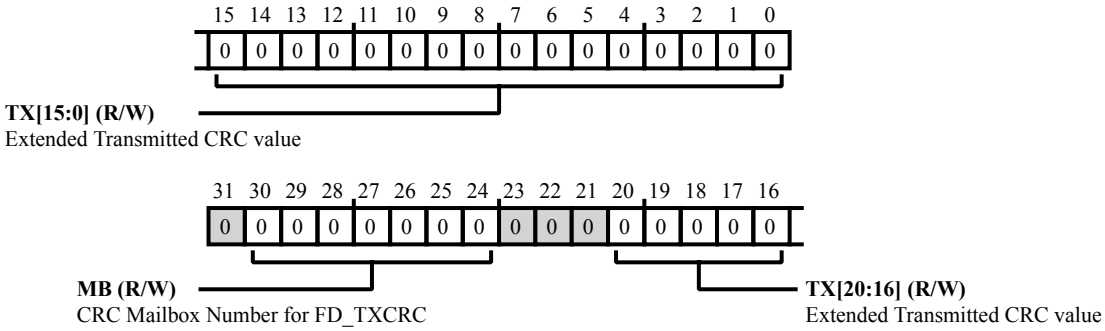

Figure 16-29: CANFD_FD_CRC Register Diagram

Table 16-47: CANFD_FD_CRC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
30:24 (R/W)	MB	CRC Mailbox Number for FD_TXCRC. The CANFD_FD_CRC.MB bit field indicates the number of the mailbox corresponding to the value in the FD_TXCRC field, for both FD and non-FD frames.

Table 16-47: CANFD_FD_CRC Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
20:0 (R/W)	TX	Extended Transmitted CRC value. The `CANFD_FD_CRC.TX` bit field contains the CRC value calculated over the most recent transmitted message. There are different CRC polynomials for different frame formats. All frames in CAN format use a 15-bit polynomial, CRC_15. CRC_17 is for frames in CAN FD format with a data field up to sixteen bytes long. The 21-bit polynomial, CRC_21, is for frames in CAN FD format with a data field longer than sixteen bytes. For CRC_15 and CRC_17, the six most significant bits and the four most significant bits are reported as zeros, respectively. For CRC_15, this register has the same content as the `CANFD_CRC` register.

CANFD Control Register

The CANFD_FD_CTL register contains control bits for CAN FD operation. It also defines the data size of message buffers allocated in different partitions of RAM (memory blocks).

When 8 bytes of payload is selected, block R0 allocates MB0 to MB31 and block R1 allocates MB32 to MB63.

When more than 8 bytes of payload is selected, the maximum number of MBs in a block is limited as described as follows:

Payload Size => Maximum Number of Message Buffers per RAM Block

8 bytes => 32

16 bytes => 21

32 bytes => 12

64 bytes => 7

Note that one memory block fits exactly 32 MBs with 8 bytes payload. For the other options of payload sizes, empty memory may exist between last MB in a block and the beginning of the next block. This empty memory corresponds to less than one MB, and must not be used.

The contents of CANFD_FD_CTL register are not affected by soft reset.

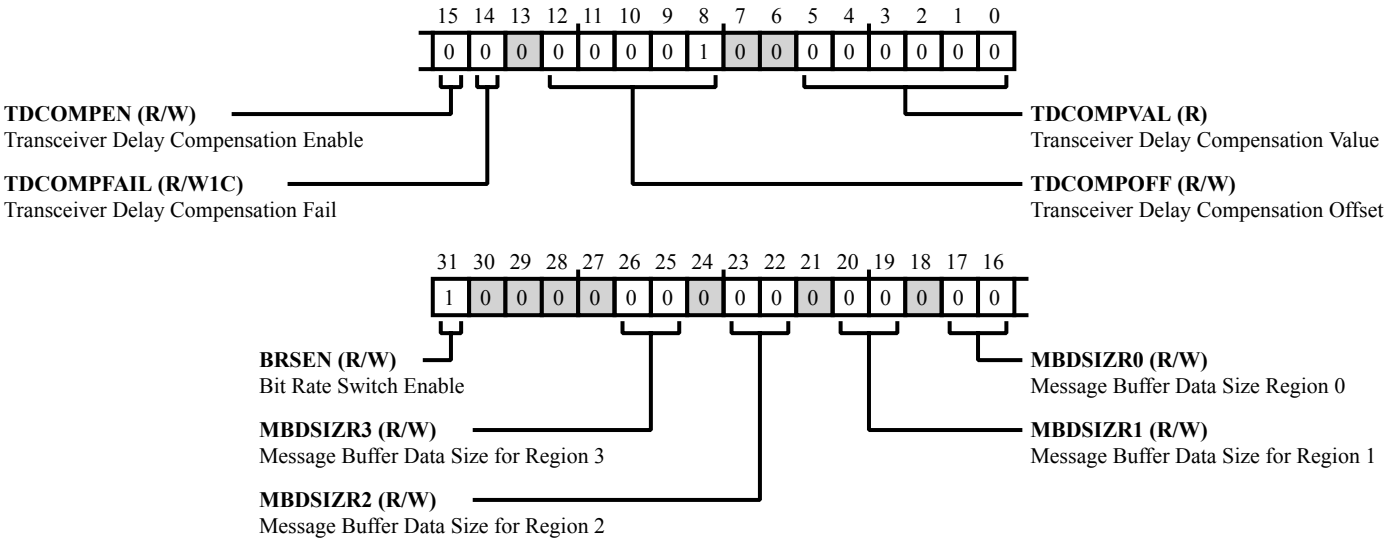

Figure 16-30: CANFD_FD_CTL Register Diagram

Table 16-48: CANFD_FD_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	BRSEN	Bit Rate Switch Enable. The CANFD_FD_CTL.BRSEN bit enables the effect of the bit rate switch (BRS) bit during the data phase of Tx messages. When the CANFD_FD_CTL.BRSEN bit is set, if the BRS bit in the Tx MB is recessive, the CANFD module transmits a frame with bit rate switching. When the CANFD_FD_CTL.BRSEN bit is clear, the BRS bit in the Tx MB has no effect and the CANFD module transmits a frame with the nominal rate. The processor can write the CANFD_FD_CTL.BRSEN bit any time, however, the effect only becomes active when the CAN bus is in the wait for bus idle, bus idle, bus off state, or when the current frame under reception or transmission reaches the inter-frame space. By negating the CANFD_FD_CTL.BRSEN bit, the processor can force all bits in CAN FD messages to be transmitted with a nominal bit rate, despite the value in the BRS bit of the Tx MBs.	
		0	Nominal Rate
		1	Bit Rate Switching
26:25 (R/W)	MBDSIZR3	Message Buffer Data Size for Region 3. The CANFD_FD_CTL.MBDSIZR3 field selects the data size for the region R3 of message buffers allocated in RAM. The CANFD_FD_CTL.MBDSIZR3 bit field can only be written in freeze mode.	
		0	8 bytes per message buffer
		1	16 bytes per message buffer
		2	32 bytes per message buffer
		3	64 bytes per message buffer
23:22 (R/W)	MBDSIZR2	Message Buffer Data Size for Region 2. The CANFD_FD_CTL.MBDSIZR2 field selects the data size for the region R2 of message buffers allocated in RAM. The CANFD_FD_CTL.MBDSIZR2 bit field can only be written in freeze mode.	
		0	8 bytes per message buffer
		1	16 bytes per message buffer
		2	32 bytes per message buffer
		3	64 bytes per message buffer

Table 16-48: CANFD_FD_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
20:19 (R/W)	MBDSIZR1	Message Buffer Data Size for Region 1. The CANFD_FD_CTL.MBDSIZR1 bit field selects the data size for the region R1 of message buffers allocated in RAM. The CANFD_FD_CTL.MBDSIZR1 bit field can only be written in freeze mode.	
		0	8 bytes per message buffer
		1	16 bytes per message buffer
		2	32 bytes per message buffer
		3	64 bytes per message buffer
17:16 (R/W)	MBDSIZR0	Message Buffer Data Size Region 0. The CANFD_FD_CTL.MBDSIZR0 bit field selects the data size for the region R0 of message buffers allocated in RAM. The CANFD_FD_CTL.MBDSIZR0 bit field can only be written in freeze mode.	
		0	8 bytes per message buffer
		1	16 bytes per message buffer
		2	32 bytes per message buffer
		3	64 bytes per message buffer
15 (R/W)	TDCOMPEN	Transceiver Delay Compensation Enable. The CANFD_FD_CTL.TDCOMPEN bit enables or disables the TDC feature. The CANFD_FD_CTL.TDCOMPEN bit can only be written in freeze mode. Note that when loop-back mode is enabled (CANFD_CTL1.LBEN), the CANFD_FD_CTL.TDCOMPEN bit must be disabled.	
		0	Disable
		1	Enable
14 (R/W1C)	TDCOMPFAIL	Transceiver Delay Compensation Fail. The CANFD_FD_CTL.TDCOMPFAIL bit indicates when the transceiver delay compensation (TDC) mechanism is out of range. When the TDC is out of range it is unable to compensate for the loop delay of the transceiver and successfully compare the delayed received bits to the transmitted ones. The CANFD_FD_CTL.TDCOMPFAIL bit is set the first time the CANFD module detects the out of range condition. To clear the CANFD_FD_CTL.TDCOMPFAIL bit, write a one to it.	
		0	Measured loop delay is in range
		1	Measured loop delay is out of range

Table 16-48: CANFD_FD_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
12:8 (R/W)	TDCOMPOFF	Transceiver Delay Compensation Offset. The `CANFD_FD_CTL.TDCOMPOFF` bit field contains the offset value that must be added to the loop delay of the measured transceiver. This defines the position of the delayed comparison point when bit rate switching is active. The `CANFD_FD_CTL.TDCOMPOFF` bit field can only be written in freeze mode. The bit field value is defined in PE clock periods and must be smaller than the CAN bit duration in the data bit rate. Do not set the `CANFD_FD_CTL.TDCOMPOFF` bit field to zero.
5:0 (R/NW)	TDCOMPVAL	Transceiver Delay Compensation Value. The `CANFD_FD_CTL.TDCOMPVAL` bit field contains the value of the transceiver loop delay measured from the transmitted EDL to R0 transition edge to the respective received one added to the value in the `CANFD_FD_CTL.TDCOMPOFF` bit field. This value is an integer multiple of the PE clock period.

Pretended Networking DLC Filter Register

The CANFD_FLTR_DLC register contains the DLC inside range target values (CANFD_FLTR_DLC.HI and CANFD_FLTR_DLC.LO) for filtering incoming messages. The DLC range is only for payload filtering. The CANFD_FLTR_DLC register can only be written in freeze mode.

Note that when a fixed quantity of data bytes is required, both the CANFD_FLTR_DLC.HI and CANFD_FLTR_DLC.LO bit fields must have the same value; otherwise, a range of DLC is considered for filtering.

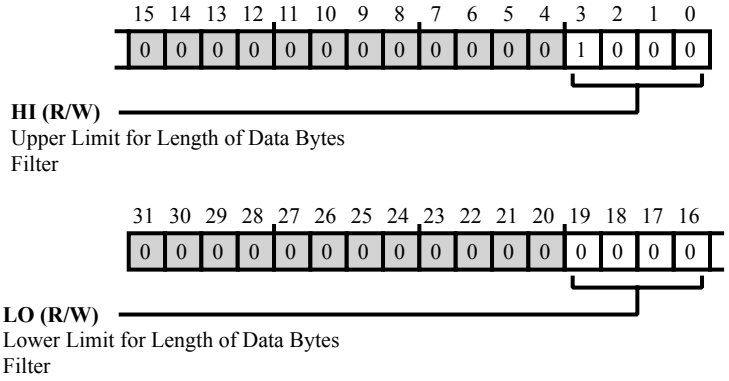

Figure 16-31: CANFD_FLTR_DLC Register Diagram

Table 16-49: CANFD_FLTR_DLC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
19:16 (R/W)	LO	Lower Limit for Length of Data Bytes Filter. The CANFD_FLTR_DLC.LO bit field specifies the lower limit on the number of data bytes considered valid for payload comparison. The CANFD_FLTR_DLC.LO bit field is part of payload reception filter.
3:0 (R/W)	HI	Upper Limit for Length of Data Bytes Filter. The CANFD_FLTR_DLC.HI bit field specifies the upper limit on the number of data bytes considered valid for payload comparison. The CANFD_FLTR_DLC.HI bit field is part of payload reception filter.

Pretended Networking ID Filter1 Register

The CANFD_FLTR_ID1 register contains the FLT_ID1 target value and the IDE and RTR target values for filtering the incoming message ID. This register is for equal to, smaller than, greater than comparisons, or as the lower limit value in an ID range detection. The CANFD_FLTR_ID1 register is only written in freeze mode.

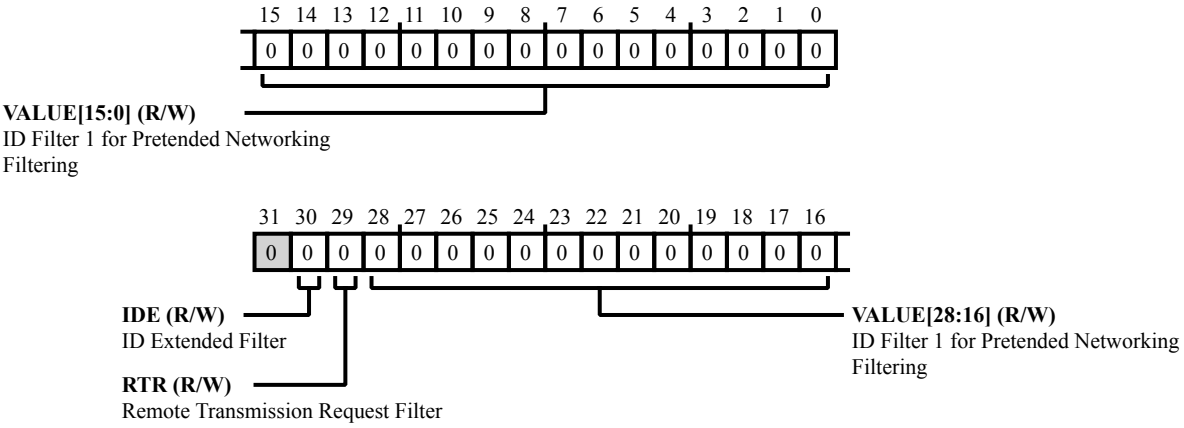

Figure 16-32: CANFD_FLTR_ID1 Register Diagram

Table 16-50: CANFD_FLTR_ID1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
30 (R/W)	IDE	ID Extended Filter. The CANFD_FLTR_ID1.IDE bit identifies if the frame format is standard or extended. It is part of the ID reception filter.	
		0	Accept standard frame format
		1	Accept extended frame format
29 (R/W)	RTR	Remote Transmission Request Filter. The CANFD_FLTR_ID1.RTR bit identifies if the frame is remote. It is part of the ID reception filter.	
		0	Reject remote frame (accept data frame)
		1	Accept remote frame
28:0 (R/W)	VALUE	ID Filter 1 for Pretended Networking Filtering. The CANFD_FLTR_ID1.VALUE bit field defines either the 29 bits of a extended frame format, considering all bits, or the 11 bits of a standard frame format, considering just the 11 leftmost bits.	

Pretended Networking ID Filter2 / IDMask Register

The CANFD_FLTR_ID2_IDMSK register contains the FLT_ID2 target value for use as the upper limit value in ID range detection. When exact ID filtering criteria is selected, the CANFD_FLTR_ID2_IDMSK register is also for storing the ID mask. The CANFD_FLTR_ID2_IDMSK.IDE and CANFD_FLTR_ID2_IDMSK.RTR bits are for ID filtering (exact and range) as part of the ID reception filter.

The CANFD_FLTR_ID2_IDMSK register can only be written in freeze mode.

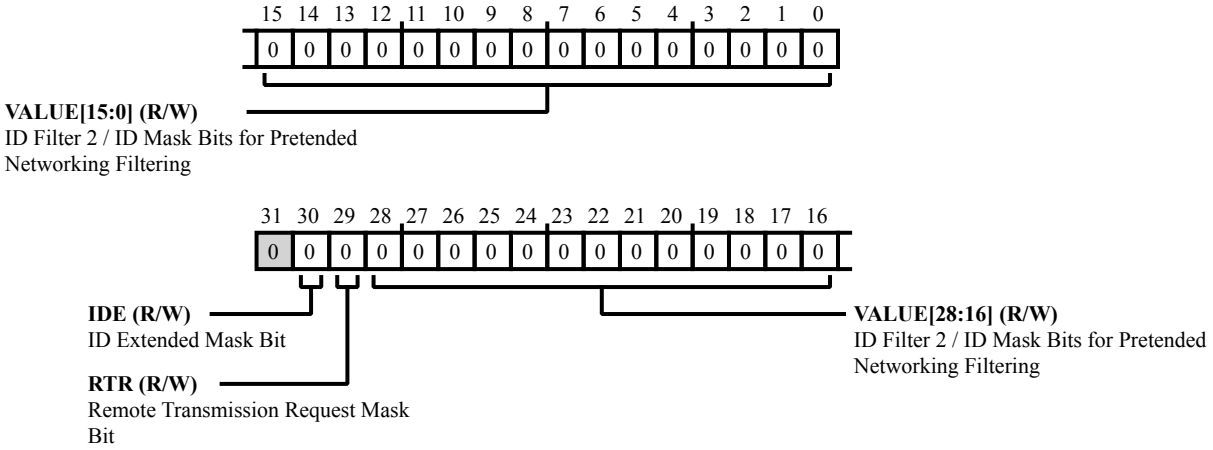

Figure 16-33: CANFD_FLTR_ID2_IDMSK Register Diagram

Table 16-51: CANFD_FLTR_ID2_IDMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
30 (R/W)	IDE	ID Extended Mask Bit. The CANFD_FLTR_ID2_IDMSK.IDE bit indicates whether the frame format (standard/extended) is used as part of the ID reception filter. If the CANFD_FLTR_ID2_IDMSK.IDE bit is set, the corresponding bit in the filter is checked. If it is cleared, the corresponding bit in the filter is a dont care.	
		0	Don't Care
		1	Checked
29 (R/W)	RTR	Remote Transmission Request Mask Bit. The CANFD_FLTR_ID2_IDMSK.RTR bit indicates if the frame type (data/remote) is part of the ID reception filter. If the CANFD_FLTR_ID2_IDMSK.RTR bit is set, the corresponding bit in the filter is checked. If it is cleared, the corresponding bit in the filter is a dont care.	
		0	Don't Care
		1	Checked

Table 16-51: CANFD_FLTR_ID2_IDMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
28:0 (R/W)	VALUE	ID Filter 2 / ID Mask Bits for Pretended Networking Filtering. The `CANFD_FLTR_ID2_IDMSK.VALUE` bit field defines the ID filter value (FLT_ID2). In extended frame format, use all 29 bits (FLT_ID2[28:0]) in the field. In standard frame format, use the upper 11 bits (FLT_ID2[28:18]) and the lower 18 bits (FLT_ID2[17:0]) have no meaning. The `CANFD_FLTR_ID2_IDMSK.VALUE` bit field can also be IDMASK in exact ID filtering to define the mask value. In extended frame format, use all 29 bits (IDMASK[28:0]) in the field. In standard frame format, use the upper 11 bits (IDMASK[28:18]) and the lower 18 bits (IDMASK[17:0]) have no meaning.

Mailbox Interrupt Flag 1 Register

The CANFD_IFLG1 register defines the flags for the 32 message buffer interrupts for MB31 to MB0. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the corresponding bit in the CANFD_IFLG1 register. If the corresponding bit in the CANFD_IMSK1 register is set, an interrupt is generated. The interrupt flag must be cleared by writing a 1 to it. Writing a zero has no effect.

Before updating the CANFD_CFG.MAXMB field, the processor must service the CANFD_IFLG1 bits whose MB value is greater than the CANFD_CFG.MAXMB to be updated; otherwise, they will remain set and be inconsistent with the number of MBs available.

There is an exception is when DMA for Rx FIFO is enabled, as described below.

Rx FIFO:

The BUF7I to BUF5I flags are also used to represent FIFO interrupts when the Rx FIFO is enabled. When the CANFD_CFG.RFEN bit is set and the CANFD_CFG.DMAEN bit is cleared, the function of the 8 least significant interrupt flags changes as follows:

- BUF7I, BUF6I, and BUF5I indicate operating conditions of the FIFO.
- BUF0I is used to empty the FIFO.
- BUF4I to BUF1I are reserved.

Before setting the CANFD_CFG.RFEN bit, the processor must service the IFLAG bits asserted in the Rx FIFO region or these IFLAG bits will mistakenly show the related MBs now belonging to the FIFO as having contents to be serviced. When the CANFD_CFG.RFEN bit is negated, the FIFO flags must be cleared. The same care must be taken when a CANFD_CTL2.RFFNUM value is selected extending Rx FIFO filters beyond MB7. For example, when the CANFD_CTL2.RFFNUM value is 0x8, the MB0–23 range is occupied by Rx FIFO filters and related IFLAG bits must be cleared.

The Rx FIFO must be disabled when the CANFD_CFG.FDEN bit is enabled.

Rx FIFO with DMA:

When both the CANFD_CFG.RFEN bit and the CANFD_CFG.DMAEN bits are set (DMA feature for Rx FIFO enabled), the function of the 8 least significant interrupt flags (BUF7I–BUF0I) are changed to support the DMA operation:

- BUF7I, BUF6I, and BUF4I–BUF1I are not used.
- BUF5I indicates operating condition of FIFO.
- BUF5I does not generate a CPU interrupt, but generates a DMA request.
- BUF0I is used to empty FIFO.

The CANFD_IMSK1 register bits in the Rx FIFO region are not considered when the CANFD_CFG.DMAEN bit is asserted. In addition, the processor must not clear the flag BUF5I when DMA is enabled. Before setting the

CANFD_CFG.DMAEN bit, the processor must service the IFLAGs asserted in the Rx FIFO region. When the CANFD_CFG.DMAEN bit is cleared, the FIFO must be empty.

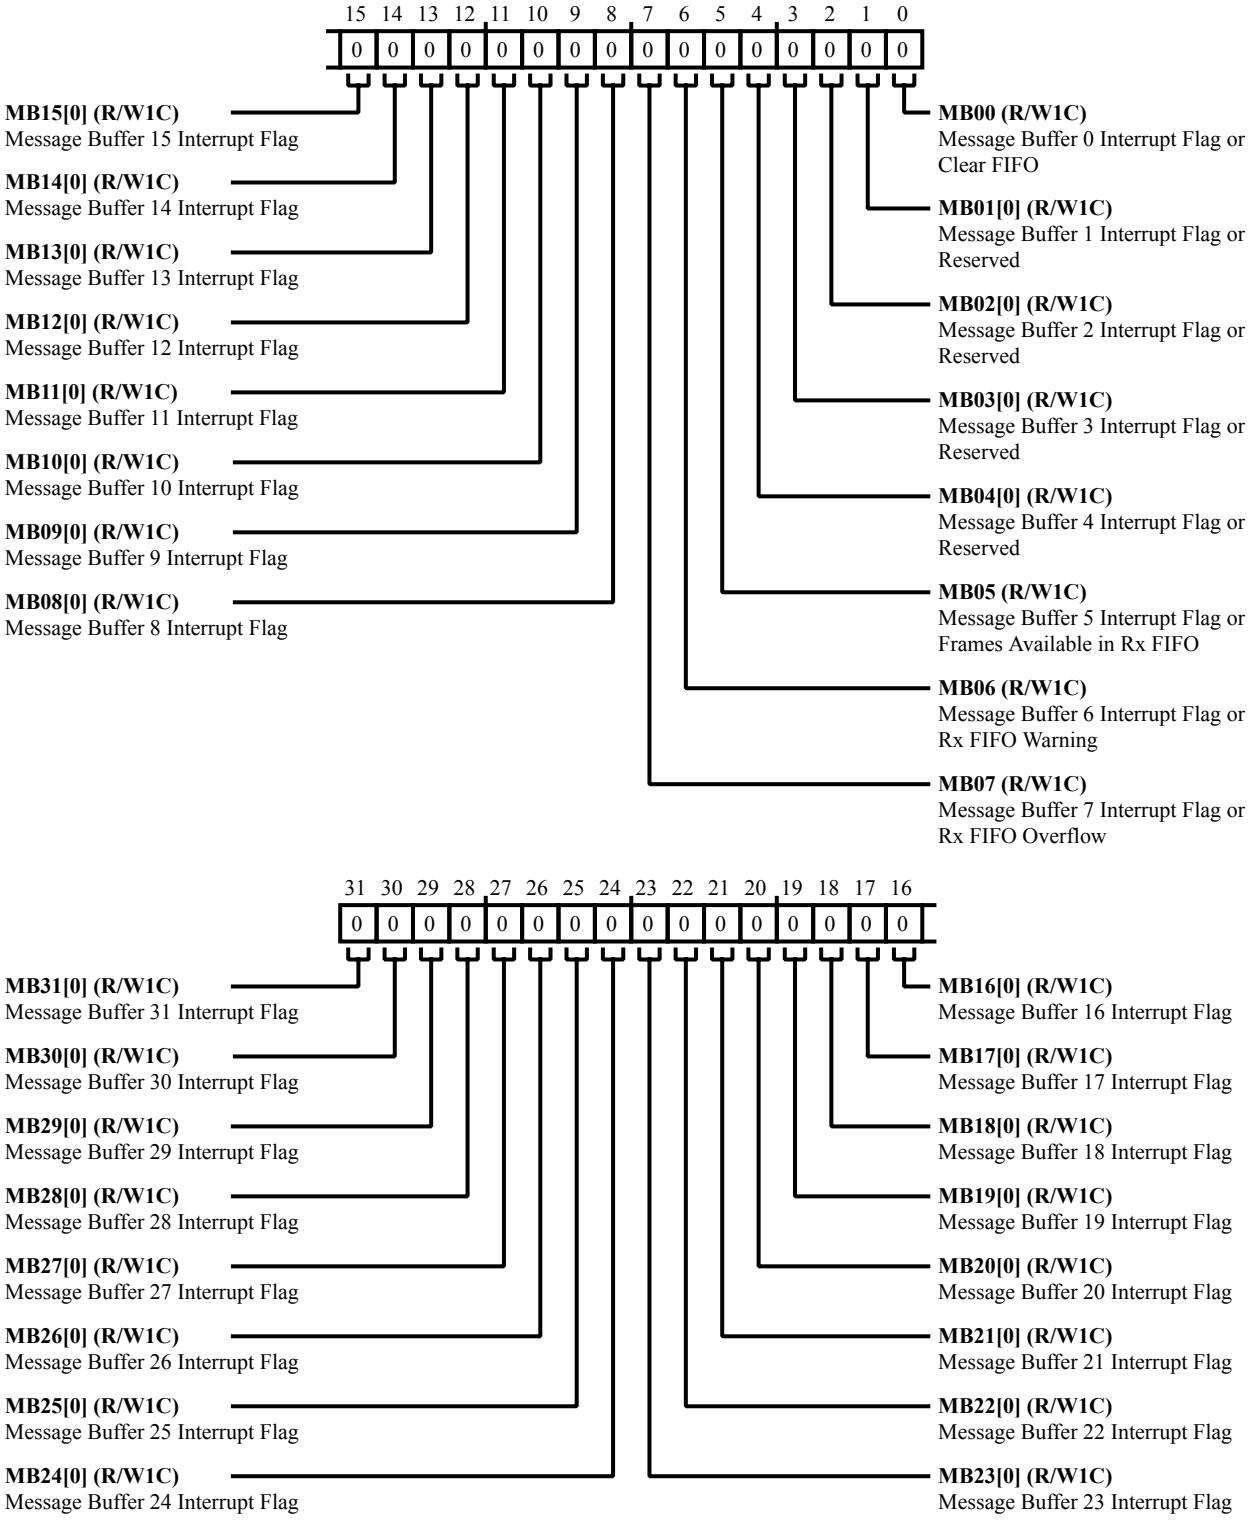

Figure 16-34: CANFD_IFLG1 Register Diagram

Table 16-52: CANFD_IFLG1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W1C)	MB31	Message Buffer 31 Interrupt Flag. The CANFD_IFLG1.MB31 bit flags the CANFD module message buffer interrupt for MB31. When the CANFD_IFLG1.MB31 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception. Only the lower 8 bits are available if parameter NUMBER_OF_MB is 16.
30 (R/W1C)	MB30	Message Buffer 30 Interrupt Flag. The CANFD_IFLG1.MB30 bit flags the CANFD module message buffer interrupt for MB30. When the CANFD_IFLG1.MB30 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception. Only the lower 8 bits are available if parameter NUMBER_OF_MB is 16.
29 (R/W1C)	MB29	Message Buffer 29 Interrupt Flag. The CANFD_IFLG1.MB29 bit flags the CANFD module message buffer interrupt for MB29. When the CANFD_IFLG1.MB29 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception. Only the lower 8 bits are available if parameter NUMBER_OF_MB is 16.
28 (R/W1C)	MB28	Message Buffer 28 Interrupt Flag. The CANFD_IFLG1.MB28 bit flags the CANFD module message buffer interrupt for MB28 When the CANFD_IFLG1.MB28 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception. Only the lower 8 bits are available if parameter NUMBER_OF_MB is 16.
27 (R/W1C)	MB27	Message Buffer 27 Interrupt Flag. The CANFD_IFLG1.MB27 bit flags the CANFD module message buffer interrupt for MB27. When the CANFD_IFLG1.MB27 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception. Only the lower 8 bits are available if parameter NUMBER_OF_MB is 16.

Table 16-52: CANFD_IFLG1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
26 (R/W1C)	MB26	Message Buffer 26 Interrupt Flag. The CANFD_IFLG1.MB26 bit flags the CANFD module message buffer interrupt for MB26. When the CANFD_IFLG1.MB26 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception. Only the lower 8 bits are available if parameter NUMBER_OF_MB is 16.
25 (R/W1C)	MB25	Message Buffer 25 Interrupt Flag. The CANFD_IFLG1.MB25 bit flags the CANFD module message buffer interrupt for MB25. When the CANFD_IFLG1.MB25 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception. Only the lower 8 bits are available if parameter NUMBER_OF_MB is 16.
24 (R/W1C)	MB24	Message Buffer 24 Interrupt Flag. The CANFD_IFLG1.MB24 bit flags the CANFD module message buffer interrupt for MB24. When the CANFD_IFLG1.MB24 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception. Only the lower 8 bits are available if parameter NUMBER_OF_MB is 16.
23 (R/W1C)	MB23	Message Buffer 23 Interrupt Flag. The CANFD_IFLG1.MB23 bit flags the CANFD module message buffer interrupt for MB23. When the CANFD_IFLG1.MB23 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception. Only the lower 8 bits are available if parameter NUMBER_OF_MB is 16.
22 (R/W1C)	MB22	Message Buffer 22 Interrupt Flag. The CANFD_IFLG1.MB22 bit flags the CANFD module message buffer interrupt for MB22. When the CANFD_IFLG1.MB22 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception. Only the lower 8 bits are available if parameter NUMBER_OF_MB is 16.

Table 16-52: CANFD_IFLG1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
21 (R/W1C)	MB21	Message Buffer 21 Interrupt Flag. The CANFD_IFLG1.MB21 bit flags the CANFD module message buffer interrupt for MB21. When the CANFD_IFLG1.MB21 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception. Only the lower 8 bits are available if parameter NUMBER_OF_MB is 16.
20 (R/W1C)	MB20	Message Buffer 20 Interrupt Flag. The CANFD_IFLG1.MB20 bit flags the CANFD module message buffer interrupt for MB20. When the CANFD_IFLG1.MB20 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception. Only the lower 8 bits are available if parameter NUMBER_OF_MB is 16.
19 (R/W1C)	MB19	Message Buffer 19 Interrupt Flag. The CANFD_IFLG1.MB19 bit flags the CANFD module message buffer interrupt for MB19. When the CANFD_IFLG1.MB19 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception. Only the lower 8 bits are available if parameter NUMBER_OF_MB is 16.
18 (R/W1C)	MB18	Message Buffer 18 Interrupt Flag. The CANFD_IFLG1.MB18 bit flags the CANFD module message buffer interrupt for MB18. When the CANFD_IFLG1.MB18 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception. Only the lower 8 bits are available if parameter NUMBER_OF_MB is 16.
17 (R/W1C)	MB17	Message Buffer 17 Interrupt Flag. The CANFD_IFLG1.MB17 bit flags the CANFD module message buffer interrupt for MB17. When the CANFD_IFLG1.MB17 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception. Only the lower 8 bits are available if parameter NUMBER_OF_MB is 16.

Table 16-52: CANFD_IFLG1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
16 (R/W1C)	MB16	Message Buffer 16 Interrupt Flag. The CANFD_IFLG1.MB16 bit flags the CANFD module message buffer interrupt for MB16. When the CANFD_IFLG1.MB16 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception. Only the lower 8 bits are available if parameter NUMBER_OF_MB is 16.
15 (R/W1C)	MB15	Message Buffer 15 Interrupt Flag. The CANFD_IFLG1.MB15 bit flags the CANFD module message buffer interrupt for MB15. When the CANFD_IFLG1.MB15 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception. Only the lower 8 bits are available if parameter NUMBER_OF_MB is 16.
14 (R/W1C)	MB14	Message Buffer 14 Interrupt Flag. The CANFD_IFLG1.MB14 bit flags the CANFD module message buffer interrupt for MB14. When the CANFD_IFLG1.MB14 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception. Only the lower 8 bits are available if parameter NUMBER_OF_MB is 16.
13 (R/W1C)	MB13	Message Buffer 13 Interrupt Flag. The CANFD_IFLG1.MB13 bit flags the CANFD module message buffer interrupt for MB13. When the CANFD_IFLG1.MB13 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception. Only the lower 8 bits are available if parameter NUMBER_OF_MB is 16.
12 (R/W1C)	MB12	Message Buffer 12 Interrupt Flag. The CANFD_IFLG1.MB12 bit flags the CANFD module message buffer interrupt for MB12. When the CANFD_IFLG1.MB12 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception. Only the lower 8 bits are available if parameter NUMBER_OF_MB is 16.

Table 16-52: CANFD_IFLG1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
11 (R/W1C)	MB11	Message Buffer 11 Interrupt Flag. The `CANFD_IFLG1.MB11` bit flags the CANFD module message buffer interrupt for MB11. When the `CANFD_IFLG1.MB11` bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception. Only the lower 8 bits are available if parameter NUMBER_OF_MB is 16.
10 (R/W1C)	MB10	Message Buffer 10 Interrupt Flag. The `CANFD_IFLG1.MB10` bit flags the CANFD module message buffer interrupt for MB10. When the `CANFD_IFLG1.MB10` bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception. Only the lower 8 bits are available if parameter NUMBER_OF_MB is 16.
9 (R/W1C)	MB09	Message Buffer 9 Interrupt Flag. The `CANFD_IFLG1.MB09` bit flags the CANFD module message buffer interrupt for MB09. When the `CANFD_IFLG1.MB09` bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception. Only the lower 8 bits are available if parameter NUMBER_OF_MB is 16.
8 (R/W1C)	MB08	Message Buffer 8 Interrupt Flag. The `CANFD_IFLG1.MB08` bit flags the CANFD module message buffer interrupt for MB08. When the `CANFD_IFLG1.MB08` bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception. Only the lower 8 bits are available if parameter NUMBER_OF_MB is 16.

Table 16-52: CANFD_IFLG1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
7 (R/W1C)	MB07	Message Buffer 7 Interrupt Flag or Rx FIFO Overflow. The CANFD_IFLG1.MB07 bit flags the CANFD module message buffer interrupt for MB7 or Rx FIFO overflow. When the CANFD_IFLG1.MB07 bit is set and CANFD_CFG.RFEN is disabled, MB7 completed transmission or reception. When the CANFD_IFLG1.MB07 bit is set and CANFD_CFG.RFEN is enabled, there is an Rx FIFO overflow. When the CANFD_IFLG1.MB07 bit is cleared and CANFD_CFG.RFEN is disabled, the corresponding buffer has no occurrence of successfully completed transmission or reception.When the CANFD_IFLG1.MB07 bit is cleared and CANFD_CFG.RFEN is enabled, there is no occurrence of Rx FIFO overflow. When the CANFD_CFG.RFEN bit is cleared (Rx FIFO disabled), the CANFD_IFLG1.MB07 bit flags the interrupt for MB7. When the CANFD_CFG.RFEN bit is set (Rx FIFO enabled), the CANFD_IFLG1.MB07 bit represents the Rx FIFO overflow. In this case, the CANFD_IFLG1.MB07 bit indicates that a message was lost because the Rx FIFO is full. Note that the CANFD_IFLG1.MB07 bit is not asserted when the Rx FIFO is full and the message was captured by a mailbox. Note that the CANFD_IFLG1.MB07 bit is cleared by the CANFD module whenever the CANFD_CFG.RFEN bit is changed by a processor write.
6 (R/W1C)	MB06	Message Buffer 6 Interrupt Flag or Rx FIFO Warning. The CANFD_IFLG1.MB06 bit flags the CANFD module message buffer interrupt for MB6 or Rx FIFO warning. When the CANFD_IFLG1.MB06 bit is set and CANFD_CFG.RFEN is disabled, MB6 completed transmission or reception. When the CANFD_IFLG1.MB06 bit is set and CANFD_CFG.RFEN is enabled, the Rx FIFO is almost full. When the CANFD_IFLG1.MB06 bit is cleared and CANFD_CFG.RFEN is disabled, the corresponding buffer has no occurrence of successfully completed transmission or reception.When the CANFD_IFLG1.MB06 bit is cleared and CANFD_CFG.RFEN is enabled, the Rx FIFO is not almost full. When the CANFD_CFG.RFEN bit is cleared (Rx FIFO disabled), the CANFD_IFLG1.MB06 bit flags the interrupt for MB6. When the CANFD_CFG.RFEN bit is set (Rx FIFO enabled), the CANFD_IFLG1.MB06 bit represents the Rx FIFO warning. In this case, BUF6I indicates when the number of unread messages in the Rx FIFO increases from 4 to 5 due to the reception of a new message, meaning that the Rx FIFO is almost full. Note that if the CANFD_IFLG1.MB06 bit is cleared while the number of unread messages is greater than 4, the CANFD_IFLG1.MB06 bit is not asserted again until the number of unread messages in the Rx FIFO decreases to 4 or less. Note that the CANFD_IFLG1.MB06 bit is cleared by the CANFD module whenever the CANFD_CFG.RFEN bit is changed by a processor write.

Table 16-52: CANFD_IFLG1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
5 (R/W1C)	MB05	Message Buffer 5 Interrupt Flag or Frames Available in Rx FIFO. The CANFD_IFLG1.MB05 bit flags the CANFD module message buffer interrupt for MB5 or Rx FIFO frames available. When the CANFD_IFLG1.MB05 bit is set and CANFD_CFG.RFEN is disabled, MB5 completed transmission or reception. When the CANFD_IFLG1.MB05 bit is set and CANFD_CFG.RFEN is enabled, the Rx FIFO has frames available. BUF5I generates a DMA request when both the CANFD_CFG.RFEN and CANFD_CFG.DMAEN bits are set. When the CANFD_IFLG1.MB05 bit is cleared and CANFD_CFG.RFEN is disabled, the corresponding buffer has no occurrence of successfully completed transmission or reception. When the CANFD_IFLG1.MB05 bit is cleared and CANFD_CFG.RFEN is enabled, no frames are available in the Rx FIFO. When the CANFD_CFG.RFEN bit is cleared (Rx FIFO disabled), CANFD_IFLG1.MB05 bit flags the interrupt for MB5. When the CANFD_CFG.RFEN bit is set (Rx FIFO enabled), the CANFD_IFLG1.MB05 bit represents the frames available in the Rx FIFO and indicates that at least one frame is available to be read from the Rx FIFO. When the CANFD_CFG.DMAEN bit is set, the CANFD_IFLG1.MB05 bit generates a DMA request and the processor must not clear the CANFD_IFLG1.MB05 bit by writing one to it. Note that the CANFD_IFLG1.MB05 bit is cleared by the CANFD module whenever the CANFD_CFG.RFEN bit is changed by a processor write.
4 (R/W1C)	MB04	Message Buffer 4 Interrupt Flag or Reserved. The CANFD_IFLG1.MB04 bit flags the interrupt for MB4, when the CANFD_CFG.RFEN bit is cleared (Rx FIFO disabled). When the CANFD_IFLG1.MB04 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception. When the CANFD_CFG.RFEN bit is set (Rx FIFO enabled), the CANFD_IFLG1.MB04 bit is reserved. Note that the CANFD_IFLG1.MB04 bit is cleared by the CANFD module whenever the CANFD_CFG.RFEN bit is changed by a processor write.

Table 16-52: CANFD_IFLG1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
3 (R/W1C)	MB03	Message Buffer 3 Interrupt Flag or Reserved. The CANFD_IFLG1.MB03 bit flags the interrupt for MB3, when the CANFD_CFG.RFEN bit is cleared (Rx FIFO disabled). When the CANFD_IFLG1.MB03 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception. When the CANFD_CFG.RFEN bit is set (Rx FIFO enabled), the CANFD_IFLG1.MB03 bit is reserved. Note that the CANFD_IFLG1.MB03 bit is cleared by the CANFD module whenever the CANFD_CFG.RFEN bit is changed by a processor write.
2 (R/W1C)	MB02	Message Buffer 2 Interrupt Flag or Reserved. The CANFD_IFLG1.MB02 bit flags the interrupt for MB2, when the CANFD_CFG.RFEN bit is cleared (Rx FIFO disabled). When the CANFD_IFLG1.MB02 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception. When the CANFD_CFG.RFEN bit is set (Rx FIFO enabled), the CANFD_IFLG1.MB02 bit is reserved. Note that the CANFD_IFLG1.MB02 bit is cleared by the CANFD module whenever the CANFD_CFG.RFEN bit is changed by a processor write.
1 (R/W1C)	MB01	Message Buffer 1 Interrupt Flag or Reserved. The CANFD_IFLG1.MB01 bit flags the interrupt for MB1, when the CANFD_CFG.RFEN bit is cleared (Rx FIFO disabled). When the CANFD_IFLG1.MB01 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception. When the CANFD_CFG.RFEN bit is set (Rx FIFO enabled), the CANFD_IFLG1.MB01 bit is reserved. Note that the CANFD_IFLG1.MB01 bit is cleared by the CANFD module whenever the CANFD_CFG.RFEN bit is changed by a processor write.

Table 16-52: CANFD_IFLG1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
0 (R/W1C)	MB00	Message Buffer 0 Interrupt Flag or Clear FIFO. The CANFD_IFLG1.MB00 bit flags the interrupt for MB0, when the CANFD_CFG.RFEN bit is cleared (Rx FIFO disabled). When the CANFD_IFLG1.MB00 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception. When the CANFD_CFG.RFEN bit is set (Rx FIFO enabled), the CANFD_IFLG1.MB00 bit triggers the clear FIFO operation. This operation empties FIFO contents. Before performing this operation, the processor must service all FIFO related IFLAGs. When the CANFD_CFG.DMAEN bit is set (DMA is enabled), this operation also clears the CANFD_IFLG1.MB05 flag and consequently aborts the DMA request. The clear FIFO operation occurs when the processor writes a one to the CANFD_IFLG1.MB00 bit, which is only allowed in freeze mode and is blocked by hardware in other conditions.

Mailbox Interrupt Flag 2 Register

The CANFD_IFLG2 register defines the flags for the 32 message buffer interrupts for MB63 to MB32. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the respective bit in the CANFD_IFLG2 bit. If the corresponding bit is set, an interrupt is generated. The interrupt flag must be cleared by writing 1 to it. Writing 0 has no effect.

Before updating the CANFD_CFG.MAXMB field, the processor must service the CANFD_IFLG2 bits whose MB value is greater than the CANFD_CFG.MAXMB to be updated; otherwise, they will remain set and be inconsistent with the number of MBs available.

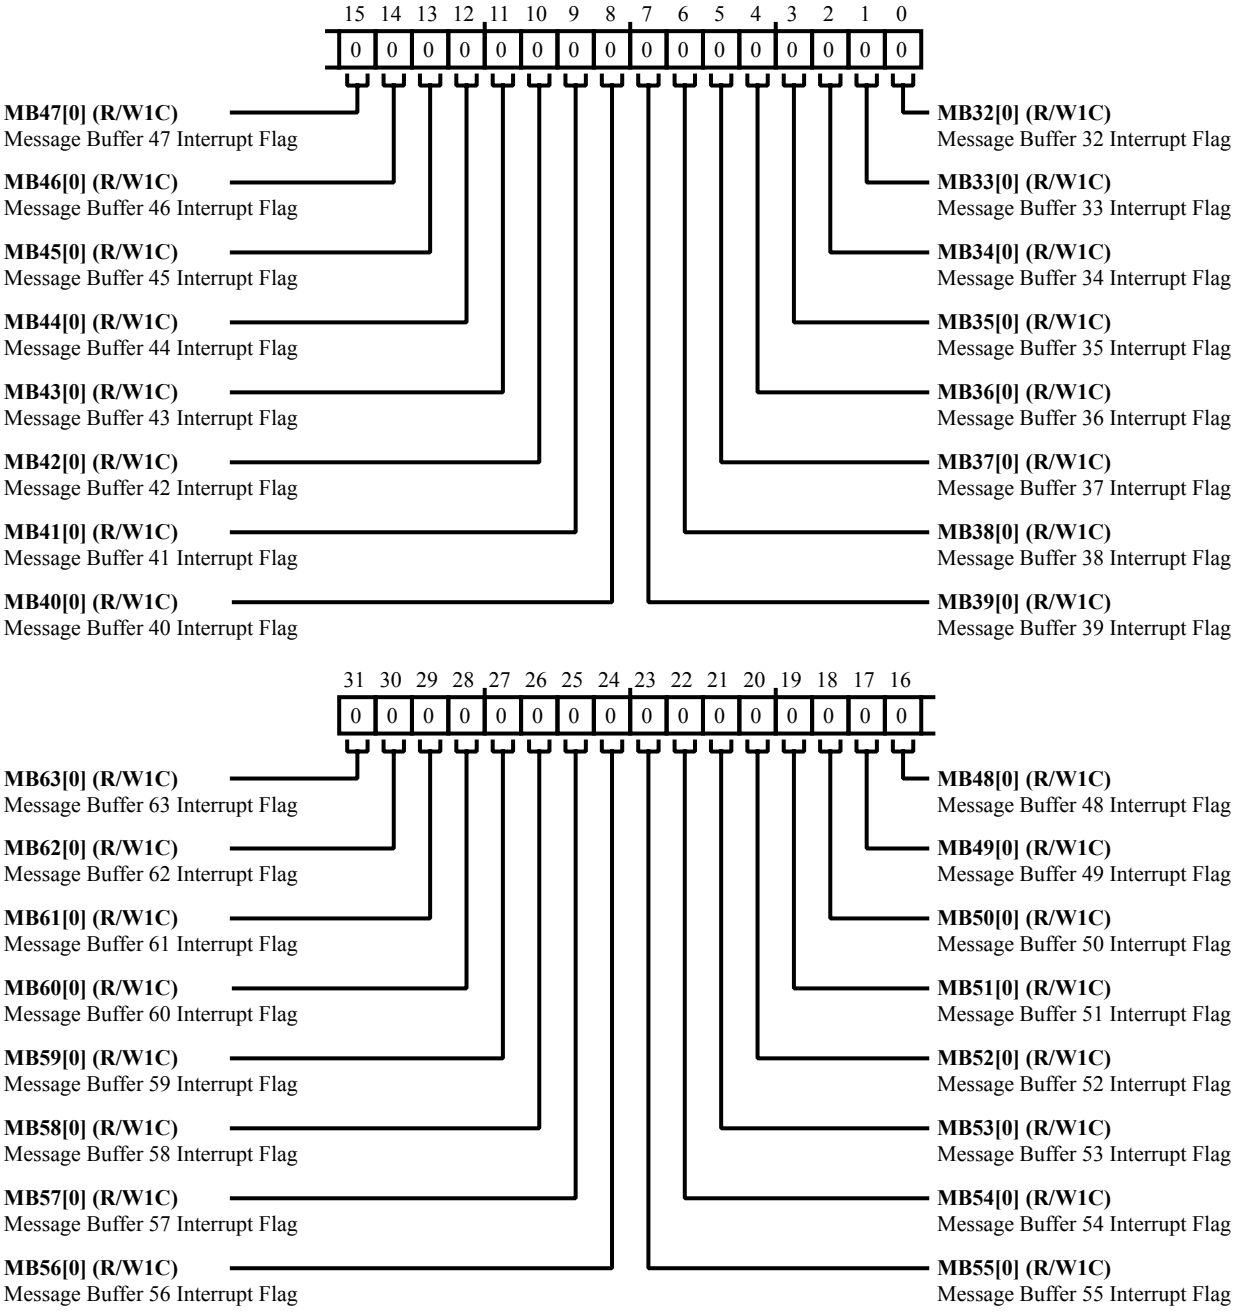

Figure 16-35: CANFD_IFLG2 Register Diagram

Table 16-53: CANFD_IFLG2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W1C)	MB63	Message Buffer 63 Interrupt Flag. The CANFD_IFLG2.MB63 bit flags the CANFD module message buffer interrupt for MB63. When the CANFD_IFLG2.MB63 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.
30 (R/W1C)	MB62	Message Buffer 62 Interrupt Flag. The CANFD_IFLG2.MB62 bit flags the CANFD module message buffer interrupt for MB62. When the CANFD_IFLG2.MB62 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.
29 (R/W1C)	MB61	Message Buffer 61 Interrupt Flag. The CANFD_IFLG2.MB61 bit flags the CANFD module message buffer interrupt for MB61. When the CANFD_IFLG2.MB61 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.
28 (R/W1C)	MB60	Message Buffer 60 Interrupt Flag. The CANFD_IFLG2.MB60 bit flags the CANFD module message buffer interrupt for MB60. When the CANFD_IFLG2.MB60 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.
27 (R/W1C)	MB59	Message Buffer 59 Interrupt Flag. The CANFD_IFLG2.MB59 bit flags the CANFD module message buffer interrupt for MB59. When the CANFD_IFLG2.MB59 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.
26 (R/W1C)	MB58	Message Buffer 58 Interrupt Flag. The CANFD_IFLG2.MB58 bit flags the CANFD module message buffer interrupt for MB58. When the CANFD_IFLG2.MB58 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.

Table 16-53: CANFD_IFLG2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
25 (R/W1C)	MB57	Message Buffer 57 Interrupt Flag. The CANFD_IFLG2.MB57 bit flags the CANFD module message buffer interrupt for MB57. When the CANFD_IFLG2.MB57 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.
24 (R/W1C)	MB56	Message Buffer 56 Interrupt Flag. The CANFD_IFLG2.MB56 bit flags the CANFD module message buffer interrupt for MB56. When the CANFD_IFLG2.MB56 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.
23 (R/W1C)	MB55	Message Buffer 55 Interrupt Flag. The CANFD_IFLG2.MB55 bit flags the CANFD module message buffer interrupt for MB55. When the CANFD_IFLG2.MB55 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.
22 (R/W1C)	MB54	Message Buffer 54 Interrupt Flag. The CANFD_IFLG2.MB54 bit flags the CANFD module message buffer interrupt for MB54. When the CANFD_IFLG2.MB54 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.
21 (R/W1C)	MB53	Message Buffer 53 Interrupt Flag. The CANFD_IFLG2.MB53 bit flags the CANFD module message buffer interrupt for MB53. When the CANFD_IFLG2.MB53 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.
20 (R/W1C)	MB52	Message Buffer 52 Interrupt Flag. The CANFD_IFLG2.MB52 bit flags the CANFD module message buffer interrupt for MB52. When the CANFD_IFLG2.MB52 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.

Table 16-53: CANFD_IFLG2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
19 (R/W1C)	MB51	Message Buffer 51 Interrupt Flag. The CANFD_IFLG2.MB51 bit flags the CANFD module message buffer interrupt for MB51. When the CANFD_IFLG2.MB51 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.
18 (R/W1C)	MB50	Message Buffer 50 Interrupt Flag. The CANFD_IFLG2.MB50 bit flags the CANFD module message buffer interrupt for MB50. When the CANFD_IFLG2.MB50 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.
17 (R/W1C)	MB49	Message Buffer 49 Interrupt Flag. The CANFD_IFLG2.MB49 bit flags the CANFD module message buffer interrupt for MB49. When the CANFD_IFLG2.MB49 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.
16 (R/W1C)	MB48	Message Buffer 48 Interrupt Flag. The CANFD_IFLG2.MB48 bit flags the CANFD module message buffer interrupt for MB48. When the CANFD_IFLG2.MB48 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.
15 (R/W1C)	MB47	Message Buffer 47 Interrupt Flag. The CANFD_IFLG2.MB47 bit flags the CANFD module message buffer interrupt for MB47. When the CANFD_IFLG2.MB47 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.
14 (R/W1C)	MB46	Message Buffer 46 Interrupt Flag. The CANFD_IFLG2.MB46 bit flags the CANFD module message buffer interrupt for MB46. When the CANFD_IFLG2.MB46 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.

Table 16-53: CANFD_IFLG2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
13 (R/W1C)	MB45	Message Buffer 45 Interrupt Flag. The CANFD_IFLG2.MB45 bit flags the CANFD module message buffer interrupt for MB45. When the CANFD_IFLG2.MB45 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.
12 (R/W1C)	MB44	Message Buffer 44 Interrupt Flag. The CANFD_IFLG2.MB44 bit flags the CANFD module message buffer interrupt for MB44. When the CANFD_IFLG2.MB44 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.
11 (R/W1C)	MB43	Message Buffer 43 Interrupt Flag. The CANFD_IFLG2.MB43 bit flags the CANFD module message buffer interrupt for MB43. When the CANFD_IFLG2.MB43 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.
10 (R/W1C)	MB42	Message Buffer 42 Interrupt Flag. The CANFD_IFLG2.MB42 bit flags the CANFD module message buffer interrupt for MB42. When the CANFD_IFLG2.MB42 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.
9 (R/W1C)	MB41	Message Buffer 41 Interrupt Flag. The CANFD_IFLG2.MB41 bit flags the CANFD module message buffer interrupt for MB41. When the CANFD_IFLG2.MB41 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.
8 (R/W1C)	MB40	Message Buffer 40 Interrupt Flag. The CANFD_IFLG2.MB40 bit flags the CANFD module message buffer interrupt for MB40. When the CANFD_IFLG2.MB40 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.

Table 16-53: CANFD_IFLG2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
7 (R/W1C)	MB39	Message Buffer 39 Interrupt Flag. The CANFD_IFLG2.MB39 bit flags the CANFD module message buffer interrupt for MB39. When the CANFD_IFLG2.MB39 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.
6 (R/W1C)	MB38	Message Buffer 38 Interrupt Flag. The CANFD_IFLG2.MB38 bit flags the CANFD module message buffer interrupt for MB38. When the CANFD_IFLG2.MB38 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.
5 (R/W1C)	MB37	Message Buffer 37 Interrupt Flag. The CANFD_IFLG2.MB37 bit flags the CANFD module message buffer interrupt for MB37. When the CANFD_IFLG2.MB37 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.
4 (R/W1C)	MB36	Message Buffer 36 Interrupt Flag. The CANFD_IFLG2.MB36 bit flags the CANFD module message buffer interrupt for MB36. When the CANFD_IFLG2.MB36 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.
3 (R/W1C)	MB35	Message Buffer 35 Interrupt Flag. The CANFD_IFLG2.MB35 bit flags the CANFD module message buffer interrupt for MB35. When the CANFD_IFLG2.MB35 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.
2 (R/W1C)	MB34	Message Buffer 34 Interrupt Flag. The CANFD_IFLG2.MB34 bit flags the CANFD module message buffer interrupt for MB34. When the CANFD_IFLG2.MB34 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.

Table 16-53: CANFD_IFLG2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
1 (R/W1C)	MB33	Message Buffer 33 Interrupt Flag. The `CANFD_IFLG2.MB33` bit flags the CANFD module message buffer interrupt for MB33. When the `CANFD_IFLG2.MB33` bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.
0 (R/W1C)	MB32	Message Buffer 32 Interrupt Flag. The `CANFD_IFLG2.MB32` bit flags the CANFD module message buffer interrupt for MB32. When the `CANFD_IFLG2.MB32` bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception.

Mailbox Interrupt Mask 1 Register

The CANFD_IMSK1 register allows any number of the 32 message buffer interrupts to be enabled or disabled for MB31 to MB. The CANFD_IMSK1 register contains one interrupt mask bit per buffer, enabling the CPU to determine which buffer generates an interrupt after a successful transmission or reception (as indicated by the corresponding bit in the register).

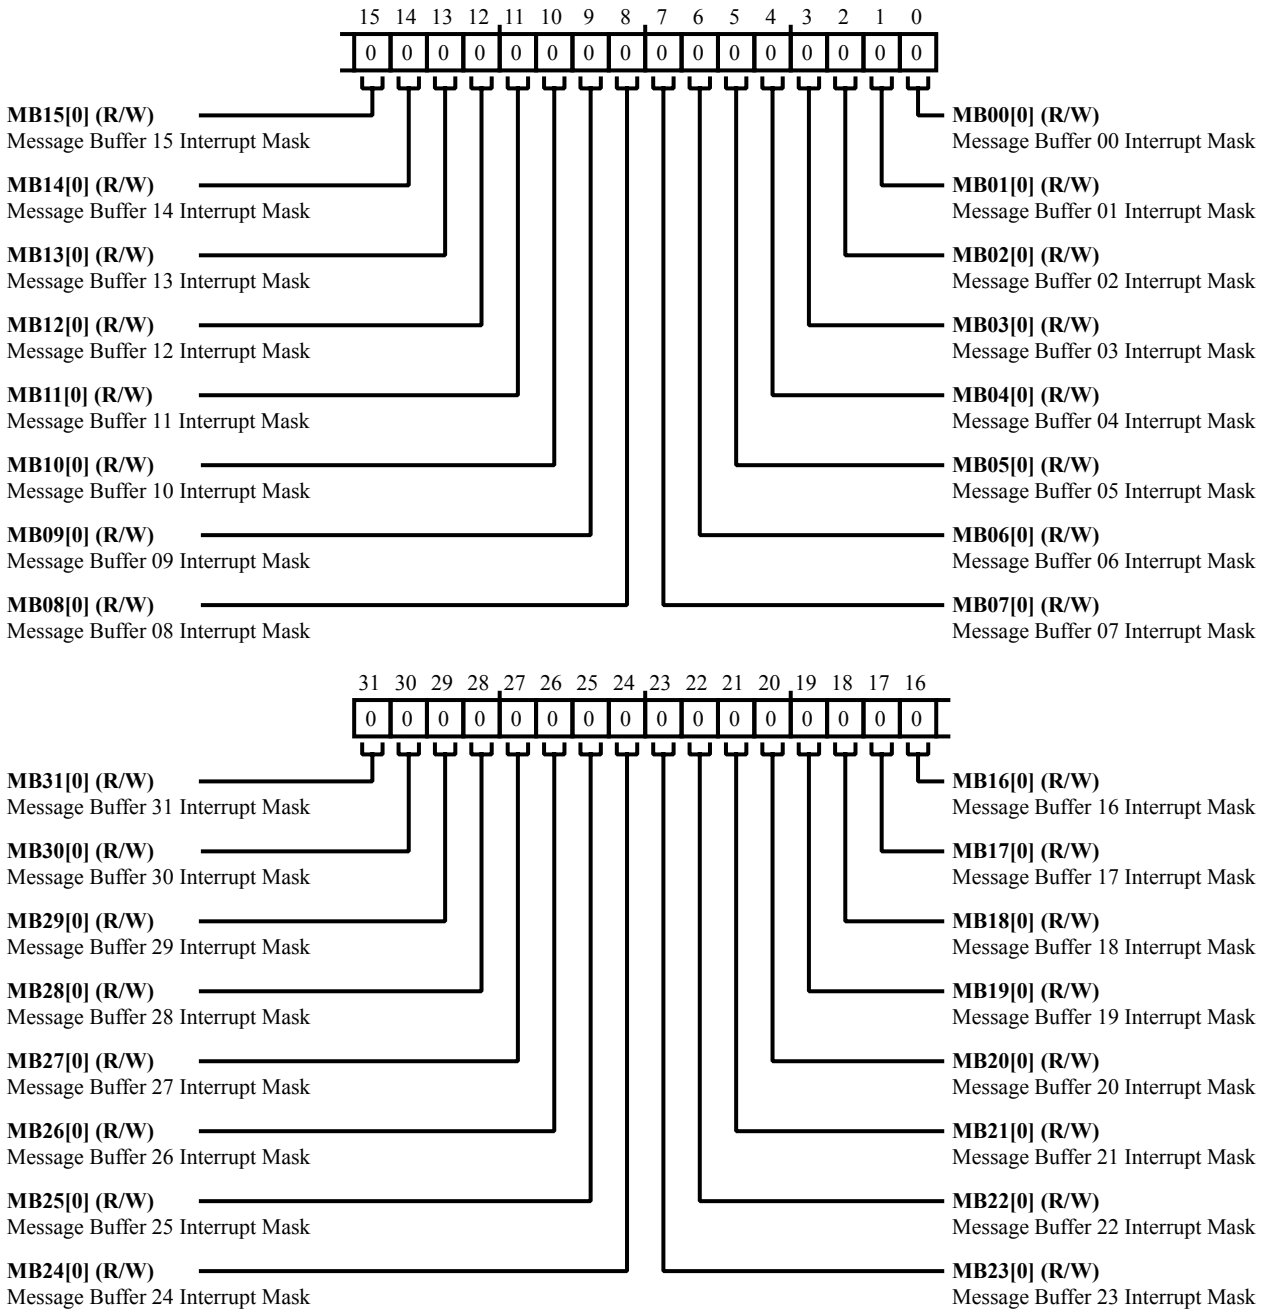

Figure 16-36: CANFD_IMSK1 Register Diagram

Table 16-54: CANFD_IMSK1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	MB31	Message Buffer 31 Interrupt Mask. The CANFD_IMSK1.MB31 bit is the CANFD module message buffer interrupt for MB31. When the CANFD_IMSK1.MB31 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK1 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG1 register is set.
30 (R/W)	MB30	Message Buffer 30 Interrupt Mask. The CANFD_IMSK1.MB30 bit is the CANFD module message buffer interrupt for MB30. When the CANFD_IMSK1.MB30 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK1 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG1 register is set.
29 (R/W)	MB29	Message Buffer 29 Interrupt Mask. The CANFD_IMSK1.MB29 bit is the CANFD module message buffer interrupt for MB29. When the CANFD_IMSK1.MB29 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK1 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG1 register is set.
28 (R/W)	MB28	Message Buffer 28 Interrupt Mask. The CANFD_IMSK1.MB28 bit is the CANFD module message buffer interrupt for MB28. When the CANFD_IMSK1.MB28 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK1 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG1 register is set.
27 (R/W)	MB27	Message Buffer 27 Interrupt Mask. The CANFD_IMSK1.MB27 bit is the CANFD module message buffer interrupt for MB27. When the CANFD_IMSK1.MB27 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK1 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG1 register is set.

Table 16-54: CANFD_IMSK1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
26 (R/W)	MB26	Message Buffer 26 Interrupt Mask. The CANFD_IMSK1.MB26 bit is the CANFD module message buffer interrupt for MB26. When the CANFD_IMSK1.MB26 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK1 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG1 register is set.
25 (R/W)	MB25	Message Buffer 25 Interrupt Mask. The CANFD_IMSK1.MB25 bit is the CANFD module message buffer interrupt for MB25. When the CANFD_IMSK1.MB25 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK1 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG1 register is set.
24 (R/W)	MB24	Message Buffer 24 Interrupt Mask. The CANFD_IMSK1.MB24 bit is the CANFD module message buffer interrupt for MB24. When the CANFD_IMSK1.MB24 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK1 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG1 register is set.
23 (R/W)	MB23	Message Buffer 23 Interrupt Mask. The CANFD_IMSK1.MB23 bit is the CANFD module message buffer interrupt for MB23. When the CANFD_IMSK1.MB23 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK1 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG1 register is set.
22 (R/W)	MB22	Message Buffer 22 Interrupt Mask. The CANFD_IMSK1.MB22 bit is the CANFD module message buffer interrupt for MB22. When the CANFD_IMSK1.MB22 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK1 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG1 register is set.

Table 16-54: CANFD_IMSK1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
21 (R/W)	MB21	Message Buffer 21 Interrupt Mask. The CANFD_IMSK1.MB21 bit is the CANFD module message buffer interrupt for MB21. When the CANFD_IMSK1.MB21 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK1 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG1 register is set.
20 (R/W)	MB20	Message Buffer 20 Interrupt Mask. The CANFD_IMSK1.MB20 bit is the CANFD module message buffer interrupt for MB20. When the CANFD_IMSK1.MB20 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK1 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG1 register is set.
19 (R/W)	MB19	Message Buffer 19 Interrupt Mask. The CANFD_IMSK1.MB19 bit is the CANFD module message buffer interrupt for MB19. When the CANFD_IMSK1.MB19 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK1 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG1 register is set.
18 (R/W)	MB18	Message Buffer 18 Interrupt Mask. The CANFD_IMSK1.MB18 bit is the CANFD module message buffer interrupt for MB18. When the CANFD_IMSK1.MB18 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK1 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG1 register is set.
17 (R/W)	MB17	Message Buffer 17 Interrupt Mask. The CANFD_IMSK1.MB17 bit is the CANFD module message buffer interrupt for MB17. When the CANFD_IMSK1.MB17 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK1 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG1 register is set.

Table 16-54: CANFD_IMSK1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
16 (R/W)	MB16	Message Buffer 16 Interrupt Mask. The CANFD_IMSK1.MB16 bit is the CANFD module message buffer interrupt for MB16. When the CANFD_IMSK1.MB16 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK1 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG1 register is set.
15 (R/W)	MB15	Message Buffer 15 Interrupt Mask. The CANFD_IMSK1.MB15 bit is the CANFD module message buffer interrupt for MB15. When the CANFD_IMSK1.MB15 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK1 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG1 register is set.
14 (R/W)	MB14	Message Buffer 14 Interrupt Mask. The CANFD_IMSK1.MB14 bit is the CANFD module message buffer interrupt for MB14. When the CANFD_IMSK1.MB14 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK1 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG1 register is set.
13 (R/W)	MB13	Message Buffer 13 Interrupt Mask. The CANFD_IMSK1.MB13 bit is the CANFD module message buffer interrupt for MB13. When the CANFD_IMSK1.MB13 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK1 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG1 register is set.
12 (R/W)	MB12	Message Buffer 12 Interrupt Mask. The CANFD_IMSK1.MB12 bit is the CANFD module message buffer interrupt for MB12. When the CANFD_IMSK1.MB12 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK1 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG1 register is set.

Table 16-54: CANFD_IMSK1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
11 (R/W)	MB11	Message Buffer 11 Interrupt Mask. The CANFD_IMSK1.MB11 bit is the CANFD module message buffer interrupt for MB11. When the CANFD_IMSK1.MB11 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK1 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG1 register is set.
10 (R/W)	MB10	Message Buffer 10 Interrupt Mask. The CANFD_IMSK1.MB10 bit is the CANFD module message buffer interrupt for MB10. When the CANFD_IMSK1.MB10 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK1 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG1 register is set.
9 (R/W)	MB09	Message Buffer 09 Interrupt Mask. The CANFD_IMSK1.MB09 bit is the CANFD module message buffer interrupt for MB09. When the CANFD_IMSK1.MB09 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK1 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG1 register is set.
8 (R/W)	MB08	Message Buffer 08 Interrupt Mask. The CANFD_IMSK1.MB08 bit is the CANFD module message buffer interrupt for MB08. When the CANFD_IMSK1.MB08 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK1 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG1 register is set.
7 (R/W)	MB07	Message Buffer 07 Interrupt Mask. The CANFD_IMSK1.MB07 bit is the CANFD module message buffer interrupt for MB07. When the CANFD_IMSK1.MB07 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK1 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG1 register is set.

Table 16-54: CANFD_IMSK1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
6 (R/W)	MB06	Message Buffer 06 Interrupt Mask. The CANFD_IMSK1.MB06 bit is the CANFD module message buffer interrupt for MB06. When the CANFD_IMSK1.MB06 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK1 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG1 register is set.
5 (R/W)	MB05	Message Buffer 05 Interrupt Mask. The CANFD_IMSK1.MB05 bit is the CANFD module message buffer interrupt for MB05. When the CANFD_IMSK1.MB05 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK1 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG1 register is set.
4 (R/W)	MB04	Message Buffer 04 Interrupt Mask. The CANFD_IMSK1.MB04 bit is the CANFD module message buffer interrupt for MB04. When the CANFD_IMSK1.MB04 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK1 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG1 register is set.
3 (R/W)	MB03	Message Buffer 03 Interrupt Mask. The CANFD_IMSK1.MB03 bit is the CANFD module message buffer interrupt for MB03. When the CANFD_IMSK1.MB03 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK1 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG1 register is set.
2 (R/W)	MB02	Message Buffer 02 Interrupt Mask. The CANFD_IMSK1.MB02 bit is the CANFD module message buffer interrupt for MB02. When the CANFD_IMSK1.MB02 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK1 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG1 register is set.

Table 16-54: CANFD_IMSK1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
1 (R/W)	MB01	Message Buffer 01 Interrupt Mask. The `CANFD_IMSK1.MB01` bit is the CANFD module message buffer interrupt for MB01. When the `CANFD_IMSK1.MB01` bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the `CANFD_IMSK1` register enables or disables an interrupt request if the corresponding bit in the `CANFD_IFLG1` register is set.
0 (R/W)	MB00	Message Buffer 00 Interrupt Mask. The `CANFD_IMSK1.MB00` bit is the CANFD module message buffer interrupt for MB00. When the `CANFD_IMSK1.MB00` bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the `CANFD_IMSK1` register enables or disables an interrupt request if the corresponding bit in the `CANFD_IFLG1` register is set.

Mailbox Interrupt Mask 2 Register

The CANFD_IMSK2 register allows any number of the 32 message buffer interrupts to be enabled or disabled for MB63 to MB32. The CANFD_IMSK2 register contains one interrupt mask bit per buffer, enabling the processor to determine which buffer generates an interrupt after a successful transmission or reception (as indicated by the corresponding bit in the register).

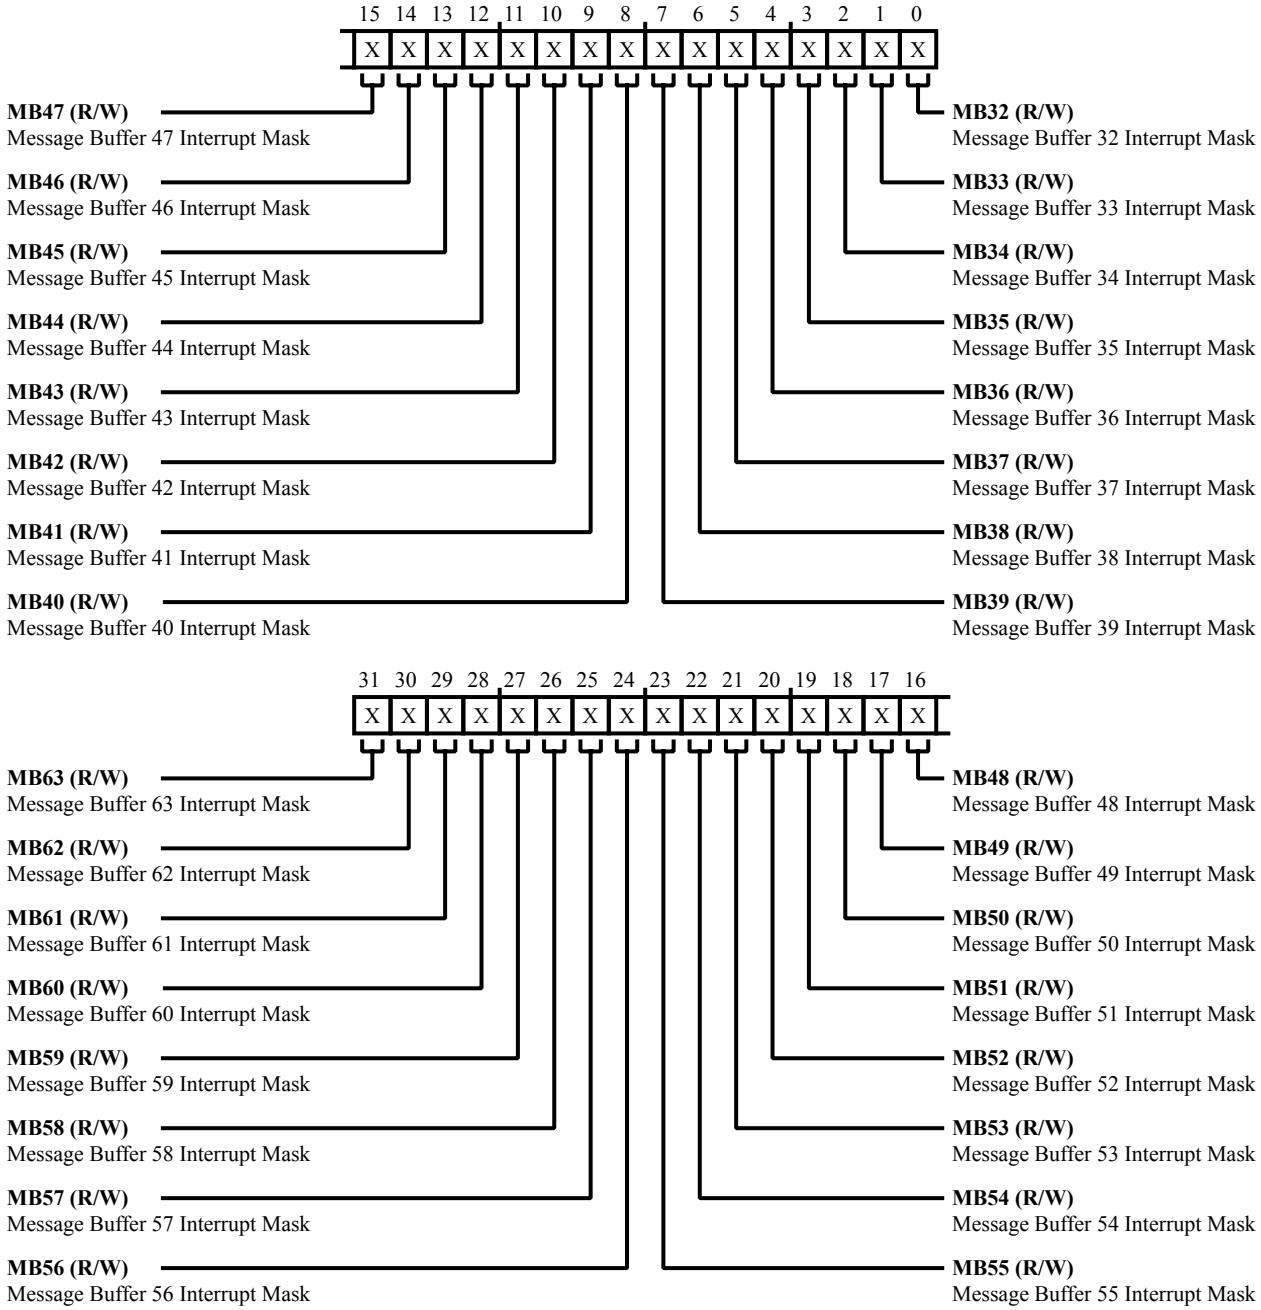

Figure 16-37: CANFD_IMSK2 Register Diagram

Table 16-55: CANFD_IMSK2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	MB63	Message Buffer 63 Interrupt Mask. The CANFD_IMSK2.MB63 bit is the CANFD module message buffer interrupt for MB63. When the CANFD_IMSK2.MB63 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.
30 (R/W)	MB62	Message Buffer 62 Interrupt Mask. The CANFD_IMSK2.MB62 bit is the CANFD module message buffer interrupt for MB62. When the CANFD_IMSK2.MB62 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.
29 (R/W)	MB61	Message Buffer 61 Interrupt Mask. The CANFD_IMSK2.MB61 bit is the CANFD module message buffer interrupt for MB61. When the CANFD_IMSK2.MB61 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.
28 (R/W)	MB60	Message Buffer 60 Interrupt Mask. The CANFD_IMSK2.MB60 bit is the CANFD module message buffer interrupt for MB60. When the CANFD_IMSK2.MB60 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.
27 (R/W)	MB59	Message Buffer 59 Interrupt Mask. The CANFD_IMSK2.MB59 bit is the CANFD module message buffer interrupt for MB59. When the CANFD_IMSK2.MB59 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.

Table 16-55: CANFD_IMSK2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
26 (R/W)	MB58	Message Buffer 58 Interrupt Mask. The CANFD_IMSK2.MB58 bit is the CANFD module message buffer interrupt for MB58. When the CANFD_IMSK2.MB58 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.
25 (R/W)	MB57	Message Buffer 57 Interrupt Mask. The CANFD_IMSK2.MB57 bit is the CANFD module message buffer interrupt for MB57. When the CANFD_IMSK2.MB57 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.
24 (R/W)	MB56	Message Buffer 56 Interrupt Mask. The CANFD_IMSK2.MB56 bit is the CANFD module message buffer interrupt for MB56. When the CANFD_IMSK2.MB56 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.
23 (R/W)	MB55	Message Buffer 55 Interrupt Mask. The CANFD_IMSK2.MB55 bit is the CANFD module message buffer interrupt for MB55. When the CANFD_IMSK2.MB55 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.
22 (R/W)	MB54	Message Buffer 54 Interrupt Mask. The CANFD_IMSK2.MB54 bit is the CANFD module message buffer interrupt for MB54. When the CANFD_IMSK2.MB54 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.

Table 16-55: CANFD_IMSK2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
21 (R/W)	MB53	Message Buffer 53 Interrupt Mask. The CANFD_IMSK2.MB53 bit is the CANFD module message buffer interrupt for MB53. When the CANFD_IMSK2.MB53 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.
20 (R/W)	MB52	Message Buffer 52 Interrupt Mask. The CANFD_IMSK2.MB52 bit is the CANFD module message buffer interrupt for MB52. When the CANFD_IMSK2.MB52 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.
19 (R/W)	MB51	Message Buffer 51 Interrupt Mask. The CANFD_IMSK2.MB51 bit is the CANFD module message buffer interrupt for MB51. When the CANFD_IMSK2.MB51 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.
18 (R/W)	MB50	Message Buffer 50 Interrupt Mask. The CANFD_IMSK2.MB50 bit is the CANFD module message buffer interrupt for MB50. When the CANFD_IMSK2.MB50 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.
17 (R/W)	MB49	Message Buffer 49 Interrupt Mask. The CANFD_IMSK2.MB49 bit is the CANFD module message buffer interrupt for MB49. When the CANFD_IMSK2.MB49 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.

Table 16-55: CANFD_IMSK2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
16 (R/W)	MB48	Message Buffer 48 Interrupt Mask. The CANFD_IMSK2.MB48 bit is the CANFD module message buffer interrupt for MB48. When the CANFD_IMSK2.MB48 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.
15 (R/W)	MB47	Message Buffer 47 Interrupt Mask. The CANFD_IMSK2.MB47 bit is the CANFD module message buffer interrupt for MB47. When the CANFD_IMSK2.MB47 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.
14 (R/W)	MB46	Message Buffer 46 Interrupt Mask. The CANFD_IMSK2.MB46 bit is the CANFD module message buffer interrupt for MB46. When the CANFD_IMSK2.MB46 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.
13 (R/W)	MB45	Message Buffer 45 Interrupt Mask. The CANFD_IMSK2.MB45 bit is the CANFD module message buffer interrupt for MB45. When the CANFD_IMSK2.MB45 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.
12 (R/W)	MB44	Message Buffer 44 Interrupt Mask. The CANFD_IMSK2.MB44 bit is the CANFD module message buffer interrupt for MB44. When the CANFD_IMSK2.MB44 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.

Table 16-55: CANFD_IMSK2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
11 (R/W)	MB43	Message Buffer 43 Interrupt Mask. The CANFD_IMSK2.MB43 bit is the CANFD module message buffer interrupt for MB43. When the CANFD_IMSK2.MB43 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.
10 (R/W)	MB42	Message Buffer 42 Interrupt Mask. The CANFD_IMSK2.MB42 bit is the CANFD module message buffer interrupt for MB42. When the CANFD_IMSK2.MB42 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.
9 (R/W)	MB41	Message Buffer 41 Interrupt Mask. The CANFD_IMSK2.MB41 bit is the CANFD module message buffer interrupt for MB41. When the CANFD_IMSK2.MB41 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.
8 (R/W)	MB40	Message Buffer 40 Interrupt Mask. The CANFD_IMSK2.MB40 bit is the CANFD module message buffer interrupt for MB40. When the CANFD_IMSK2.MB40 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.
7 (R/W)	MB39	Message Buffer 39 Interrupt Mask. The CANFD_IMSK2.MB39 bit is the CANFD module message buffer interrupt for MB39. When the CANFD_IMSK2.MB39 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.

Table 16-55: CANFD_IMSK2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
6 (R/W)	MB38	Message Buffer 38 Interrupt Mask. The CANFD_IMSK2.MB38 bit is the CANFD module message buffer interrupt for MB39. When the CANFD_IMSK2.MB38 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.
5 (R/W)	MB37	Message Buffer 37 Interrupt Mask. The CANFD_IMSK2.MB37 bit is the CANFD module message buffer interrupt for MB37. When the CANFD_IMSK2.MB37 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.
4 (R/W)	MB36	Message Buffer 36 Interrupt Mask. The CANFD_IMSK2.MB36 bit is the CANFD module message buffer interrupt for MB36. When the CANFD_IMSK2.MB36 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.
3 (R/W)	MB35	Message Buffer 35 Interrupt Mask. The CANFD_IMSK2.MB35 bit is the CANFD module message buffer interrupt for MB35. When the CANFD_IMSK2.MB35 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.
2 (R/W)	MB34	Message Buffer 34 Interrupt Mask. The CANFD_IMSK2.MB34 bit is the CANFD module message buffer interrupt for MB34. When the CANFD_IMSK2.MB34 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.

Table 16-55: CANFD_IMSK2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
1 (R/W)	MB33	Message Buffer 33 Interrupt Mask. The CANFD_IMSK2.MB33 bit is the CANFD module message buffer interrupt for MB33. When the CANFD_IMSK2.MB33 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.
0 (R/W)	MB32	Message Buffer 32 Interrupt Mask. The CANFD_IMSK2.MB32 bit is the CANFD module message buffer interrupt for MB32. When the CANFD_IMSK2.MB32 bit is set, the corresponding buffer interrupt is enabled. When the bit is cleared, the corresponding buffer interrupt is disabled. Note that setting or clearing a bit in the CANFD_IMSK2 register enables or disables an interrupt request if the corresponding bit in the CANFD_IFLG2 register is set.

Module Configuration Register

The CANFD_CFG register configures the operation modes and settings for the CANFD module. This register defines global system configurations, such as the module operation modes and the maximum message buffer configuration.

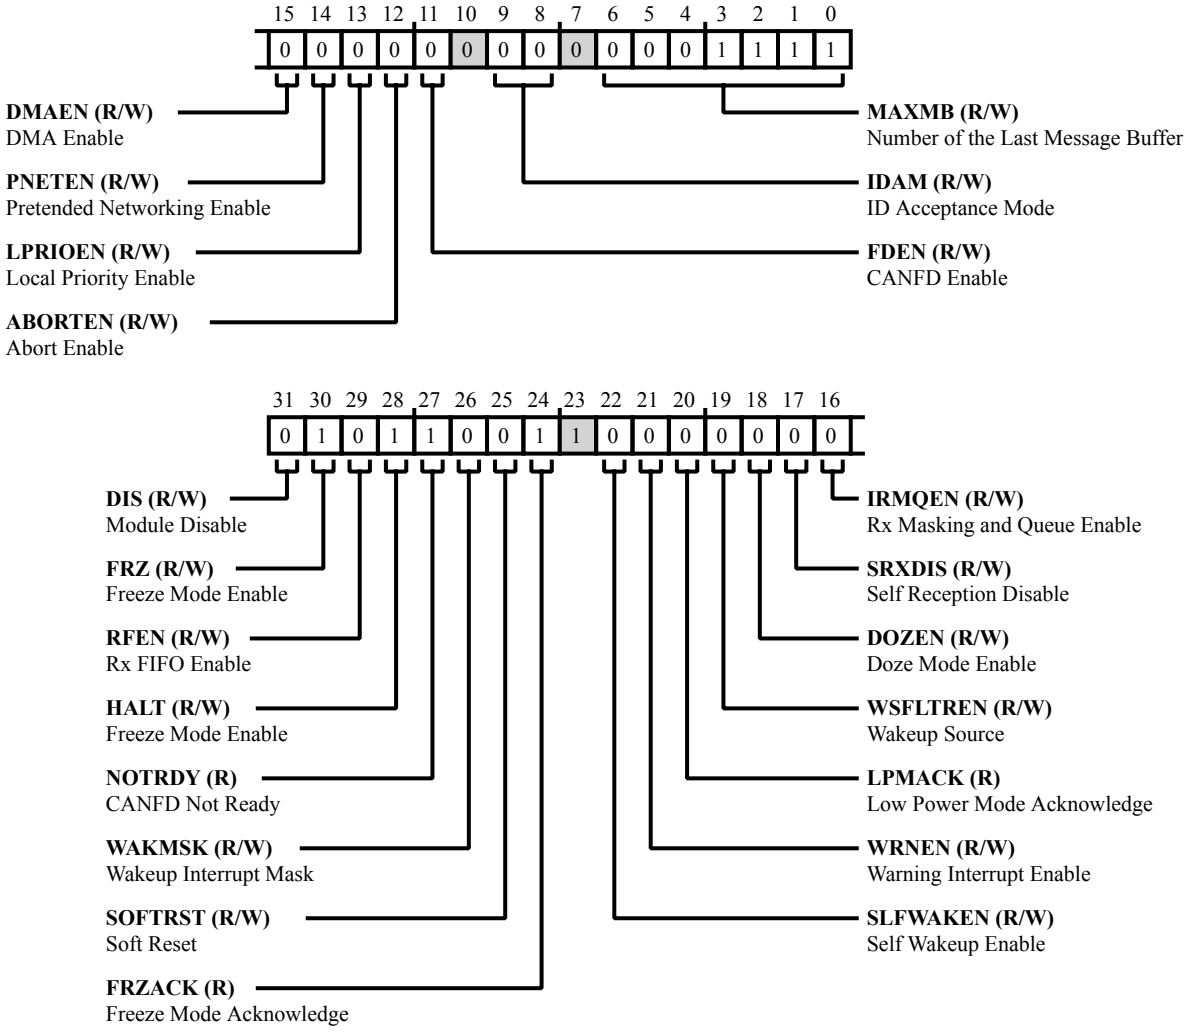

Figure 16-38: CANFD_CFG Register Diagram

Table 16-56: CANFD_CFG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	DIS	Module Disable. The CANFD_CFG.DIS bit disables or enables the CANFD module. When the CANFD_CFG.DIS bit is set, the CANFD module disables the clocks to the PE and CHI submodules. This bit is not affected by a soft reset.	
		0	Enable
		1	Disable
30 (R/W)	FRZ	Freeze Mode Enable. The CANFD_CFG.FRZ bit specifies the CANFD module behavior when the CANFD_CFG.HALT bit is set or when there is a debug mode request at the chip level. When the CANFD_CFG.FRZ bit is set, the CANFD module enters freeze mode. Negation of the CANFD_CFG.FRZ bit causes the CANFD module to exit from freeze mode. The CANFD_CFG.FRZ bit is set by hardware when a non-correctable error is detected and the CANFD_MEC.NCERRFRZEN bit is set.	
		0	Disable
		1	Enable
29 (R/W)	RFEN	Rx FIFO Enable. The CANFD_CFG.RFEN bit enables the Rx FIFO. When the CANFD_CFG.RFEN bit is set, do not use MBs 05 for normal reception and transmission. The corresponding memory region (0x800xDC) is used by the FIFO engine and additional MBs (up to 32, depending on the CANFD_CTL2.RFFNUM bit setting) are used as Rx FIFO ID filter table elements. The CANFD_CFG.RFEN bit also impacts the minimum number of peripheral clocks per CAN bit. The CANFD_CFG.RFEN bit can only be written in freeze mode because it is blocked by hardware in other modes. Note that the CANFD_CFG.RFEN bit cannot be set when the CANFD_CFG.FDEN bit is set.	
		0	Disable
		1	Enable

Table 16-56: CANFD_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
28 (R/W)	HALT	Freeze Mode Enable. Setting the CANFD_CFG.HALT bit puts the CANFD module into freeze mode. The processor clears the CANFD_CFG.HALT bit after initializing the message buffers, the CANFD_CTL1 register, and the CANFD_CTL2 register. The CANFD module does not receive or transmit data before the CANFD_CFG.HALT bit is cleared. The CANFD module cannot enter freeze mode while it is in a low-power mode. The CANFD_CFG.HALT bit is set by hardware when a non-correctable error is detected and the CANFD_MEC.NCERRFRZEN bit is set.	
		0	Disable
		1	Enable
27 (R/NW)	NOTRDY	CANFD Not Ready. The CANFD_CFG.NOTRDY bit is a read-only bit that indicates the CANFD module is either in module disable, doze, stop, or freeze mode. The CANFD_CFG.NOTRDY bit is negated once the CANFD module exits these modes. Soft reset does not affect the CANFD_CFG.NOTRDY bit.	
		0	Normal, Listen-Only, or Loop-Back Mode
		1	Module Disable, Doze, Stop, or Freeze Mode
26 (R/W)	WAKMSK	Wakeup Interrupt Mask. The CANFD_CFG.WAKMSK bit enables the wakeup interrupt using the self wakeup mechanism.	
		0	Disable
		1	Enable
25 (R/W)	SOFTRST	Soft Reset. When the CANFD_CFG.SOFTRST bit is set, the internal state machines and some of the memory mapped registers of the CANFD module reset. For the processor to directly assert a soft reset, write to the CANFD_CFG.SOFTRST bit. A soft reset can also occur when a global soft reset is requested at the chip level. Soft reset is synchronous and has to follow a request/acknowledge procedure across clock domains, so it takes time to fully propagate the effect. The CANFD_CFG.SOFTRST bit remains set while reset is pending and is automatically negated when the reset completes. Poll the CANFD_CFG.SOFTRST bit to know when the soft reset has completed. Soft reset cannot be applied while clocks are shut down in a low-power mode. Remove the CANFD module from low-power mode before applying soft reset. A soft reset does not affect the CANFD_CFG.SOFTRST bit.	

Table 16-56: CANFD_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
24 (R/NW)	FRZACK	Freeze Mode Acknowledge. The CANFD_CFG.FRZACK bit is a read-only bit that indicates the CANFD module is in freeze mode and the prescaler is stopped. A freeze mode request is only granted after the current transmission or reception processes completes. Poll the CANFD_CFG.FRZACK bit in software to know when the CANFD module enters freeze mode. If a freeze mode request is negated, the CANFD_CFG.FRZACK bit is negated after the CANFD module prescaler is running again. If freeze mode is requested while the CANFD module is in a low-power mode, the CANFD_CFG.FRZACK bit sets only when the module exits the low-power mode. Soft reset does not affect the CANFD_CFG.FRZACK bit. Note that the CANFD_CFG.FRZACK bit is set within 178 CAN bits of the freeze mode request. It is negated within 2 CAN bits after a freeze mode request removal.	
		0	No Freeze Mode Prescaler is running.
		1	Freeze Mode The prescaler stopped.
22 (R/W)	SLFWAKEN	Self Wakeup Enable. The CANFD_CFG.SLFWAKEN bit enables the self wakeup feature when the CANFD module is in a low-power mode other than module disable. When the self wakeup feature is enabled, the CANFD module monitors the bus for a wakeup event (a recessive-to-dominant transition). If a wake up event is detected during doze mode, the CANFD module requests resumption of the clocks and when the CANFD_CFG.SLFWAKEN bit is enabled generates a wakeup interrupt to the processor. If a wakeup event is detected during stop mode, the CANFD module, when the CANFD_CFG.SLFWAKEN bit is enabled, generates a wake up interrupt to the processor so that it can exit stop mode globally and the CANFD module can request to resume the clocks. When the CANFD module is in a low-power mode other than module disable, the CANFD_CFG.SLFWAKEN bit cannot be written as it is blocked by hardware. Disable self wakeup when pretended networking mode is set.	
		0	Disable
		1	Enable

Table 16-56: CANFD_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
21 (R/W)	WRNEN	Warning Interrupt Enable. The CANFD_CFG.WRNEN bit enables the generation of the TWRNINT and RWRNINT flags in the CANFD_ESR1 register. If the CANFD_CFG.WRNEN bit is negated, the TWRNINT and RWRNINT flags will always be zero, independent of the values of the error counters. No warning interrupt is generated. The CANFD_CFG.WRNEN bit can only be written in freeze mode and is blocked by hardware in other modes.	
		0	Disable
		1	Enable
20 (R/NW)	LPMACK	Low Power Mode Acknowledge. The CANFD_CFG.LPMACK bit is a read-only bit that indicates that the CANFD module is in a low-power mode (module disable, doze, or stop). The module can only enter a low-power mode when all current transmission or reception processes have finished. Poll the CANFD_CFG.LPMACK bit to know when the CANFD module is in low-power mode. The CANFD_CFG.LPMACK bit is not affected by soft reset. Note that the CANFD_CFG.LPMACK bit is set within 180 CAN bits of the low-power mode request by the processor. It is negated within 2 CAN bits after removing the low-power mode request. When the CANFD module is in pretended networking mode, the CANFD_CFG.LPMACK bit is negated within 180 CAN bits from the removal of the low-power mode request.	
		0	Disable Not in low-power mode
		1	Enable In low-power mode
19 (R/W)	WSFLTREN	Wakeup Source. The CANFD_CFG.WSFLTREN bit controls whether the integrated low-pass filter is applied to protect the Rx CAN input from spurious wakeup. When enabled, the CANFD module uses the filtered Rx input to detect recessive-to-dominant edges on the CAN bus. When disabled the CANFD module uses the unfiltered Rx input to detect recessive-to-dominant edges on the CAN bus. The CANFD_CFG.WSFLTREN bit can only be written in freeze mode and is blocked by hardware in other modes.	
		0	Disable
		1	Enable

Table 16-56: CANFD_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
18 (R/W)	DOZEN	Doze Mode Enable. The CANFD_CFG.DOZEN bit controls whether the CANFD module can enter low-power mode when doze mode is requested at the chip level. When the CANFD_CFG.DOZEN bit is set the CANFD module can enter low-power mode and when it is cleared the module cannot. The CANFD_CFG.DOZEN bit is automatically reset when the CANFD module wakes up from doze mode upon detecting activity on the CAN bus (CANFD_CFG.SLFWAKEN enabled).	
		0	Disable
		1	Enable
17 (R/W)	SRXDIS	Self Reception Disable. The CANFD_CFG.SRXDIS bit controls whether the CANFD module can receive frames transmitted from itself. When the CANFD_CFG.SRXDIS bit is set, frames transmitted by the CANFD module are not stored in any MB, regardless of whether the MB is programmed with an ID that matches the transmitted frame. No interrupt flag or interrupt signal is generated due to the frame reception. The CANFD_CFG.SRXDIS bit can only be written in freeze mode and is blocked by hardware in other modes.	
		0	Enable
		1	Disable
16 (R/W)	IRMQEN	Rx Masking and Queue Enable. The CANFD_CFG.IRMQEN bit controls whether the Rx matching process is based on individual masking and queue or on a masking scheme with the CANFD_RX_MB_GMSK, CANFD_RX_14_MSK, CANFD_RX_15_MSK, and CANFD_RX_FIFO_GMSK registers. The CANFD_CFG.IRMQEN bit can only be written in freeze mode and is blocked by hardware in other modes. For backward compatibility, when CANFD_CFG.IRMQEN is disabled, reading a C/S word locks the MB even when it is empty.	
		0	Disable
		1	Enable

Table 16-56: CANFD_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	DMAEN	DMA Enable. The CANFD_CFG.DMAEN bit enables or disables the DMA feature. The DMA feature is only for use with the Rx FIFO and the CANFD_CFG.RFEN bit must be set. When both the CANFD_CFG.DMAEN and CANFD_CFG.RFEN bits are set, CANFD_IFLG1.MB05 generates the DMA request and no Rx FIFO interrupt is generated. The CANFD_CFG.DMAEN bit can only be written in freeze mode and is blocked by hardware in other modes.	
		0	Disable
		1	Enable
14 (R/W)	PNETEN	Pretended Networking Enable. The CANFD_CFG.PNETEN bit enables the pretended networking mode. When pretended networking is enabled, the PE submodule is kept operational in doze mode and stop mode. It is able to process Rx message filtering as defined by the pretended networking configuration registers. The CANFD_CFG.PNETEN bit can be only be written in freeze mode.	
		0	Disable
		1	Enable
13 (R/W)	LPRIOEN	Local Priority Enable. The CANFD_CFG.LPRIOEN bit controls whether the local priority feature is enabled and is provided for backward compatibility with legacy applications. Local priority expands the arbitration ID. With this expanded ID concept, the arbitration process is based on the full 32-bit word, but the actual transmitted ID still has 11 bits for standard frames and 29 bits for extended frames. The CANFD_CFG.LPRIOEN bit can only be written only in freeze mode and is blocked by hardware in other modes.	
		0	Disable
		1	Enable

Table 16-56: CANFD_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W)	ABORTEN	Abort Enable. The CANFD_CFG.ABORTEN bit enables the Tx abort mechanism. The Tx abort mechanism ensures a safe procedure for aborting a pending transmission, so that no frame is sent on the CAN bus without notification. The CANFD_CFG.ABORTEN bit can only be written only in freeze mode and is blocked by hardware in other modes. Note that when the CANFD_CFG.ABORTEN bit is set, the abort mechanism must only be used for updating mailboxes configured for transmission. Writing the abort code into Rx mailboxes can cause unpredictable results when the CANFD_CFG.ABORTEN bit is enabled.	
		0	Disable
		1	Enable
11 (R/W)	FDEN	CANFD Enable. The CANFD_CFG.FDEN bit enables CAN with Flexible Data rate (CAN FD) operation. When the CANFD_CFG.FDEN bit is enabled, the CANFD module can receive and transmit messages in both CAN FD and CAN 2.0 formats. When it is disabled, the CANFD module can only receive and transmit messages in CAN 2.0 format. The CANFD_CFG.FDEN bit can only be written in freeze mode only. Note that the CANFD_CFG.RFEN bit cannot be set if the CANFD_CFG.FDEN bit is set.	
		0	Disable
		1	Enable
9:8 (R/W)	IDAM	ID Acceptance Mode. The CANFD_CFG.IDAM bit field identifies the format of the Rx FIFO ID Filter Table elements (ID Acceptance Mode). All elements of the table are configured at the same time by the CANFD_CFG.IDAM bit field (they are all the same format). The CANFD_CFG.IDAM bit field can only be written in freeze mode and is blocked by hardware in other modes.	
		0	Format A. There is one full ID (standard and extended) per ID filter table element.
		1	Format B. There are two full standard IDs or two partial 14-bit (standard and extended) IDs per ID filter table element.
		2	Format C. There are four partial 8-bit standard IDs per ID filter table element.
		3	Format D. All frames are rejected.

Table 16-56: CANFD_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
6:0 (R/W)	MAXMB	Number of the Last Message Buffer. The CANFD_CFG.MAXMB bit field defines the number of the last message buffer that will take part in the matching and arbitration processes. The reset value (0x0F) is equivalent to a 16 message buffer configuration. The CANFD_CFG.MAXMB bit field can only be written in freeze mode and is blocked by hardware in other modes. Note that the CANFD_CFG.MAXMB bit field must be programmed with a value smaller than or equal to the number of available message buffers. Additionally, the definition of the CANFD_CFG.MAXMB bit value must take into account the region of MBs occupied by Rx FIFO and the ID filters table space defined by the CANFD_CTL2.RFFNUM bit. The CANFD_CFG.MAXMB bit field impacts the minimum number of peripheral clocks per CAN bit.

Memory Error Control Register

The CANFD_MEC register contains control bits for memory error detection and correction (ECC).

Note that when the CANFD_CTL2.ECRWREN bit is disabled, writes to the CANFD_MEC register are blocked, with the exception of the CANFD_MEC.ECRWRDIS bit.

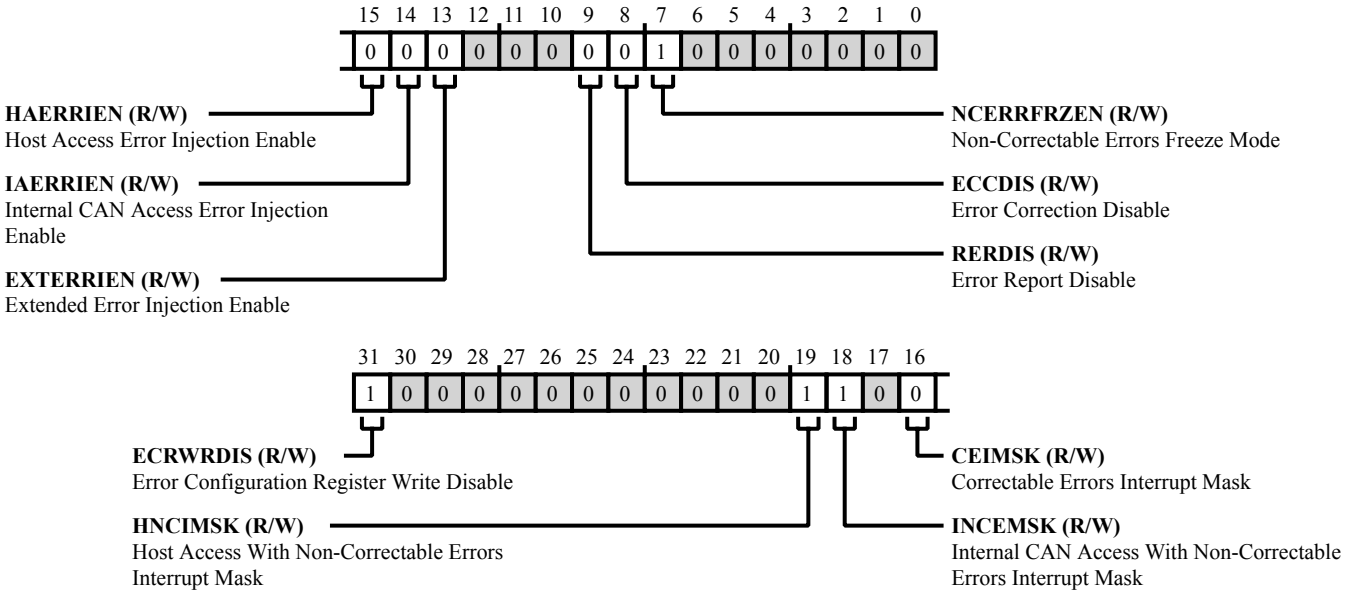

Figure 16-39: CANFD_MEC Register Diagram

Table 16-57: CANFD_MEC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	ECRWRDIS	Error Configuration Register Write Disable. The CANFD_MEC.ECRWRDIS bit disables writes to the CANFD_MEC register. The CANFD_MEC.ECRWRDIS bit is automatically set to 1 (disabled) when the CANFD_CTL2.ECRWREN bit is enabled. See the protocol described in the Detection and Correction of Memory Errors section of the CANFD chapter.	
		0	Enable
		1	Disable
19 (R/W)	HNCIMSK	Host Access With Non-Correctable Errors Interrupt Mask. The CANFD_MEC.HNCIMSK bit enables the interrupt in case of non-correctable errors detected in memory reads issued by the host.	
		0	Disable
		1	Enable

Table 16-57: CANFD_MEC Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
18 (R/W)	INCEMSK	Internal CAN Access With Non-Correctable Errors Interrupt Mask. The `CANFD_MEC.INCEMSK` bit enables the interrupt in case of non-correctable errors detected in memory reads issued by the CAN internal processes.	
		0	Disable
		1	Enable
16 (R/W)	CEIMSK	Correctable Errors Interrupt Mask. The `CANFD_MEC.CEIMSK` bit enables the interrupt in case of correctable errors detected in memory reads issued by the host or CANFD module internal processes.	
		0	Disable
		1	Enable
15 (R/W)	HAERRIEN	Host Access Error Injection Enable. The `CANFD_MEC.HAERRIEN` bit enables the injection of errors for memory reads issued by the host.	
		0	Disable
		1	Enable
14 (R/W)	IAERRIEN	Internal CAN Access Error Injection Enable. The `CANFD_MEC.IAERRIEN` bit enables the injection of errors for memory reads issued by the CAN internal processes.	
		0	Disable
		1	Enable
13 (R/W)	EXTERRIEN	Extended Error Injection Enable. Memory accesses performed by internal CANFD processes are 64-bit accesses. The `CANFD_MEC.EXTERRIEN` bit extends the error injection on 32-bit memory accesses to the complementary 32-bit word using the same 32-bit error injection data and parity words. When the `CANFD_MEC.EXTERRIEN` bit is enabled, the error injection is applied to the 64-bit word. When the bit is disabled, error injection is only applied to the 32-bit word. See the descriptions of the `CANFD_ERR_IDP` and `CANFD_ERR_IPP` registers.	
		0	Disable
		1	Enable

Table 16-57: CANFD_MEC Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W)	RERDIS	Error Report Disable. The `CANFD_MEC.RERDIS` bit disables the update of the error report registers. When the error report registers are disabled, the update of error-related flags and the generation of bus transfer errors are still active. Note that when reading the report registers, the `CANFD_MEC.RERDIS` bit must be set to ensure coherence on the consecutive register reads.	
		0	Enable
		1	Disable
8 (R/W)	ECCDIS	Error Correction Disable. The `CANFD_MEC.ECCDIS` bit disables the memory detection and correction mechanism. In addition to disabling the error report mechanism, when the `CANFD_MEC.ECCDIS` bit is set, the update of the error-related flags and generation of bus transfer errors also stops. The parity bits continue to be calculated and written into memory on write transactions.	
		0	Enable
		1	Disable
7 (R/W)	NCERRFRZEN	Non-Correctable Errors Freeze Mode. The `CANFD_MEC.NCERRFRZEN` bit determines the response when a non-correctable error is detected in a memory read performed by CANFD module internal processes. Enabling the `CANFD_MEC.NCERRFRZEN` bit puts the CANFD module in freeze mode, preventing corrupted data from being treated as valid by CANFD internal processes. Disabling the bit maintains normal operation.	
		0	Disable
		1	Enable

Pretended Networking Payload Low Filter2 Register

The CANFD_FLTR_DATA1_HI register contain Payload Filter 1 high order bits of the target value. This is for filtering the incoming message payload in pretended networking mode. It is for =, ≤, or ≥ to comparisons; or as the lower limit value in payload range detection.

The CANFD_FLTR_DATA1_HI register can only be written in freeze mode.

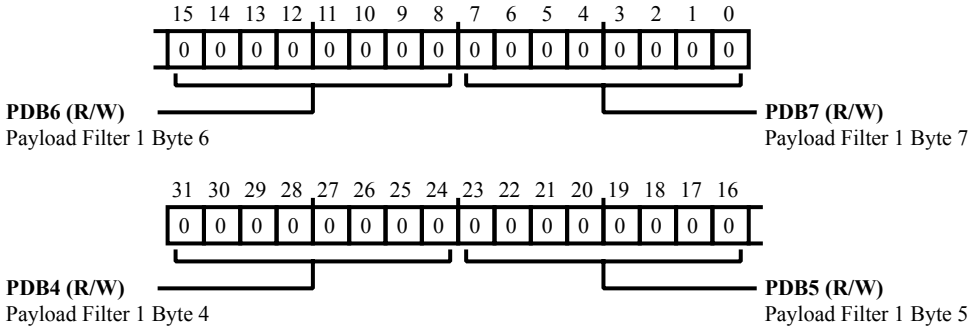

Figure 16-40: CANFD_FLTR_DATA1_HI Register Diagram

Table 16-58: CANFD_FLTR_DATA1_HI Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	PDB4	Payload Filter 1 Byte 4. The CANFD_FLTR_DATA1_HI.PDB4 bit field contains the payload filter 1 high order bits for pretended networking payload filtering corresponding to data byte 4.
23:16 (R/W)	PDB5	Payload Filter 1 Byte 5. The CANFD_FLTR_DATA1_HI.PDB5 bit field contains the payload filter 1 high order bits for pretended networking payload filtering corresponding to data byte 5.
15:8 (R/W)	PDB6	Payload Filter 1 Byte 6. The CANFD_FLTR_DATA1_HI.PDB6 bit field contains the payload filter 1 high order bits for pretended networking payload filtering corresponding to data byte 6.
7:0 (R/W)	PDB7	Payload Filter 1 Byte 7. The CANFD_FLTR_DATA1_HI.PDB7 bit field contains the payload filter 1 high order bits for pretended networking payload filtering corresponding to data byte 7.

Pretended Networking Payload Low Filter1 Register

The CANFD_FLTR_DATA1_LO register contain Payload Filter 1 low order bits of the target value. This is for filtering the incoming message payload in pretended networking mode. It is for =, ≤, or ≥ to comparisons; or as the lower limit value in payload range detection.

The CANFD_FLTR_DATA1_LO register can only be written in freeze mode.

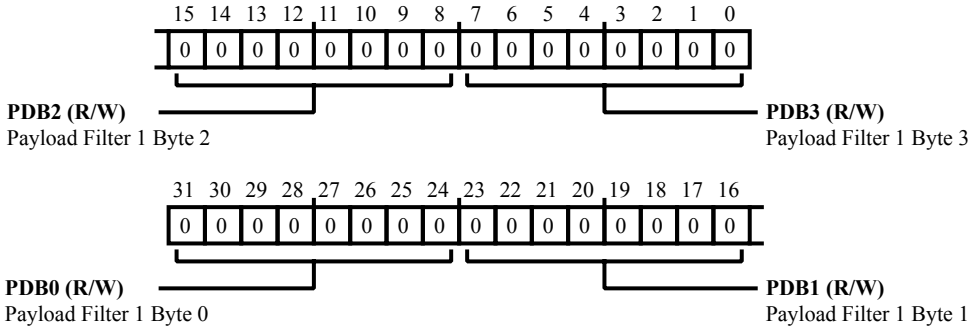

Figure 16-41: CANFD_FLTR_DATA1_LO Register Diagram

Table 16-59: CANFD_FLTR_DATA1_LO Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	PDB0	Payload Filter 1 Byte 0. The CANFD_FLTR_DATA1_LO.PDB0 bit field contains the payload filter 1 low order bits for pretended networking payload filtering corresponding to data byte 0.
23:16 (R/W)	PDB1	Payload Filter 1 Byte 1. The CANFD_FLTR_DATA1_LO.PDB1 bit field contains the payload filter 1 low order bits for pretended networking payload filtering corresponding to data byte 1.
15:8 (R/W)	PDB2	Payload Filter 1 Byte 2. The CANFD_FLTR_DATA1_LO.PDB2 bit field contains the payload filter 1 low order bits for pretended networking payload filtering corresponding to data byte 2.
7:0 (R/W)	PDB3	Payload Filter 1 Byte 3. The CANFD_FLTR_DATA1_LO.PDB3 bit field contains the payload filter 1 low order bits for pretended networking payload filtering corresponding to data byte 3.

Pretended Networking Payload High Filter2 High Order Bits / Payload High Mask Register

The CANFD_FLTR_DATA2_DMSK_HI register has two functions:

It contains the high order bits for the Payload Filter 2 value for use as the upper limit in payload range detection.

When exact payload filtering criteria is selected, the CANFD_FLTR_DATA2_DMSK_HI register is the payload mask.

Otherwise, the CANFD_FLTR_DATA2_DMSK_HI register is not used. It can only be written in freeze mode.

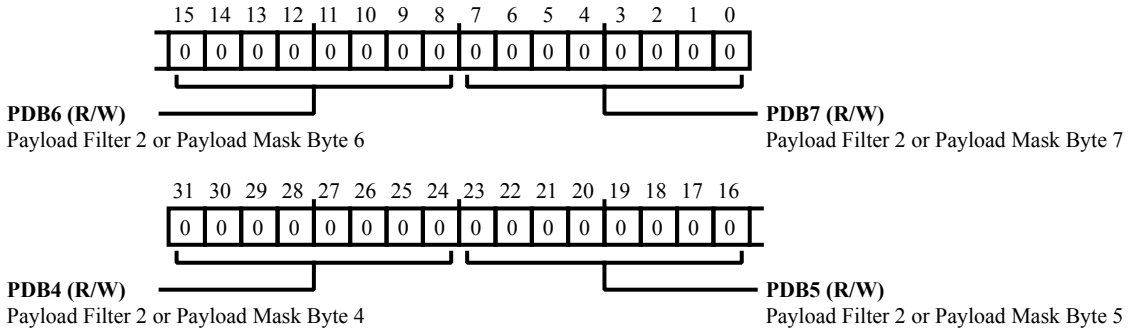

Figure 16-42: CANFD_FLTR_DATA2_DMSK_HI Register Diagram

Table 16-60: CANFD_FLTR_DATA2_DMSK_HI Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	PDB4	Payload Filter 2 or Payload Mask Byte 4. The CANFD_FLTR_DATA2_DMSK_HI.PDB4 bit field contains the payload filter 2 high order bits or payload mask high order bits for pretended networking payload filtering corresponding to data byte 4.
23:16 (R/W)	PDB5	Payload Filter 2 or Payload Mask Byte 5. The CANFD_FLTR_DATA2_DMSK_HI.PDB5 bit field contains the payload filter 2 high order bits or payload mask high order bits for pretended networking payload filtering corresponding to data byte 5.
15:8 (R/W)	PDB6	Payload Filter 2 or Payload Mask Byte 6. The CANFD_FLTR_DATA2_DMSK_HI.PDB6 bit field contains the payload filter 2 high order bits or payload mask high order bits for pretended networking payload filtering corresponding to data byte 6.
7:0 (R/W)	PDB7	Payload Filter 2 or Payload Mask Byte 7. The CANFD_FLTR_DATA2_DMSK_HI.PDB7 bit field contains the payload filter 2 high order bits or payload mask high order bits for pretended networking payload filtering corresponding to data byte 7.

Pretended Networking Payload Low Filter2 / Payload Low Mask Register

The CANFD_FLTR_DATA2_DMSK_LO register has two functions:

It contains the low order bits for the Payload Filter 2 value for use as the upper limit in payload range detection.

When exact payload filtering criteria is selected, the CANFD_FLTR_DATA2_DMSK_LO register is the payload mask.

Otherwise, the CANFD_FLTR_DATA2_DMSK_LO register is not used. It can only be written in freeze mode.

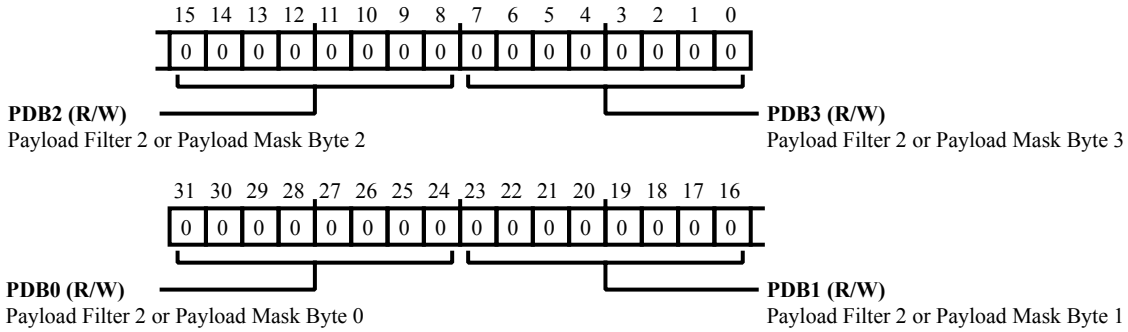

Figure 16-43: CANFD_FLTR_DATA2_DMSK_LO Register Diagram

Table 16-61: CANFD_FLTR_DATA2_DMSK_LO Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	PDB0	Payload Filter 2 or Payload Mask Byte 0. The CANFD_FLTR_DATA2_DMSK_LO.PDB0 bit field contains the payload filter 2 low order bits or payload mask low order bits for pretended networking payload filtering corresponding to data byte 0.
23:16 (R/W)	PDB1	Payload Filter 2 or Payload Mask Byte 1. The CANFD_FLTR_DATA2_DMSK_LO.PDB1 bit field contains the payload filter 2 low order bits or payload mask low order bits for pretended networking payload filtering corresponding to data byte 1.
15:8 (R/W)	PDB2	Payload Filter 2 or Payload Mask Byte 2. The CANFD_FLTR_DATA2_DMSK_LO.PDB2 bit field contains the payload filter 2 low order bits or payload mask low order bits for pretended networking payload filtering corresponding to data byte 2.
7:0 (R/W)	PDB3	Payload Filter 2 or Payload Mask Byte 3. The CANFD_FLTR_DATA2_DMSK_LO.PDB3 bit field contains the payload filter 2 low order bits or payload mask low order bits for pretended networking payload filtering corresponding to data byte 3.

Error Report Address Register

The CANFD_ERR_RADDR register reports the address of an access with an error (correctable or non-correctable) and reports the identification of the source of that access.

The address is 32-bit aligned. Non-aligned accesses, where the CANFD_ERRADDR[1:0] bits are non-zero, are reported with the address aligned and the data in the CANFD_ERR_RDAT register shifted accordingly. If there is an error in an access that is larger than 32 bits (as performed by CANFD internal processes), the address of the 32-bit word with the error is reported. In case of errors detected in more than one 32-bit word, only the least significant address is reported.

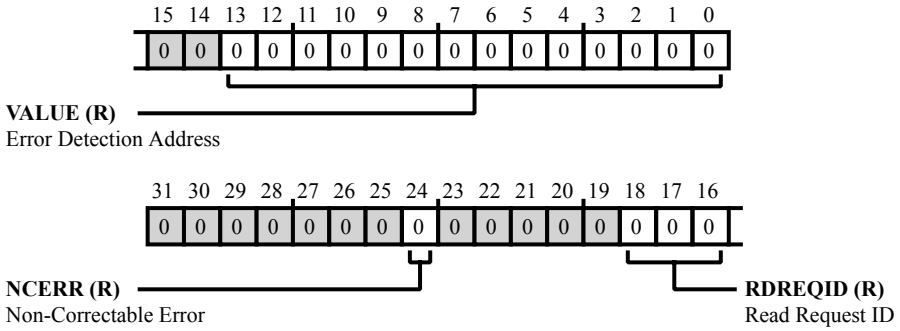

Figure 16-44: CANFD_ERR_RADDR Register Diagram

Table 16-62: CANFD_ERR_RADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
24 (R/NW)	NCERR	Non-Correctable Error. The CANFD_ERR_RADDR.NCERR bit indicates that a report is due to an non-correctable error. When the CANFD_ERR_RADDR.NCERR bit is set, it is reporting a non-correctable error. When it is cleared, it is reporting a correctable-error.	
18:16 (R/NW)	RDREQID	Read Request ID. The CANFD_ERR_RADDR.RDREQID bit field identifies the details of a memory read request.	
		0	Move-Out CANFD Access
		1	Move-In CANFD Access
		2	TX Arbitration
		3	Rx Matching
		4	Move-Out Host Access
		5	Reserved
		6	Reserved
		7	Reserved

Table 16-62: CANFD_ERR_RADDR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
13:0 (R/NW)	VALUE	Error Detection Address. The `CANFD_ERR_RADDR.VALUE` bit field contains the address where the error was detected. See the description of the Error Injection Address Register (`CANFD_ERR_IADDR`).

Error Report Data Register

The CANFD_ERR_RDAT register reports the raw data (unmodified by the ECC logic correction) read from the memory with the error. The value reported does not represent the transient values of the BUSY bit when reading a message buffer.

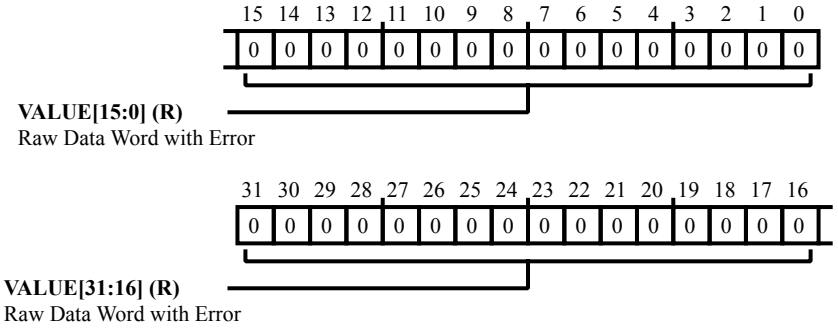

Figure 16-45: CANFD_ERR_RDAT Register Diagram

Table 16-63: CANFD_ERR_RDAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Raw Data Word with Error. The CANFD_ERR_RDAT.VALUE bit field contains the raw data word read from memory with error. This data word is unmodified by the correction performed by ECC logic and does not represent the transient values of the BUSY bit when reading the message buffer.

Error Report Syndrome Register

The CANFD_ERR_RSYN register holds the syndrome detected in a memory read with an error. It reports the bytes that are read in the 32-bit read transaction.

Each SYNDn field indicates the type of error and which bit in byte (n) is affected by the error. The CANFD_ERR_RSYN.SYND3 bit field corresponds to the most significant byte in the data word read from memory and the CANFD_ERR_RSYN.SYND0 bit field corresponds to the least significant.

Each BEn field indicates which byte in the 32-bit word reported was effectively read. The syndrome bits are calculated for all bytes, even for the non-read ones. Errors detected in non-read bytes are indicated and reported.

See the Detection and Correction of Memory Errors section of the CANFD chapter for more details.

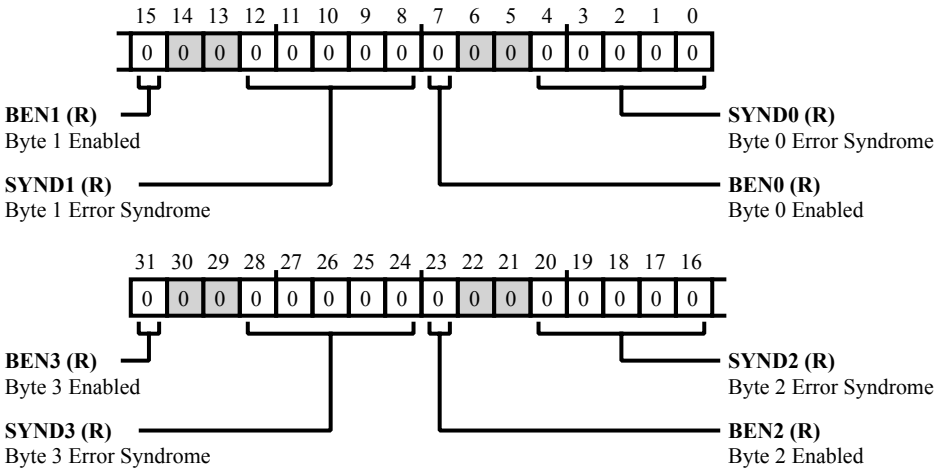

Figure 16-46: CANFD_ERR_RSYN Register Diagram

Table 16-64: CANFD_ERR_RSYN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/NW)	BEN3	Byte 3 Enabled. The CANFD_ERR_RSYN.BEN3 bit indicates if byte 3 (most significant) was read. If the CANFD_ERR_RSYN.BEN3 bit is enabled the byte was read, and if it is disabled then it was not read.	
		0	Disable
		1	Enable
28:24 (R/NW)	SYND3	Byte 3 Error Syndrome. The CANFD_ERR_RSYN.SYND3 bit field contains the error syndrome for byte 3. The Syndrome Definition table in the CANFD chapter defines the values for the CANFD_ERR_RSYN.SYND3 bit field.	

Table 16-64: CANFD_ERR_RSYN Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
23 (R/NW)	BEN2	Byte 2 Enabled. The CANFD_ERR_RSYN.BEN2 bit indicates if byte 2 was read. If the CANFD_ERR_RSYN.BEN2 bit is enabled the byte was read, and if it is disabled then it was not read.	
		0	Disable
		1	Enable
20:16 (R/NW)	SYND2	Byte 2 Error Syndrome. The CANFD_ERR_RSYN.SYND2 bit field contains the error syndrome for byte 2. The Syndrome Definition table in the CANFD chapter defines the values for the CANFD_ERR_RSYN.SYND2 bit field.	
15 (R/NW)	BEN1	Byte 1 Enabled. The CANFD_ERR_RSYN.BEN1 bit indicates if byte 1 was read. If the CANFD_ERR_RSYN.BEN1 bit is enabled the byte was read, and if it is disabled then it was not read.	
		0	Disable
		1	Enable
12:8 (R/NW)	SYND1	Byte 1 Error Syndrome. The CANFD_ERR_RSYN.SYND1 bit field contains the error syndrome for byte 1. The Syndrome Definition table in the CANFD chapter defines the values for the CANFD_ERR_RSYN.SYND1 bit field.	
7 (R/NW)	BEN0	Byte 0 Enabled. The CANFD_ERR_RSYN.BEN0 bit indicates if byte 2 (least significant) was read. If the CANFD_ERR_RSYN.BEN0 bit is enabled the byte was read, and if it is disabled then it was not read.	
		0	Disable
		1	Enable
4:0 (R/NW)	SYND0	Byte 0 Error Syndrome. The CANFD_ERR_RSYN.SYND0 bit field contains the error syndrome for byte 0 (least significant). The Syndrome Definition table in the CANFD chapter defines the values for the CANFD_ERR_RSYN.SYND0 bit field.	

Receive Mailbox14 Mask Register

The CANFD_RX_14_MSK register is located in RAM.

When the CANFD_CFG.IRMQEN bit is asserted, the CANFD_RX_14_MSK register has no effect.

The CANFD_RX_14_MSK register is used to mask the filter fields of message buffer 14.

This register can only be programmed while the CANFD module is in freeze mode as it is blocked by hardware in other modes.

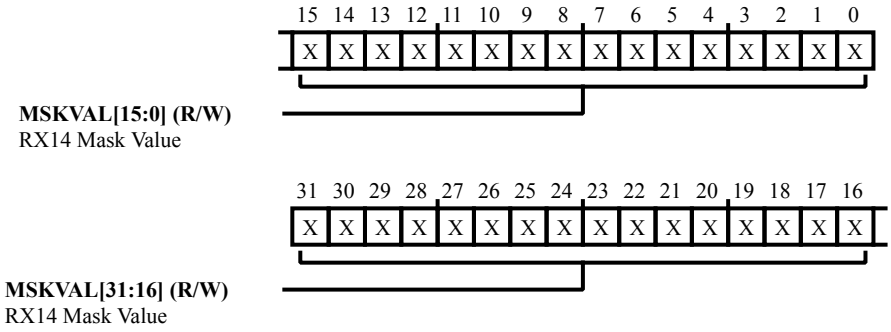

Figure 16-47: CANFD_RX_14_MSK Register Diagram

Table 16-65: CANFD_RX_14_MSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	MSKVAL	RX14 Mask Value. In the CANFD_RX_14_MSK.MSKVAL bit field, if a bit is a zero the corresponding bit in the filter is a don't care. If it is a one, the corresponding bit in the filter is checked. Each mask bit masks the corresponding mailbox 14 filter field in the same way that the CANFD_RX_MB_GMSK register masks other mailbox filters.

Receive Mailbox15 Mask Register

The CANFD_RX_15_MSK register is located in RAM.

When the CANFD_CFG.IRMQEN bit is asserted, the CANFD_RX_15_MSK register has no effect.

The CANFD_RX_15_MSK register is used to mask the filter fields of message buffer 15.

This register can only be programmed while the CANFD module is in freeze mode as it is blocked by hardware in other modes.

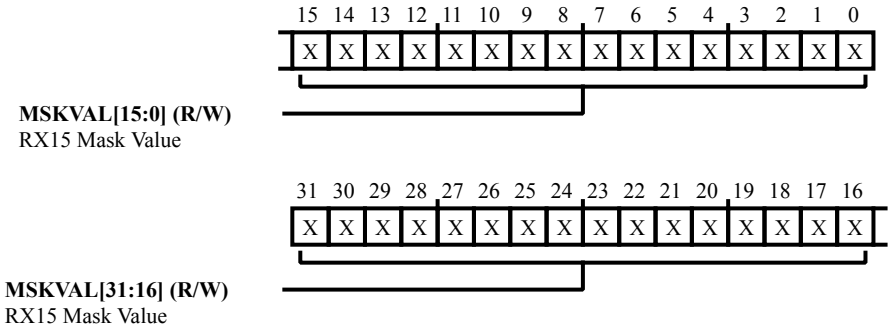

Figure 16-48: CANFD_RX_15_MSK Register Diagram

Table 16-66: CANFD_RX_15_MSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	MSKVAL	RX15 Mask Value. In the CANFD_RX_15_MSK.MSKVAL bit field, if a bit is a zero the corresponding bit in the filter is a don't care. If it is a one, the corresponding bit in the filter is checked. Each mask bit masks the corresponding mailbox 15 filter field in the same way that the CANFD_RX_MB_GMSK register masks other mailbox filters.

Receive FIFO Global Mask Register

The CANFD_RX_FIFO_GMSK register is located in RAM.

If the Rx FIFO is enabled, the CANFD_RX_FIFO_GMSK register is used to mask the Rx FIFO ID filter table elements that do not have a corresponding CANFD_RX_IMSK according to the CANFD_CTL2.RFFNUM bit field setting.

The CANFD_RX_FIFO_GMSK register can only be written in freeze mode as it is blocked by hardware in other modes.

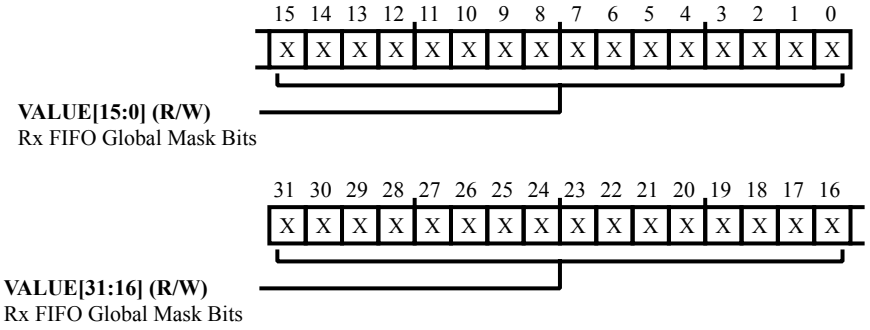

Figure 16-49: CANFD_RX_FIFO_GMSK Register Diagram

Table 16-67: CANFD_RX_FIFO_GMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Rx FIFO Global Mask Bits. The CANFD_RX_FIFO_GMSK.VALUE bits mask the ID filter table elements bits in a perfect alignment. If the CANFD_RX_FIFO_GMSK.VALUE bit is set, the corresponding bit in the filter is checked. If it is clear, the corresponding bit in the filter is a dont care. See the Identifier Acceptance Filter Fields for Global Mask Bits table in the CANFD chapter.

Receive FIFO Information Register

The CANFD_RX_FIFO register provides information on the Rx FIFO.

The CANFD_RX_FIFO register is the port through which the processor accesses the output of the RXFIR FIFO located in RAM. The CANFD_RX_FIFO register is written by the CANFD module whenever a new message is moved into the Rx FIFO and the register output is updated whenever the output of the Rx FIFO is updated with the next message.

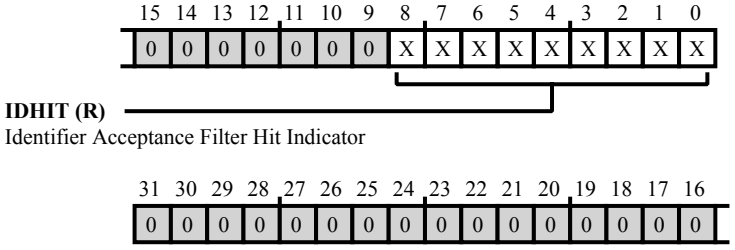

Figure 16-50: CANFD_RX_FIFO Register Diagram

Table 16-68: CANFD_RX_FIFO Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
8:0 (R/NW)	IDHIT	Identifier Acceptance Filter Hit Indicator. The CANFD_RX_FIFO.IDHIT bit field indicates which identifier acceptance filter was hit by the received message that is in the output of the Rx FIFO. If multiple filters match the incoming message ID, the first matching IDAF found (lowest number) by the matching process is indicated. The CANFD_RX_FIFO.IDHIT bit field is valid only while the CANFD_IFLG1.MB05 bit is set.

Receive Individual Mask Register

The CANFD_RX_IMSK[n] registers are used to store the acceptance masks for ID filtering in Rx MBs and the Rx FIFO.

When the Rx FIFO is disabled (CANFD_CFG.RFEN is disabled), an individual mask is provided for each available Rx mailbox on a one-to-one correspondence. When the Rx FIFO is enabled (CANFD_CFG.RFEN is enabled), an individual mask is provided for each Rx FIFO ID Filter table element on a one-to-one correspondence depending on the setting of the CANFD_CTL2.RFFNUM bit.

The CANFD_RX_IMSK0 register stores the individual mask associated with either MB0 or ID Filter Table Element 0, CANFD_RX_IMSK1 stores the individual mask associated with either MB1 or ID Filter Table Element 1, and so on.

The CANFD_RX_IMSK[n] registers are only be accessed by the processor while the CANFD is in freeze mode and are otherwise blocked by hardware.

The CANFD_RX_IMSK[n] registers are not affected by reset. They are located in RAM and must be explicitly initialized prior to any reception.

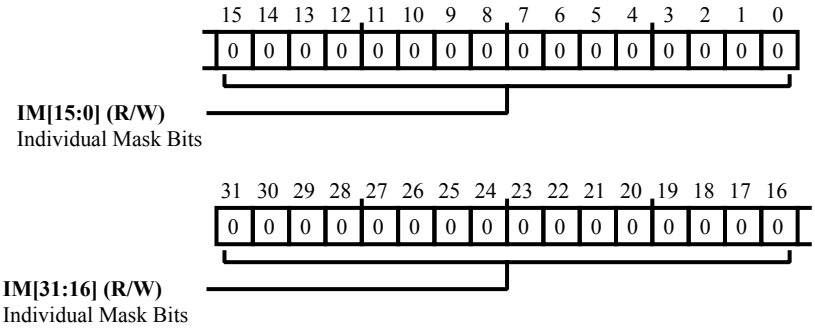

Figure 16-51: CANFD_RX_IMSK[n] Register Diagram

Table 16-69: CANFD_RX_IMSK[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	IM	Individual Mask Bits. The CANFD_RX_IMSK[n].IM bits masks the corresponding bit in both the mailbox filter and Rx FIFO ID filter table element in distinct ways. For mailbox filters, see the CANFD_RX_MB_GMSK register description. For Rx FIFO ID filter table elements, see the CANFD_RX_FIFO_GMSK register description. If a bit in the CANFD_RX_IMSK[n].IM field is set, the corresponding bit in the filter is checked. If it is cleared, the corresponding bit in the filter is a don't care.

Receive Mailbox Global Mask Register

The CANFD_RX_MB_GMSK register is located in RAM.

When the CANFD_CFG.IRMQEN bit is disabled, the CANFD_RX_MB_GMSK register is always in effect (the bits in the MG field will mask the mailbox filter bits).

When the CANFD_CFG.IRMQEN bit is enabled, the CANFD_RX_MB_GMSK register has no effect (the bits in the MG field will not mask the mailbox filter bits).

The CANFD_RX_MB_GMSK register is used to mask the filter fields of all Rx MBs, excluding MBs 14–15, which have individual mask registers.

The CANFD_RX_MB_GMSK register can only be written in freeze mode and is blocked by hardware in other modes.

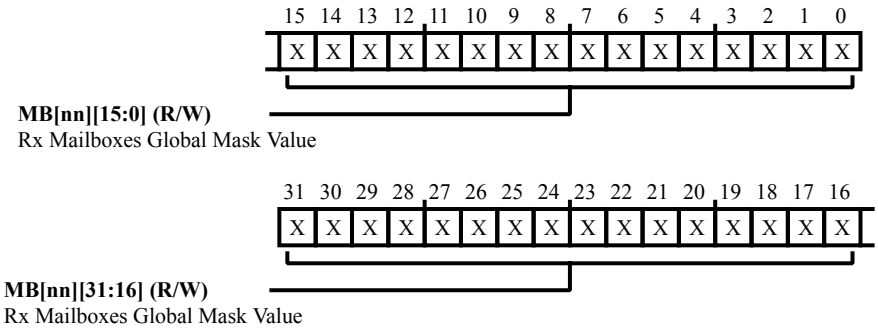

Figure 16-52: CANFD_RX_MB_GMSK Register Diagram

Table 16-70: CANFD_RX_MB_GMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:0 (R/W)	MB[nn]	Rx Mailboxes Global Mask Value. For all CANFD_RX_MB_GMSK.MB[nn] bits, write =0 for stop, and write =1 for start. Read =1 when timer is running. The bits in the CANFD_RX_MB_GMSK.MB[nn] bit field mask the mailbox filter bits. If a bit in the field is a zero, the corresponding bit in the filter is a don't care. If the bit is a one, the corresponding bit in the filter is checked. Note that the alignment with the ID word of the mailbox is not perfect as the two most significant bits affect the fields RTR and IDE, which are located in the control and status (C/S) word of the mailbox. For more details on this bit field, see the Mailbox Global Filter Field Mask table in the CANFD chapter.	
		0	Don't Care
		1	Checked

Free Running Timer Register

The CANFD_TMR register is a 16-bit free running counter. The timer starts from 0x0 after reset, counts linearly to 0xFFFF, and wraps around.

The timer is incremented by the CAN bit clock, which defines the baud rate on the CAN bus. During a message transmission/reception, the timer increments by one for each bit that is received or transmitted. When there is no message on the bus, the timer counts using the previously programmed baud rate. The timer is not incremented during module disable, doze, stop, pretended networking, and freeze modes.

The timer value is captured when the second bit of the identifier field of any frame is on the CAN bus. This captured value is written into the time stamp entry in a message buffer after the successful reception or transmission of a message.

If the CANFD_CTL1.TSYNEN bit is enabled, the timer is reset whenever a message is received in the first available mailbox, according to the CANFD_CTL2.RFFNUM setting.

The processor can write to this register anytime. However, if the write occurs at the same time that the timer is being reset by a reception in the first mailbox, then the write value is discarded.

Reading this register affects the mailbox unlocking procedure.

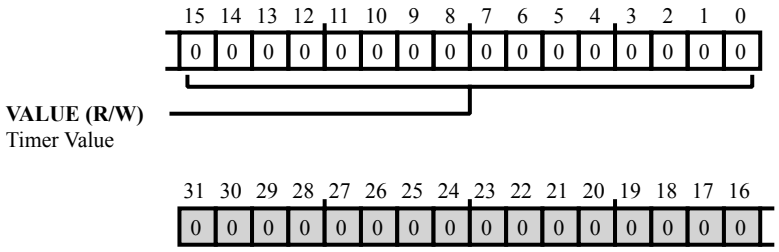

Figure 16-53: CANFD_TMR Register Diagram

Table 16-71: CANFD_TMR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Timer Value. The CANFD_TMR.VALUE bit field contains the free-running counter value.

Wakeup Message Buffer Data 4-7 Register

The CANFD_WMB[n]_DATA_HI registers are the wakeup message buffer data 4-7 registers. Each of the four wake up message buffers contains a register to store the data bytes 4 to 7 of the payload information of an incoming Rx message. This register content is cleared when the incoming matched message is either a remote frame (RTR=1) or a data frame with DLC=0.

Note that the data 4-7 registers are located at 0xB4C for WMB0, 0xB5C for WMB1, 0xB6C for WMB2, and 0xB7C for WMB3.

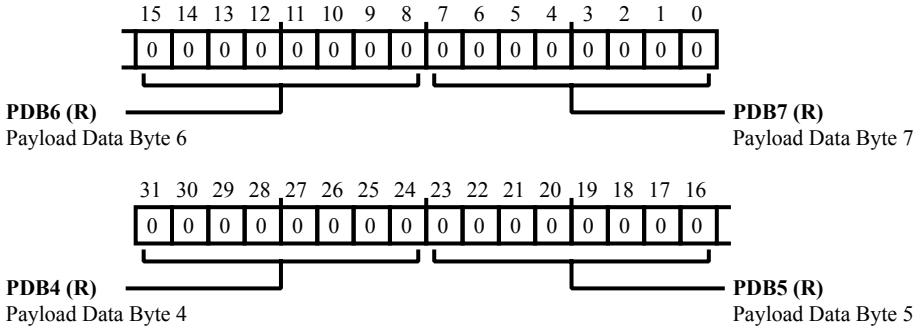

Figure 16-54: CANFD_WMB[n]_DATA_HI Register Diagram

Table 16-72: CANFD_WMB[n]_DATA_HI Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/NW)	PDB4	Payload Data Byte 4. The CANFD_WMB[n]_DATA_HI.PDB4 bit field contains the received payload corresponding to data byte 4 in pretended networking mode.
23:16 (R/NW)	PDB5	Payload Data Byte 5. The CANFD_WMB[n]_DATA_HI.PDB5 bit field contains the received payload corresponding to data byte 5 in pretended networking mode.
15:8 (R/NW)	PDB6	Payload Data Byte 6. The CANFD_WMB[n]_DATA_HI.PDB6 bit field contains the received payload corresponding to data byte 6 in pretended networking mode.
7:0 (R/NW)	PDB7	Payload Data Byte 7. The CANFD_WMB[n]_DATA_HI.PDB7 bit field contains the received payload corresponding to data byte 7 in pretended networking mode.

Wakeup Message Buffer Data 0-3 Register

The CANFD_WMB[n]_DATA_LO registers are the wakeup message buffer data 0-3 registers. Each of the four wake up message buffers contains a register to store the data bytes 0 to 3 of the payload information of an incoming Rx message. This register content is cleared when the incoming matched message is either a remote frame (RTR=1) or a data frame with DLC=0.

Note that the data 0-3 registers are located at 0xB48 for WMB0, 0xB58 for WMB1, 0xB68 for WMB2, and 0xB78 for WMB3.

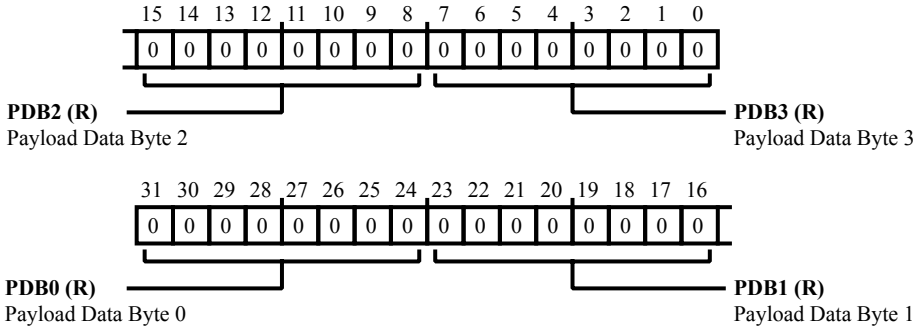

Figure 16-55: CANFD_WMB[n]_DATA_LO Register Diagram

Table 16-73: CANFD_WMB[n]_DATA_LO Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/NW)	PDB0	Payload Data Byte 0. The CANFD_WMB[n]_DATA_LO.PDB0 bit field contains the received payload corresponding to data byte 0 in pretended networking mode.
23:16 (R/NW)	PDB1	Payload Data Byte 1. The CANFD_WMB[n]_DATA_LO.PDB1 bit field contains the received payload corresponding to data byte 1 in pretended networking mode.
15:8 (R/NW)	PDB2	Payload Data Byte 2. The CANFD_WMB[n]_DATA_LO.PDB2 bit field contains the received payload corresponding to data byte 2 in pretended networking mode.
7:0 (R/NW)	PDB3	Payload Data Byte 3. The CANFD_WMB[n]_DATA_LO.PDB3 bit field contains the received payload corresponding to data byte 3 in pretended networking mode.

Wakeup Message ID Buffer Register

The CANFD_WMB[n]_ID registers are the wakeup message ID buffers. Each of the four wake up message buffers contains a register to store the ID information of an incoming Rx message.

Note that the ID registers are located at 0xB44 for WMB0, 0xB54 for WMB1, 0xB64 for WMB2, and 0xB74 for WMB3.

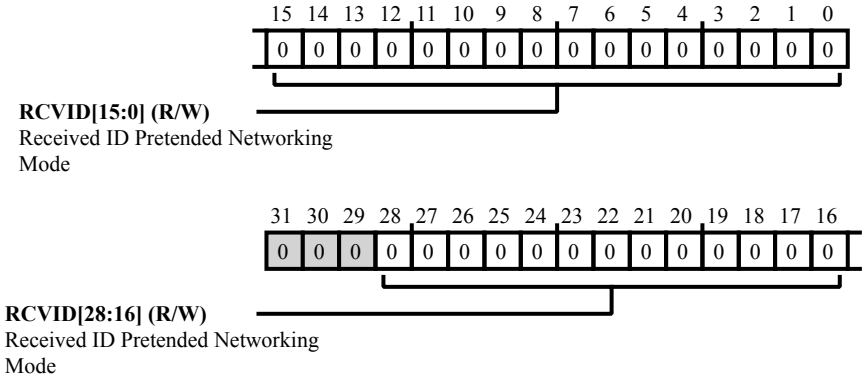

Figure 16-56: CANFD_WMB[n]_ID Register Diagram

Table 16-74: CANFD_WMB[n]_ID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
28:0 (R/W)	RCVID	Received ID Pretended Networking Mode. The CANFD_WMB[n]_ID.RCVID bit field stores the received ID as either, the 29 bits of the extended frame format (considering the ID[28:0] field) or the 11 bits of the standard frame format (considering the ID[28:18] field only. In the standard frame format, the remaining bits in the ID[17:0] range have no meaning.

Wakeup Message Buffer Control/Status Register

The CANFD_WMB[n]_STAT registers are the for wakeup message buffer control and status information. Each of the four wake up message buffers contains a register to store the control status information (IDE, RTR and DLC fields) of an incoming Rx message.

Note that the control status registers are located at 0xB40 for WMB0, 0xB50 for WMB1, 0xB60 for WMB2, and 0xB70 for WMB3.

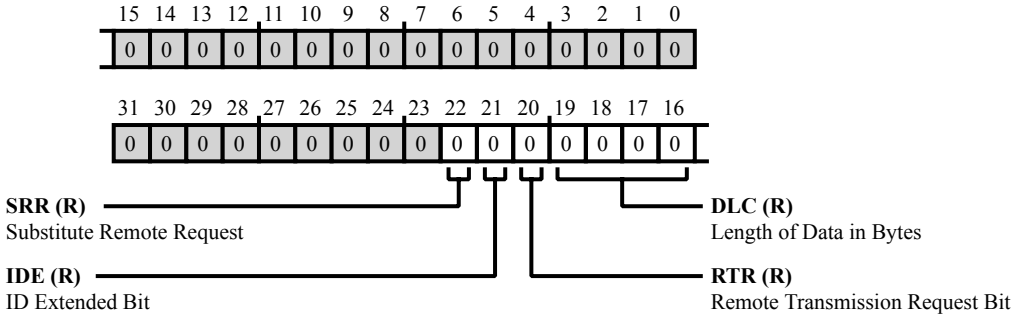

Figure 16-57: CANFD_WMB[n]_STAT Register Diagram

Table 16-75: CANFD_WMB[n]_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
22 (R/NW)	SRR	Substitute Remote Request. The CANFD_WMB[n]_STAT.SRR bit is received as either recessive or dominant.	
21 (R/NW)	IDE	ID Extended Bit. The CANFD_WMB[n]_STAT.IDE bit identifies is the frame format is standard or extended.	
		0	Standard Frame Format
		1	Extended Frame Format
20 (R/NW)	RTR	Remote Transmission Request Bit. The CANFD_WMB[n]_STAT.RTR bit identifies if the frame is remote.	
		0	Data Frame (Not Remote)
		1	Remote Frame
19:16 (R/NW)	DLC	Length of Data in Bytes. The CANFD_WMB[n]_STAT.DLC bit field represents the length (in bytes) of the Rx data received when the CANFD module is in pretended networking mode. The CANFD_WMB[n]_STAT.DLC bit field is written by the CANFD module, copied from the data length code (DLC) field of the received frame. The DLC field indicates which data bytes are valid.	

Pretended Networking Wakeup Match Register

The CANFD_WUM register contains wake up information related to the matching processes performed while the CANFD module receives frames under pretended networking mode.

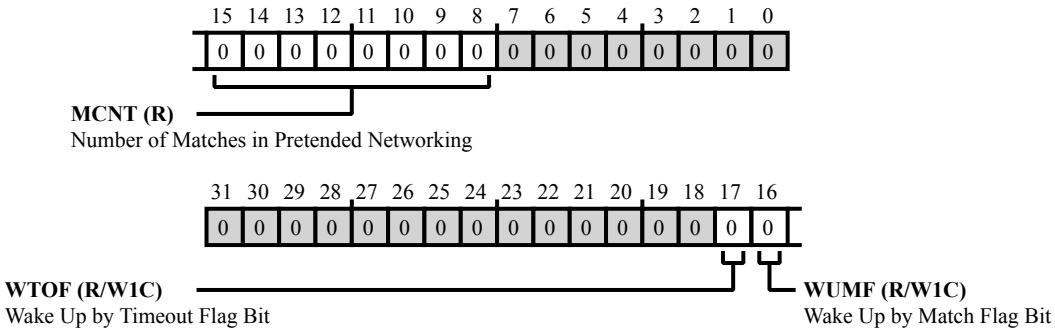

Figure 16-58: CANFD_WUM Register Diagram

Table 16-76: CANFD_WUM Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/W1C)	WTOF	Wake Up by Timeout Flag Bit. The CANFD_WUM.WTOF bit indicates if the CANFD module detects a timeout event during a time interval defined by the CANFD_PN_CTL2.MATCHTO bit field. WTOF generates a wakeup event if the CANFD_PN_CTL1.WTOFMSK enabled.	
		0	No event detected
		1	Wakeup event detected
16 (R/W1C)	WUMF	Wake Up by Match Flag Bit. The CANFD_WUM.WUMF bit indicates whether the CANFD module detects a matching Rx incoming message passing the filtering criteria specified in the CANFD_PN_CTL1 register. WUMF generates a wakeup event if the CANFD_PN_CTL1.WUMFMSK bit is enabled.	
		0	No event detected
		1	Wakeup event detected
15:8 (R/NW)	MCNT	Number of Matches in Pretended Networking. The CANFD_WUM.MCNT bit field reports the number of times a given message matches the predefined filtering criteria for ID and/or PL before a wake up event. The CANFD_WUM.MCNT bit field is reset by the CANFD module when it enters pretended networking mode. This bit field and is not affected by a soft reset.	

ADSP-SC59x MISCREG Register Descriptions

Misc registers for module are for integration purpose (MISCREG) contains the following registers.

Table 16-77: ADSP-SC59x MISCREG Register List

Name	Description
MISCREG_CAN_SYSCTL	CANFD Low Power Selection Mode
MISCREG_ECO_REG9	Error Register
MISCREG_PLL2_CONTROL	PLL2 Control Register
MISCREG_SH0_PFB_RANGE_SELECT	SH0 Prefetch Range Selection Register
MISCREG_SH1_PFB_RANGE_SELECT	SH1 Prefetch Range Selection Register
MISCREG_SHARC_BRIDGE_REMAP	SPORT Direct Interrupt Enable for SH0 and SH1

CANFD Low Power Selection Mode

The MISCREG_CAN_SYSCTL register contains the control bits for the different low power modes supported in the CANFD module.

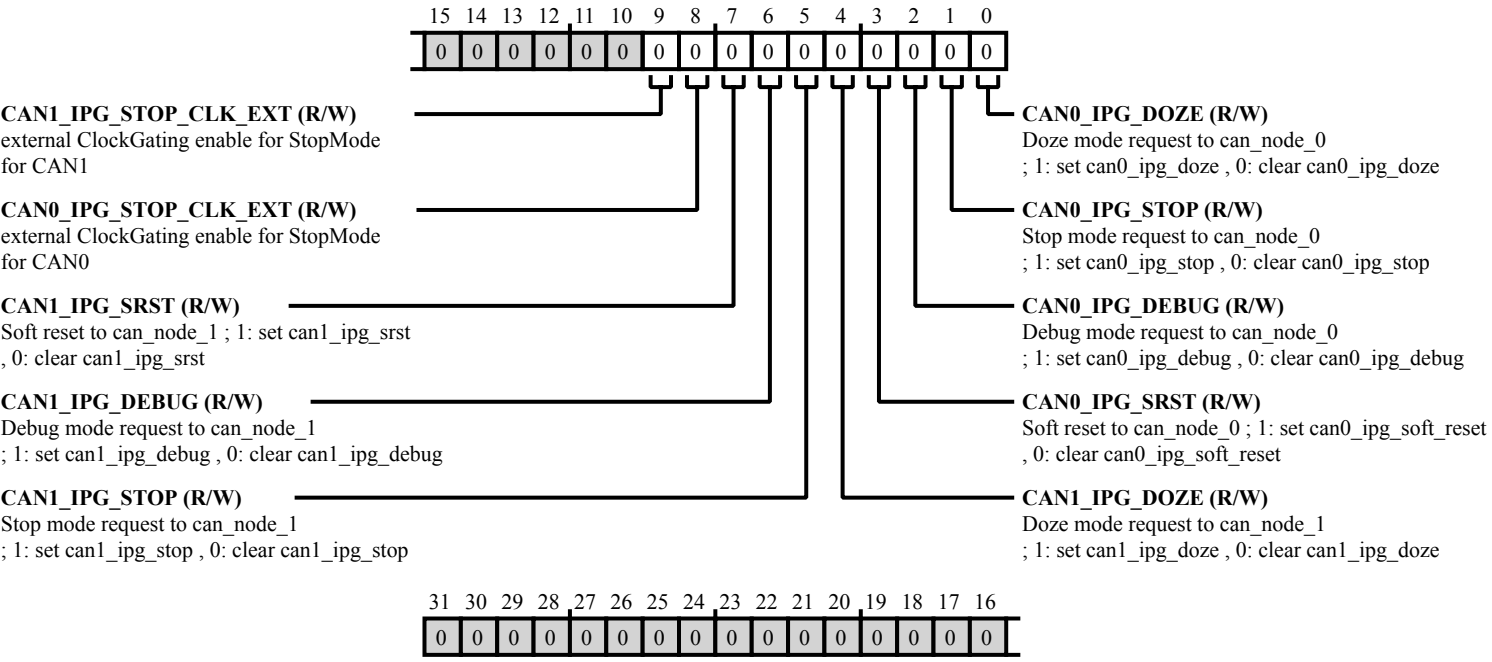

Figure 16-59: MISCREG_CAN_SYSCTL Register Diagram

Table 16-78: MISCREG_CAN_SYSCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
9 (R/W)	CAN1_IPG_STOP_CLK_EXT	external ClockGating enable for StopMode for CAN1.
8 (R/W)	CAN0_IPG_STOP_CLK_EXT	external ClockGating enable for StopMode for CAN0.
7 (R/W)	CAN1_IPG_SRST	Soft reset to can_node_1 ; 1: set can1_ipg_srst , 0: clear can1_ipg_srst.
6 (R/W)	CAN1_IPG_DEBUG	Debug mode request to can_node_1 ; 1: set can1_ipg_debug , 0: clear can1_ipg_debug.

Bit No. (Access)	Bit Name	Description/Enumeration
1 (R/W1)	EMAC0_DMA1_TX_ERR	DMA received a 2nd start (stop) trigger before a stop (start) trigger.
0 (R/W1)	EMAC0_DMA0_TX_ERR	DMA received a 2nd start (stop) trigger before a stop (start) trigger.

PLL2 Control Register

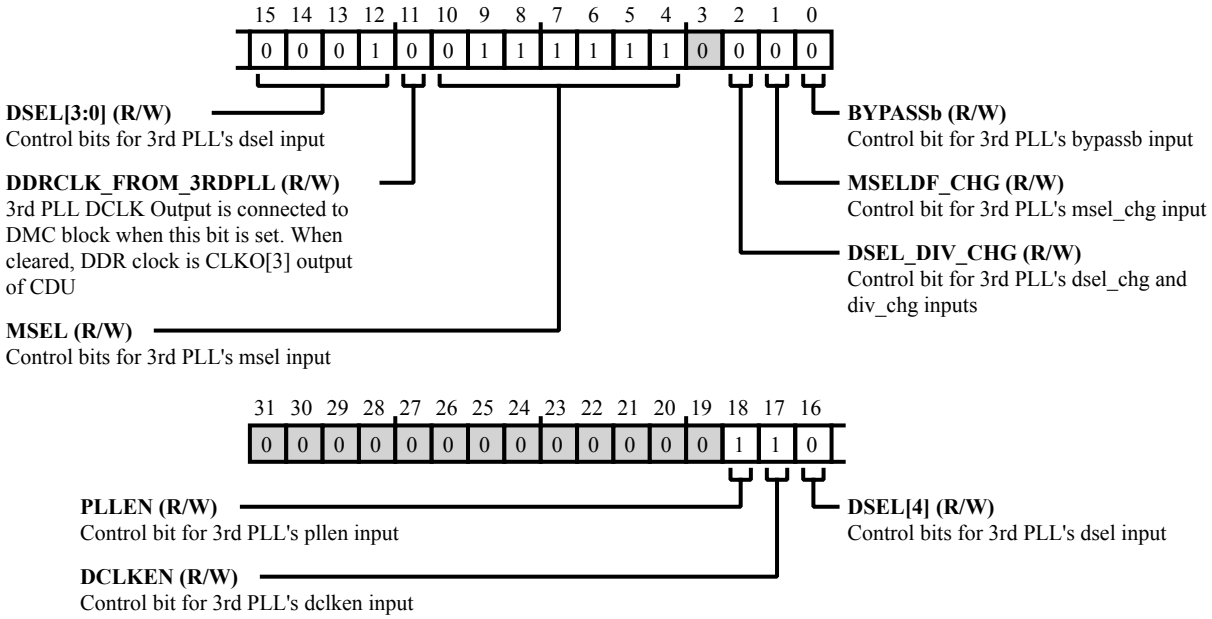

Figure 16-61: MISCREG_PLL2_CONTROL Register Diagram

Table 16-80: MISCREG_PLL2_CONTROL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
18 (R/W)	PLLEN	Control bit for 3rd PLL's pllen input. Internal signal from Dynamic Power Management Unit (DPM) which enables/disables the PLL system (e.g. in Active mode, during BYPASS.)
17 (R/W)	DCLKEN	Control bit for 3rd PLL's dclken input. Enables DCLK clock buffer
16:12 (R/W)	DSEL	Control bits for 3rd PLL's dsel input. Selects DCLK divide ratio
11 (R/W)	DDRCLK_FROM_3RDPLL	3rd PLL DCLK Output is connected to DMC block when this bit is set. When cleared, DDR clock is CLKO[3] output of CDU. 3rd PLL DCLK Output is connected to DMC block when this bit is set. When cleared, DDR clock is CLKO[3] output of CDU
10:4 (R/W)	MSEL	Control bits for 3rd PLL's msel input. The `MISCREG_PLL2_CONTROL.MSEL` selects the multiplier in the PLLCLK equation: PLLCLK frequency = (SYS_CLKIN frequency / (DF+1)) * MSEL * 2 Where the value of MSEL is between 1 and 127.

Table 16-80: MISCREG_PLL2_CONTROL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
2 (R/W)	DSEL_DIV_CHG	Control bit for 3rd PLL's dsel_chg and div_chg inputs. Signal from PCU indicating a DDR clock frequency change
1 (R/W)	MSELDF_CHG	Control bit for 3rd PLL's msel_chg input. Signal from PLL Control Unit indicating a frequency change resulting from a change in either the DF or MSEL bits.
0 (R/W)	BYPASSB	Control bit for 3rd PLL's bypassb input. Active-low control bit to bypass the PLL which forces CLKIN on all output clocks

SH0 Prefetch Range Selection Register

In the MISCREG_SH0_PFB_RANGE_SELECT register, each bit field controls if the corresponding address range will be prefetched. When an address range is set it is prefetched and when it is zero there is no prefetch.

The MISCREG_SH0_PFB_RANGE_SELECT[31:16] bits control the range selection for the instruction cache, and MISCREG_SH0_PFB_RANGE_SELECT[15:0] bits control the range selection for the data cache.

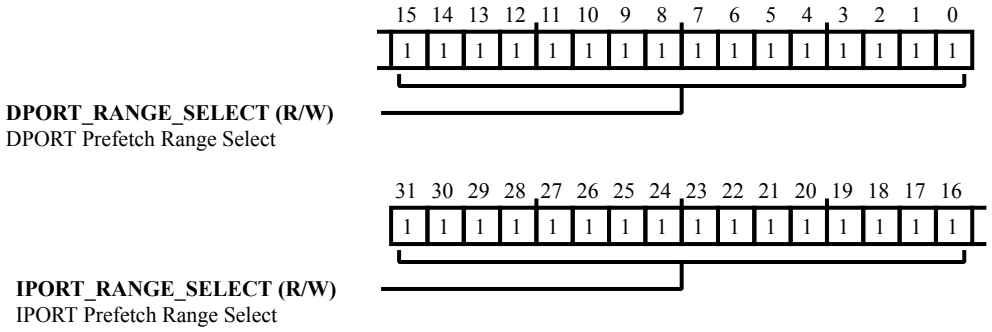

Figure 16-62: MISCREG_SH0_PFB_RANGE_SELECT Register Diagram

Table 16-81: MISCREG_SH0_PFB_RANGE_SELECT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/W)	IPORT_RANGE_SELECT	IPORT Prefetch Range Select. Prefetch Range Selection for IPORT
15:0 (R/W)	DPORT_RANGE_SELECT	DPORT Prefetch Range Select. Prefetch Range Selection for DPORT

SH1 Prefetch Range Selection Register

Each bit field controls if the corresponding address range will be prefetched. When an address range is set it is prefetched an when it is zero there is no prefetch.

The MISCREG_SH1_PFB_RANGE_SELECT[31:16] bits control the range selection for the instruction cache, and MISCREG_SH1_PFB_RANGE_SELECT[15:0] bits control the range selection for the data cache.

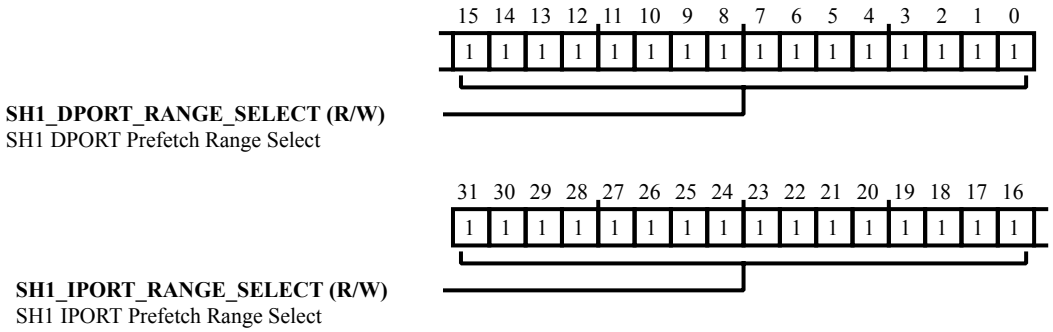

Figure 16-63: MISCREG_SH1_PFB_RANGE_SELECT Register Diagram

Table 16-82: MISCREG_SH1_PFB_RANGE_SELECT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/W)	SH1_IPORT_RANGE_SELECT	SH1 IPORT Prefetch Range Select. Prefetch Range Selection for IPORT
15:0 (R/W)	SH1_DPORT_RANGE_SELECT	SH1 DPORT Prefetch Range Select. Prefetch Range Selection for DPORT

SPORT Direct Interrupt Enable for SH0 and SH1

The bits in the MISCREG_SHARC_BRIDGE_REMAP register control the direct connection of SPORT interrupts to the SHARC core.

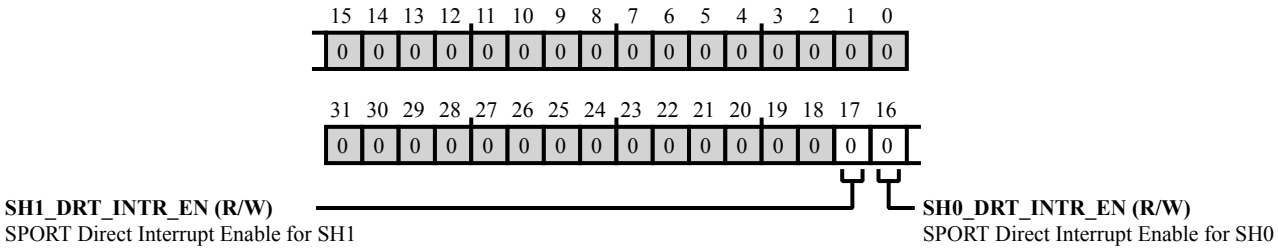

Figure 16-64: MISCREG_SHARC_BRIDGE_REMAP Register Diagram

Table 16-83: MISCREG_SHARC_BRIDGE_REMAP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
17 (R/W)	SH1_DRT_INTR_EN	SPORT Direct Interrupt Enable for SH1. If the MISCREG_SHARC_BRIDGE_REMAP.SH1_DRT_INTR_EN bit is set a direct connection is enabled for SH1. Do not set the MISCREG_SHARC_BRIDGE_REMAP.SH1_DRT_INTR_EN bit when IIR1 of the SH1 is in use. If this bit is zero the direct connection is disabled.
16 (R/W)	SH0_DRT_INTR_EN	SPORT Direct Interrupt Enable for SH0. If the MISCREG_SHARC_BRIDGE_REMAP.SH0_DRT_INTR_EN bit is set a direct connection is enabled for SH0. Do not set the MISCREG_SHARC_BRIDGE_REMAP.SH0_DRT_INTR_EN bit when IIR1 of the SH0 is in use. If this bit is zero the direct connection is disabled.

17 Watchdog Timer (WDOG)

The processor has a 32-bit watchdog timer that can be used to verify system reliability by generating an event to the processor core when the watchdog expires before software updates it.

WDOG Features

The watchdog timer has the following features:

- Programmable 32-bit watchdog count value
- 8-bit disable bit pattern
- General-purpose core event generation

The watchdog timer can supervise system software stability by periodically reloading it to prevent expiration of the downward-counting timer (such that the count never becomes 0). When used in this fashion, an expiring timer can indicate the system software is not running normally.

Expiration of the WDOG counter generates a general-purpose interrupt, which can be used in a variety of ways:

- as an interrupt vector sent through the System Event Controller (SEC) to the core to be serviced by a handler function, providing full software control of device resources (for example, GPIO management and reset control).
- as a fault condition through the SEC to provide hardware-automated:
    - signaling of the fault condition on external pins to the system,
    - system reset requests to the Reset Control Unit (RCU), and/or
    - trigger outputs (SEC0_FAULT trigger generator) through the Trigger Routing Unit (TRU) to initiate activities in a variety of potential trigger receiver (for example, GPIO control).

To help debugging, the watchdog timer does not decrement (even when enabled) if the processor is in emulation mode.

WDOG Functional Description

When enabled, the 32-bit watchdog timer counts downward every SCLK0_0 cycle. If it reaches zero, the watchdog expiration event is generated, which can be used in many ways.

To start the watchdog timer:

1. Program the watchdog timeout period (in SCLK0_0 cycles) in the WDOG_CNT register. With the watchdog disabled, this write also preloads the WDOG_STAT register.
2. Enable the watchdog timer by writing any value other than 0xAD to the WDOG_CTL.WDEN field.

Once the watchdog is enabled, writes to the WDOG_CNT register are ignored. The counter begins decrementing, and the current counter value can be read from the 32-bit WDOG_STAT register at any time.

To prevent the counter from expiring, software must "kick" the watchdog by writing any value to the WDOG_STAT register while the current count is non-zero. While the value written is irrelevant and ignored, this action resets the current counter in the WDOG_STAT register to the programmed WDOG_CNT value, and decrementing continues. The internal counter continues decrementing until it reaches zero, at which point the expiration event is generated, and the WDOG_CTL.WDRO rollover bit is set.

Watchdog operation continues in this manner unless disabled by explicitly writing 0xAD to the WDOG_CTL.WDEN field.

The watchdog expiration event can be used in a variety of ways, as listed below.

- The watchdog expiration event itself is one of numerous interrupt sources that is managed by the System Event Controller. Like other peripheral sources, this event can be used to cause a vector to a handler function that executes based on interrupt priority.
- The watchdog expiration event can be used to initiate automated hardware response through the SEC Fault Interface (SFI).

For this, the WDOG expiry must be configured as the fault source in the SEC. Then the response to the WDOG expiry can be set to any of the following actions:

- Signaling through the external fault pin.
- System reset.
- Trigger outputs to numerous potential trigger completers.

For further details on how watchdog expiration event can be used with the SFI, see Configuring the WDOG Expiry Event to Issue a System Reset.

ADSP-SC59x WDOG Register List

The Watchdog Timer unit (WDOG) provides a software-based watchdog timer that can improve system reliability by generating an event to the processor core if the watchdog expires before being updated by software. A set of registers governs WDOG operations. For more information on WDOG functionality, see the WDOG register descriptions.

Table 17-1: ADSP-SC59x WDOG Register List

WDOG Block Diagram

The ***Watchdog Timer Block Diagram*** figure shows the detailed block diagram for the watchdog timer.

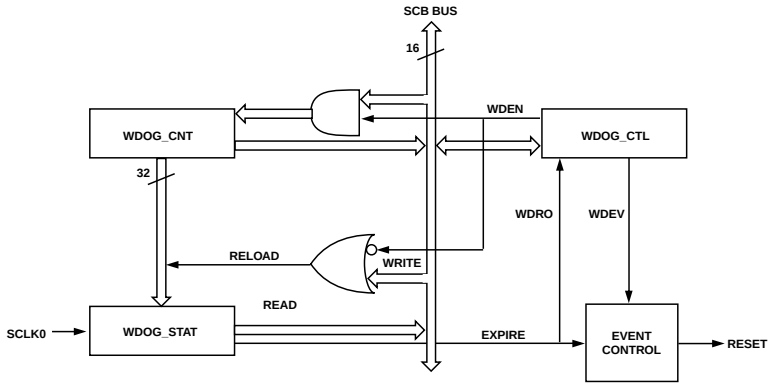

Figure 17-1: Watchdog Timer Block Diagram

Internal Interface

The system clock (SCLK0) clocks the watchdog timer. The registers are accessed through the peripheral MMR access bus. 32-bit read/write operations always access the 32-bit `WDOG_CNT` and `WDOG_STAT` registers. Hardware ensures that those accesses are atomic. When the counter expires, the WDOG expiration event is generated.

External Interface

The watchdog timer does not directly interact with any external pins.

ADSP-SC59x WDOG Register Descriptions

Watchdog Timer Unit (WDOG) contains the following registers.

Table 17-5: ADSP-SC59x WDOG Register List

Name	Description
`WDOG_CNT`	Count Register
`WDOG_CTL`	Control Register
`WDOG_STAT`	Watchdog Timer Status Register
`WDOG_WIN`	Watchdog Timer Window Register

Count Register

The WDOG_CNT register holds the programmable, unsigned count value. A valid write to this register also pre-loads the WDOG counter. For added safety, the WDOG_CNT register can be updated only when the WDOG timer is disabled. A write to the WDOG_CNT register while the timer is enabled does not modify the contents of this register. This register must be accessed with 32-bit read/writes only.

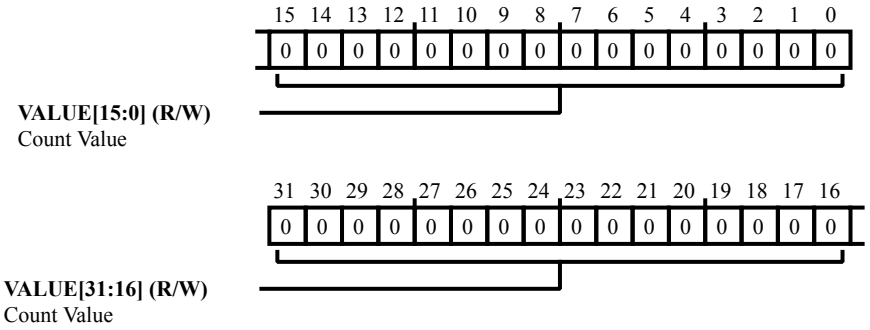

Figure 17-2: WDOG_CNT Register Diagram

Table 17-6: WDOG_CNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Count Value. The WDOG_CNT.VALUE bit field holds the programmable, unsigned count value.

Control Register

The WDOG_CTL register controls the watchdog timer. This register supports enabling/disabling the watchdog timer and supports checking the timer rollover status. Note that when the processor is in emulation mode, the watchdog timer counter will not decrement even if it is enabled.

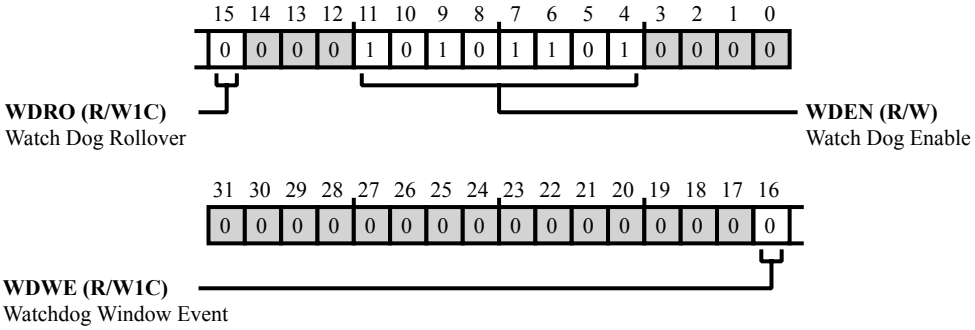

Figure 17-3: WDOG_CTL Register Diagram

Table 17-7: WDOG_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/W1C)	WDWE	Watchdog Window Event. Software can determine whether the timer has been serviced unexpectedly early by interrogating the WDOG_CTL.WDWE status bit. This is a sticky bit that is set whenever the watchdog is serviced and the WDOG_STAT value is greater than the WDOG_WIN value. It is cleared only by disabling the watchdog timer and by writing a 1 to the bit.	
		0	Window Event has not occurred
		1	Window Event has occurred
15 (R/W1C)	WDRO	Watch Dog Rollover. Software can determine whether the timer has rolled over by interrogating the WDOG_CTL.WDRO status bit. This is a sticky bit that is set whenever the watch dog timer count reaches 0 and cleared only by disabling the watch dog timer and then writing a 1 to the bit.	
		0	WDT Has Not Expired
		1	WDT Has Expired
11:4 (R/W)	WDEN	Watch Dog Enable. The WDOG_CTL.WDEN field is used to enable and disable the watchdog timer. Writing any value other than the disable value into this field enables the watchdog timer. This multi-bit disable key minimizes the chance of inadvertently disabling the watchdog timer.	
		173	Counter Disabled. All other values mean that the counter is enabled.

Watchdog Timer Status Register

The WDOG_STAT register contains the current count value of the watchdog timer. Reads of this register return the current count value. When the watchdog timer is enabled, the WDOG_STAT register is decremented by 1 on each SCLK0 cycle. When the count value reaches 0, the watchdog timer stops counting, and the expiry event is generated. The WDOG_STAT register is a 32-bit unsigned system MMR that must be accessed with 32-bit reads and writes.

Values cannot be stored directly in this register but are instead copied from the WDOG_CNT register. This copy process can happen in two ways:

- While the watchdog timer is disabled, writing the WDOG_CNT register pre-loads the WDOG_STAT register.
- While the watchdog timer is enabled, writing the WDOG_STAT register loads it with the value in the WDOG_CNT register.
- While the watchdog timer is disabled, writing to the WDOG_STAT register also reloads it with the value in the WDOG_CNT register.

When the processor executes a write (of an arbitrary value) to the WDOG_STAT register, the value in the WDOG_CNT register is copied into the WDOG_STAT register. Typically, software sets the value of WDOG_CNT at initialization, then periodically writes to the WDOG_STAT register before the watchdog timer expires. This reloads the watchdog timer with the value from WDOG_CNT and prevents generation of the expiry event.

If the program does not reload the counter before SCLK0 x count register cycles, an expiry event is generated, and the WDOG_CTL.WDRO bit is set. When this happens, the counter stops decrementing and remains at zero. If the counter is enabled with a zero loaded to the counter, the WDOG_CTL.WDRO bit is set immediately and the counter remains at zero and does not decrement.

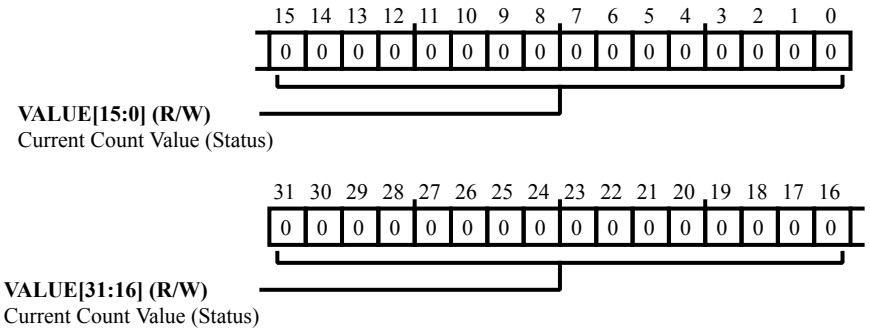

Figure 17-4: WDOG_STAT Register Diagram

Table 17-8: WDOG_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Current Count Value (Status). The `WDOG_STAT.VALUE` bit field contains the current count value of the watchdog timer.

Watchdog Timer Window Register

Watchdog window register holds the unsigned window value programmed. The window register can be programmed while the WDOG is disabled; any write to the register when WDOG is enabled doesn't alter the contents of the register. When the WDOG is enabled and the core services the WDOG by doing a write to `WDOG_STAT` register while the `WDOG_STAT` value is greater than `WDOG_WIN`, the WDWE event is generated and also the counter stops decrementing.

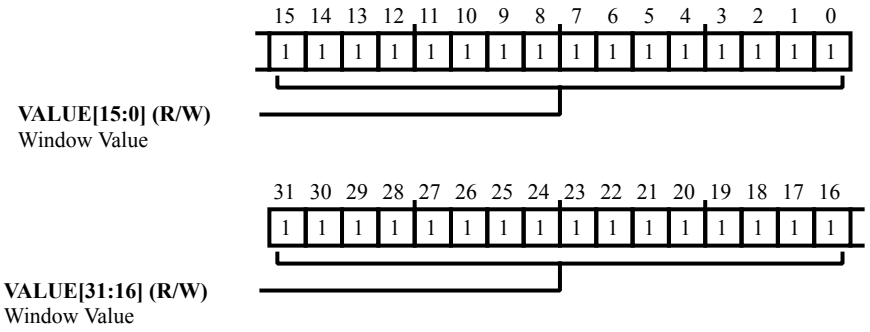

Figure 17-5: WDOG_WIN Register Diagram

Table 17-9: WDOG_WIN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Window Value. The `WDOG_WIN.VALUE` bit field contains the unsigned window value.

18 Enhanced Mobile Storage Interface (eMSI)

The eMSI is a high performance, highly configurable and programmable, eMMC (embedded Multi-Media Card) and SD (secure digital) host controller. The eMSI is required to communicate with SD cards and eMMC devices targeted for the mobile/portable markets. The device memory to which the eMSI sends or receives data is typically a device for NAND flash storage. The eMSI is optimized for portable electronic devices and high-speed storage applications (for example embedded applications).

eMSI Features

The eMSI includes the following features.

General Features

- Supports eMMC protocols including JEDEC eMMC 5.1 specification
- Supported eMMC modes
  - Legacy (0-26 MHz SDR – 1-bit, 4-bit, 8-bit support)
  - HS SDR (0-50 MHz SDR –1-bit, 4-bit, 8-bit support)
  - HS DDR (0-50 MHz DDR – 4-bit, 8-bit support)
  - Supports boot operation and alternative boot operation
- Supports SD memory (SDSC, SDHC, SDXC) and wake up interrupt for SD cards
- Supported SD modes
  - Default Speed/DS (0-25 MHz SDR – 1-bit, 4-bit support)
  - High Speed/HS (0-44.4 MHz SDR – 1-bit, 4-bit support)
- Supports an internal DMA with the following data transfer types for eMMC modes:
  - SDMA (Single operation DMA)
  - ADMA2 (Advance DMA 2)

  - ADMA3 (Advance DMA 3)
- Maximum block size of 1024 bytes supported
- FIFO size is 2048 bytes (parity enabled)
- Supports Command Queuing Engine (CQE) and compliant with eMMC CQ HCI
- Programmable scheduler algorithm selection of task execution. Supports data prefetch for back-to-back write operations
- 10 MHz CQE timer clock

Supported Standards Compliance

- JEDEC eMMC 5.1 Specification - JESD84-B51, February 2015
- SD Specifications Part A2 SD Host Controller Standard Specification Version 4.20, August 2015
- SD Specifications Part A2 Host Controller Version 4.20 Supplementary Notes Version 1.00 Draft 0.60 December 2015
- SD Specifications Part 1 Physical layer Specification Version 6.00 February 2017

eMSI Functional Description

The following sections describe the function of the eMSI controller.

ADSP-SC59x EMSI Register List

The enhanced mobile storage interface (eMSI) is a high speed JEDEC eMMC 5.1 complaint controller. The eMSI controller can connect to single SD card or eMMC device at a time. A set of registers governs eMSI controller operations. For more information on eMSI functionality, see the eMSI controller Register Descriptions section.

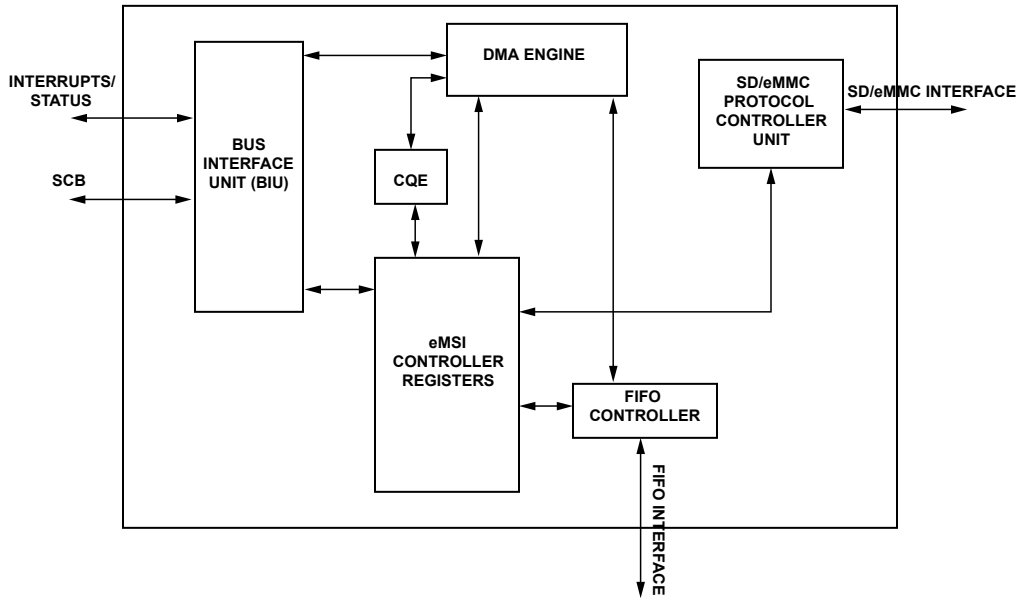
eMSI Block Diagram

The eMSI Block Diagram shows the main functional blocks within the eMSI. These blocks are described in more detail in eMSI Architectural Concepts.

Figure 18-1: eMSI Block Diagram



NOTE: The card-detect and write-protect signals are from the SD card socket and not from the SD card.

eMSI Architectural Concepts

The following sections describe the functions and features of the eMSI controller as well as the eMMC and SD protocols.

The eMSI controller communicates with the device using a message-based bus protocol in which the eMSI controller sends commands serially using the EMSI_CMD signal. Some commands require response from the eMMC device. This response is also sent serially on the EMSI_CMD signal.

Data transfers, both to and from the eMMC device, occur using the data signals. The number of data lines used for the data transfer can be configured to 1 (EMSI_D0) bit, 4 (EMSI_D3–EMSI_D0) bit, or 8 (EMSI_D7–EMSI_D0) bit. All EMSI_CMD and EMSI_D[n] transfers are synchronous with EMSI_CLK. Cyclic redundancy codes (CRC) are used to protect commands, responses, and data transfers from transmission errors. A CRC7 code is generated for every command sent by the eMSI and every response returned by the eMMC device on the EMSI_CMD signal.

Bus Interface Unit (BIU)

The Bus Interface Unit (BIU) implements the logic to transfer data to SCB (system crossbars). The SCB transfers data to and from the system memory through the SCB, respectively. This unit has logic to primarily access the eMSI controller registers by using an SCB and MMRG fabric. This module supports only the little-endian scheme for register accesses.

DMA Engine

The DMA engine unit handles data transfer between controller and system memory. The key features of this unit are as follows.

- Supports SDMA/ADMA2/ADMA3 modes based on the configuration.
- Fetching the descriptor and data.
- Write back the received data packets to the system memory.

eMSI Controller Registers

The eMSI controller register unit is comprised of the standard SD host controller registers as specified in the SD Specifications Part A2 SD Host Controller Standard Specification Version 4.20. It also includes command queuing registers that are compliant to the JEDEC eMMC 5.1 specification.

The host ensures the clock supply to the controller. The clock supply is required for accessing the registers in eMSI controller.

FIFO Controller

The FIFO controller interfaces the packet buffer (FIFO) of the eMSI controller and the SD/eMMC protocol controller unit (SD/eMMC unit). The buffer (FIFO) depth is 2048 bytes. The FIFO stores data along with parity bits generated by the MEPU. The parity error is handled by the MEC.

SD/eMMC Protocol Controller Unit

The SD/eMMC protocol controller unit is responsible for handling SD and eMMC interface protocols. The key features of this unit are:

- Generate SD/eMMC command and data packets
- Generate CRC and check for command and data packets
- Handle packet timeouts
- Support 1-bit, 4-bit, and 8-bit bus width for eMMC data transfer
- Support 1-bit and 4-bit bus width for SD card data transfer

Command Queuing Engine (CQE)

The Command Queueing Engine (CQE) denotes the hardware unit executing the Command Queueing (CQ) activities. The CQE manages the interface between the host software and the eMMC device as well as the data transfers.

Generating SD/eMMC Commands

The eMSI controller generates SD/eMMC commands and sends a command to the eMSI bus (this includes the internally generated CRC7). When initiating a transaction using SDMA (Single Operation DMA) generated transfers, ADMA (Advanced DMA) generated transfers, and non-data transfers, the host driver programs registers sequentially from `EMSI_SDMA_ADDR` to `EMSI_CMD`. The beginning register may be chosen based on the type of transaction. Table 18-5 Register Programming Sequence Before Issuing Commands shows the register programming sequence needed before issuing the commands. The last written register is always `EMSI_CMD` because writing to the upper byte of this register triggers the issuance of an SD/eMMC command.

The host driver should not read the SDMA system address, block size and block count registers during a data transaction unless the transfer is stopped because the value is changing and not stable.

To prevent an overwrite of registers while issuing data transfer based commands, the 32-bit block count (`EMSI_SDMA_ADDR`), block size (`EMSI_BLKSZ`), 16-bit block count (`EMSI_BLKCNT`) and transfer mode (`EMSI_TRNSFRMODE`) registers is write protected by the eMSI controller, while command inhibit (`EMSI_PSTATE.CMD_INHIBIT_DAT`) is set to 1. (When host version 4 enable = 0, the SDMA system address is not protected by this signal.) The host driver must not write the argument and command registers while `EMSI_PSTATE.CMD_INHIBIT_DAT` is set to 1.

Table 18-5: Register Programming Sequence Before Issuing Commands

Command Type	Register to program before issuing the commands in sequence
Non Data transfer based commands	`EMSI_ARG`, `EMSI_CMD`
Data transfer based commands	`EMSI_SDMA_ADDR`, `EMSI_BLKSZ`, `EMSI_BLKCNT`, `EMSI_ARG`, `EMSI_TRNSFRMODE`, `EMSI_CMD`

Block Count

The block count parameter used by the eMSI controller to determine the total data length of the data transfer. It does this by multiplying the block length (block size). The data transfer length set to the SD/eMMC data transfer must be equivalent to data transfer length sets to ADMA2 and ADMA3 descriptors (in predefined data transfers).

Selection of 16-Bit or 32-bit Block Count

Due to the increased capacity of eMMC devices, the data that is available to transfer to and from these devices has also increased. To allow for this increase the eMSI controller extends block counts from 16-bit to 32-bit for all operations in SD/eMMC mode, SDMA and ADMA.

Because SDMA may use the ADMA system address register (EMSI_ADMA_ADDR_LO) to support 32-bit addressing, the SDMA system address register (EMSI_SDMA_ADDR) is re-assigned to the 32-bit block count register. Selection of the block count registers is either 16-bit (EMSI_BLKCNT) or 32-bit block count (EMSI_SDMA_ADDR) and is defined as follows, which allows mixed use of 16-bit or 32-bit block count.

- If the Host Version 4 Enable bit (EMSI_CTL2.HOST_VER4_EN) is cleared to 0 or the 16-bit EMSI_BLKCNT register is configured to non-zero, the 16-bit EMSI_BLKCNT register is selected.
- If Host Version 4 Enable is set to 1 and 16-bit EMSI_BLKCNT register is configured to 0000h, the 32-bit block count register is selected.

Use of block count is enabled by setting the EMSI_TRNSFRMODE.BLOCK_COUNT_EN bit during data transfers.

Preset Value Registers

As the operating eMSI bus clock frequency depends on the system implementation, it is difficult to determine the frequency parameters in using the standard host driver. When the preset value enable is set using the EMSI_CTL2.PRESET_VAL_EN bit, automatic eMSI bus clock frequency generation is performed without considering frequency dividers set by the host driver (EMSI_CLK_CTL.FREQ_SEL/ EMSI_CLK_CTL.UPPER_FREQ_SEL). The eMSI controller automatically selects the eMSI bus clock frequency as specified in the preset value (as per frequency dividers values set in preset value registers) depending on the selected bus speed mode (EMSI_CTL2.EMMC_MODE_SEL). For example, if the program selects the eMMC legacy speed mode then the eMSI controller chooses dividers from the EMSI_PRESET_LEGACY.FREQ_SEL bit field and the same dividers are set in the EMSI_CLK_CTL.FREQ_SEL bit field. If the bit is cleared to 0, the eMSI bus clock frequency is selected by the host driver frequency dividers that are set by the host driver using the EMSI_CLK_CTL.FREQ_SEL/EMSI_CLK_CTL.UPPER_FREQ_SEL bit field.

A preset value for initialization (EMSI_PRESET_INIT) is not selected by the bus speed mode. Before starting the initialization sequence, the host driver needs to set a clock preset value to EMSI_CLK_CTL.FREQ_SEL/ EMSI_CLK_CTL.UPPER_FREQ_SEL by reading the contents of the EMSI_PRESET_INIT register. Preset value enable (EMSI_CTL2.PRESET_VAL_EN) can be set after initialization is completed.

Automatic Command Generation (Auto CMD)

The eMSI controller internally generates Auto CMD12 (STOP_TRANSMISSION) or Auto CMD23 (SET_BLOCK_COUNT) commands as per configuration in the EMSI_TRNSFRMODE.AUTO_CMD_EN bit field. Automatic commands generation improve the performance as it eliminates the process of manually writing registers.

Auto CMD23

Auto CMD23 feature is useful in predefined multiple block operations. A block count is configured in the argument of CMD23 to specify a transfer length of following CMD18 (READ_MULTIPLE_BLOCK) or CMD25 (WRITE_MULTIPLE_BLOCK) commands. Auto CMD23 is a feature that automatically issues a CMD23 before a CMD18 or CMD25 is sent to the SD cards/eMMC device (when `EMSI_TRNSFRMODE.AUTO_CMD_EN` = 0x2). This avoids performance deterioration during memory accesses by removing the interrupt service of CMD23. The `EMSI_SDMA_ADDR` register is assigned to the 32-bit block count register for CMD23.

NOTE: CMD23 is supported in version 3.00 and above SD cards.

Auto CMD12

Open ended multiple block transfers for SD cards/eMMC require CMD12 (STOP_TRANSMISSION) command to stop the data transactions. The eMSI controller automatically issues CMD12 when the last block transfer is completed. The host driver can enable this command using the `EMSI_TRNSFRMODE.AUTO_CMD_EN` bit = 0x1 when issuing multiple block transfer (CMD18 and CMD25) commands. Auto CMD12 timing synchronization with the last data block is accomplished by hardware in the eMSI controller. Auto CMD12 is useful when block count is finite(>0, block count is enabled) and CMD23 is not used (for example in open ended transfers).

Data Transfer Modes

The eMSI controller supports data transfer using Direct Memory Access (DMA). There are three types pf DMA operations available: SDMA, ADMA2 and ADMA3.

Direct Memory Access (DMA)

The Direct Memory Access (DMA) transfers data from the host memory to the device port and conversely. The controller uses a descriptor (except in SDMA transfers) to move data efficiently from source to destination with minimal core intervention. Programs can configure the controller to interrupt the core in situations such as data transmit and receive transfer completion from the eMMC device, as well as other normal or error conditions. The DMA transfers the data received from the eMMC device to the data buffer in the host memory, and it transfers transmit data from the data buffer in the host memory to the eMSI FIFO. Descriptors that reside in the memory act as pointers to these buffers. DMA supports both single block and multi-block transfers.

Non Descriptor (Single Operation) DMA

SDMA (Single Operation DMA) performs a single read/write SD/eMMC command operation at a time. SDMA is suitable for short data transfers because SDMA requires an address update at the page boundary of system memory. A DMA interrupt generated at every page boundary uses core resources to reprogram the new system address. For short data transfers, writing a register is preferred to creating descriptors.

SDMA supports various size page boundaries (from 4 kB to 512 kB, configured using the `EMSI_BLKSZ.SDMA_BUF_BDARY` bit field). A page boundary is the size of a contiguous buffer in system memory. The SDMA transfer waits at every boundary specified by the `EMSI_BLKSZ.SDMA_BUF_BDARY` bit field

and the eMSI controller generates the DMA interrupt to request the host driver to update the SDMA system address register.

Descriptor (Advanced) DMA

A long data transfer should use ADMA (Advanced DMA) to avoid performance bottlenecks caused when an interrupt occurs at every page boundary. ADMA2 and ADMA3 adopt the scatter gather DMA algorithm so that higher data transfer speeds are available. The host driver can program a list of data transfers between system memory and an SD card eMMC using the descriptor table. ADMA2 performs one read/write command operation at a time. ADMA3 can program multiple read/write operations in a descriptor table. ADMA3 is used to perform large data transfers.

Advanced DMA 2 (ADMA2)

Figure 18-2 ADAM2 Block Diagram, shows the ADMA2 data transfer between the eMSI controller and the system memory as well as the descriptor table that is created by the host driver (for more information, see ADMA2 Descriptor Format). A 32-bit address descriptor table is used for a system with 32-bit addressing. In the descriptor table, each line contains information about the address, its length (descriptor data transfer size) and an attributes that specifies the operation of the descriptor line. ADMA2 uses the 32-bit ADMA address register (`EMSI_ADMA_ADDR_LO`) for the descriptor pointer. An ADMA2 transfer is triggered by writing to the command register and ADMA2 processes each line in the descriptor table. The descriptor table is created in the system memory by the host driver. ADMA2 fetches one descriptor line and executes it until the end of descriptor denoted by (End = 1 in attribute) is found.

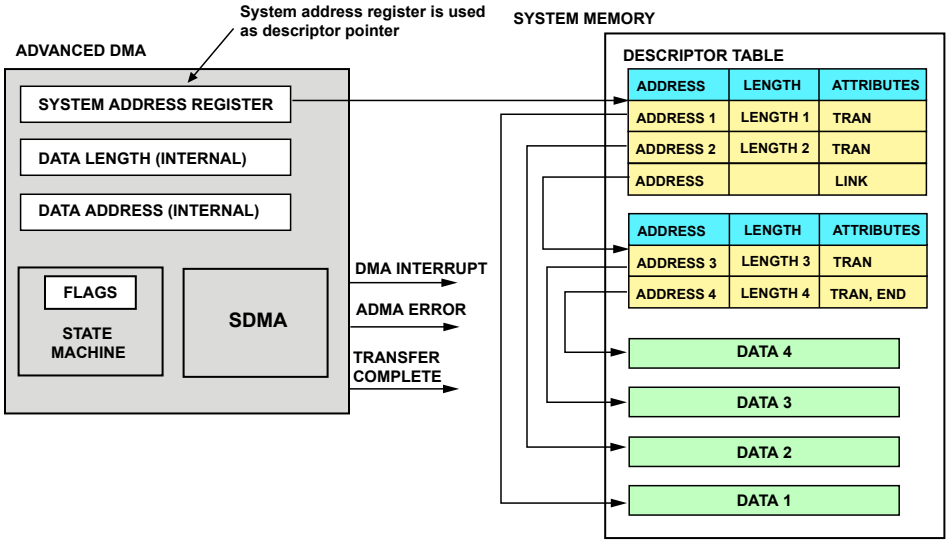


Figure 18-2: ADAM2 Block Diagram

Figure 18-3 ADMA2 Data Transfer Example shows a typical ADMA2 descriptor program. The host driver describes the descriptor table with each slice is placed somewhere in contiguous system memory. The host driver describes the descriptor table that contain the address, length, and attributes. Each sliced data is transferred in turn as programmed in the descriptor.

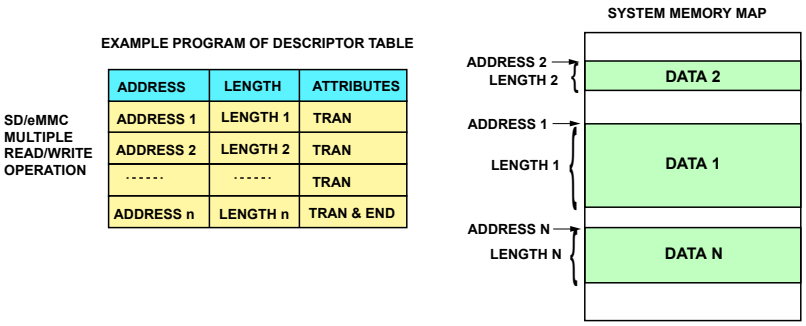

Figure 18-3: ADMA2 Data Transfer Example

Data Address and Data Length Requirements

There are three requirements to program the descriptor:

1. The minimum unit of address is 4 bytes (32-bits).
2. The maximum data length of each descriptor line is less than 64 KB (if data length set to 10-bit) or 64 MB (if data length set to 26-bit).
3. Total Length = Length 1 + Length 2 + Length 3 + ... + Length n = multiple of block size

Using 4 byte units of address simplifies byte enable control on the 32-bit data bus. If the total length of a descriptor were not a multiple of block size, ADMA2 transfers might not be terminated. In this case, a data timeout occurs and the transfer is stopped by an abort command. Therefore the total length should be a multiple of block size.

It is recommended that the total of the data lengths of all descriptors be equal to the total data transfer size where: total data transfer size = block count x block size.

General Descriptor Table Format

Figure 18-4 General Descriptor Table Format shows the general format of a descriptor table. One descriptor line consumes 64 bits (8 bytes) using 32-bit addressing mode. The attribute is used to control the descriptor. Act0 = 0 is assigned to ADMA2 descriptor. Act0 = 1 is assigned to the ADMA3 descriptor and is used to extend descriptors for ADMA3. Refer to Advanced DMA 3 (ADMA3) for more information.

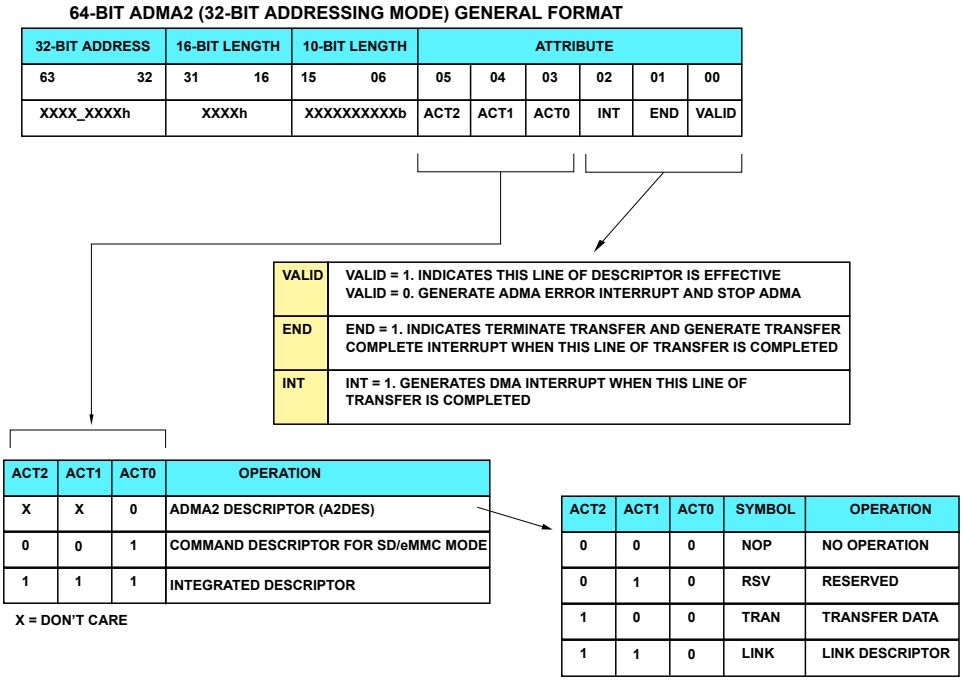

Figure 18-4: General Descriptor Table Format

ADMA2 Descriptor Format

Figure 18-5 ADMA2 Descriptor Table Format shows the ADMA2 descriptor table. Act0 = 0 is assigned to the ADMA2 descriptor. Three action symbols are specified by the combination of Act2 and Act1. A no operation (NOP) skips the current descriptor line and fetches the next one. A Tran operation transfers data designated by address and length field. A Link operation is used to connect separated two descriptors. The address field of link points to next descriptor table. The combination of Act2 = 0 and Act1 = 1 is reserved and defined in the same operation as a NOP. All other combinations are the same as No Operation (NOP).

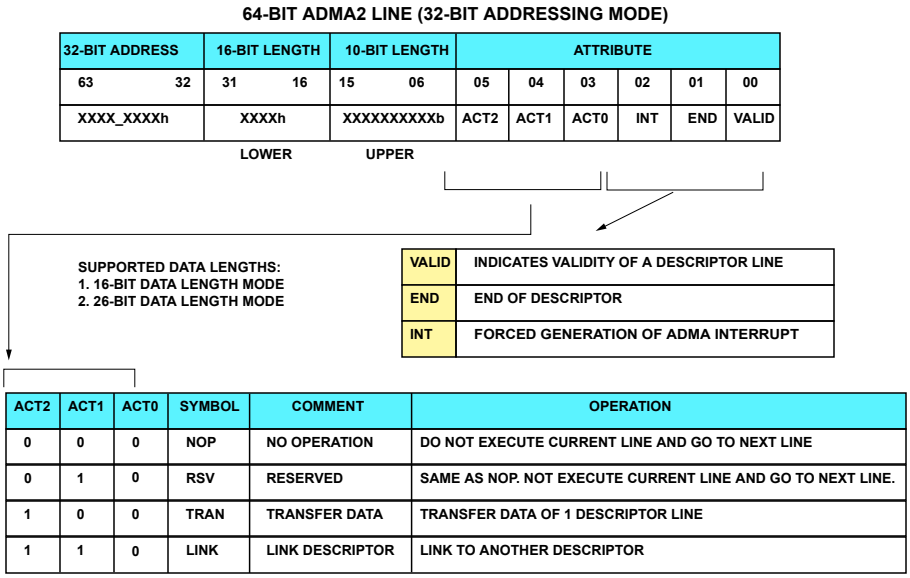

Figure 18-5: ADMA2 Descriptor Table Format

The Int attribute may be set only in an ADMA2 descriptor. The 26-bit data length mode is added to reduce the number of descriptor lines for large continuous data. The following tables shows the definition of 16-bit data length and 26-bit data length. 16-bit data length is selected when the `EMSI_CTL2.ADMA2_LEN_MODE` bit is cleared to 0. 26-bit data length is selected when the `EMSI_CTL2.ADMA2_LEN_MODE` bit is set to 1.

Table 18-6: ADMA2 16-bit Length Mode

16-bit Length (D31-D16)	Value of Length
000h	65536 bytes
0001h	1 byte
0002h	2 bytes
...	...
FFFFh	65535 bytes

Table 18-7: ADMA2 26-bit Length Mode

26-bit Length (D15-D06, D31-D16)	Value of Length
000_0000h	64M bytes
000_0001h	1 byte
000_0002h	2 bytes
000_0003h	3 bytes
...	...
3FF_FFFFh	64M-1 bytes

ADMA2 Error Status Register

An error that occurs during an ADMA2 transfer may stop ADMA2 operation and generate an ADMA error interrupt. The EMSI_ADMA_ERR_STAT.ERR_STATES bit field holds state of ADMA2 stopped.

Advanced DMA 3 (ADMA3)

As described above for ADMA2, SD/eMMC commands are issued when the host driver writes to the eMSI controller registers. For ADMA3, a host program performs multiple ADMA2 operations using command descriptors to issue SD/eMMC commands. A multi-block data transfer between system memory and an SD card/eMMC is programmed by using a pair of command descriptors and an ADMA2 descriptor. ADMA3 performs multiple multi-block data transfers by using an integrated descriptor. Figure 18-6 Example of ADMA3 Operation shows an example ADMA3 operation where three data blocks (data A, data B and data C) are written to different areas of the SD card/eMMC.

An integrated descriptor consists of pointers to command descriptors. Each command descriptor is followed by an ADMA2 descriptor. The first descriptor pair is programed to transfer data A, the second pair data B and the third pair data C. The location of the integrated descriptor is configured using the ADMA3 integrated descriptor address register (EMSI_ADMA_DESADDR_LO). ADMA3 fetches pointers one by one in the integrated descriptor and executes descriptors designated by the pointer. ADMA3 sets the contents of a command descriptor in the eMSI controller registers (EMSI_SDMA_ADDR to EMSI_CMD sequentially) to issue an SD/eMMC command and then executes the ADMA2 descriptor. The first operation transfers data A from system memory to the SD card/eMMC. The second operation transfers data B and the third operation transfers data C. When execution of all descriptors pointed by the integrated descriptor is completed, ADMA3 generates a transfer complete interrupt to inform the host driver that the operation is complete.

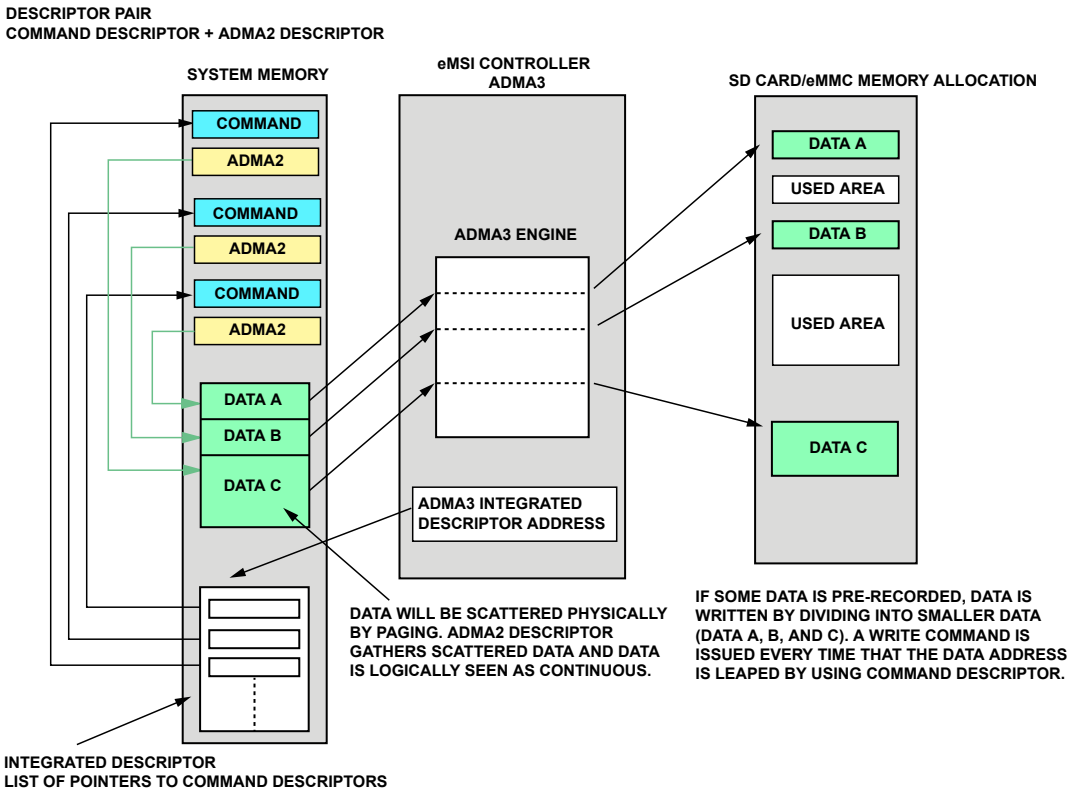

Figure 18-6: Example of ADMA3 Operation

Command Descriptor Format

As shown in Figure 18-7 Command Descriptor Format, 32-bit register data is configured in bits 63-32 of each descriptor line. Command descriptor types are distinguished by Attribute. If Attribute indicates the command descriptor for SD/eMMC mode (Act2-0 = 001b), the 32-bit register fields are written to the eMSI controller registers sequentially from the `EMSI_SDMA_ADDR` to `EMSI_CMD` registers. When the `EMSI_CMD` register is written, an SD/eMMC command is issued. The eMSI controller has a pointer to a descriptor line for the command descriptor and the ADMA2 descriptor. The pointer is incremented after reading every descriptor line. When the last line of the command descriptor is read, the pointer is assumed to point to the top of the ADMA2 descriptor, which is placed just after the command descriptor. The eMSI controller ignores the INT of Attribute in this descriptor.

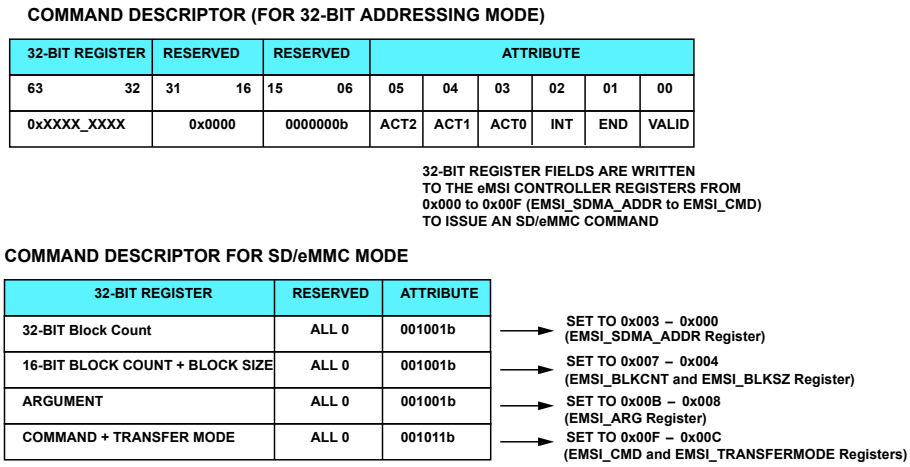

Figure 18-7: Command Descriptor Format

The programing requirements of command descriptors for SD/eMMC mode are:

- Setting infinite data transfer (`EMSI_TRNSFRMODE.BLOCK_COUNT_EN` = 0) is not allowed, except for single block transfers (`EMSI_TRNSFRMODE.MULTI_BLK_SEL` = 0).
- As ADMA3 only supports 32-bit block count mode, the `EMSI_TRNSFRMODE.BLOCK_COUNT_EN` bit must be set to 1 and the 16-bit block count must be set to 0x0000 (`EMSI_BLKCNT`). Clearing stop count (32-bit block count = 0) `EMSI_SDMA_ADDR` is not allowed, except for single block transfers (`EMSI_TRNSFRMODE.MULTI_BLK_SEL` = 0).
- Configuring no data transfer (block size = 0) is not allowed, except when using the no data transfer command in a command descriptor (where CDEnd set to 1).
- When using the memory data transfer command, The Auto CMD Auto Select of Auto CMD Enable (`EMSI_TRNSFRMODE.AUTO_CMD_EN`) must be used so that Auto CMD 23 is sent to the eMMC device if `EMSI_CTL2.CMD23_EN` = 1. For Auto CMD 12, Auto Command Disabled (`EMSI_TRNSFRMODE.AUTO_CMD_EN` = 0) is used.

Integrated Descriptor Format

Figure 18-8 Integrated Descriptor Format shows how multiple of pointers to command descriptors are configured in the integrated descriptor. The pointer of a 32-bit address is configured to bit 63-32 in the 64-bit integrated descriptor. The eMSI controller ignores the INT of Attribute in this descriptor.

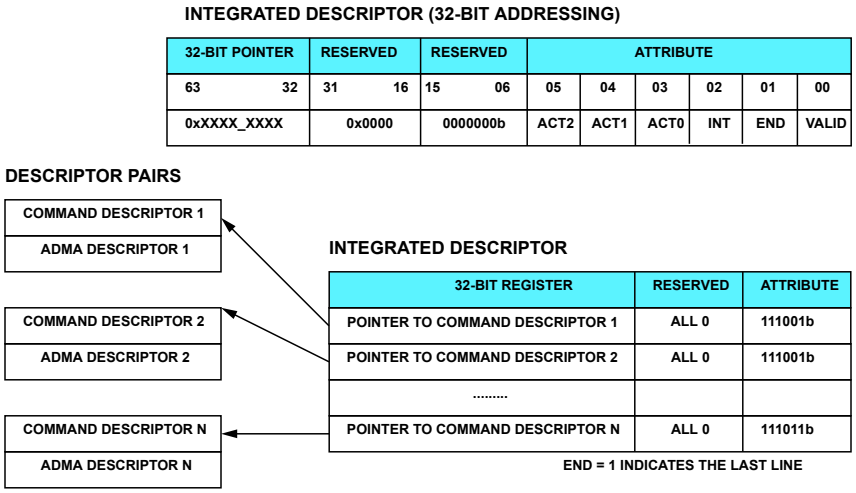

Figure 18-8: Integrated Descriptor Format

The ADMA3 integrated descriptor address register (EMSI_ADMA_DESADDR_LO) is used to designate the location of the integrated descriptor. The start of an ADMA3 is triggered by writing to offset EMSI_ADMA_DESADDR_LO in 32-bit addressing mode.

Response Error Check During ADMA3 Operation

The eMSI controller should perform response checks to prevent performance loss due to the host driver doing this task. When creating the command descriptor, configure the following 3 bits in the transfer mode register to: EMSI_TRNSFRMODE.RESP_INT_DIS = 1, EMSI_TRNSFRMODE.RESP_ERR_CHK_EN = 1. Clear EMSI_TRNSFRMODE.RESP_TYPE = 0 if the command is for an SD/eMMC enabled response check by the eMSI controller.

In SD/eMMC mode, if an error is detected in R1, a response error interrupt is generated in the EMSI_ERR_STAT register. ADMA3 is stopped and the host driver can read the error response from the EMSI_RESP0 register.

Command Queueing Engine

The Command Queueing Engine (CQE) denotes the hardware unit executing the Command Queueing (CQ) activities. The CQE manages the interface between the host software and the eMMC device, and the data transfers. The CQE receives tasks from the software though a Task Descriptor List (TDL) in the host memory and the doorbell register. The CQE issues CQ commands, CMD44 (QUEUED_TASK_PARAMS) and CMD45 (QUEUED_TASK_ADDRESS), to the eMMC device and stores the task information. The CQE also reads the queue status register of the device, decides the task to execute and issues the EXECUTE commands, CMD46 (EXECUTE_READ_TASK) and CMD47 (EXECUTE_WRITE_TASK).

The Command Queuing Engine has the following features:

- Non-blocking issuance of data transfer tasks using a task list in host memory
- Optional notification upon completion via interrupt, with interrupt coalescing

- Direct-Command (DCMD) tasks through which software can send any eMMC command, by its index and argument, to the device, using CQE
- Queue-Barrier (QBR) where software can control the execution order of tasks, and task management and error recovery executed by software, by halting the CQE at known locations

To implement queuing of tasks in the eMMC device, the host asynchronously issues tasks using the TDL, which is in a memory location known to the CQE and contains up to 32 fixed-size slots. Each slot contains one task descriptor and one transfer descriptor. To issue a task, the software selects an available TDL slot and constructs the following two descriptors in it.

- Task Descriptor - encodes all information that defines the task. For instance, the start address, block count, and priority. This information is later passed to the device. The task descriptor can alternatively encode any arbitrary command that is sent directly to the device.
- Transfer Descriptor - points either to one continuous data buffer to/from which data is transferred (TRAN Descriptor) or to a scatter/gather list of any length (LINK descriptor). Figure 18-9 Command Queuing Host Controller Interface (HCI) Structure shows the structure of the TDL in the host memory and the slot numbers in the TDL. The slot numbers in the figure store the following information:
  - 0 – Stores a data transfer task with a TRAN descriptor
  - 1 – Stores a data transfer task with a LINK descriptor, pointing to a scatter/gather list
  - 31 – Stores a DCMD descriptor

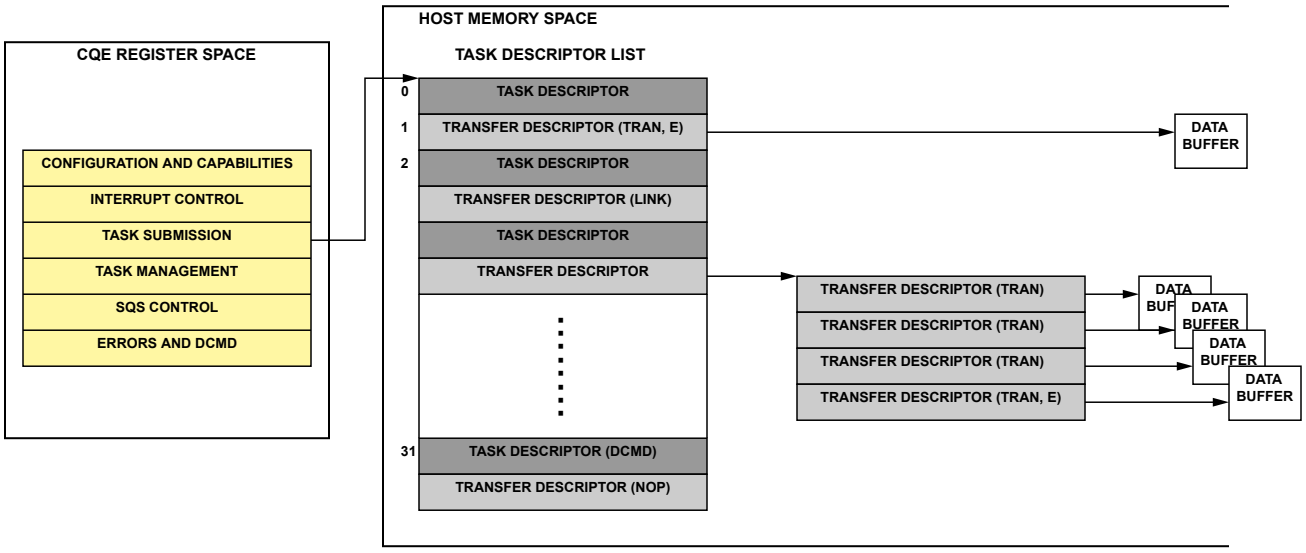

Figure 18-9: Command Queuing Host Controller Interface (HCI) Structure

Task Processing

Once the two descriptors are written in slot i, software issues the task by writing 1 to bit i in the `EMSI_CQ_TDBR` register. This action signals to the CQE to process the task. Software must not write the `EMSI_CQ_TDBR` register

to issue the task before valid descriptors are ready in the appropriate slot. The CQE then reads the descriptors. Based on the information encoded in the task descriptor, the CQE generates QUEUED_TASK_PARAMS (CMD44) and QUEUED_TASK_ADDRESS (CMD45), and sends them to the device.

Task Selection and Execution

The CQE is also in charge of reading the device's queue status register (QSR) to determine which tasks are ready for execution, selecting tasks for execution, and ordering their execution. These actions are described in this subsection.

Reading the QSR: When task(s) are queued in the device, the CQE reads the QSR to determine which tasks are ready for execution. The QSR is read using SEND_ QUEUE_STATUS (CMD13) commands. If a data transfer is ongoing, the CQE sends the SQS towards the end of the data transfer, as configured in the `EMSI_CQ_SSCFG1.SQSCMD_BLK_CNT` register field. If the bus is idle, the CQE periodically sends SQS commands, as configured in the `EMSI_CQ_SSCFG1.SQSCMD_IDLE_TMR` register field.

Selecting a Task: When one or more data transfer tasks are ready for execution and the bus is idle (or a previous data transfer is about to end), CQE is expected to select a task for execution. The selected task must be marked as ready for execution by the device.

Ordering Task Execution: When the bus is idle, the CQE sends EXECUTE_READ_TASK (CMD46) or EXECUTE_WRITE_TASK (CMD47), ordering the device to execute a task, identified by its task ID.

The CQE also feeds the task's transfer descriptor(s) to a DMA engine as a pointer to the data buffer in the host memory. A task's execution is considered completed once the data transfer phase is completed.

Task Completion: Interrupts and Interrupt Coalescing

Upon the completion of a data transfer task, after the data has been transferred, an interrupt may be generated, if requested. If the INT bit in the task descriptor is set, a task complete (TCC) interrupt is generated. If the INT bit is not set, the transfer is counted towards coalescing. DCMD tasks are not counted towards coalescing. The interrupt coalescing mechanism allows the host to moderate its interrupt load. The mechanism is also timer-protected to avoid high latency in low-load cases.

Direct Command (DCMD) Submission

When CQ is enabled, software still retains the ability to efficiently issue eMMC commands by their index and argument. To use the DCMD feature, it must be enabled where `EMSI_CQ_CFG.DCMD_EN` = 1. To issue a direct command, the software writes a DCMD task descriptor to slot #31 of the TDL and rings the doorbell register (`EMSI_CQ_TDBR`). The command's index and argument are encoded directly in the DCMD task descriptor (in the fields otherwise used for address and block count).

The DCMD feature is targeted for the transmission of non-data commands which are allowed when CQ mode is enabled, such as CMD0, CMD12, or CMD13.

When processing the task descriptor, the CQE constructs the command by its index and argument, sends it to the device, and stores the response in a dedicated register.

The DCMD task descriptor is identified by the CQE by its placement in slot #31 of the TDL. Therefore, it may only be issued using slot #31, and may only be sent one at a time. The transfer descriptor following the DCMD descriptor is ignored by CQE.

Queue-Barrier (QBR) Tasks

To enable a host's control on the ordering between tasks, a task can be marked as a Queue-Barrier (QBR) task by setting the QBR bit in the task descriptor. The following are guaranteed by the eMSI controller:

- A QBR task is only sent to the device after all the tasks issued before it have been executed (when the task queue in the device is empty).
- New tasks (tasks issued after the QBR task) are sent to the device after the QBR task execution is completed.

Specifically, the following rules apply:

- When the task marked with QBR is a data transfer task, the CQE may send the related QUEUED_ TASK_PARAMS (CMD44) and QUEUED_ TASK_ADDRESS (CMD45) commands to the device only after receiving the response for the EXECUTE_READ_TASK(CMD46)/ EXECUTE_WRITE_TASK(CMD47) for the last data transfer task in the device's queue (data transfer may still be on-going).
- When the task marked with QBR is a DCMD task, the CQE can send the related command only after all previously issued tasks have completed, including the associated data transfers.
- Commands related to tasks which are queued after the QBR task, may only be sent after the QBR task execution is completed.

After the CQE has halted, the device waits for the next command, so it is effectively halted as well. The CQE notifies software that it is halted by setting the `EMSI_CQ_CTL.HALT` bit and, optionally by an interrupt (`EMSI_CQ_ISTAT.HAC`). It is guaranteed that neither the device nor the host hardware (the CQE) will initiate any operation while the CQE is in the halt state. When software wants the CQE to resume operation, it clears the `EMSI_CQ_CTL.HALT` bit = 0. When 0 is written, the CQE continues its normal operation, based on the current state. In some error conditions, the halt bit may never actually set, because a response has not been received from the device. In these cases, software may assume the CQE is halted after waiting for a long enough time.

eMMC Command Queuing Data Structures

This section describes the descriptor structures used in eMMC Command Queuing. As mentioned in the previous section, the host writes a pair of descriptors—task descriptor and transfer descriptor, which are organized in the host memory in the task descriptor list. This section discusses the following structures:

- Task Descriptor Structure
- Transfer Descriptor Structure
- Task Descriptor for Direct-Command (DCMD) Tasks

Task Descriptor Structure

Table 18-8 Task Descriptor Structure; Lower 64 bits (Data Transfer Tasks) and Table 18-9 Task Descriptor Structure Upper 64 bits summarize the task descriptor structure for lower and upper 64 bits, and Table 18-10 Task Descriptor Fields describes task descriptor fields.

Table 18-8: Task Descriptor Structure; Lower 64 bits (Data Transfer Tasks)

Block Address	Block Count	Task Parameters Field							Attribute			
63:32	31:16	15	14	13	12	11	10:7	6	5:3	2	1	0
xxxx_xxxxh	xxxxh	Reliable Write	QBR	Priority	Data Direction	Tag request	Context	Forced programming	Act=101	Int	End= 1	Valid =1

Table 18-9: Task Descriptor Structure Upper 64 bits

Reserved	Task Parameters Field				Reserved
127:112	111	110:106	105:104	103:96	96:64
0x0000	0b	00000b	Transaction Type	0x00	X

Table 18-10: Task Descriptor Fields

Field Name	Bit Location	Description	Encoded in CMD
Valid	0	1 – The descriptor is effective and must be processed by hardware. 0 – The descriptor line must not be used.	
End	1	Must always be set to 1. Every Task Descriptor is standalone.	
Int	2	Indicates the interrupt generation policy required for this task. 1 – Hardware generates an interrupt upon the task completion. 0 – Hardware counts task completion for interrupt coalescing.	
Act	5:3	Must be configured to b101 to indicate that this is a Task Descriptor.	
Forced Programming (FP)	6	When 1, FP is enabled. Data is forcefully programmed to a non-volatile storage instead of volatile cache while cache is turned ON.	CMD44
Context ID	10:7	A context is an active session, configured for a specific read/write pattern. A device may support one or more concurrent contexts, defined by a Context ID. Each context ID (besides #0) has a configuration field in EXT_CSD to control its behavior.	CMD44
Tag Request	11	Indicates request to receive information (about specific data types) from the host.	CMD44
Data Direction	12	Indicates the direction of data transfer. 1 – Device to Host (Read) 0 – Host to Device(Write)	CMD44

Table 18-10: Task Descriptor Fields (Continued)

Field Name	Bit Location	Description	Encoded in CMD
Priority	13	1 – high 0 – simple	CMD44
Queue Barrier (QBR)	14	Indicates the control of the host on the ordering between tasks.	
Reliable Write	15	Indicates multiple block write with pre-defined block count and Reliable Write parameters.	CMD44
Block Count	31:16	Number of blocks to be read/written.	CMD44
Block Address	63:32	Data block address	CMD45
Reserved	95:64		N/A
Reserved	103:96		N/A
Transaction Type	105:104	Transaction Type (TT) Field value description: 00 - Simple Data Task 01 - Data Task w/ Immediate Partition Access 10 - Device Management Sequence (DMS) 11 - reserved **NOTE:** When 64 b descriptors are used, the implied value of this field is 0b	CMD44
Reserved	127:106		N/A

Transfer Descriptor Structure

Table 18-11 Transfer Descriptor Structure (32-Bit Addressing) summarizes the transfer descriptor structure for 32-bit addressing. Table 18-12 Transfer Descriptor Fields describes transfer descriptor fields.

Table 18-11: Transfer Descriptor Structure (32-Bit Addressing)

Address	Length	Reserved	Attribute			
63:32	31:16	15:6	5:3	2	1	0
0xXXXX_XXXX	xxxxh	0000000000	Act	Int	End	Valid

Table 18-12: Transfer Descriptor Fields

Field Name	Bit Location	Description
Valid	10	1 – The descriptor is effective and must be processed by hardware. 0 – The descriptor line must not be used.
End	1	1 – The descriptor is the last descriptor in a descriptor list. 0 – Additional descriptors follow this descriptor. In the case of a TRAN descriptor, the value of this bit is 1.

Table 18-12: Transfer Descriptor Fields (Continued)

Field Name	Bit Location	Description
Int	2	The value of this bit is cleared to 0 in command queuing.
Act	5:3	100 – TRAN – Address field of descriptor points to a data buffer. 110 – LINK – Address field of descriptor points to another descriptor. 000 – NOP no operation. Others: Reserved
Reserved	15:6	Reserved
Length	31:16	Length of data buffer in bytes. A value of 0000 means 64 kB.
Address (32- bit)	63:32	Data buffer address in host memory, in 32-bit addressing mode Address must be configured for 32-bit boundary (lower 2 bits cleared to 0)

Task Descriptor for Direct-Command (DCMD) Tasks

Table 18-13 Task Descriptor Structure summarizes the transfer descriptor structure for the DCMD tasks and Table 18-14 Transfer Descriptor Fields describes transfer descriptor fields.

Table 18-13: Task Descriptor Structure

Command Argument	Command Parameters				Task Parameters Field			Attribute			
63:32	31:25	24:23	22	21:16	15	14	13:6	5:3	2	1	0
xxxx_xxxxh	Reserved (0000000)	Response Type	CMD timing	CMD Index	Rsvd (0)	QBR	Reserved (0000000)	Act=101	Int	End=1	Valid =1

Table 18-14: Transfer Descriptor Fields

Field Name	Bit Location	Description
Valid	0	1 – The descriptor is effective and must be processed by hardware. 0 – The descriptor line must not be used.
End	1	Must always be set to 1. Every Task Descriptor is standalone.
Int	2	Indicates the interrupt generation policy required for this task. 1 – Hardware generates an interrupt upon the task completion. 0 – Hardware does not generate an interrupt upon the task completion. Interrupt coalescing is not used with DCMD.
Act	5:3	Is set to b101 to indicate that this is a Task Descriptor.
Reserved	13:6	
Queue Barrier (QBR)	14	Indicates the control of the host on the ordering between tasks.
Reserved	15	

Table 18-14: Transfer Descriptor Fields (Continued)

Field Name	Bit Location	Description
CMD Index	21:16	The index of the command to be sent to the device.
CMD Timing	22	1 – Command may be sent to device during data activity or busy time. 0 – Command may not be sent to device during data activity or busy time. **NOTE:** Software is 0 if response type is b11 (R1b).
Response Type	24:23	This field indicates to the eMSI controller the response expected to be received from the device. 00 – No Response Expected 01 – Reserved 10 – R1, R4 11 – R1b **NOTE:** R2 and R3 are not supported in DCMD.
Reserved	31:25	
CMD Argument	63:32	The argument of the command to be sent to the device.

NOTE: For more information on CQE please refer to *Annex B (Normative) Host Controller Interface for Command Queuing* from the JEDEC eMMC 5.1 specification.

eMMC Boot Operation

The eMSI controller supports both mandatory and alternate boot operations as per the JEDEC eMMC 5.1 specifications in 1-bit, 4-bit, and 8-bit SDR or legacy mode up to 50 MHz. In boot operation mode, the eMSI controller can read boot data from the eMMC by keeping the CMD line low (for mandatory boot) or sending CMD0 with the argument (0xFFFFFFFA) (alternate boot), before issuing CMD1. The data can be read from either the boot area or the user area depending on the extended CSD register configurations.

Mandatory Boot Operation

If the CMD line is held low for 74 clock cycles and more after power-up or reset operation (either through CMD0 with the argument of 0xF0F0F0F0 or assertion of hardware reset for eMMC, if it is enabled in extended CSD register byte [162], bits [1:0]) before the first command is issued, the eMMC recognizes that boot mode is being initiated and starts preparing boot data internally.

The partition that from the eMSI controller reads the boot data can be selected in advance using EXT_CSD byte [179], bits [5:3]. The eMSI controller can choose to use single data rate mode with backward-compatible interface timing or single data rate with high-speed interface timing by setting a proper value in EXT_CSD register byte [177] bits [4:3]. EXT_CSD register byte [228], bit 2 tells the eMSI controller if the high-speed timing during boot is supported by the device.

The configuration in eMMC device should be done before configuring eMSI controller for booting operation.

See eMMC Device Boot Programming Sequences for more information.

Refer to the JEDEC eMMC 5.1 specifications for more information. The mandatory boot timing is shown in the figure below.

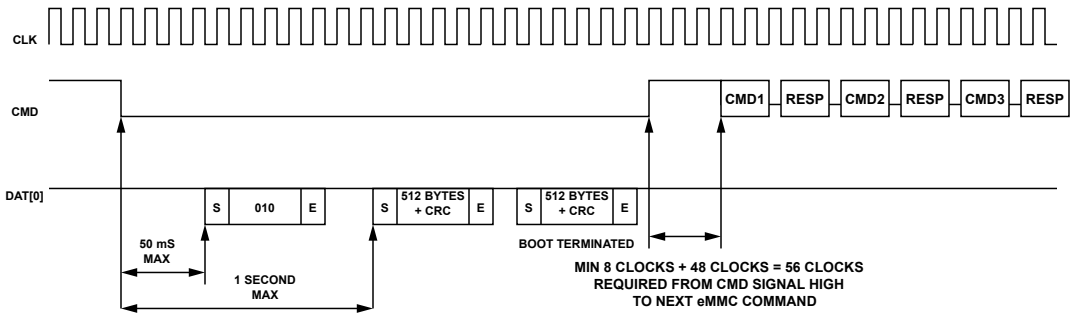

Figure 18-10: Mandatory Boot Timing

Alternate Boot Operation

Alternate boot is a command-based boot operation. After a power-up or reset operation (either assertion of CMD0 with the argument of 0xF0F0F0F0 or a hardware reset if it is enabled), the host issues CMD0 with the argument of 0xFFFFFFFA. After 74 clock cycles, before CMD1 is issued or the CMD line goes low, the eMMC recognizes that the boot mode is being initiated and starts preparing boot data internally.

All the mandatory boot operation EXT_CSD register configurations are applicable for alternate boot operations.

The configuration in eMMC device should be done before configuring eMSI controller for booting operation.

See eMMC Device Boot Programming Sequences for more information. The alternate boot timing is shown in the figure below.

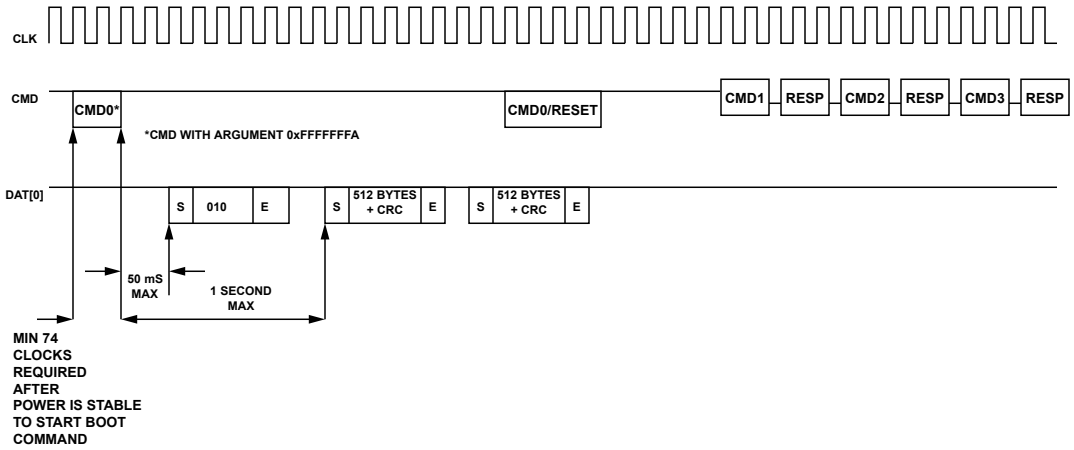

Figure 18-11: Alternate Boot Timing

eMSI Event Control and Interrupts

Interrupts

The eMSI controller generates interrupts based on various events. There are two interrupt outputs provided by the eMSI controller: EMSI_STAT and EMSI_WAKEUP. The interrupt signal must be used as the interrupt for different events. The interrupts are of level type, that is, the interrupt remains asserted (high) until it is cleared by the host or the software.

The interrupt status registers (EMSI_ERR_STAT, EMSI_ISTAT) indicate the events that caused the interrupt. Each event can be prevented from asserting the interrupt on the interrupt status by setting the corresponding mask bits in the EMSI_ERR_STAT_EN and EMSI_ISTAT_EN registers. A bit in interrupt status register is set only if the corresponding interrupt status enable is set and interrupt event is observed. The bit set in interrupt status register asserts an interrupt to the core only if the corresponding bit in the interrupt signal enable in the EMSI_ERR_STAT_INTEN and EMSI_ISTAT_INTEN registers is set.

During standby mode (when the SD card is not being accessed) the EMSI_WAKEUP signal can be used to identify any wakeup event, such as card removal or insertion.

NOTE: The host driver is responsible for enabling wakeup signals and disabling interrupt signals when the host system enters standby mode and for disabling wakeup signals and enabling interrupt signals when the host system goes into active mode, when the SD card is in use. The host driver must not enable both at same time. Interrupt signals are enabled using the interrupt signal enable and wakeup signals are enabled using the wakeup event enable.

For information about status interrupts, refer to the EMSI_ERR_STAT, EMSI_ISTAT, and EMSI_WU_CTL registers.

Error Detection

The eMSI controller can detect different types of errors in SD and eMMC transactions. Error are detected in either the command or data portion of the transaction. When an error is detected, the error interrupt in the interrupt status register (EMSI_ISTAT.ERR_INTERRUPT) is set. The controller uses the error interrupt status register (EMSI_ERR_STAT) to report errors in SD and eMMC mode. The abort command is used to recover from errors that are detected during data transfers. Additionally, the auto command status register (EMSI_AUTOCMD_STAT) is used to report errors during Auto CMD operation and the ADMA error status register (EMSI_ADMA_ERR_STAT) used to report errors in all ADMA based data transfer modes.

Response Error Check

The eMSI controller supports a R1 response error check function to avoid the overhead of response error checking by the host driver. If an error is detected, the response error interrupt is generated in the error interrupt status register (EMSI_ERR_STAT.RESP_ERR).

Table 18-15: Response Error Check

Bit	Error
Error status checked in R1	
31	OUT_OF_RANGE
30	ADDRESS_ERROR
29	BLOCK_LEN_ERROR
26	WP_VIOLATION
25	CARD_IS_LOCKED
23	COM_CRC_ERROR
21	CARD_ECC_FAILED
20	CC_ERROR
19	ERROR

NOTE: Please refer to Device Status section from JEDEC eMMC 5.1 specifications for more information.

eMSI Programming Model

This section provides detailed procedures for programming the eMSI controller.

Initial Programming Sequence

This section explains the programming steps required for the eMSI controller and the eMMC device before starting a data transfer with a connected eMMC device. Both the eMSI controller and the eMMC device need to be initialized.

1. Ensure clock supply to the eMSI controller. This clock is required for accessing most of the registers in eMSI controller.
2. Check if the card is already inserted by reading the present state register (`EMSI_PSTATE`). This step is required for a removable card. If the card is already inserted, then go to Step 4.
3. Wait for the card insertion interrupt. This step is required for a removable card. The card detection sequence is described in Card Detection.
4. Configure the basic settings for the eMSI controller as described in eMSI Controller Setup Sequence. This includes the timeout counter value and clock generation parameters. The setup sequence for an SD/eMMC device is provided.
5. Enable all clocks signals as discussed in the programming sequence in eMSI Controller Clock Setup Sequence. At this stage, the eMSI controller is ready to communicate with the eMMC device.

6. If the eMSI controller is connected to an SD card, then the programming sequence described in SD Card Interface Detection must be executed and if the eMSI controller is connected to an eMMC device, then the programming sequence described in eMMC Card Interface Setup must be executed. This is a simplified sequence especially for an eMMC card as the card type is always known.
7. The sequence for Initializing and Identifying an eMMC Device must be executed for initializing and identifying an eMMC device. For SD cards, the SD Card Initialization and Identification sequence must be executed.
8. When the eMSI controller and eMMC device are initialized, the controller can start sending commands to the SD/eMMC device to perform the data transfer. Control and data commands are two types of commands that can be issued to the SD card/eMMC device. The control command is used to read or write any register in the SD card/eMMC device. The data command is used for writing or reading data to or from the device. Below are the control and data command sequences for SD card/eMMC devices.
   - Control CMD – Issuing CMD Without Data Transfer
   - Data CMD – Issuing CMD With Data Transfer

   ADDITIONAL INFORMATION: Data transfer can be aborted using Abort Command Sequence.

Card Detection

The following figure and procedure shows the sequence for detecting an SD card. The procedure applies to removable cards (SD and cards that use external sockets). This programming sequence is not required for an eMMC device as it is non- removable.

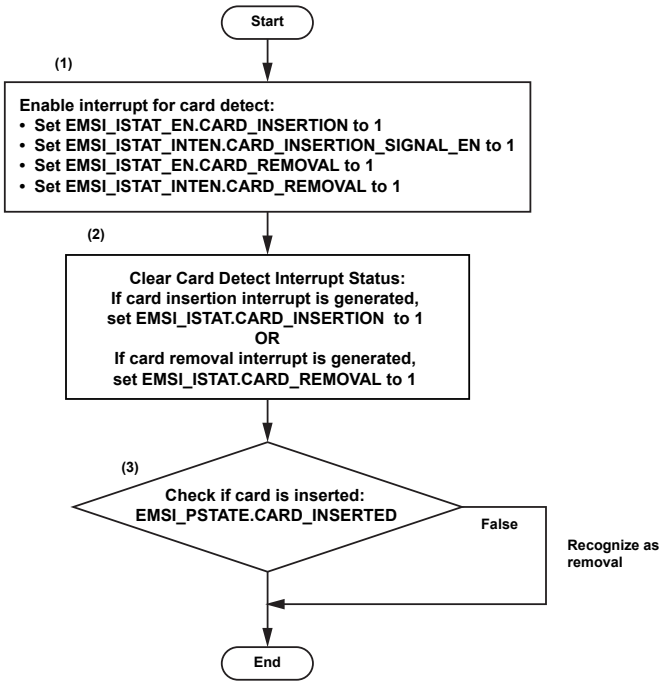

Figure 18-12: Card Detection

1. Enable interrupt for card detect:
    a. Set `EMSI_ISTAT_EN.CARD_INSERTION` to 1.
    b. Set `EMSI_ISTAT_INTEN.CARD_INSERTION` to 1.
    c. Set `EMSI_ISTAT_EN.CARD_REMOVAL` to 1.
    d. Set `EMSI_ISTAT_INTEN.CARD_REMOVAL` to 1.
2. Clear card detect interrupt status:
    - If card insertion interrupt is generated, set `EMSI_ISTAT.CARD_INSERTION` to 1.
    - If card removal interrupt is generated, set `EMSI_ISTAT.CARD_REMOVAL` to 1.
3. Check if card is inserted: `EMSI_PSTATE.CARD_INSERTED` (0 = reset, debouncing, or no card).

eMSI Controller Setup Sequence

This section discusses the eMSI controller setup sequence for an SD/eMMC device.

eMMC Device Setup

The *eMSI Controller Setup Sequence for eMMC Interface* figure and procedure shows the eMSI controller setup sequence for an eMMC device. For more information on bit fields set in this sequence please refer to register descriptions.

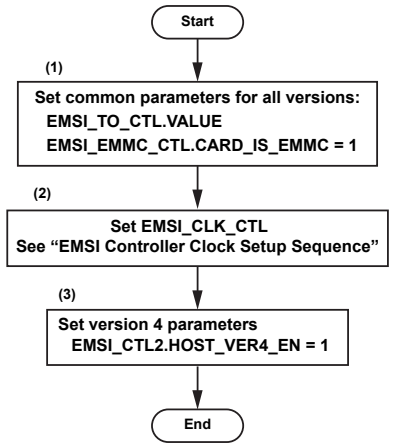

Figure 18-13: eMSI Controller Setup Sequence for eMMC Interface

1. Configure common parameters for all versions
    a. `EMSI_TO_CTL.VALUE`.
    b. `EMSI_EMMC_CTL.CARD_IS_EMMC` = 1.
2. Configure `EMSI_CLK_CTL` see eMSI Controller Clock Setup Sequence.

3. Configure version 4 parameters.
    a. `EMSI_CTL2.HOST_VER4_EN` = 1.

SD Interface Setup

The *eMSI Controller Setup Sequence for SD Interface* figure and procedure shows the eMSI controller setup sequence for an SD interface.

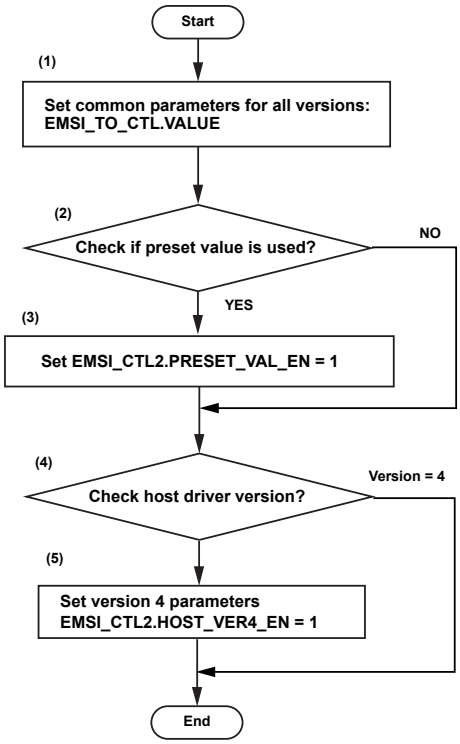

Figure 18-14: eMSI Controller Setup Sequence for SD Interface

NOTE: The eMSI controller supports version 4 mode.

1. Configure common parameters for all versions using the `EMSI_TO_CTL.VALUE` bit field.
2. Check if preset value is used?
    - If no go to step 4.
    - If yes go to step 3.
3. Set `EMSI_CTL2.PRESET_VAL_EN` = 1.
4. Check host driver version?
    - If version other than 4 go to end.
    - If version equal to 4 go to step 5.

5. Configure version 4 parameters, `EMSI_CTL2.HOST_VER4_EN` = 1.

Clock Control

This section discusses the programming sequence for setting up controller internal clocks and the eMSI bus clock which is provided to the eMMC device. This section also describes programming sequence for changing eMSI bus clock frequency after initial clock setup is completed.

This section includes the following sequences:

- eMSI Controller Clock Setup Sequence
- eMSI Bus Clock Supply and Stop Sequence
- eMSI Bus Clock Frequency Change Sequence

eMSI Controller Clock Setup Sequence

The *eMSI Controller Clock Setup Sequence* figure shows the sequence for setting up internal clocks for eMSI controller. The eMSI controller requires an eMSI input clock and eMSI TIMER CMQ clock from the system and an eMSI bus clock (clock supplied to eMMC device). The internal clocks should be initialized before accessing any eMSI controller registers.

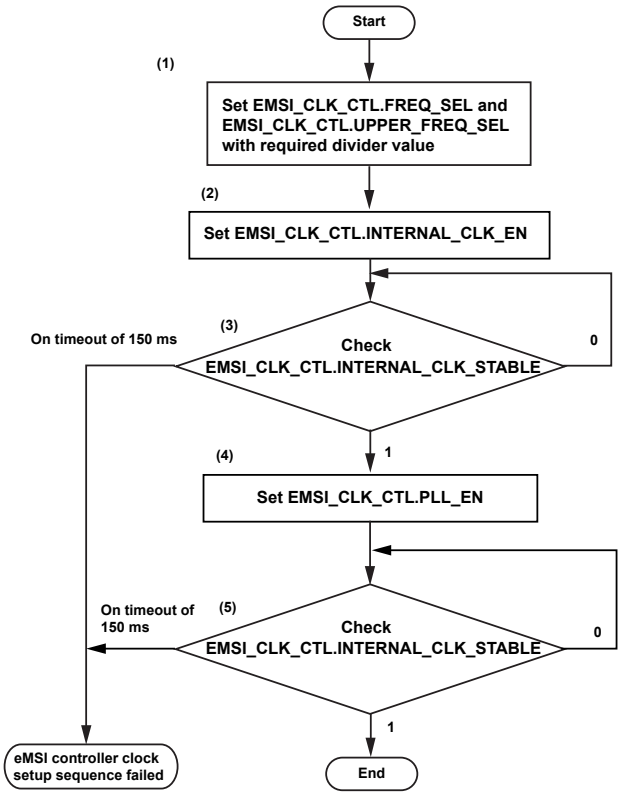

Figure 18-15: eMSI Controller Clock Setup Sequence

1. Configure the EMSI_CLK_CTL.UPPER_FREQ_SEL and EMSI_CLK_CTL.FREQ_SEL bits with the required divider value.
2. Configure the EMSI_CLK_CTL.INTERNAL_CLK_EN register.
3. Check the EMSI_CLK_CTL.INTERNAL_CLK_EN bit.
   - If 0 recheck the EMSI_CLK_CTL.INTERNAL_CLK_STABLE bit.
   - If 1 go to step 4.

   ADDITIONAL INFORMATION: On timeout of 150 ms eMSI controller clock setup sequence failed.
4. Configure the EMSI_CLK_CTL.PLL_EN bit.
5. Check the EMSI_CLK_CTL.INTERNAL_CLK_STABLE bit.
   - If 0 recheck the EMSI_CLK_CTL.INTERNAL_CLK_STABLE bit.
   - If 1 go to End

   ADDITIONAL INFORMATION: On timeout of 150 ms eMSI controller clock setup sequence failed.

eMSI Bus Clock Supply and Stop Sequence

The *eMSI Bus Clock Supply and Stop Sequence* figure shows the flow chart for stopping and supplying the eMSI bus clock. The procedure outlined in the figure applies to SD card/eMMC device.

NOTE: The clock supply and stop sequence is initiated, if required, only when there is no active data transfer between the eMSI controller and the eMMC device.

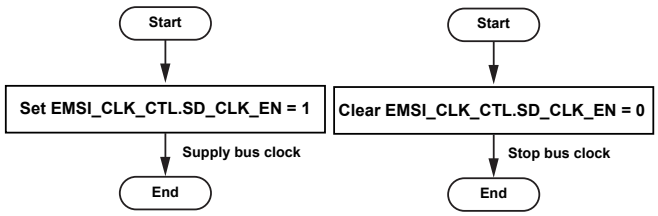

Figure 18-16: eMSI Bus Clock Supply and Stop Sequence

eMSI Bus Clock Frequency Change Sequence

The *eMSI Bus Clock Frequency Change* figure shows the sequence for changing eMSI bus clock frequency.

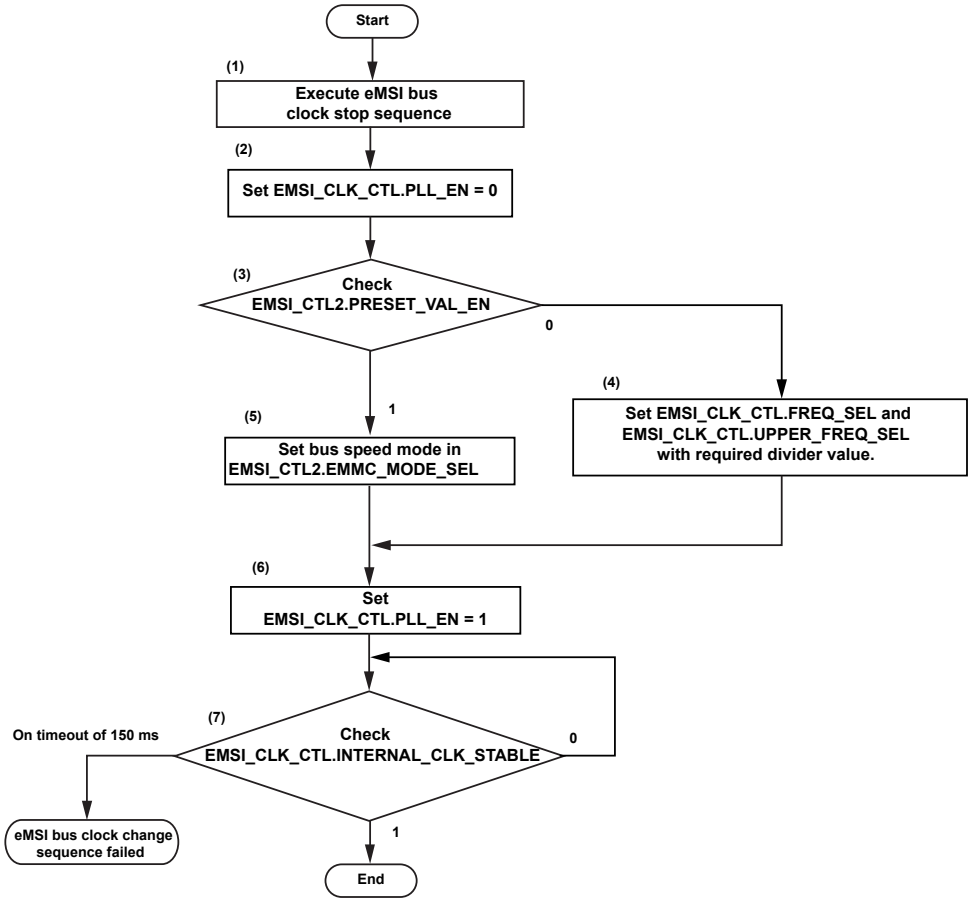

Figure 18-17: eMSI Bus Clock Frequency Change

1. Execute the eMSI bus clock stop sequence.
2. Clear the `EMSI_CLK_CTL.PLL_EN` bit = 0.
3. Check the `EMSI_CTL2.PRESET_VAL_EN` bit.
   - If 0 go to step 4.
   - If 1 go to step 5.
4. Configure bus speed mode in the `EMSI_CTL2.EMMC_MODE_SEL` bit field.
5. Configure `EMSI_CLK_CTL.FREQ_SEL` and `EMSI_CLK_CTL.UPPER_FREQ_SEL` with required divider value.
6. Set `EMSI_CLK_CTL.PLL_EN` = 1.
7. Check the `EMSI_CLK_CTL.INTERNAL_CLK_STABLE` bit.
   - If 0 recheck the `EMSI_CLK_CTL.INTERNAL_CLK_STABLE` bit.
   - If 1 go to End.

ADDITIONAL INFORMATION: On timeout of 150 ms eMSI bus clock frequency change sequence failed.

NOTE: Software must issue `EMSI_SWRST.DAT` and `EMSI_SWRST.CMD` after an eMSI bus clock frequency change sequence to avoid the effect of any glitch on the sampling clock. The program must also disable the CDU clock output for the eMSI, before executing an eMSI bus clock frequency change sequence. After sequence execution, the program should reenable the CDU clock. Additionally, enable the eMSI bus clock using the eMSI bus clock supply sequence (to ensure a clock is supplied to the eMMC device for further operations).

Card Interface Setup Sequence

This section discusses the programming sequence for setting up the card interface for an SD or eMMC card and contains the following topics:

- See SD Card Setup Sequence
- See eMMC Card Interface Setup

SD Card Setup Sequence

The *SD Card Setup Sequence* figure shows the programming sequence to set up the SD card. This sequence configures the eMSI controller for detection of an SD card.

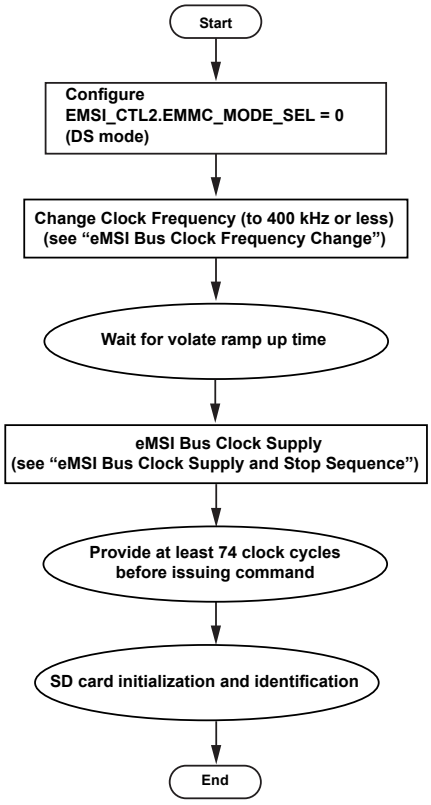

Figure 18-18: SD Card Setup Sequence

eMMC Card Interface Setup

The *eMMC Card Setup Sequence* figure and procedure shows the programming sequence to set up an eMMC device. This sequence configures the eMSI controller for detection of an eMMC device.

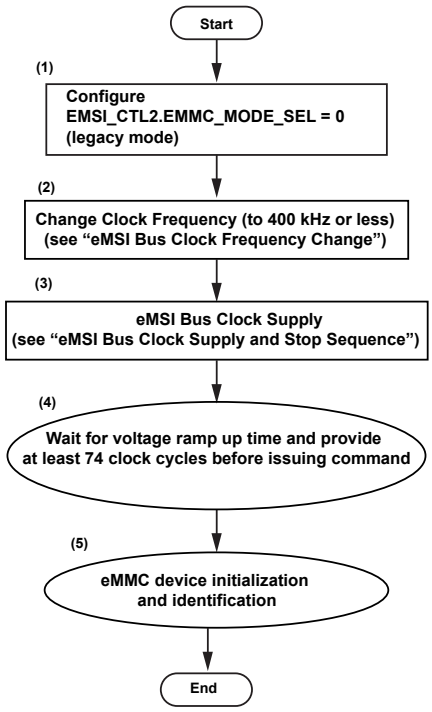

Figure 18-19: eMMC Card Setup Sequence

1. Configure `EMSI_CTL2.EMMC_MODE_SEL` = 0 bit for legacy mode.
2. Change the clock frequency (to 400 kHz or less). See eMSI Bus Clock Frequency Change Sequence.
3. Perform eMMC clock supply. See eMSI Bus Clock Supply and Stop Sequence.
4. Wait for voltage ramp up time and provide at least 74 clock cycles before issuing command.
5. eMMC device initialization and identification.

Setting Timeout on the eMSI Bus

The *Setting eMSI Bus Timeout* figure and procedure shows the sequence for setting timeout on the eMSI bus. This value determines the interval by which DAT line timeouts are detected. For more information please refer to the corresponding register descriptions.

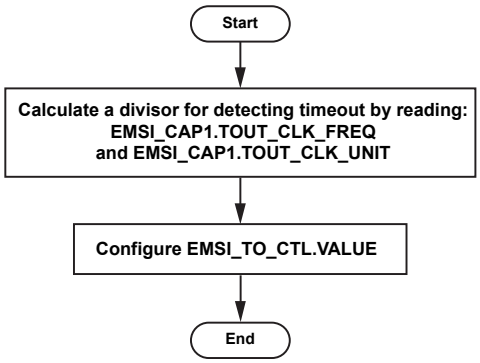

Figure 18-20: Setting eMSI Bus Timeout

1. Calculate a divisor for detecting timeout by reading the `EMSI_CAP1.TOUT_CLK_FREQ` and `EMSI_CAP1.TOUT_CLK_UNIT` registers.
2. Configure the `EMSI_TO_CTL.VALUE` register.

Abort Transaction

An abort command to the SD/eMMC device is issued to abort an ongoing data transaction. To abort a transaction on an SD/eMMC device, CMD12 is issued.

Following are the instances when an abort command must be issued:

- To stop an infinite block transfer
- To stop a transfer due to a request from an application
- To stop a transfer due to an error detection

The sequence to issue an abort command is shown in Abort Command Sequence. An abort command can be issued asynchronously during data transfer. In an asynchronous abort the abort command is issued at any time irrespective of the state of data transfer as a subcommand. The method is explained in Asynchronous Abort.

Abort Command Sequence

The *Abort Command Sequence* figure and procedure describe the abort command sequence.

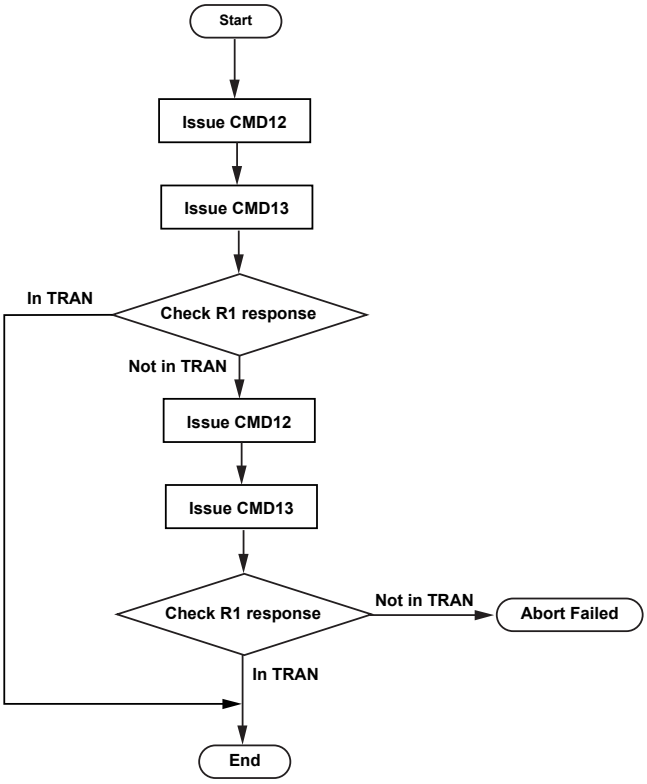

Figure 18-21: Abort Command Sequence

1. Issue CMD12.
2. Issue CMD13.
3. Check R1.
   - If in TRAN go to End.
   - If not in TRAN go to step 5.
4. Issue CMD12.
5. Issue CMD13.
6. Check R1.
   - If in TRAN go to End.
   - If not in TRAN abort failed.

   ADDITIONAL INFORMATION: Keep sending CMD13 until the card returns to the transfer state. In some cases it takes more than twice to send CMD13 for correctly detecting the transfer state. Applicable when CMD 12 is successfully sent.

Asynchronous Abort

The *Asynchronous Abort Sequence* figure and procedure describe the asynchronous abort command sequence.

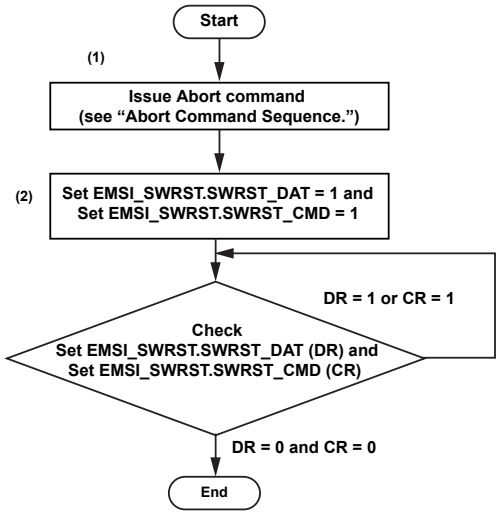

Figure 18-22: Asynchronous Abort Sequence

1. Issue abort command (see Abort Command Sequence).
2. Set the `EMSI_SWRST.DAT` and `EMSI_SWRST.CMD` bits = 1.
3. Check the `EMSI_SWRST.DAT` (DR) and `EMSI_SWRST.CMD` (CR) bits.
   - DR = 1 or CR = 1 recheck the `EMSI_SWRST.DAT` and `EMSI_SWRST.CMD` bits.
   - DR = 0 and CR = 0 go to End.

eMMC Transaction Mode

This section discusses the programming sequences for setting the eMSI controller for an eMMC interface. This section also discusses how to program and initiate different boot speed modes.

This section discusses the following programming sequences:

- Initializing and Identifying an eMMC Device
- Issuing CMD With or Without Data Transfers for an eMMC Device
- Switching to Various Speed Modes in an eMMC Device
- Changing the Data Bus Width for an eMMC Device
- Command Queueing
- eMMC Device Boot Programming Sequences

Initializing and Identifying an eMMC Device

The *Card Initialization and Identification Programming Sequence* figure shows the programming sequence to initialize and identify an eMMC device.

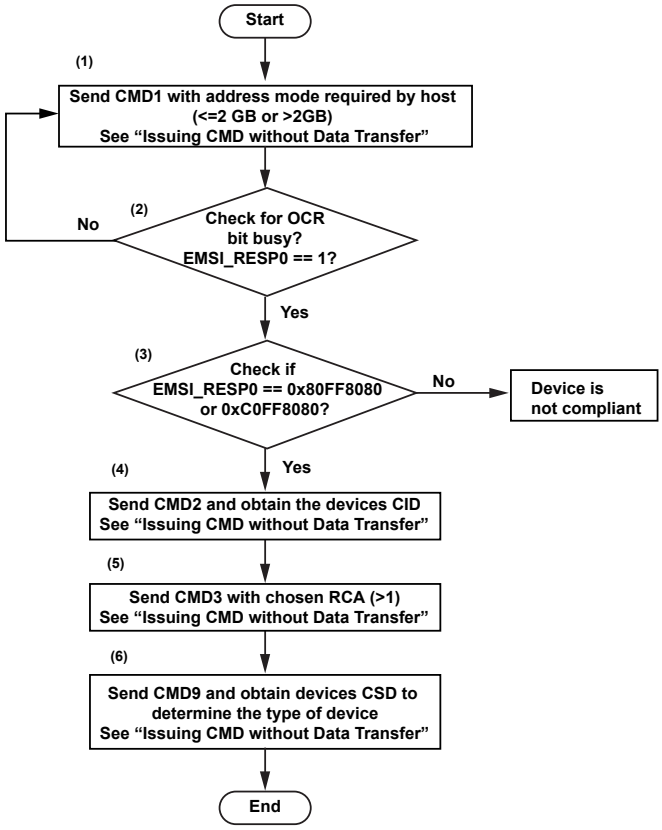

Figure 18-23: Card Initialization and Identification Programming Sequence

1. Send CMD1 with address mode required by host (≤2 GB or >2GB). See Issuing CMD Without Data Transfer.
2. Check for OCR bit busy `EMSI_RESP0` == 1?
   a. No - go back to step 1.
   b. Yes - Go to step 3.
3. Check if `EMSI_RESP0` == 0x80FF8080 or 0xC0FF8080? If not, the device is not compliant.
4. Send CMD2 and obtain the devices CID See Issuing CMD Without Data Transfer.
5. Send CMD3 with chosen RCA (>1) See Issuing CMD Without Data Transfer.
6. Send CMD9 and obtain devices CSD to determine the type of device See Issuing CMD Without Data Transfer.

Switching to Various Speed Modes in an eMMC Device

The *Programming Sequence to Switch to Various Speed Modes in an eMMC Device* figure and procedure shows the programming sequence to switch to various speed modes in an eMMC device. In the figure, note that CMD6 is effective only during the transfer state.

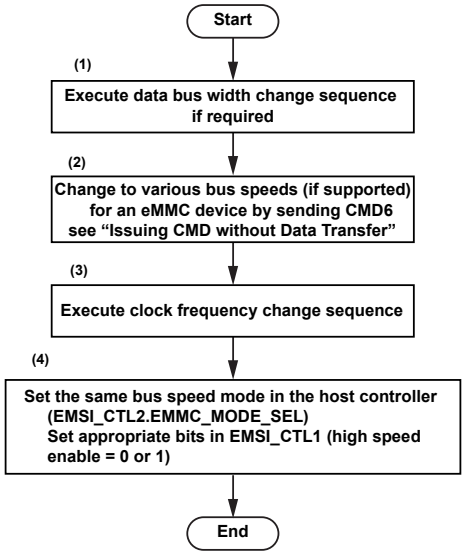

Figure 18-24: Programming Sequence to Switch to Various Speed Modes in an eMMC Device

1. Execute data bus width change sequence if required.
2. Change to various bus speeds (if supported) for an eMMC card by sending CMD6 see Issuing CMD Without Data Transfer.
3. Execute clock frequency change sequence
4. Configure the same bus speed mode in the host controller using the `EMSI_CTL2.EMMC_MODE_SEL` bit field. Configure the `EMSI_CTL1.HIGH_SPEED_EN` bit field (high speed enable = 0 or 1).

Changing the Data Bus Width for an eMMC Device

The *Programming Sequence to Change Data Bus Width for an eMMC Device* figure shows the programming sequence to change the data bus width for an eMMC device. In the figure, note that CMD6 is effective only during transfer state.

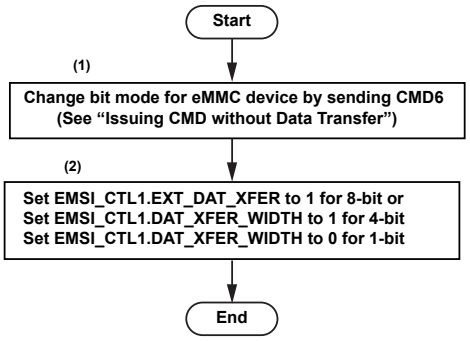

Figure 18-25: Programming Sequence to Change Data Bus Width for an eMMC Device

1. Change bit mode for eMMC card by sending CMD6 (See Issuing CMD Without Data Transfer).
2. Set the `EMSI_CTL1.EXT_DAT_XFER` bit to 1 for 8-bit or set the `EMSI_CTL1.DAT_XFER_WIDTH` bit to 1 for 4-bit or clear to 0 for 1-bit.

Error Recovery in eMMC Mode

The *Error Recovery Sequence in eMMC Mode* figure and procedure shows the error recovery sequence for eMMC mode.

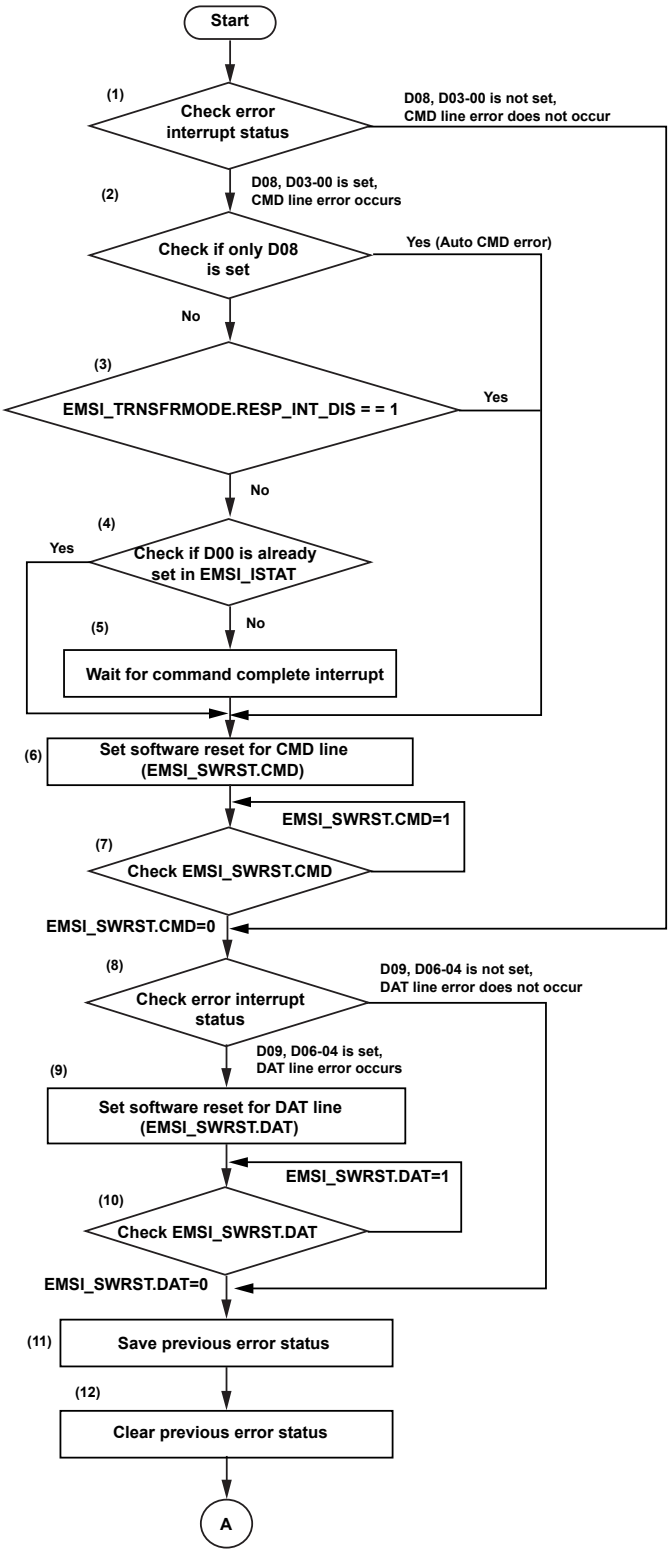

Figure 18-26: Error Recovery Sequence in eMMC Mode

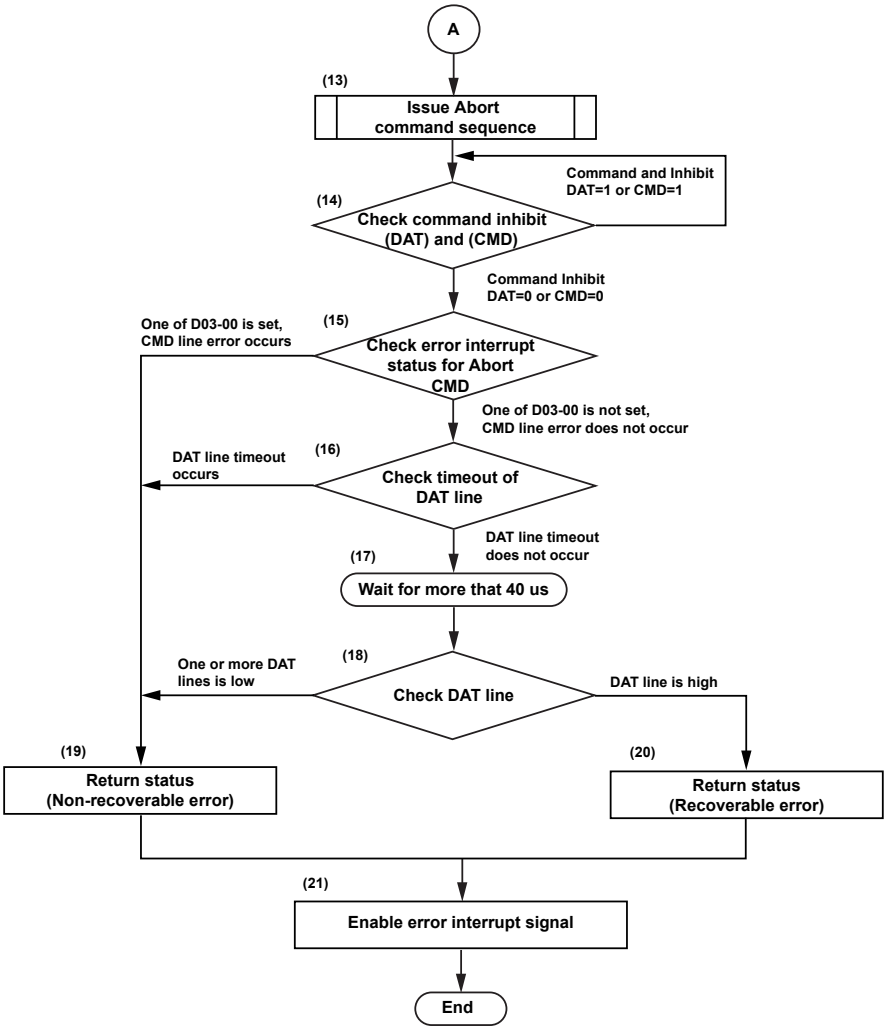

Figure 18-27: Error Recovery Sequence in eMMC Mode (continued)

1. Check error interrupt status.
   - D08, D03-00 is not set, CMD line error does not occur - go to step 8.
   - D08, D03-00 is set, CMD line error occurs - go to step 3.
2. Check if only D8 is set.
   - Yes (Auto CMD error) - go to step 6.
   - No - go to step 3.
3. `EMSI_TRNSFRMODE.RESP_INT_DIS` = = 1
   - Yes - go to step 6.
   - No - go to step 4.

4. Check if D00 is already set in the EMSI_ISTAT register.
    - Yes - go to step 6.
    - No - go to step 5.
5. Wait for command complete interrupt.
6. Set software reset for CMD line using the EMSI_SWRST.CMD bit.
7. Check the EMSI_SWRST.CMD bit.
    - If = 1 recheck.
    - If = 0 - go to step 8.
8. Check error interrupt status.
    - D09, D06-04 is not set, DAT line error does not occur - go to step 11.
    - D09, D06-04 is set, DAT line error occurs - go to step 9.
9. Set software reset for DAT line using the EMSI_SWRST.DAT bit.
10. Check the EMSI_SWRST.DAT bit.
    - If = 1 recheck.
    - If = 0 - go to step 11.
11. Save previous error status.
12. Clear previous error status.
13. Issue Abort command sequence.
14. Check command inhibit (DAT) and (CMD)
    - Command and Inhibit DAT = 1 or CMD = 1 - recheck.
    - Command Inhibit DAT = 0 or CMD = 0 - go to step 15.
15. Check error interrupt status for Abort CMD
    - One of D03-00 is set, CMD line error occurs - go to step 19.
    - One of D03-00 is not set, CMD line error does not occur - go to step 16.
16. Check timeout of DAT line.
    - DAT line timeout occurs - go to step 19.
    - DAT line timeout does not occur - go to step 17.
17. Wait for more that 40 us.
18. Check DAT line

- One or more DAT lines is low - go to step 19.
- DAT line is high - go to step 20.

19. Return status (Non-recoverable error).
20. Return status (Recoverable error).
21. Enable error interrupt signal.

NOTE: The error recovery sequence returns either a *Recoverable Error* or a *Non-Recoverable Error* status. When a recoverable error is returned, the error is recovered fully. When the non-recoverable error status returns, both the controller and the eMMC device must be re-initialized after performing a power cycle for the eMMC device.

Set the `EMSI_CMD.TYPE` bit field to 0x3 while issuing the abort CMD using CMD12. The software driver must issue a software reset for the DAT line while issuing a software reset for the CMD line. D00, D01, D02, D03, etc. corresponds to bit field 0 , 1, 2, 3 respectively from the `EMSI_ERR_STAT` register.

Issuing CMD With or Without Data Transfers for an eMMC Device

Programs can issue commands with or without data transfers.

- The programming sequence for issuing a command without a data transfer for an eMMC device is like the sequence described in Issuing CMD Without Data Transfer.
- The programming sequence for issuing a command with a data transfer for an eMMC device is like the programming sequence described in the sections following Issuing CMD With Data Transfer. Data transfers can be performed using DMA. The supported DMA modes are SDMA, ADMA2, and ADMA3.

NOTE: The application must ensure that the `EMSI_BOOT_CTL.BOOT_ACK_ENABLE` bit is cleared (when set due to a previous boot CMD) before initiating any data transfer CMD.

Issuing CMD Without Data Transfer

The *eMMC Command Issue and Complete* figure and procedure show the steps to issue a CMD without a data transfer.

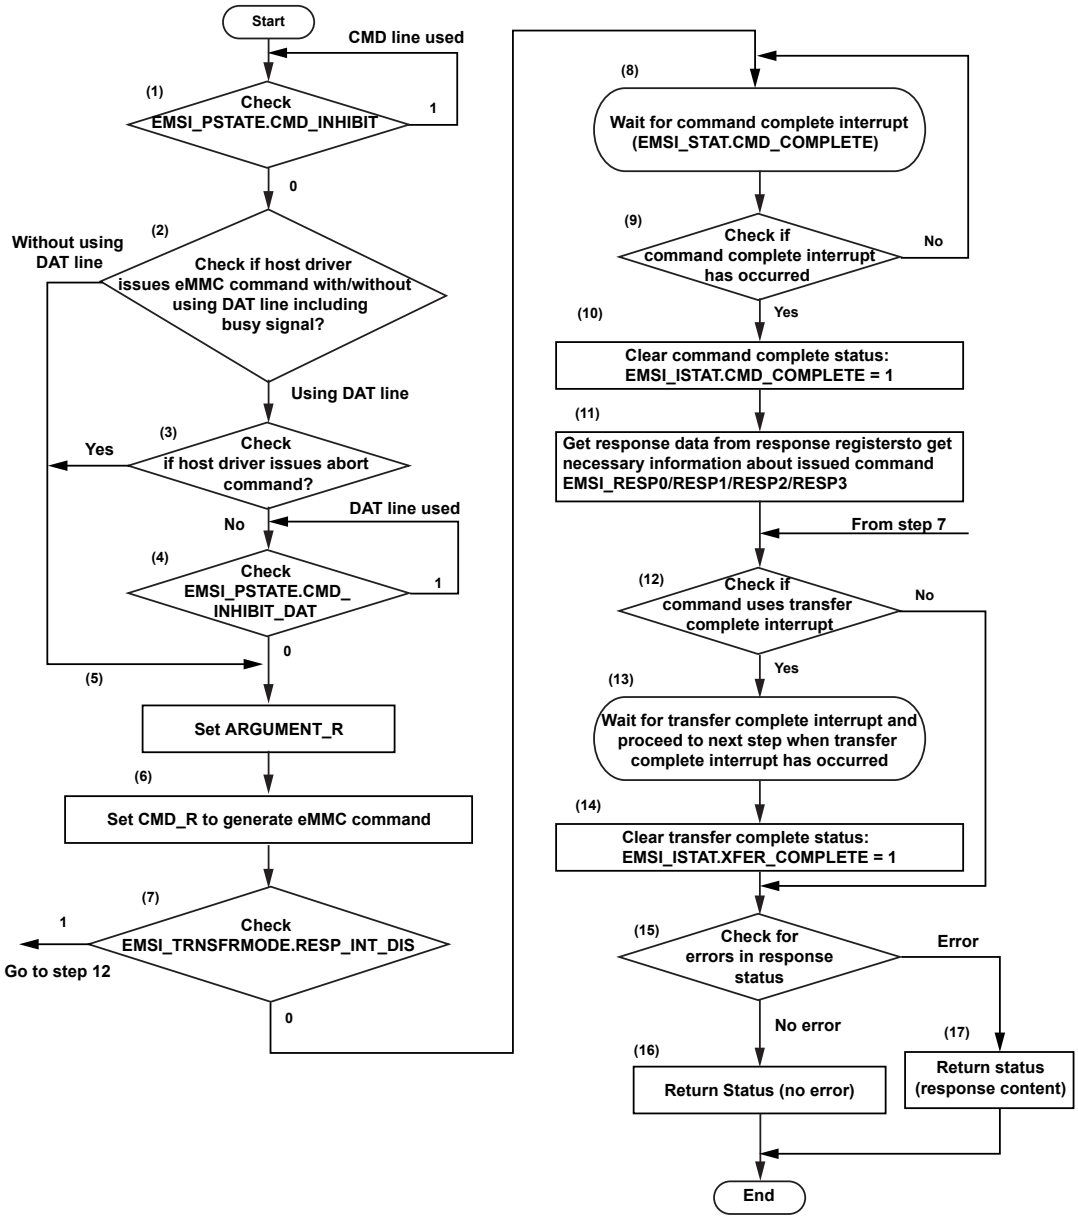

Figure 18-28: eMMC Command Issue and Complete

1. Check the `EMSI_PSTATE.CMD_INHIBIT` bit.
    a. If 1 - CMD line used. Recheck until the `EMSI_PSTATE.CMD_INHIBIT` bit = 0.
    b. If 0 - go to step 2.
2. Check if host driver issues an eMMC command with/without using DAT line including busy signal.
    a. Without using DAT line - go to step 5.
    b. Using DAT line - go to step 3.

3. Check if host driver issues abort command.
    a. Yes - go to step 5.
    b. No - go to step 4.
4. Check `EMSI_PSTATE.CMD_INHIBIT_DAT`.
    a. If 1 - DAT line used. Repeat until 0.
    b. If 0 - go to step 5.
5. Configure ARGUMENT_R to generate an eMMC command.
6. Configure CMD_R.
7. Check `EMSI_TRNSFRMODE.RESP_INT_DIS`
    a. If 1 - go to step 12.
    b. If 0 - go to step 8.
8. Wait for command complete interrupt (`EMSI_ISTAT.CMD_COMPLETE`).
9. Check if command complete interrupt has occurred.
    a. No - go back to step 8.
    b. Yes- go to step 10.
10. Set `EMSI_ISTAT.CMD_COMPLETE` = 1.
11. Get response data from response registers to get necessary information about issued command from the `EMSI_RESP0`/`EMSI_RESP1`/`EMSI_RESP2`/`EMSI_RESP3` registers.
12. Check if command uses transfer complete interrupt.
    a. No - go to step 15.
    b. Yes - go to step 13.
13. Wait for transfer complete interrupt and proceed to next step when transfer complete interrupt has occurred.
14. Clear transfer complete interrupt (`EMSI_ISTAT.XFER_COMPLETE` = 1).
15. Check for errors in response status.
    a. Error - go to step 17.
    b. No error - go to step 16.
16. Return Status (no error).
17. Return status (response contents).

NOTE: Before issuing next command for an extra check, the program can poll on the `EMSI_PSTATE.DAT_LINE_ACTIVE` bit until it is cleared for R1b response command types.

Issuing CMD With Data Transfer

This section includes the sequence to issues a eMMC command with data transfer using SDMA, ADMA, and ADMA3 modes.

NOTE: While using ADMA2 or ADMA3, the host memory data buffer size and start address must not exceed 128 MB. When greater than 128 MB, the data buffer must be split using two descriptors such that a transfer attempting to cross the limit (of 128 MB) is not generated.

This section discusses the following programming sequences:

- Issuing CMD with Data Transfer (Using SDMA)
- Issuing CMD with Data Transfer (Using ADMA2)
- Issuing CMD with Data Transfer (Using ADMA3)

The ADMA3 ID descriptor, command descriptor, and ADMA2 descriptor are organized in a location in the host memory. Please refer to Advanced DMA 2 (ADMA2) and Advanced DMA 3 (ADMA3) for more information on ADMA2 and ADMA3 descriptors.

NOTE: The ADMA3 ID address, command descriptor address, and ADMA2 descriptor address should be 32-bit aligned.

Issuing CMD with Data Transfer (Using SDMA)

The *Transaction Control with Data Transfer Using SDMA* figure and procedure shows the transaction that uses SDMA for data transfer using the DAT line. The `EMSI_ERR_STAT.ADMA_ERR` bit is set (=1) for all DMA (SDMA, ADMA2 and ADMA3) transfers for error response.

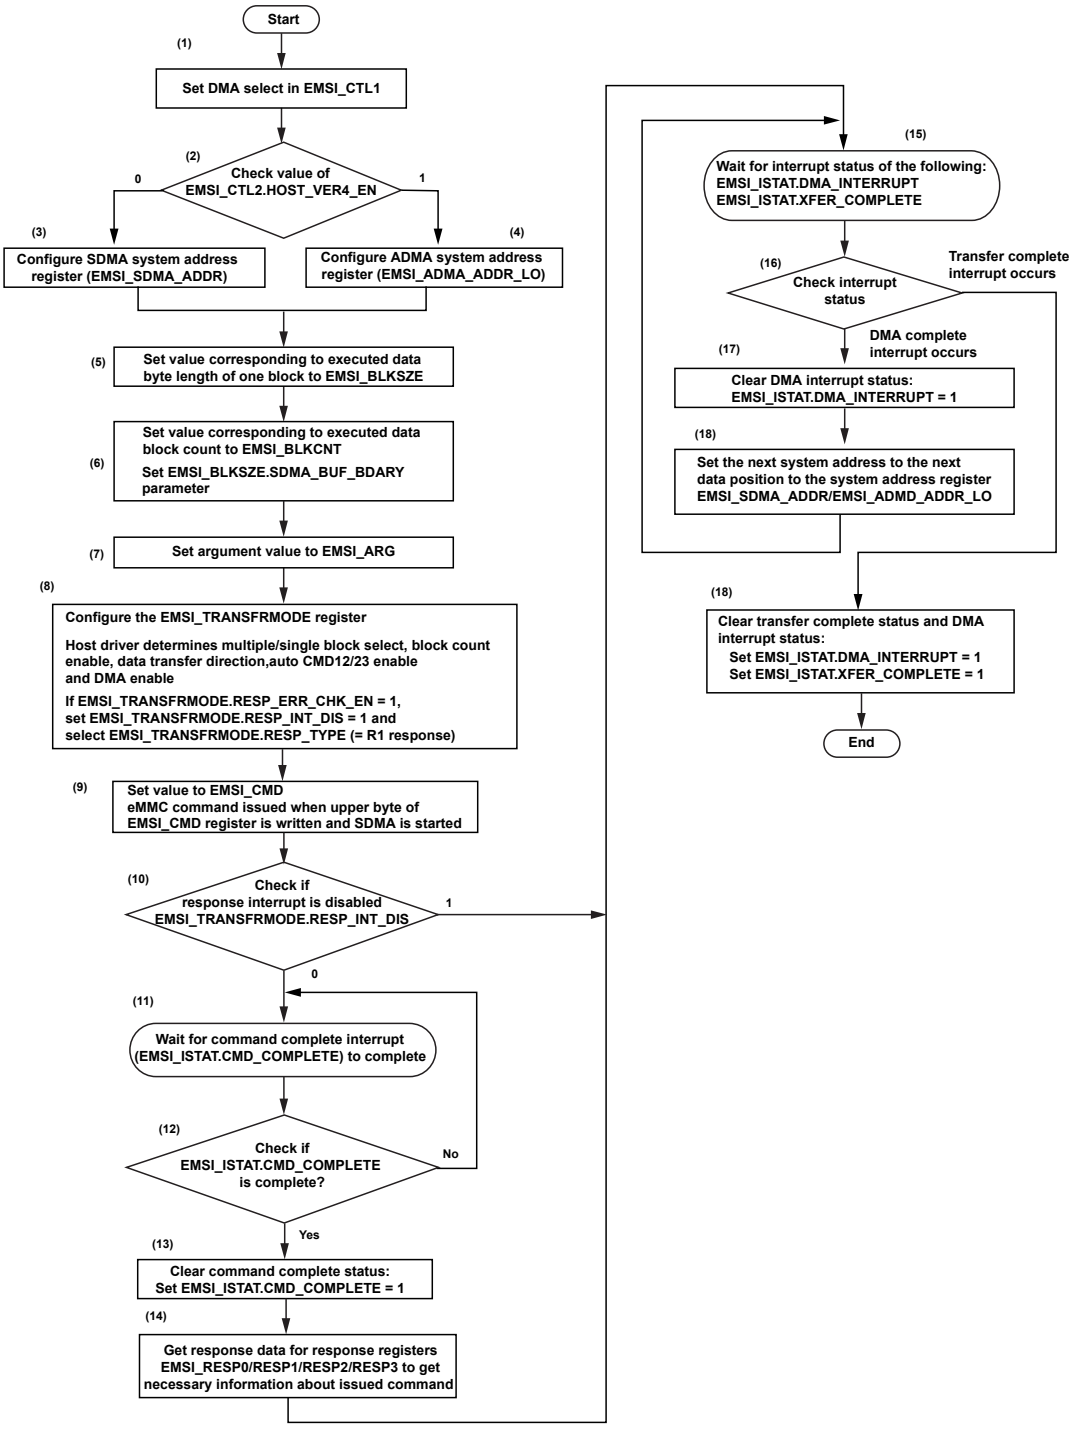

Figure 18-29: Transaction Control with Data Transfer Using SDMA

1. Configure the `EMSI_CTL1.DMA_SEL` bit field for SDMA.
2. Check the value of the `EMSI_CTL2.HOST_VER4_EN` bit.

a. If 0 - go to step 3.

b. If 1 - go to step 4.

3. Configure the SDMA system address register (EMSI_SDMA_ADDR).
4. Configure the ADMA system address register (EMSI_ADMA_ADDR_LO).
5. Configure the value corresponding to executed data byte length of one block to the EMSI_BLKSZ register.
6. Configure value corresponding to executed data block count to the EMSI_BLKCNT register. Configure the size of contiguous buffer in system memory using the EMSI_BLKSZ.SDMA_BUF_BDARY bit field.
7. Configure the argument value in the EMSI_ARG register.
8. Configure the EMSI_TRNSFRMODE register.

   The host driver determines multiple/single block select, block count enable, data transfer direction, auto CMD12/23 enable and DMA enable. If EMSI_TRNSFRMODE.RESP_ERR_CHK_EN = 1, set EMSI_TRNSFRMODE.RESP_INT_DIS = 1 and select the transfer mode type in the EMSI_TRNSFRMODE.RESP_TYPE register (= R1 response).
9. The eMMC command issued when the upper byte of the EMSI_CMD register is written and SDMA is started.
10. Check if the response interrupt is disabled in the EMSI_TRNSFRMODE.RESP_INT_DIS bit.

    a. If 1 - go to step 15.

    b. If 0 - go to step 11.
11. Wait for the command complete interrupt (EMSI_ISTAT.CMD_COMPLETE) to complete.
12. Check if the EMSI_ISTAT.CMD_COMPLETE interrupt is complete.

    a. If no - go back to step 11.

    b. If yes - go to step 13.
13. Clear the command complete status by setting EMSI_ISTAT.CMD_COMPLETE = 1.
14. Get response data for response registers EMSI_RESP0/EMSI_RESP1/EMSI_RESP2/EMSI_RESP3 to get the necessary information about the issued command.
15. Wait for the interrupt status of the EMSI_ISTAT.DMA_INTERRUPT and EMSI_ISTAT.XFER_COMPLETE bits.
16. Check the interrupt status.

    a. Transfer complete interrupt occurs - go to step 19.

    b. DMA interrupt occurs - go to step 17
17. Clear the DMA interrupt status by setting EMSI_ISTAT.DMA_INTERRUPT = 1.

18. Configure the next system address to the next data position to the system address register EMSI_SDMA_ADDR/EMSI_ADMA_ADDR_LO.
19. Clear the transfer complete status and DMA interrupt status by setting the EMSI_ISTAT.DMA_INTERRUPT and EMSI_ISTAT.XFER_COMPLETE bits = 1.

NOTE: As per the SDMA Buffer Boundary parameter, the program should ensure that the buffer is properly aligned so that it is continuous in the memory up to the specified buffer boundary.

Issuing CMD with Data Transfer (Using ADMA2)

The *Transaction Control with Data Transfer Using DAT Line (Using ADMA2)* figure and procedure describe transaction control using the DAT line for ADMA2 data transfers. For more information on ADMA2 operation and descriptor, see Advanced DMA 2 (ADMA2).

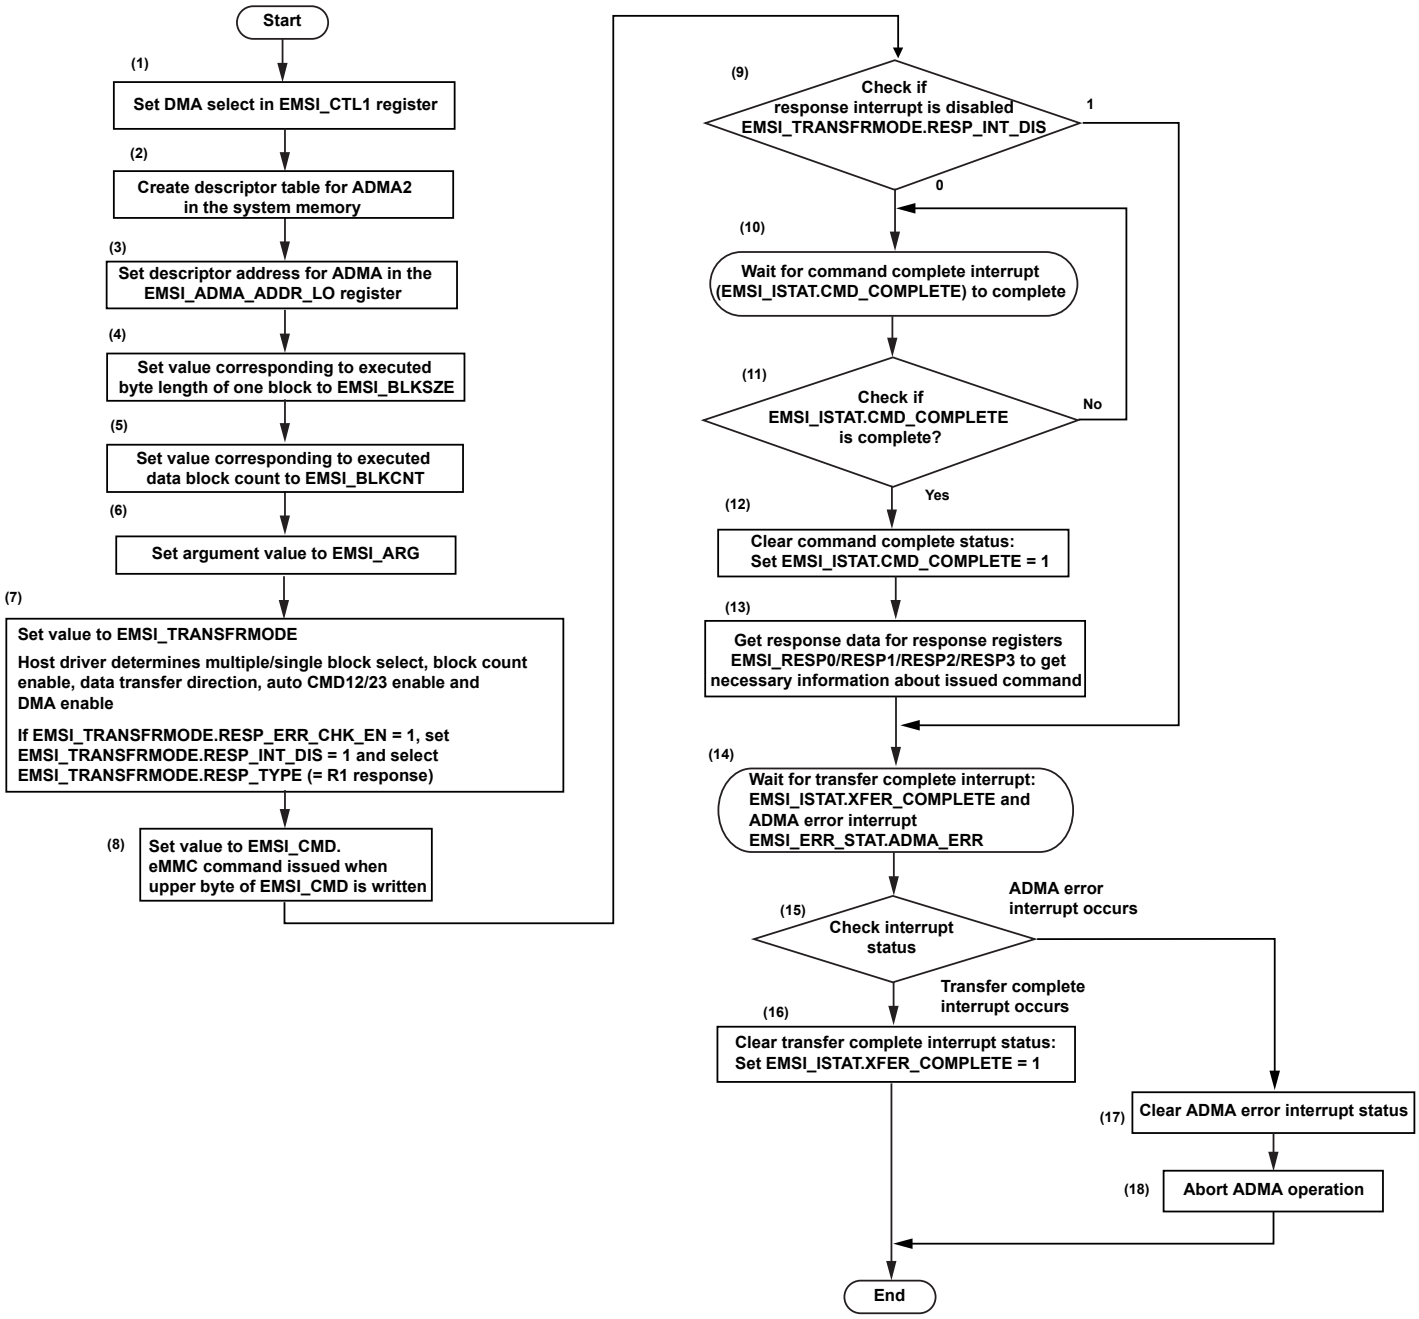

Figure 18-30: Transaction Control with Data Transfer Using DAT Line (Using ADMA2)

1. Configure DMA select in the `EMSI_CTL1.DMA_SEL` bit field.
2. Create a descriptor table for ADMA in the system memory.
3. Configure the descriptor address for ADMA in the `EMSI_ADMA_ADDR_LO` registers
4. Configure the value corresponding to the executed byte length of one block in the `EMSI_BLKSZ` register.

5. Configure the value corresponding to the executed data block count in the EMSI_BLKCNT register.
6. Configure the argument value in the EMSI_ARG register.
7. Configure the EMSI_TRNSFRMODE register (= R1 response).

   The host driver determines multiple/single block select, block count enable, data transfer direction, auto CMD12 enable and DMA enable. If EMSI_TRNSFRMODE.RESP_ERR_CHK_EN = 1, set EMSI_TRNSFRMODE.RESP_INT_DIS = 1 and select EMSI_TRNSFRMODE.RESP_TYPE.
8. Configure the argument value in the EMSI_CMD register. The eMMC command is issued when the upper byte of the EMSI_CMD register is written.
9. Check if the response interrupt is disabled in the EMSI_TRNSFRMODE.RESP_INT_DIS bit.
   a. If 1 - go to step 14.
   b. If 0 - go to step 10.
10. Wait for the command complete interrupt (EMSI_ISTAT.CMD_COMPLETE) to complete.
11. Check if EMSI_ISTAT.CMD_COMPLETE is complete.
   a. If no - go back to step 10.
   b. If yes - go to step 12.
12. Clear command complete status by setting EMSI_ISTAT.CMD_COMPLETE = 1
13. Get response data for response registers EMSI_RESP0/EMSI_RESP1/EMSI_RESP2/EMSI_RESP3 to get the necessary information about the issued command.
14. Wait for transfer complete interrupt in the EMSI_ISTAT.XFER_COMPLETE bit and the ADMA error interrupt in the EMSI_ERR_STAT.ADMA_ERR bit.
15. Check the interrupt status.
   a. Transfer complete interrupt occurs - go to step 19.
   b. DMA interrupt occurs - go to step 17
16. Clear transfer complete interrupt status by setting EMSI_ISTAT.XFER_COMPLETE = 1
17. Clear ADMA error interrupt status.
18. Abort ADMA operation.

NOTE: During card read/write DMA operations, it is recommended that the very last transfer descriptor also has the End bit set for marginal performance improvement. The End bit should always be set on a descriptor of type TRAN (not for link descriptor or other type descriptor). Descriptor types are provided in the following table for quick reference. The descriptor type recommendation in Table 18-16 Descriptor Types is applicable only to ADMA2 and ADMA3 transfers.

Table 18-16: Descriptor Types

Act2	Act1	Act0	Symbol	Comment	ADMA2 Descriptor Address
0	0	0	NOP	No operation	Do not execute current line and go to next line
0	1	0	rsv	Reserved	Same as NOP
1	0	0	Tran	Transfer data	Transfer data of one descriptor line
1	1	0	Link	Link descriptor	Link to another descriptor

Issuing CMD with Data Transfer (Using ADMA3)

The *Transaction Control with Data Transfer Using DAT Line (Using ADMA3)* figure and procedure describe transaction control using the DAT line for ADMA3 data transfers.

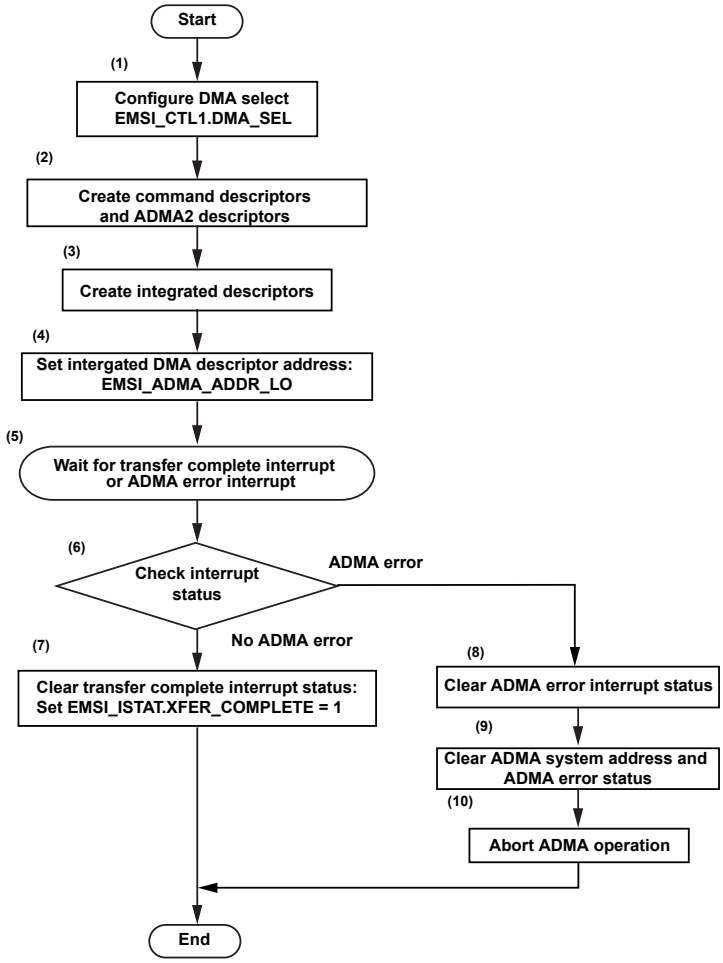

Figure 18-31: Transaction Control with Data Transfer Using DAT Line (Using ADMA3)

1. Configure DMA select.
2. Create command descriptors and ADMA2 descriptors.

3. Create integrated descriptors.
4. Configure the integrated DMA descriptor address in the EMSI_ADMA_ADDR_LO register.
5. Wait for transfer complete interrupt or ADMA error interrupt.
6. Check interrupt status.
    a. ADMA error - go to step 8.
    b. No ADMA error - go to step 7.
7. Clear transfer complete interrupt status by setting EMSI_ISTAT.XFER_COMPLETE = 1.
8. Clear the ADMA error interrupt status
9. Clear the ADMA system address and ADMA error status.
10. Abort the ADMA operation.

The following list describes the descriptor requirements for an ADMA3 CMD:

- Configuring infinite data transfer (EMSI_TRNSFRMODE.BLOCK_COUNT_EN = 0) is not allowed except for single block transfer (EMSI_TRNSFRMODE.MULTI_BLK_SEL = 0)
- As ADMA3 only supports 32-bit block count mode, EMSI_TRNSFRMODE.BLOCK_COUNT_EN is set to 1 and 16-bit block count (EMSI_BLKCNT.VALUE) is configured to 0x0000. Configuring stop count (32-bit block count = 0) is not allowed except for single block transfers (EMSI_TRNSFRMODE.MULTI_BLK_SEL = 0).
- Configuring no data transfer (Block Size = 0) is not allowed, except for no data transfer command in the command descriptor (CDEnd = 1).
- In cases where the memory data transfer command is used, the Auto CMD Auto Select option (0x3) in the EMSI_TRNSFRMODE.AUTO_CMD_EN bit field is used so that the command descriptor is independent of eMMC device support CMD23. For other commands, auto command disabled (0x0) is used. If EMSI_CTL2.CMD23_EN = 1 then Auto CMD23 is issued before the transfer commands and if EMSI_CTL2.CMD23_EN = 0, then Auto CMD12 is issued after the transfer complete. For SD cards that do not support CMD23 (card versions 2.00 and below) configure the EMSI_CTL2 register accordingly.

During card read/write DMA operations, it is recommended that the very last transfer descriptor also has the End bit set for marginal performance improvement. The End bit should always be set on a descriptor of type TRAN. The following table is applicable only to ADMA2 and ADMA3 transfers.

Table 18-17: Descriptor Types

Act2	Act1	Act0	Symbol	Comment	ADMA2 Descriptor Address
0	0	0	NOP	No Operation	Do not execute current line and go to the next line

Table 18-17: Descriptor Types (Continued)

Act2	Act1	Act0	Symbol	Comment	ADMA2 Descriptor Address
0	1	0	RSV	Reserved	Same as Nop. Do not execure current line and go to next line
1	0	0	TRAN	Transfer Data	Transfer data of one descriptor line
1	1	0	LINK	Link Descriptor	Link to another descriptor

Command Queueing

The following sections describe the processes for initializing the command queuing engine and submitting and completing a task in the Command Queuing engine.

Initializing the Command Queuing Engine

The *Initializing the Command Queuing Engine* figure shows the programming sequence to initialize the command queuing engine.

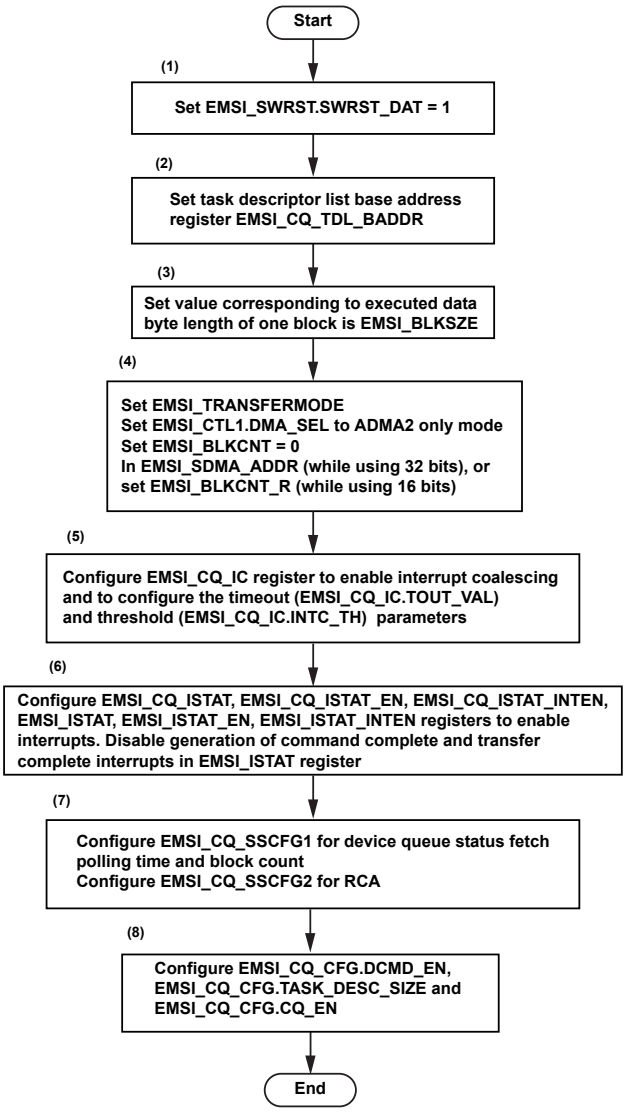

Figure 18-32: Initializing the Command Queuing Engine

1. Set `EMSI_SWRST.DAT` = 1.
2. Configure the task descriptor list base address register, `EMSI_CQ_TDL_BADDR`.
3. Configure a value corresponding to executed data byte length of one block in the `EMSI_BLKSZ` register.
4. Configure the following registers and bits:
    a. `EMSI_TRNSFRMODE` register.
    b. Configure `EMSI_CTL1.DMA_SEL` to ADMA2 only mode.
    c. Clear `EMSI_BLKCNT` = 0.

   d. In the EMSI_SDMA_ADDR register (while using 32 bits) or configure the EMSI_BLKCNT register (while using 16 bits).

5. Configure the command queuing interrupt coalescing register to enable interrupt coalescing and to configure the timeout (EMSI_CQ_IC.TOUT_VAL) and threshold (EMSI_CQ_IC.INTC_TH) parameters.
6. Configure the following interrupt registers to enable interrupts.
   a. EMSI_CQ_ISTAT, EMSI_CQ_ISTAT_EN, EMSI_CQ_ISTAT_INTEN.
   b. EMSI_ISTAT, EMSI_ISTAT_EN, EMSI_ISTAT_INTEN.
   c. Disable generation of command complete and transfer complete interrupts (EMSI_ISTAT.XFER_COMPLETE, EMSI_ISTAT.CMD_COMPLETE).
7. Configure the EMSI_CQ_SSCFG1 register for device queue status fetch polling time and block count. Configure the EMSI_CQ_SSCFG2 register for RCA.
8. Configure the EMSI_CQ_CFG.DCMD_EN, EMSI_CQ_CFG.TASK_DESC_SIZE and EMSI_CQ_CFG.CQ_EN bits.

Check the EXT_CSD register byte 308 for command queuing support from card side. Byte 307 of the EXT_CSD register denotes the command queuing depth that the device supports. The program must also enable command queuing from the eMMC device side before enabling from the eMSI controller side (CMDQ_MODE_EN [15] in the EXT_CSD register).

Submitting and Completing a Task in the Command Queuing Engine

The *Submitting and Completing a Task* figure and procedure shows the sequence to submit and complete a task in a command queuing engine.

NOTE: Task descriptors and transfer descriptors in the host memory are aligned to an 8-byte boundary.

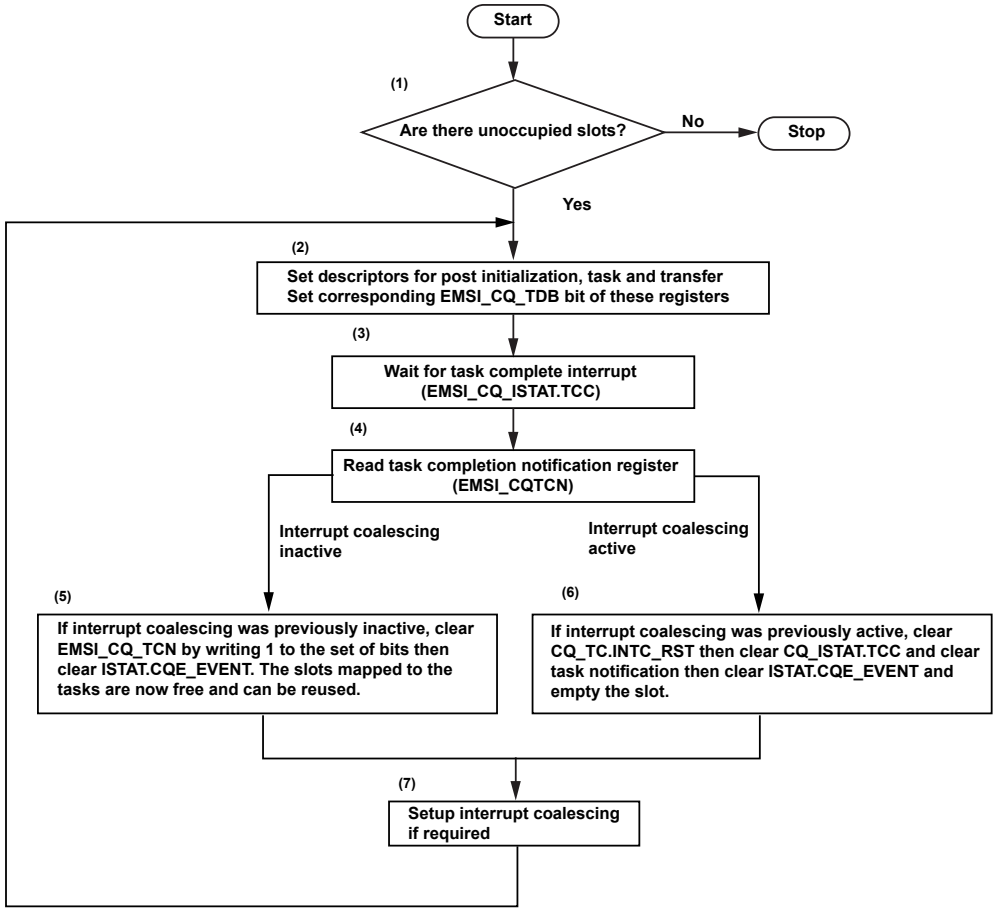

Figure 18-33: Submitting and Completing a Task

1. Are there unoccupied slots?
    a. If no - Stop.
    b. If yes - go to step 2.
2. Configure descriptors for post initialization, task, and transfer. Set the corresponding `EMSI_CQ_TDBR` bit of these registers.
3. Wait for the task complete interrupt (`EMSI_CQ_ISTAT.TCC`).
4. Read the task completion notification register (`EMSI_CQ_TCN`). If interrupt coalescing is inactive go to step 5. If interrupt coalescing is active go to step 6.
5. If interrupt coalescing was previously inactive, clear the `EMSI_CQ_TCN` register by writing 1 to the set of bits then clear the `EMSI_ISTAT.CQE_EVENT` bit. The slots mapped to the tasks are now free and can be reused.

6. If interrupt coalescing was previously active, clear the EMSI_CQ_IC.INTC_RST bit then clear the EMSI_CQ_ISTAT.TCC bit and clear task notification. Then clear the EMSI_ISTAT.CQE_EVENT bit and empty the slot.
7. Setup interrupt coalescing if required.

CQE Error Recovery

The *CQE Recovery Mode* figure and procedure shows the error recovery sequence for CQE mode.

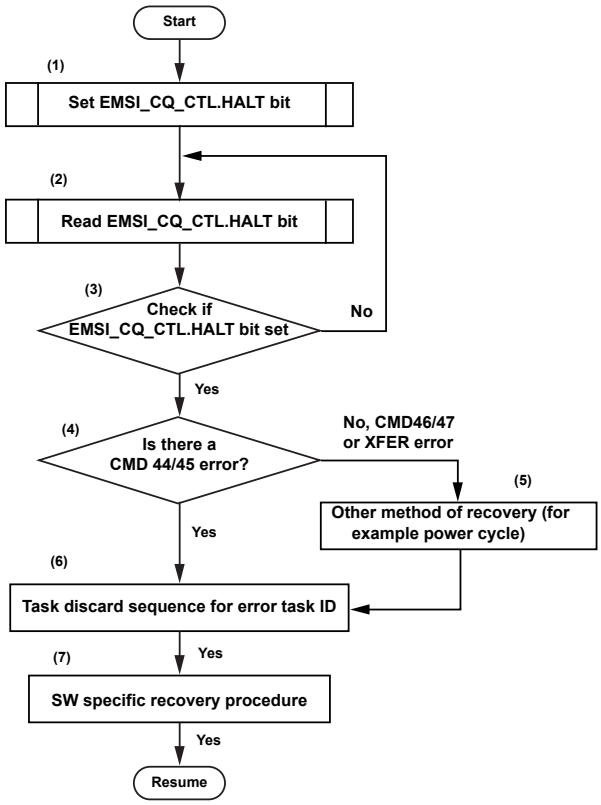

Figure 18-34: CQE Recovery Mode

1. Set the EMSI_CQ_CTL.HALT bit.
2. Read the EMSI_CQ_CTL.HALT bit.
3. Check if EMSI_CQ_CTL.HALT bit set.
    a. No - go to step 2.
    b. Yes - go to step 4.
4. Is there a CMD 44/45 error?
    a. No, CMD46/47 or XFER error - go to step 5.
    b. Yes - go to step 6.

5. Other method of recovery (for example power cycle).
6. Task discard sequence for error task ID.
7. SW specific recovery procedure.

NOTE: Writes to the Command Queuing DoorBell register (EMSI_CQ_TDBR) after requesting a HALT (by writing 1 to the EMSI_CQ_CTL.HALT bit field may be ignored by the eMSI controller. An ignored EMSI_CQ_TDBR write generates an error.

eMMC Device Boot Programming Sequences

Software must adhere to the following steps when working with boot operation. The partition that from the eMSI controller reads the boot data, can be selected in advance using EXT_CSD byte [179], bits [5:3]. The eMSI controller can choose to use the

- Single data rate mode with backward-compatible interface timing,
- Single data rate with high-speed interface timing

The EXT_CSD register byte [228], bit 2 tells the eMSI controller if the high-speed timing during boot is supported by the device.

Configure the eMMC device before configuring the eMSI controller for boot operation.

Please refer to *JEDEC eMMC 5.1* specification for more information.

NOTE: The eMSI controller does not support boot operation in DDR speed mode.

Preparing for a Boot

The *Programming Sequence to Prepare for a Boot* figure and procedure shows the programming sequence to prepare for a boot. This sequence is common for both the mandatory and alternate modes.

NOTE: The eMSI controller does not support boot in ADMA3 mode.

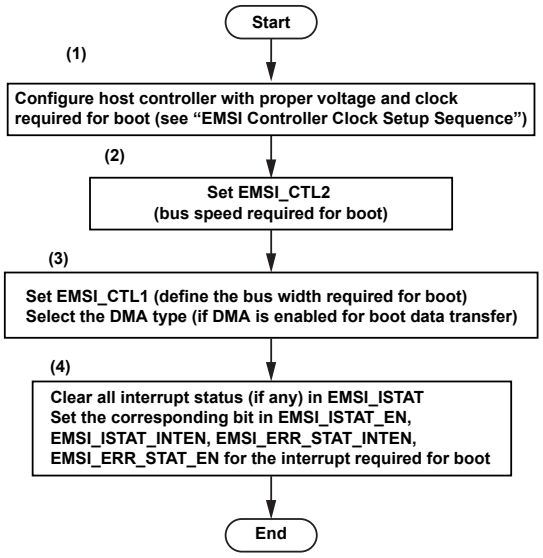

Figure 18-35: Programming Sequence to Prepare for a Boot

1. Configure the host controller with the proper voltage and clock required for booting (see eMSI Controller Clock Setup Sequence).
2. Configure the `EMSI_CTL2` register with the bus speed required for boot.
3. Configure the `EMSI_CTL1` register to define the bus width required for boot. Select the DMA type (if DMA is enabled for boot data transfer).
4. Clear all interrupt status (if any) in the `EMSI_ISTAT` register. Configure the corresponding bits in the `EMSI_ISTAT_EN`,`EMSI_ISTAT_INTEN`, `EMSI_ERR_STAT_INTEN` and `EMSI_ERR_STAT_EN` registers for the interrupt required for boot.

Initiating a Mandatory Boot in SDMA Mode

The *Programming Sequence to Initiate a Mandatory Boot in SDMA Mode* figure and procedure shows the programming sequence to initiate a mandatory boot in SDMA mode.

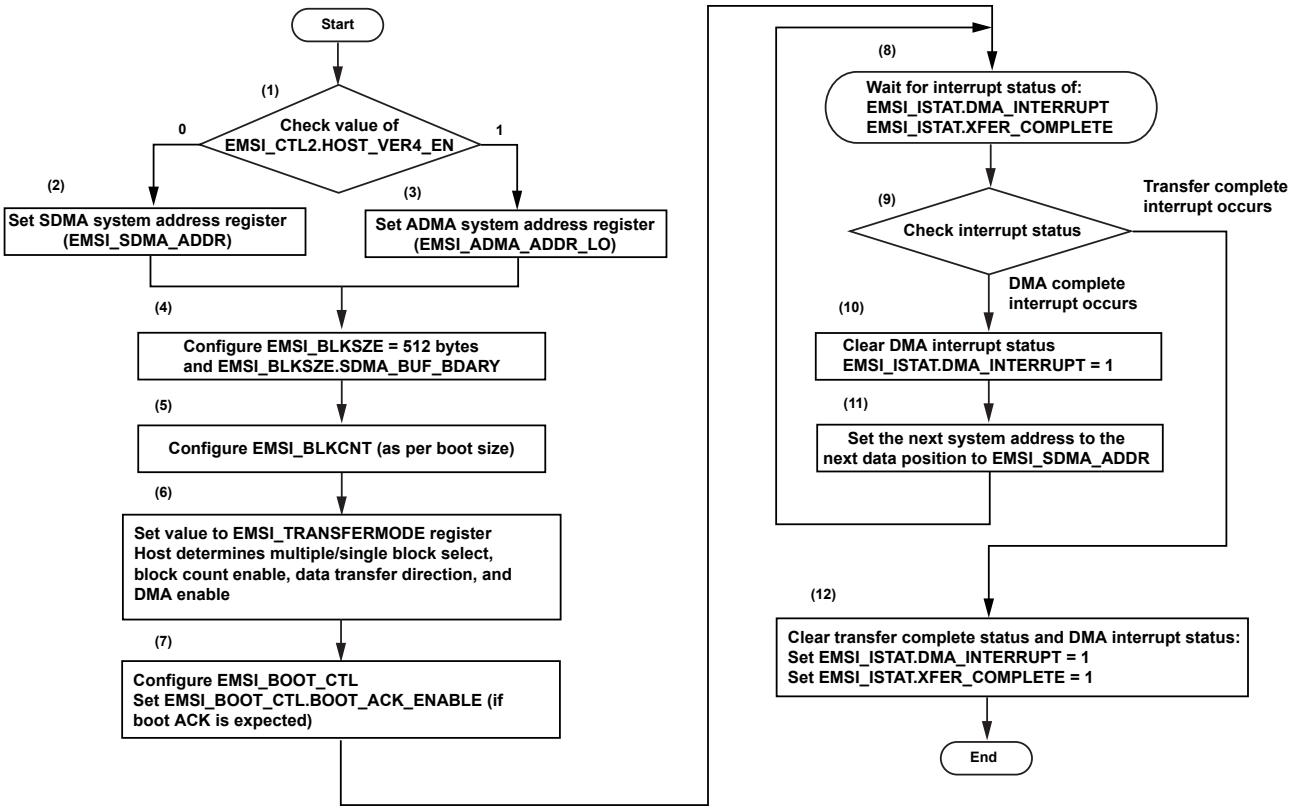

Figure 18-36: Programming Sequence to Initiate a Mandatory Boot in SDMA Mode

1. Check the value of the `EMSI_CTL2.HOST_VER4_EN` bit field.
   a. 0 - go to step 2.
   b. 1 - go to step 3
2. Configure the SDMA system address register (`EMSI_SDMA_ADDR`).
3. Configure the ADMA system address register (`EMSI_ADMA_ADDR_LO`).
4. Configure `EMSI_BLKSZ` = 512 bytes.
5. Configure `EMSI_BLKCNT` (as per boot size).
6. Configure the `EMSI_TRNSFRMODE` register. The host determines multiple/single block select, block count enable, data transfer direction, and DMA enable.
7. Configure the `EMSI_BOOT_CTL` register. Set `EMSI_BOOT_CTL.BOOT_ACK_ENABLE` if boot ACK is expected.
8. Wait for interrupt status of the `EMSI_ISTAT.DMA_INTERRUPT` and `EMSI_ISTAT.XFER_COMPLETE` bits.
9. Check interrupt status.

a. Transfer complete interrupt occurs - go to step 12.

b. DMA complete interrupt occurs - go to step 10.

10. Clear the DMA interrupt status (`EMSI_ISTAT.DMA_INTERRUPT` = 1).
11. Configure the next system address to the next data position to `EMSI_SDMA_ADDR`.
12. Clear the transfer complete status and DMA interrupt status bits. Set `EMSI_ISTAT.DMA_INTERRUPT` = 1 and `EMSI_ISTAT.XFER_COMPLETE` = 1.

Initiating a Mandatory Boot in ADMA2 Mode

The *Programming Sequence to Initiate a Mandatory Boot in ADMA2 Mode* figure shows the programming sequence for initiating a mandatory boot in ADMA2 mode.

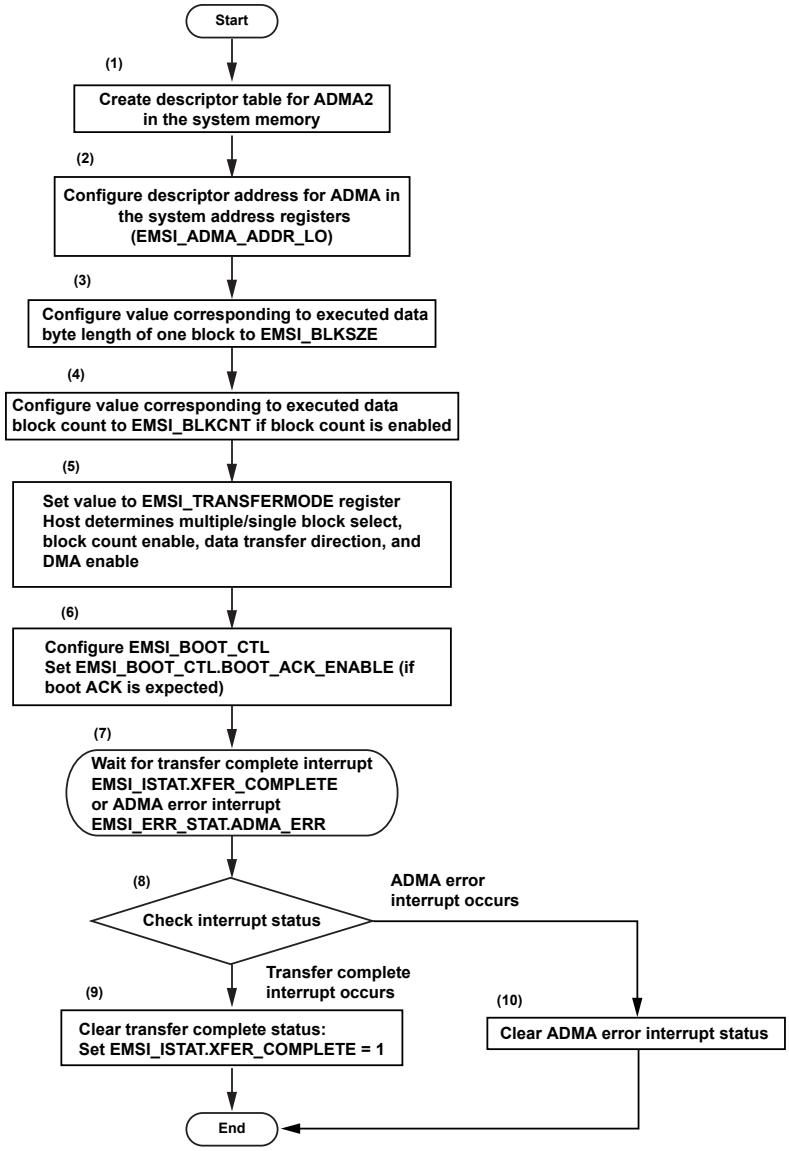

Figure 18-37: Programming Sequence to Initiate a Mandatory Boot in ADMA2 Mode

1. Create a descriptor table for ADMA in the system memory.
2. Configure the descriptor address for ADMA in the system address registers (EMSI_ADMA_ADDR_LO).
3. Configure the value corresponding to the executed data byte length of one block to the EMSI_BLKSZ register.
4. Configure the value corresponding to the executed data block count to the EMSI_BLKCNT register when block count is enabled.
5. Configure the EMSI_TRNSFRMODE register. The host determines multiple/single block select, block count enable, data transfer direction, and DMA enable.

6. Configure the EMSI_BOOT_CTL register. Set the EMSI_BOOT_CTL.BOOT_ACK_ENABLE bit (if boot ACK is expected).
7. Wait for the transfer complete interrupt EMSI_ISTAT.XFER_COMPLETE or ADMA error interrupt EMSI_ERR_STAT.ADMA_ERR.
8. Check interrupt status.
    a. Transfer complete interrupt occurs - go to step 9.
    b. ADMA error interrupt occurs - go to step 10.
9. Clear transfer complete status by setting EMSI_ISTAT.XFER_COMPLETE = 1.
10. Clear ADMA error interrupt status.

Initiating Alternate Boot

Alternate Boot is a command-based boot operation and can be initiated by issuing CMD0 with the 0xFFFFFFFA argument. For the programming sequence for initiating an alternate boot, see Issuing CMD with Data Transfer (Using SDMA) and Issuing CMD with Data Transfer (Using ADMA2) with the following exceptions:

- If boot acknowledgment is expected, the EMSI_BOOT_CTL.BOOT_TOUT_CNT is programmed to configure the timeout counter for boot acknowledgment before setting the EMSI_CMD register.
- Response check cannot be performed as CMD0 has no response.
- Issue CMD0 with 0xFFFFFFFA argument with EMSI_CMD.DATA_PRESENT_SEL set to 1.

When the boot is initiated, the device is assumed to be in pre-boot state and 74 clock cycles has expired after power is stable before issuing CMD0.

SD Transaction Mode

This section includes the sequences to generate and control different types of SD transactions that can be classified as transactions without data transfer using the DAT/CMD line and transactions with data transfer using the DAT/CMD line. The following procedures are included in this section.

- SD Card Initialization and Identification
- Changing Bus Width for an SD Card
- Changing Bus Speed Mode for an SD Card
- Issuing CMD Without Data Transfer
- Issuing CMD With Data Transfer

SD Card Initialization and Identification

The *SD Card Initialization and Identification* figure shows the sequence for SD card initialization and identification.

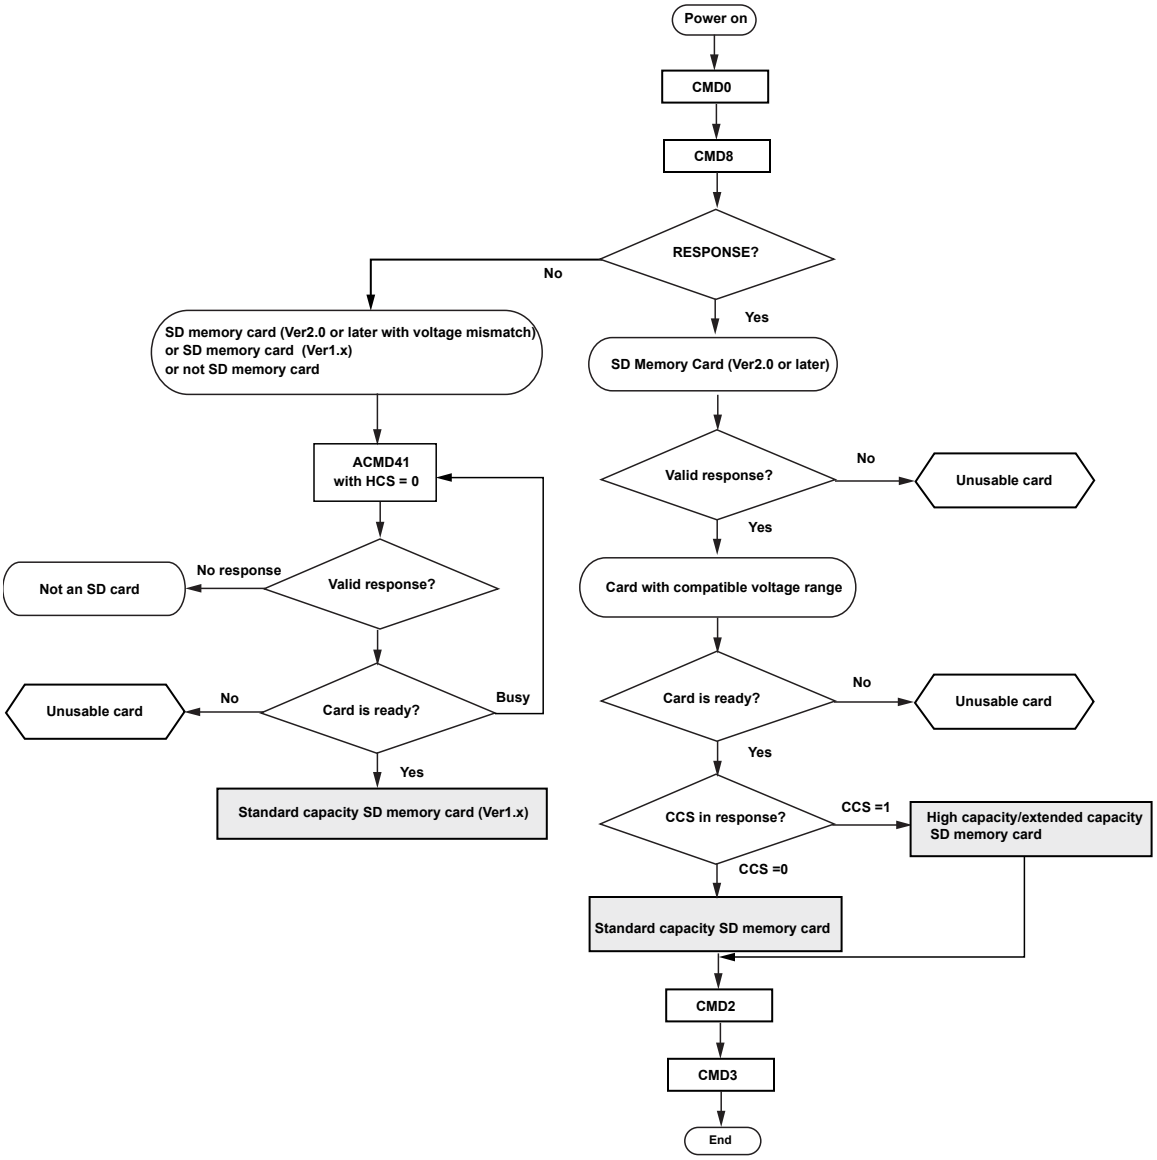

Figure 18-38: SD Card Initialization and Identification

Changing Bus Width for an SD Card

The *SD Card Change Bus Width* figure shows the sequence for changing the bit mode in a SD card.

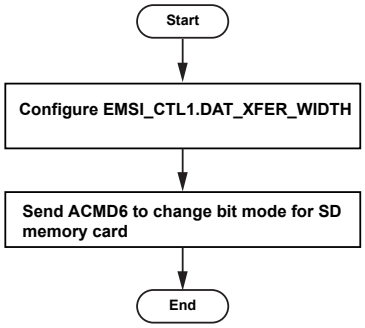

Figure 18-39: SD Card Change Bus Width

Changing Bus Speed Mode for an SD Card

The *Changing Bus Speed Mode* figure shows the process for changing bus speed mode in a SD card.

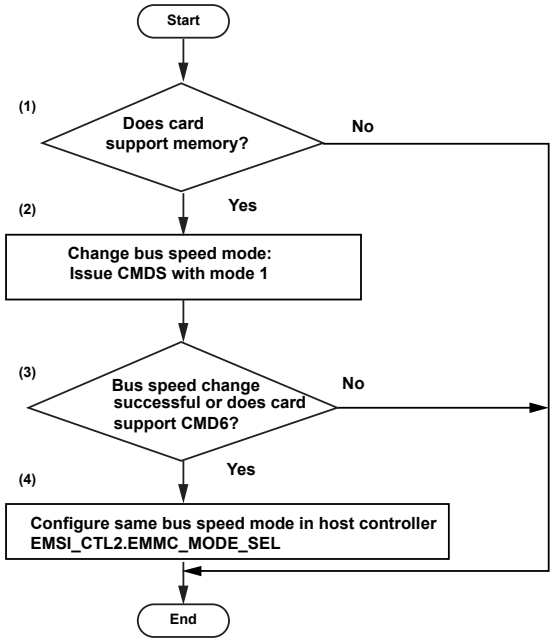

Figure 18-40: Changing Bus Speed Mode

Issuing CMD With or Without Data Transfers for an SD Card

Programs can issue commands with or without data transfers.

- The programming sequence for issuing a command without a data transfer for an SD card is like the sequence described in the Issuing CMD Without Data Transfer section.
- The programming sequence for issuing a command with a data transfer for an SD card is like the programming sequence described in the sections following Issuing CMD With Data Transfer.

  Data transfers can be performed using DMA. The supported DMA modes are SDMA, ADMA2, and ADMA3.

ADSP-SC59x EMSI Register Descriptions

The Enhanced Mobile Storage Interface (EMSI) contains the following registers.

Table 18-18: ADSP-SC59x EMSI Register List

Name	Description
EMSI_ADMA_ADDR_LO	ADMA System Address Register - Low
EMSI_ADMA_DESADDR_LO	ADMA3 Integrated Descriptor Address Register - Low
EMSI_ADMA_ERR_STAT	ADMA Error Status Register
EMSI_ARG	Argument Register
EMSI_AUTOCMD_STAT	Auto CMD Status Register
EMSI_BASEADDR0	Base Address 0 Register
EMSI_BASEADDR1	Base Address 1 Register
EMSI_BLKCNT	16-bit Block Count Register
EMSI_BLKSZ	Block Size Register
EMSI_BOOT_CTL	eMMC Boot Control Register
EMSI_CAP1	Capabilities 1 Register - 0 to 31
EMSI_CAP2	Capabilities Register - 32 to 63
EMSI_CLK_CTL	Clock Control Register
EMSI_CMD	Command Register
EMSI_CQVER	Command Queuing Version Register
EMSI_CQ_CAP	Command Queuing Capabilities Register
EMSI_CQ_CFG	Command Queuing Configuration Register
EMSI_CQ_CRARG	CQ Command Response Argument Register
EMSI_CQ_CRDCT	Command Response for Direct Command Register
EMSI_CQ_CRI	CQ Command Response Index
EMSI_CQ_CTL	Command Queuing Control Register
EMSI_CQ_DPT	Device Pending Tasks Register
EMSI_CQ_DQSTAT	Device Queue Status Register
EMSI_CQ_IC	Command Queuing Interrupt Coalescing Register
EMSI_CQ_ISTAT	Command Queuing Interrupt Status Register
EMSI_CQ_ISTAT_EN	Command Queuing Interrupt Status Enable Register
EMSI_CQ_ISTAT_INTEN	Command Queuing Interrupt Signal Enable Register
EMSI_CQ_RMEM	Command Response Mode Error Mask Register
EMSI_CQ_SSCFG1	CQ Send Status Configuration 1 Register

Table 18-18: ADSP-SC59x EMSI Register List (Continued)

Name	Description
EMSI_CQ_SSCFG2	CQ Send Status Configuration 2 Register
EMSI_CQ_TCLR	Command Queuing Task Clear Register
EMSI_CQ_TCN	Command Queuing Task Completion Notification Register
EMSI_CQ_TDBR	Command Queuing DoorBell Register
EMSI_CQ_TDL_BADDR	Command Queuing Task Descriptor List Base Address Register
EMSI_CQ_TERRINFO	CQ Task Error Information Register
EMSI_CTL1	EMSI Control 1 Register
EMSI_CTL2	EMSI Control 2 Register
EMSI_HOST_CNTRL_VERS	SD Host Controller Specification Version
EMSI_EMMC_CTL	eMMC Control Register
EMSI_ERR_STAT	Error Interrupt Status Register
EMSI_ERR_STAT_EN	Error Interrupt Status Enable Register
EMSI_ERR_STAT_INTEN	Error Interrupt Signal Enable Register
EMSI_FRC_AUTOCMDSTAT	Force Event Register for Auto CMD Error Status Register
EMSI_FRC_ERRSTAT	Force Event Register for Error Interrupt Status
EMSI_ISTAT	Interrupt Status Register
EMSI_ISTAT_EN	Interrupt Status Enable Register
EMSI_ISTAT_INTEN	Interrupt Signal Enable Register
EMSI_PRESET_DS	Preset Value for Default Speed
EMSI_PRESET_HSDDR	Preset Value for HSDDR
EMSI_PRESET_HSSDR	Preset Value for HSSDR
EMSI_PRESET_INIT	Preset Value for Initialization
EMSI_PRESET_LEGACY	Preset Value for Legacy Mode
EMSI_PSTATE	Present State Register
EMSI_RESP0	Response Register 0
EMSI_RESP1	Response Register 1
EMSI_RESP2	Response Register 2
EMSI_RESP3	Response Register 3
EMSI_SDMA_ADDR	SDMA System Address Register
EMSI_SWRST	Software Reset Register
EMSI_TO_CTL	Timeout Control Register

Table 18-18: ADSP-SC59x EMSI Register List (Continued)

Name	Description
EMSI_TRNSFRMODE	Transfer Mode Register
EMSI_VER_ID	EMSI Version
EMSI_VER_TYPE	EMSI Version Type
EMSI_WU_CTL	Wakeup Control Register

ADMA System Address Register - Low

The EMSI_ADMA_ADDR_LO register holds the 32-bit system address for DMA transfer. This register is applicable for eMMC mode.

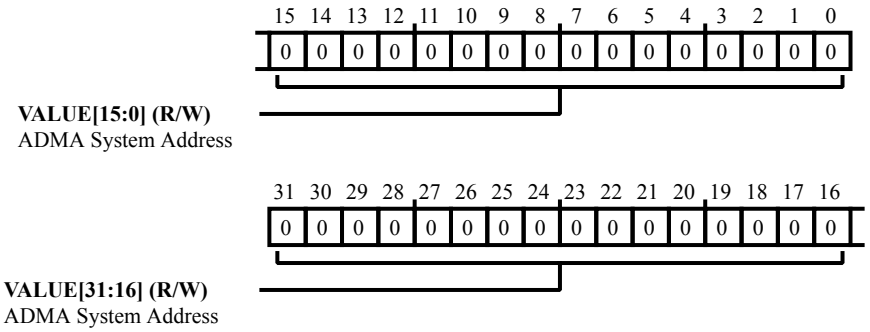

Figure 18-41: EMSI_ADMA_ADDR_LO Register Diagram

Table 18-19: EMSI_ADMA_ADDR_LO Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	ADMA System Address. The EMSI_ADMA_ADDR_LO.VALUE bits indicate the 32 bits of the ADMA system address. -SDMA: If Host Version 4 Enable is set (=1), this register stores the system address of the data location -ADMA2: This register stores the byte address of the executing command of the descriptor table -ADMA3: This register is set by ADMA3. ADMA2 increments the address of this register that points to the next line, every time a descriptor line is fetched.

ADMA3 Integrated Descriptor Address Register - Low

The EMSI_ADMA_DESADDR_LO register holds the 32-bit Integrated Descriptor address.This register is applicable for eMMC mode.

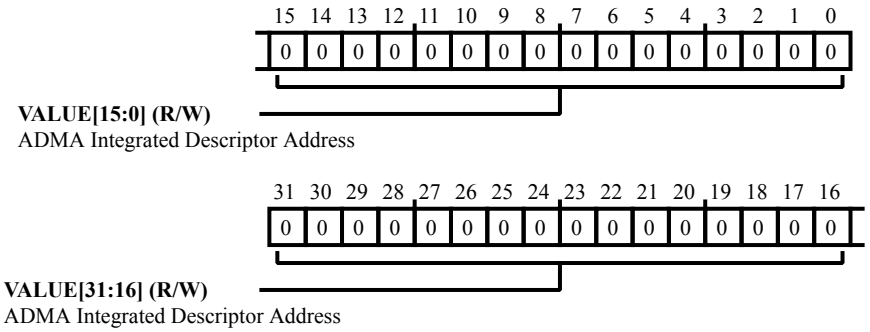

Figure 18-42: EMSI_ADMA_DESADDR_LO Register Diagram

Table 18-20: EMSI_ADMA_DESADDR_LO Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	ADMA Integrated Descriptor Address. The EMSI_ADMA_DESADDR_LO.VALUE bits indicate the 32-bit of the ADMA integrated descriptor address. The start address of integrated descriptor is set to these register bits. The ADMA3 fetches one descriptor address and increments these bits to indicate the next descriptor address.

ADMA Error Status Register

The EMSI_ADMA_ERR_STAT register stores the ADMA state during an ADMA error. This register is applicable for an eMMC mode.

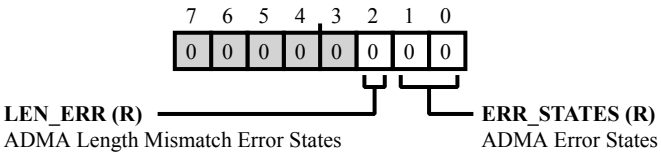

Figure 18-43: EMSI_ADMA_ERR_STAT Register Diagram

Table 18-21: EMSI_ADMA_ERR_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/NW)	LEN_ERR	ADMA Length Mismatch Error States. This error occurs in the following instances: - While the block count enable is being set, the total data length specified by the descriptor table is different from that specified by the block count and block length - When the total data length cannot be divided by the block length	
		0	No Error
		1	Error
1:0 (R/NW)	ERR_STATES	ADMA Error States. The EMSI_ADMA_ERR_STAT.ERR_STATES bits indicate the state of ADMA when an error occurs during ADMA data transfer.	
		0	Stop DMA - SYS_ADR Register Points to a Location Next to the Error Descriptor
		1	Fetch Descriptor - SYS_ADR Register Points to the Error Descriptor
		2	Reserved
		3	Transfer Data - SYS_ADR Register Points to a Location Next to the Error Descriptor

Argument Register

The EMSI_ARG register is used to configure the eMMC command argument.

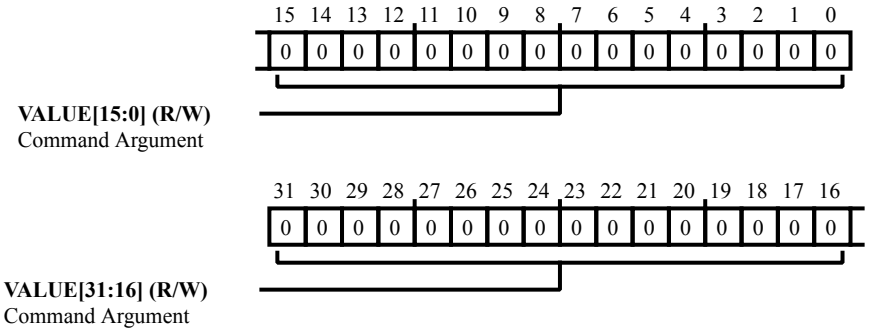

Figure 18-44: EMSI_ARG Register Diagram

Table 18-22: EMSI_ARG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Command Argument. The EMSI_ARG.VALUE bits specify the eMMC command argument that is specified in bits 39-8 of the Command format.

Auto CMD Status Register

The EMSI_AUTOCMD_STAT register is used to indicate the CMD12 response error of Auto CMD12, and the CMD23 response error of Auto CMD23. The host driver can determine the kind of Auto CMD12/CMD23 errors that can occur in this register. Auto CMD23 errors are indicated in bit 04-01.

This register is valid only when Auto CMD Error is set in the EMSI_ERR_STAT register. This register is applicable for eMMC mode.

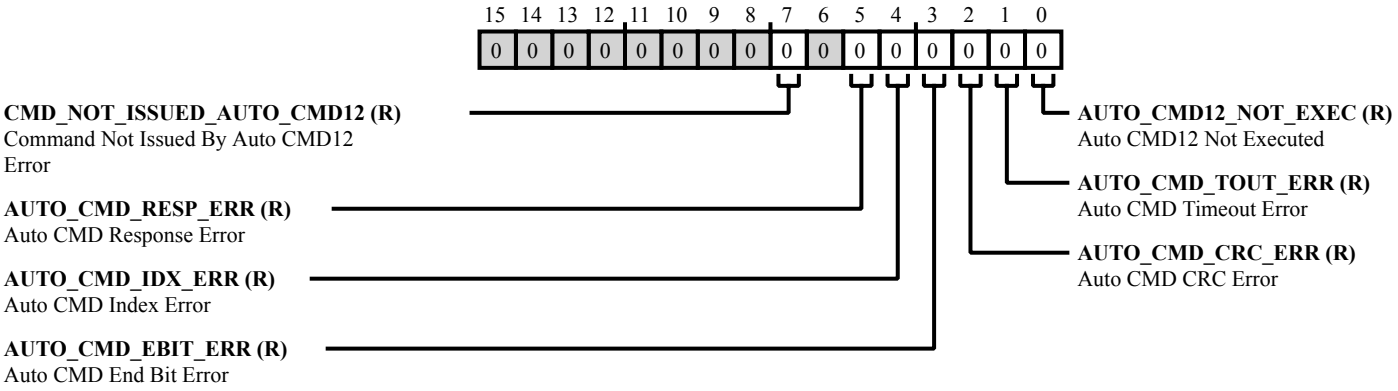

Figure 18-45: EMSI_AUTOCMD_STAT Register Diagram

Table 18-23: EMSI_AUTOCMD_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/NW)	CMD_NOT_ISSUED_AUTO_CMD12	Command Not Issued By Auto CMD12 Error. If the EMSI_AUTOCMD_STAT.CMD_NOT_ISSUED_AUTO_CMD12 bit is set (=1), CMD_wo_DAT is not executed due to an Auto CMD12 Error (D04-D01) in this register. The EMSI_AUTOCMD_STAT.CMD_NOT_ISSUED_AUTO_CMD12 bit is cleared (= 0) when Auto CMD Error is generated by Auto CMD23.	
		0	No Error
		1	Not Issued
5 (R/NW)	AUTO_CMD_RESP_ERR	Auto CMD Response Error. The EMSI_AUTOCMD_STAT.AUTO_CMD_RESP_ERR bit is set when Response Error Check Enable in the Transfer Mode register is set (=1) and an error is detected in R1 response of either Auto CMD12 or CMD13. This status is ignored if any bit between D00 to D04 is set (=1).	
		0	No Error
		1	Error

Table 18-23: EMSI_AUTOCMD_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/NW)	AUTO_CMD_IDX_ERR	Auto CMD Index Error. The EMSI_AUTOCMD_STAT.AUTO_CMD_IDX_ERR bit is set if the command index error occurs in response to a command.	
		0	No Error
		1	Error
3 (R/NW)	AUTO_CMD_EBIT_ERR	Auto CMD End Bit Error. The EMSI_AUTOCMD_STAT.AUTO_CMD_EBIT_ERR bit is set when detecting that the end bit of command response is 0.	
		0	No Error
		1	End Bit Error Generated
2 (R/NW)	AUTO_CMD_CRC_ERR	Auto CMD CRC Error. The EMSI_AUTOCMD_STAT.AUTO_CMD_CRC_ERR bit is set when detecting a CRC error in the command response.	
		0	No Error
		1	CRC Error Generated
1 (R/NW)	AUTO_CMD_TOUT_ERR	Auto CMD Timeout Error. The EMSI_AUTOCMD_STAT.AUTO_CMD_TOUT_ERR bit is set if no response is returned with 64 eMSI bus clock cycles from the end bit of the command. If the EMSI_AUTOCMD_STAT.AUTO_CMD_TOUT_ERR bit is set (=1), error status bits (D04-D01) are meaningless.	
		0	No Error
		1	Time Out
0 (R/NW)	AUTO_CMD12_NOT_EXEC	Auto CMD12 Not Executed. If multiple memory block data transfer is not started due to a command error, the EMSI_AUTOCMD_STAT.AUTO_CMD12_NOT_EXEC bit is not set because it is not necessary to issue an Auto CMD12. When the EMSI_AUTOCMD_STAT.AUTO_CMD12_NOT_EXEC bit is set (=1), the eMSI controller cannot issue Auto CMD12 to stop multiple memory block data transfer, due to some error. If the EMSI_AUTOCMD_STAT.AUTO_CMD12_NOT_EXEC bit is set (=1), error status bits (D04-D01) is meaningless. The EMSI_AUTOCMD_STAT.AUTO_CMD12_NOT_EXEC bit is cleared (=0) when Auto CMD Error is generated by Auto CMD23.	
		0	Executed
		1	Not Executed

Base Address 0 Register

The EMSI_BASEADDR0 register used as a pointer for the base address 0 register.

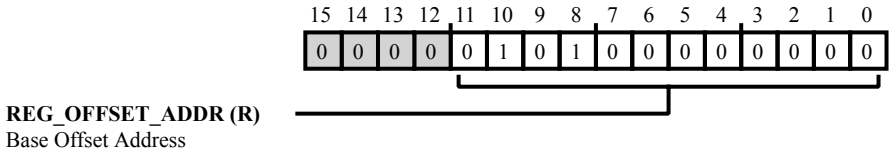

Figure 18-46: EMSI_BASEADDR0 Register Diagram

Table 18-24: EMSI_BASEADDR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
11:0 (R/NW)	REG_OFFSET_ADDR	Base Offset Address.

Base Address 1 Register

The EMSI_BASEADDR1 register used as a pointer for the base address 1 register.

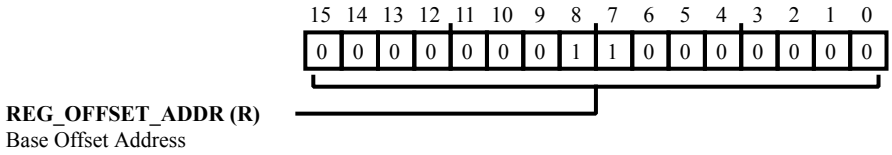

Figure 18-47: EMSI_BASEADDR1 Register Diagram

Table 18-25: EMSI_BASEADDR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	REG_OFFSET_ADDR	Base Offset Address.

16-bit Block Count Register

The EMSI_BLKCNT register is used to configure the number of data blocks. This register is applicable for eMMC mode.

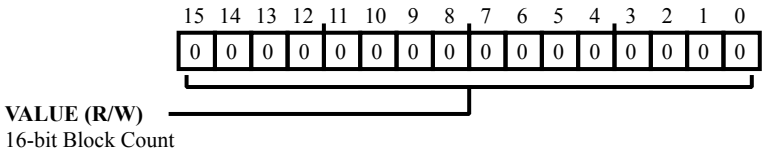

Figure 18-48: EMSI_BLKCNT Register Diagram

Table 18-26: EMSI_BLKCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	16-bit Block Count. The EMSI_BLKCNT.VALUE bit field has the following settings: If the Host Version 4 Enable bit is set 0 or the 16-bit Block Count register is set to non-zero, the 16-bit Block Count register is selected. If the Host Version 4 Enable bit is set 1 and the 16-bit Block Count register is set to zero, the 32-bit Block Count register is selected. Following are the values for this bit field: 0x0: Stop Count 0x1: 1 Block 0x2: 2 Blocks ... - ... 0xFFFF: 65535 Blocks Note: For Host Version 4 Enable = 0, this register must be set to 0000h before programming the 32-bit block count register when Auto CMD23 is enabled for non-DMA and ADMA modes.

Block Size Register

The EMSI_BLKSZ register is used to configure an SDMA buffer boundary and the number of bytes in a data block. This register is applicable for eMMC mode.

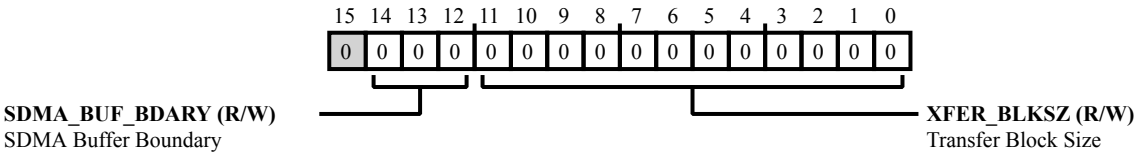

Figure 18-49: EMSI_BLKSZ Register Diagram

Table 18-27: EMSI_BLKSZ Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
14:12 (R/W)	SDMA_BUF_BDARY	SDMA Buffer Boundary. The EMSI_BLKSZ.SDMA_BUF_BDARY bits specify the size of contiguous buffer in system memory. The SDMA transfer waits at every boundary specified by these fields and the eMSI controller generates the DMA interrupt to request the host driver to update the SDMA system address register.	
		0	4K Bytes SDMA Buffer Boundary
		1	8K Bytes SDMA Buffer Boundary
		2	16K Bytes SDMA Buffer Boundary
		3	32K Bytes SDMA Buffer Boundary
		4	64K Bytes SDMA Buffer Boundary
		5	128K Bytes SDMA Buffer Boundary
		6	256K Bytes SDMA Buffer Boundary
		7	512K Bytes SDMA Buffer Boundary

Table 18-27: EMSI_BLKSZ Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
11:0 (R/W)	XFER_BLKSZ	Transfer Block Size. The `EMSI_BLKSZ.XFER_BLKSZ` bits specify the block size of data transfers. When using an eMMC device, this bit field is set to 512 bytes. The `EMSI_BLKSZ.XFER_BLKSZ` bits can be accessed only if no transaction is executing. Read operations to the bit field during transfers may return an invalid value, and write operations are ignored. The following are the value settings. - 0x1: 1 byte - 0x2: 2 bytes - 0x3: 3 bytes - ..... - 0x1FF: 511 byte - 0x200: 512 bytes - ..... - 0x800: 2048 bytes Note: This register must be programmed with a non-zero value for data transfer.

eMMC Boot Control Register

The EMSI_BOOT_CTL register is used to control the eMMC Boot operation.

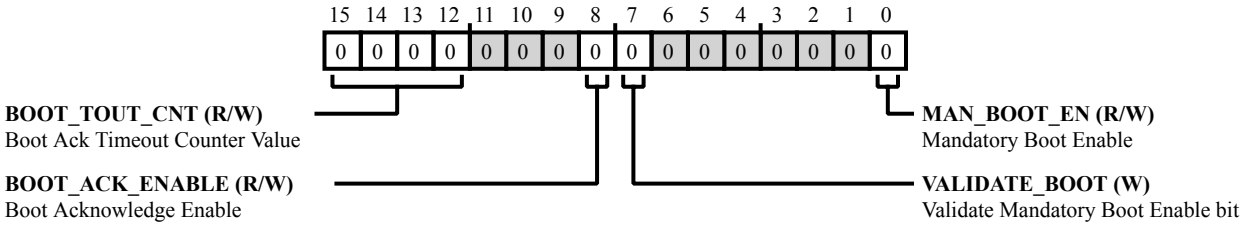

Figure 18-50: EMSI_BOOT_CTL Register Diagram

Table 18-28: EMSI_BOOT_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15:12 (R/W)	BOOT_TOUT_CNT	Boot Ack Timeout Counter Value. The EMSI_BOOT_CTL.BOOT_TOUT_CNT value determines the interval by which boot ack timeout (50 ms) is detected when boot ack is expected during boot operation. - 0xF: Reserved - 0xE: TMCLK x 2^27 -... - 0x1: TMCLK x 2^14 - 0x0: TMCLK x 2^13 NOTE: Please refer to EMSI_CAP1.TOUT_CLK_FREQ for TMCLK.	
8 (R/W)	BOOT_ACK_ENABLE	Boot Acknowledge Enable. When the EMSI_BOOT_CTL.BOOT_ACK_ENABLE bit set, eMSI controller checks for boot acknowledge start pattern of 0-1-0 during boot operation. The EMSI_BOOT_CTL.BOOT_ACK_ENABLE bit is applicable for both mandatory and alternate boot mode.	
		0	Boot Ack Disable
		1	Boot Ack Enable
7 (RX/W)	VALIDATE_BOOT	Validate Mandatory Boot Enable bit. The EMSI_BOOT_CTL.VALIDATE_BOOT bit is used to validate the MAN_BOOT_EN bit.	
		0	Ignore Mandatory Boot Enable Bit
		1	Validate Mandatory Boot Enable Bit

Table 18-28: EMSI_BOOT_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	MAN_BOOT_EN	Mandatory Boot Enable. The `EMSI_BOOT_CTL.MAN_BOOT_EN` bit is used to initiate the mandatory boot operation. The application sets the `EMSI_BOOT_CTL.MAN_BOOT_EN` bit along with VALIDATE_BOOT bit. Writing 0 is ignored. The eMSI controller clears the `EMSI_BOOT_CTL.MAN_BOOT_EN` bit after the boot transfer is completed or terminated.	
		0	Mandatory Boot Disable
		1	Mandatory Boot Enable

Capabilities 1 Register - 0 to 31

The EMSI_CAP1 register provides the host driver with information specific to the eMSI controller implementation.

The eMSI controller may implement these values as fixed or during power on initialization. This register is segregated into two 32-bit registers: EMSI_CAP1-2. The EMSI_CAP1 register is the lower part of capabilities register.

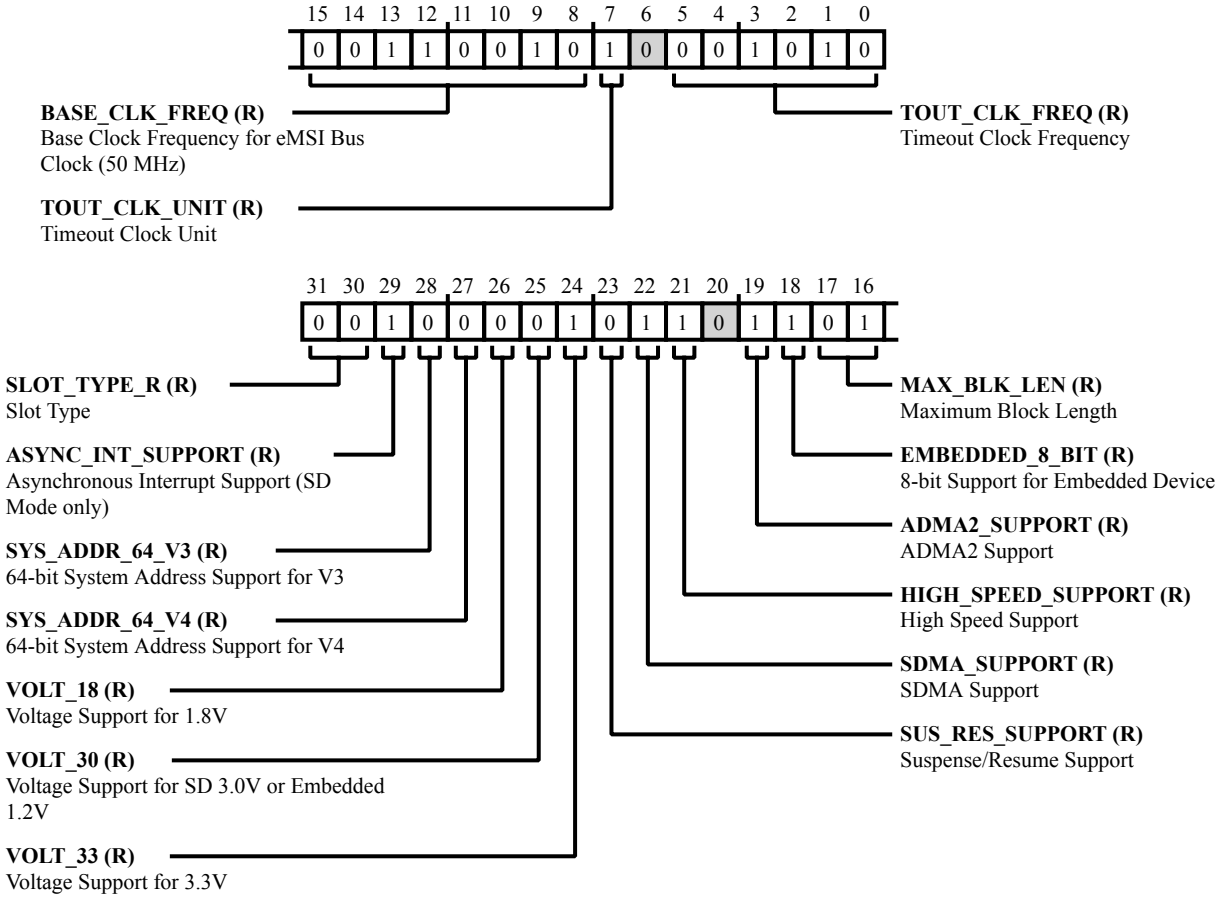

Figure 18-51: EMSI_CAP1 Register Diagram

Table 18-29: EMSI_CAP1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:30 (R/NW)	SLOT_TYPE_R	Slot Type. The EMSI_CAP1.SLOT_TYPE_R bits indicate usage of a slot by a specific host system.	
		0	Removable Card Slot
		1	Embedded Slot for One Device
		2	Shared Bus Slot (SD Mode)
		3	UHS-II Multiple Embedded Devices
29 (R/NW)	ASYNC_INT_SUPPORT	Asynchronous Interrupt Support (SD Mode only).	
		0	Asynchronous Interrupt Not Supported
		1	Asynchronous Interrupt Supported
28 (R/NW)	SYS_ADDR_64_V3	64-bit System Address Support for V3. The EMSI_CAP1.SYS_ADDR_64_V3 bit sets the eMSI controller to support 64-bit system addressing of V3 mode. SDMA cannot be used in 64-bit addressing in Version 3 mode. If the EMSI_CAP1.SYS_ADDR_64_V3 bit is set (=1), to use 64-bit ADMA2 with a 96-bit descriptor is enabled by setting Host Version 4 Enable (EMSI_CTL2.HOST_VER4_EN= 0) and DMA select (EMSI_CTL1.DMA_SEL = 11b).	
		0	64-bit System Address for V3 is Not Supported
		1	64-bit System Address for V3 is Supported
27 (R/NW)	SYS_ADDR_64_V4	64-bit System Address Support for V4. The EMSI_CAP1.SYS_ADDR_64_V4 bit sets the eMSI controller to support 64-bit system addressing of V4 mode. When the EMSI_CAP1.SYS_ADDR_64_V4 bit is set (=1), full or part of 64-bit address must be used to decode the eMSI controller registers so that eMSI controller registers can be placed above system memory area. The 64-bit address decode of eMSI controller registers is effective regardless of setting to 64-bit addressing in the EMSI_CTL2 register. If the EMSI_CAP1.SYS_ADDR_64_V4 bit is set (=1), 64-bit DMA addressing for version 4 is enabled by setting Host Version 4 Enable (EMSI_CTL2.HOST_VER4_EN =1) and by setting 64-bit addressing (=1). SDMA can be used and ADMA2 uses a 128-bit descriptor.	
		0	64-bit System Address for V4 is Not Supported
		1	64-bit System Address for V4 is Supported

Table 18-29: EMSI_CAP1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
26 (R/NW)	VOLT_18	Voltage Support for 1.8V.	
		0	1.8V Not Supported
		1	1.8V Supported
25 (R/NW)	VOLT_30	Voltage Support for SD 3.0V or Embedded 1.2V.	
		0	SD 3.0V or Embedded 1.2V Not Supported
		1	SD 3.0V or Embedded Supported
24 (R/NW)	VOLT_33	Voltage Support for 3.3V.	
		0	3.3V Not Supported
		1	3.3V Supported
23 (R/NW)	SUS_RES_SUPPORT	Suspense/Resume Support. The `EMSI_CAP1.SUS_RES_SUPPORT` bit indicates whether the eMSI controller supports suspend/resume functionality. If the `EMSI_CAP1.SUS_RES_SUPPORT` bit is 0, the host driver does not issue either suspend or resume commands because the suspend and resume mechanism is not supported.	
		0	Not Supported
		1	Supported
22 (R/NW)	SDMA_SUPPORT	SDMA Support. The `EMSI_CAP1.SDMA_SUPPORT` bit indicates whether the eMSI controller is capable of using SDMA to transfer data between the system memory and the host controller directly.	
		0	SDMA Not Supported
		1	SDMA Supported
21 (R/NW)	HIGH_SPEED_SUPPORT	High Speed Support. The `EMSI_CAP1.HIGH_SPEED_SUPPORT` bit indicates whether the eMSI controller and the host system supports high speed mode and they can supply the eMSI bus clock frequency from 25 MHz to 50 MHz.	
		0	High Speed Not Supported
		1	High Speed Supported
19 (R/NW)	ADMA2_SUPPORT	ADMA2 Support. The `EMSI_CAP1.ADMA2_SUPPORT` bit indicates whether the eMSI controller is capable of using ADMA2.	
		0	ADMA2 Not Supported
		1	ADMA2 Supported

Table 18-29: EMSI_CAP1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
18 (R/NW)	EMBEDDED_8_BIT	8-bit Support for Embedded Device. The `EMSI_CAP1.EMBEDDED_8_BIT` bit indicates whether the eMSI controller is capable of using an 8-bit bus width mode. The `EMSI_CAP1.EMBEDDED_8_BIT` bit is not effective when the Slot Type is set to 10b.	
		0	8-bit Bus Width Not Supported
		1	8-bit Bus Width Supported
17:16 (R/NW)	MAX_BLK_LEN	Maximum Block Length. The `EMSI_CAP1.MAX_BLK_LEN` bit indicates the maximum block size that the host driver can read and write to the buffer in the eMSI controller. The buffer transfers this block size without wait cycles.	
		0	512 Byte
		1	1024 Byte
		2	2048 Byte
		3	Reserved

Table 18-29: EMSI_CAP1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
15:8 (R/NW)	BASE_CLK_FREQ	Base Clock Frequency for eMSI Bus Clock (50 MHz). The EMSI_CAP1.BASE_CLK_FREQ field indicate the base (maximum) clock frequency for the eMSI bus clock. The definition of these bits depend on the SD host controller version. - 6-Bit Base Clock Frequency: This mode is supported by the SD host controller version 1.00 and 2.00. The upper 2 bits are not effective and are always 0. The unit values are 1 MHz. The supported clock range is 10 MHz to 63 MHz. - 0x00: Get information through another method - 0x01: 1 MHz - 0x02: 2 MHz ..... - 0x3F: 63 MHz - 0x40-0xFF: Not Supported - 8-Bit Base Clock Frequency: This mode is supported by the SD host controller version 3.00. The unit values are 1 MHz. The supported clock range is 10 MHz to 255 MHz. - 0x00: Get information through another method - 0x01: 1 MHz - 0x02: 2 MHz -- ..... - 0xFF: 255 MHz If the frequency is 16.5 MHz, the larger value is set to 0001001b (17 MHz) because the host driver uses this value to calculate the clock divider value and it does not exceed the upper limit of the eMSI bus clock frequency. If the EMSI_CAP1.BASE_CLK_FREQ field are all 0, the host system has to get information using a different method.	
7 (R/NW)	TOUT_CLK_UNIT	Timeout Clock Unit. The EMSI_CAP1.TOUT_CLK_UNIT bit shows the unit of base clock frequency used to detect data timeout error.	
		0	KHz
		1	MHz

Table 18-29: EMSI_CAP1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
5:0 (R/NW)	TOUT_CLK_FREQ	Timeout Clock Frequency. The `EMSI_CAP1.TOUT_CLK_FREQ` bit shows the base clock frequency used to detect Data Timeout Error. The timeout clock unit defines the unit of timeout clock frequency. It can be configured for kHz or MHz. - 0x00: Get information through another method - 0x01: 1KHz / 1MHz - 0x02: 2KHz / 2MHz - 0x03: 3KHz / 3MHz - ..... - 0x3F: 63KHz / 63MHz

Capabilities Register - 32 to 63

The EMSI_CAP2 register provides the host driver with information specific to the eMSI controller implementation.

The eMSI controller may implement these values as fixed or loaded from the flash memory during power on initialization. This register is segregated into two 32-bit registers: EMSI_CAP2-EMSI_CAP1 The EMSI_CAP2 register is the upper part of capabilities register.

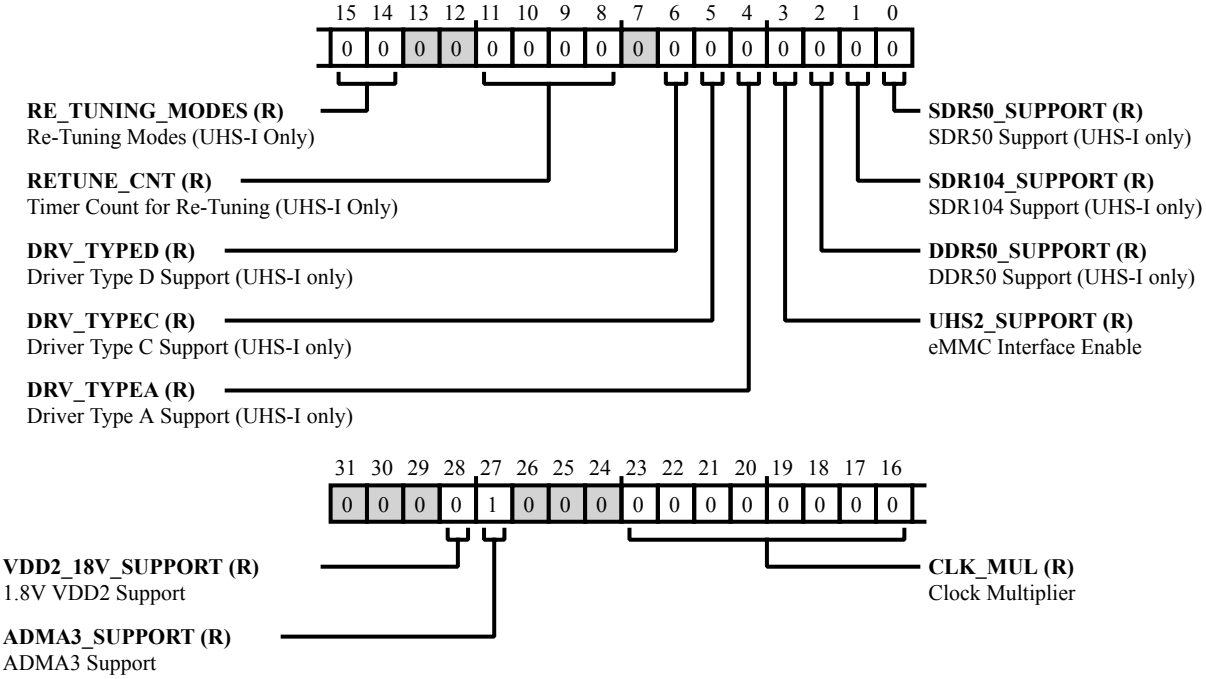

Figure 18-52: EMSI_CAP2 Register Diagram

Table 18-30: EMSI_CAP2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
28 (R/NW)	VDD2_18V_SUPPORT	1.8V VDD2 Support. The EMSI_CAP2.VDD2_18V_SUPPORT bit indicates support of VDD2 for the Host System.	
		0	1.8V VDD2 is Not Supported
		1	1.8V VDD2 is Supported

Table 18-30: EMSI_CAP2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
27 (R/NW)	ADMA3_SUPPORT	ADMA3 Support. The `EMSI_CAP2.ADMA3_SUPPORT` bit indicates whether the eMSI controller is capable of using ADMA3.	
		0	ADMA3 Not Supported
		1	ADMA3 Supported
23:16 (R/NW)	CLK_MUL	Clock Multiplier. The `EMSI_CAP2.CLK_MUL` field indicate the clock multiplier of the programmable clock generator. Clearing (=0) the `EMSI_CAP2.CLK_MUL` field indicates that the eMSI controller does not support a programmable clock generator. - 0x0: Clock Multiplier is not Supported - 0x1: Clock Multiplier M = 2 - 0x2: Clock Multiplier M = 3 - ..... - 0xFF: Clock Multiplier M = 256	
15:14 (R/NW)	RE_TUNING_MODES	Re-Tuning Modes (UHS-I Only). The `EMSI_CAP2.RE_TUNING_MODES` bits select the re-tuning method and limit the maximum data length.	
		0	Timer
		1	Timer and Re-Tuning Request (Not Supported)
		2	Auto Re-Tuning (for Transfer)
		3	Reserved
11:8 (R/NW)	RETUNE_CNT	Timer Count for Re-Tuning (UHS-I Only). - 0x0: Re-Tuning Timer disabled - 0x1: 1 seconds - 0x2: 2 seconds - 0x3: 4 seconds - ..... - 0xB: 1024 seconds - 0xC: Reserved - 0xD: Reserved - 0xE: Reserved - 0xF: Get information from other source	

Table 18-30: EMSI_CAP2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6 (R/NW)	DRV_TYPED	Driver Type D Support (UHS-I only). The `EMSI_CAP2.DRV_TYPED` bit indicates support of driver type D for 1.8 signaling.	
		0	Driver Type D is Not Supported
		1	Driver Type D is Supported
5 (R/NW)	DRV_TYPEC	Driver Type C Support (UHS-I only). The `EMSI_CAP2.DRV_TYPEC` bit indicates support of driver type C for 1.8 signaling.	
		0	Driver Type C is Not Supported
		1	Driver Type C is Supported
4 (R/NW)	DRV_TYPEA	Driver Type A Support (UHS-I only). The `EMSI_CAP2.DRV_TYPEA` bit indicates support of driver type A for 1.8 signaling.	
		0	Driver Type A is Not Supported
		1	Driver Type A is Supported
3 (R/NW)	UHS2_SUPPORT	eMMC Interface Enable. The `EMSI_CAP2.UHS2_SUPPORT` bit is used to enable the eMMC interface.	
		0	UHS-II is Not Supported
		1	Reserved
2 (R/NW)	DDR50_SUPPORT	DDR50 Support (UHS-I only).	
		0	DDR50 is Not Supported
		1	DDR50 is Supported
1 (R/NW)	SDR104_SUPPORT	SDR104 Support (UHS-I only). The `EMSI_CAP2.SDR104_SUPPORT` bit reports that SDR104 requires tuning.	
		0	SDR104 is Not Supported
		1	SDR104 is Supported
0 (R/NW)	SDR50_SUPPORT	SDR50 Support (UHS-I only). The `EMSI_CAP2.SDR50_SUPPORT` bit indicates that SDR50 is supported. The bit 13 (USE_TUNING_SDR50) indicates whether SDR50 requires tuning or not.	
		0	SDR50 is Not Supported
		1	SDR50 is Supported

Clock Control Register

The EMSI_CLK_CTL register controls the eMSI bus clock to an eMMC device. This register is applicable for eMMC mode.

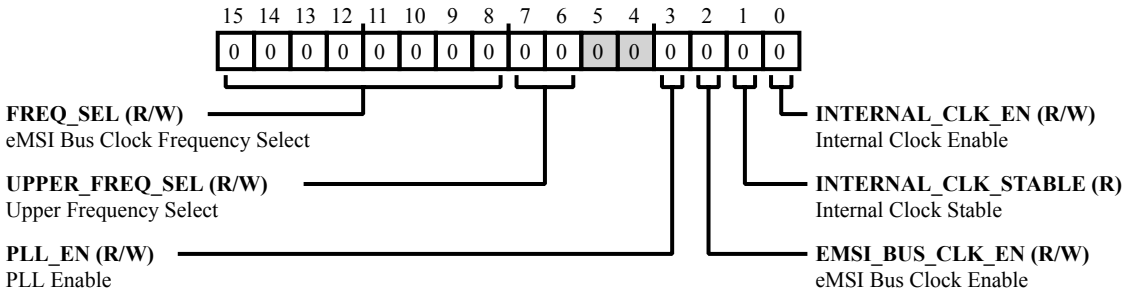

Figure 18-53: EMSI_CLK_CTL Register Diagram

Table 18-31: EMSI_CLK_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:8 (R/W)	FREQ_SEL	eMSI Bus Clock Frequency Select. The EMSI_CLK_CTL.FREQ_SEL bits are used to select the frequency of the eMSI bus clock signal. These bits depend on setting of (EMSI_CTL2.PRESET_VAL_EN). If preset value enable = 0, these bits are set by the host driver. If preset value enable = 1, these bits are automatically set to a value specified in one of the preset value register. The value is reflected on the lower 8-bit of the frequency divider signal. 10-bit Divided Clock Mode: - 0x3FF: 1/2046 divided clock - ..... - N : 1/2N divided clock - ..... - 0x002: 1/4 divided clock - 0x001: 1/2 divided clock - 0x000: base clock (0 to 50MHz)
7:6 (R/W)	UPPER_FREQ_SEL	Upper Frequency Select. The EMSI_CLK_CTL.UPPER_FREQ_SEL bits specify the upper 2 bits of 10-bit eMSI bus clock frequency select control. The value is reflected on the upper 2 bits of the frequency divider.

Table 18-31: EMSI_CLK_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	PLL_EN	PLL Enable. The EMSI_CLK_CTL.PLL_EN bit is used to activate the PLL (applicable when Host Version 4 Enable = 1). When Host Version 4 Enable = 0, INTERNAL_CLK_EN bit may be used to activate PLL. Note: If the EMSI_CLK_CTL.PLL_EN bit is not used to active the PLL when EMSI_CTL2.HOST_VER4_EN = 1, it is recommended to set the EMSI_CLK_CTL.PLL_EN bit to 1.	
		0	PLL is in Low Power Mode
		1	PLL is Enabled
2 (R/W)	EMSI_BUS_CLK_EN	eMSI Bus Clock Enable. The EMSI_CLK_CTL.EMSI_BUS_CLK_EN bit stops the SDCLK when cleared (=0). The SDCLK Frequency Select bit can be changed when the EMSI_CLK_CTL.EMSI_BUS_CLK_EN bit is cleared (=0).	
		0	Disable Providing eMSI Bus Clock
		1	Enable Providing eMSI Bus Clock
1 (R/NW)	INTERNAL_CLK_STABLE	Internal Clock Stable. The EMSI_CLK_CTL.INTERNAL_CLK_STABLE bit enables the host driver to check the clock stability twice after the Internal Clock Enable bit is set and after the PLL Enable bit is set.	
		0	Not Ready
		1	Ready
0 (R/W)	INTERNAL_CLK_EN	Internal Clock Enable. The EMSI_CLK_CTL.INTERNAL_CLK_EN bit is cleared (=0) when the host driver is not using the eMSI controller. The eMSI controller must stop its internal clock to enter a very low power state. However, registers can still be read and written to. If the EMSI_CLK_CTL.INTERNAL_CLK_EN bit is not used to control the internal clock, it is recommended to set the EMSI_CLK_CTL.INTERNAL_CLK_EN bit to 1.	
		0	Stop
		1	Oscillate

Command Register

The EMSI_CMD register is used to provide the information related to a command and a response packet. This register is applicable for eMMC mode. Writing to the upper byte of this register triggers eMMC command generation.

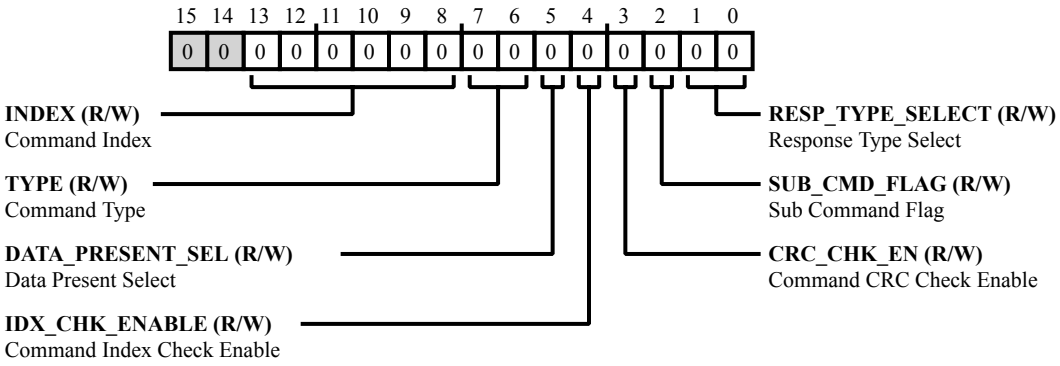

Figure 18-54: EMSI_CMD Register Diagram

Table 18-32: EMSI_CMD Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
13:8 (R/W)	INDEX	Command Index. The EMSI_CMD.INDEX bits are set to the command number that is specified in bits 45-40 of the Command Format.	
7:6 (R/W)	TYPE	Command Type. The EMSI_CMD.TYPE bits indicate the command type. Note: While issuing Abort CMD (CMD12) this field is set to 0x3.	
		0	Normal
		1	Reserved
		2	Reserved
		3	Abort
5 (R/W)	DATA_PRESENT_SEL	Data Present Select. The EMSI_CMD.DATA_PRESENT_SEL bit is set (=1) to indicate that data is present and that the data is transferred using the DAT line. The EMSI_CMD.DATA_PRESENT_SEL bit is cleared (=0) in the following instances: - Command using the CMD line - Command with no data transfer but using busy signal on the DAT[0] line	
		0	No Data Present
		1	Data Present

Table 18-32: EMSI_CMD Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/W)	IDX_CHK_ENABLE	Command Index Check Enable. The `EMSI_CMD.IDX_CHK_ENABLE` bit enables the eMSI controller to check the index field in the response to verify if it has the same value as the command index. If the value is not the same, it is reported as a Command Index error. Note: `EMSI_CMD.IDX_CHK_ENABLE` must be cleared (=0) for the command with no response, R2 response, R3 response and R4 response.	
		0	Disable
		1	Enable
3 (R/W)	CRC_CHK_EN	Command CRC Check Enable. The `EMSI_CMD.CRC_CHK_EN` bit enables the eMSI controller to check the CRC field in the response. If an error is detected, it is reported as a Command CRC error. Note: CRC Check enable must be cleared (=0) for the command with no response, R3 response, and R4 response.	
		0	Disable
		1	Enable
2 (R/W)	SUB_CMD_FLAG	Sub Command Flag. The `EMSI_CMD.SUB_CMD_FLAG` bit distinguishes between a main command and a sub command. The Sub Command flag is set =1 while issuing an abort command (CMD12) while using asynchronous abort.	
		0	Main Command
		1	Sub Command
1:0 (R/W)	RESP_TYPE_SELECT	Response Type Select. The `EMSI_CMD.RESP_TYPE_SELECT` bit indicates the type of response expected from the card.	
		0	No Response
		1	Response Length 136
		2	Response Length 48
		3	Response Length 48; Check Busy After Response

Command Queuing Version Register

The EMSI_CQVER register provides information about the version of the eMMC Command Queueing standard, which is implemented by the CQE in BCD format.

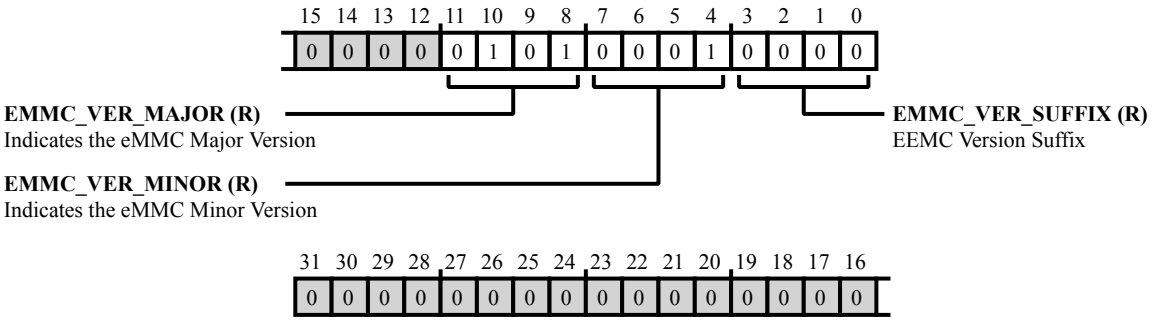

Figure 18-55: EMSI_CQVER Register Diagram

Table 18-33: EMSI_CQVER Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
11:8 (R/NW)	EMMC_VER_MAJOR	Indicates the eMMC Major Version. The EMSI_CQVER.EMMC_VER_MAJOR bit indicates the eMMC major version (1st digit left of decimal point) in BCD format
7:4 (R/NW)	EMMC_VER_MINOR	Indicates the eMMC Minor Version. The EMSI_CQVER.EMMC_VER_MINOR bit indicates the eMMC minor version (1st digit right of decimal point) in BCD format
3:0 (R/NW)	EMMC_VER_SUFFIX	EEMC Version Suffix. The EMSI_CQVER.EMMC_VER_SUFFIX bit indicates the eMMC version suffix (2nd digit right of decimal point) in BCD format

Command Queuing Capabilities Register

The EMSI_CQ_CAP register indicates the capabilities of the command queuing engine.

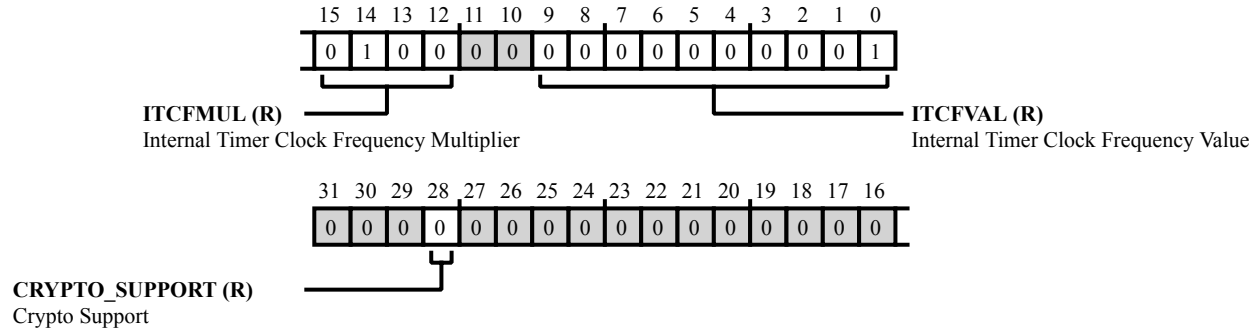

Figure 18-56: EMSI_CQ_CAP Register Diagram

Table 18-34: EMSI_CQ_CAP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
28 (R/NW)	CRYPTO_SUPPORT	Crypto Support. The EMSI_CQ_CAP.CRYPTO_SUPPORT bit indicates whether the Host Controller supports cryptographic operations.	
		0	Crypto Not Supported
		1	Crypto Supported
15:12 (R/NW)	ITCFMUL	Internal Timer Clock Frequency Multiplier. The EMSI_CQ_CAP.ITCFMUL bit field indicates the frequency of the clock used for interrupt coalescing timer and for determining the SQS polling period. See the EMSI_CQ_CAP.ITCFVAL definition for details. Values 0x5 to 0xF are reserved.	
		0	1KHz Clock
		1	10KHz Clock
		2	100KHz Clock
		3	1MHz Clock
		4	10MHz Clock
9:0 (R/NW)	ITCFVAL	Internal Timer Clock Frequency Value. The EMSI_CQ_CAP.ITCFVAL bit field scales the frequency of the timer clock provided by EMSI_CQ_CAP.ITCFMUL. The final clock frequency of actual timer clock is calculated as ITCFVAL x ITCFMUL. The default value is 10MHz.	

Command Queuing Configuration Register

The EMSI_CQ_CFG register controls CQE behavior affecting the general operation of command queuing engine.

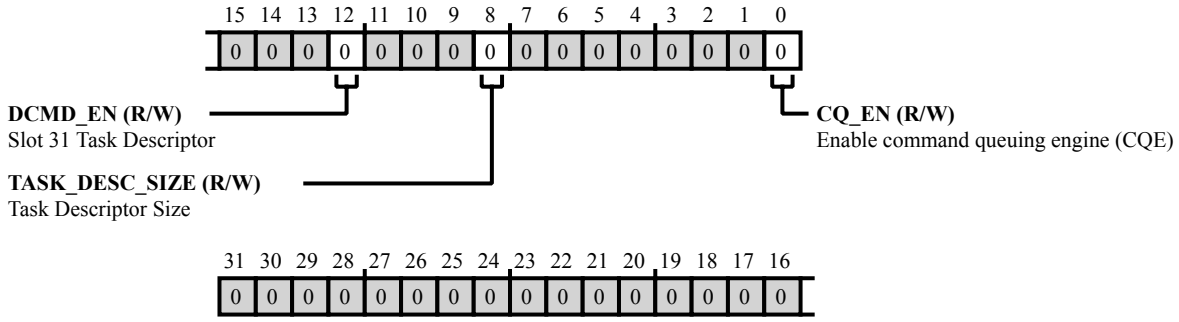

Figure 18-57: EMSI_CQ_CFG Register Diagram

Table 18-35: EMSI_CQ_CFG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W)	DCMD_EN	Slot 31 Task Descriptor. The EMSI_CQ_CFG.DCMD_EN bit indicates to the hardware whether the task descriptor in slot #31 of the TDL is a data transfer descriptor or a direct-command descriptor. The CQE uses the EMSI_CQ_CFG.DCMD_EN bit when a task is issued in slot #31, to determine how to decode the Task Descriptor.	
		0	Task Descriptor in Slot #31 is a Data Transfer Task Descriptor
		1	Task Descriptor in Slot #31 is a DCMD Task Descriptor
8 (R/W)	TASK_DESC_SIZE	Task Descriptor Size. The EMSI_CQ_CFG.TASK_DESC_SIZE bit indicates the size of task descriptor used in host memory. The EMSI_CQ_CFG.TASK_DESC_SIZE bit can only be configured when Command Queuing Enable bit is 0 (command queuing is disabled).	
		0	Task Descriptor Size is 64 Bits
		1	Task Descriptor Size is 128 Bits

Table 18-35: EMSI_CQ_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	CQ_EN	Enable command queuing engine (CQE). When the CQE is disable, the software controls the eMSI bus using the registers between EMSI_SDMA_ADDR (offset 0x000) to EMSI_HOST_CNTRL_VERS (offset 0x0FE). Before the software writes to the EMSI_CQ_CFG.CQ_EN bit, the software verifies that the eMSI controller is in idle state and there are no ongoing commands or data transfers. When software wants to exit command queuing mode, it clears all previous tasks (if any) before clearing (=0) the EMSI_CQ_CFG.CQ_EN bit.	
		0	Disable Command Queuing
		1	Enable Command Queuing

CQ Command Response Argument Register

The EMSI_CQ_CRARG register stores the argument of the last received command response.

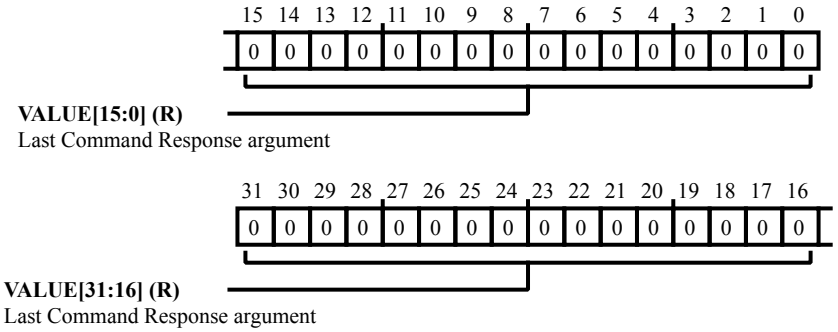

Figure 18-58: EMSI_CQ_CRARG Register Diagram

Table 18-36: EMSI_CQ_CRARG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Last Command Response argument. The EMSI_CQ_CRARG.VALUE bit field stores the argument of the last received command response. The controller updates the value every time a command response is received.

Command Response for Direct Command Register

The EMSI_CQ_CRDCT register stores the response of last executed DCMD.

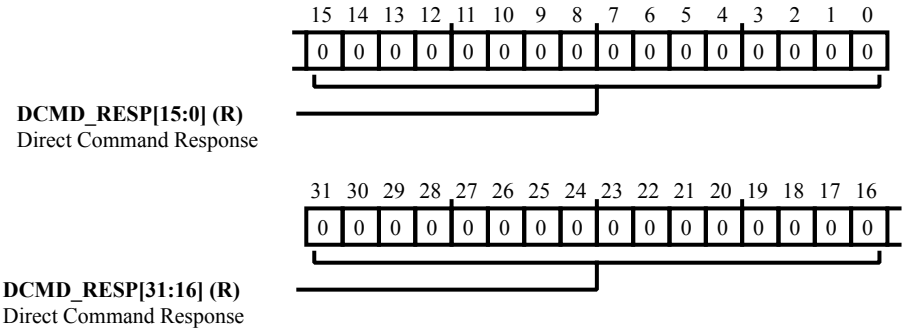

Figure 18-59: EMSI_CQ_CRDCT Register Diagram

Table 18-37: EMSI_CQ_CRDCT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	DCMD_RESP	Direct Command Response. The EMSI_CQ_CRDCT.DCMD_RESP bit field contains the response of the command generated by the last direct command (DCMD) task that was sent. The contents of the EMSI_CQ_CRDCT.DCMD_RESP bit field are valid only after bit 31 of the register is cleared by the controller.

CQ Command Response Index

The EMSI_CQ_CRI register stores the index of the last received command response.

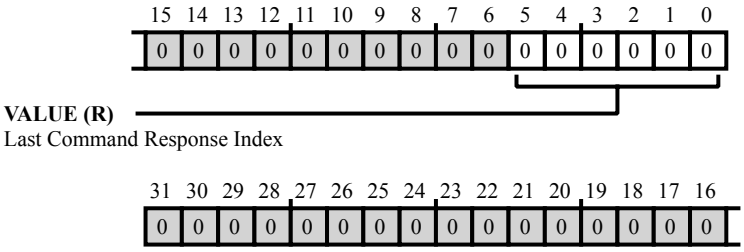

Figure 18-60: EMSI_CQ_CRI Register Diagram

Table 18-38: EMSI_CQ_CRI Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
5:0 (R/NW)	VALUE	Last Command Response Index. The EMSI_CQ_CRI.VALUE bit field stores the index of the last received command response. The controller updates the value every time a command response is received.

Command Queuing Control Register

The EMSI_CQ_CTL register controls CQE behavior affecting the general operation of command queuing module or simultaneous operation of multiple tasks.

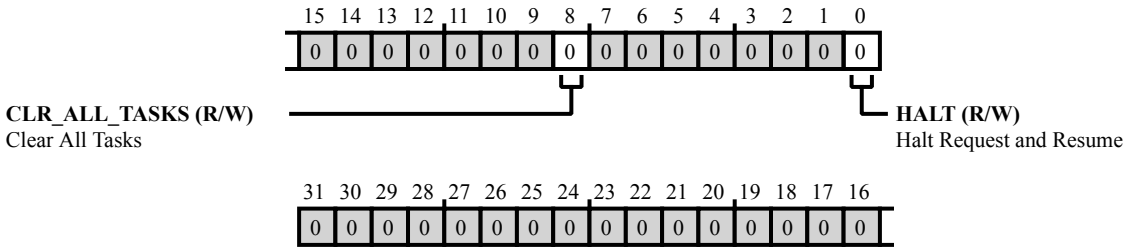

Figure 18-61: EMSI_CQ_CTL Register Diagram

Table 18-39: EMSI_CQ_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W)	CLR_ALL_TASKS	Clear All Tasks. The EMSI_CQ_CTL.CLR_ALL_TASKS bit can only be written when the controller is halted. The EMSI_CQ_CTL.CLR_ALL_TASKS bit does not clear tasks in the eMMC device. The software has to use the CMDQ_TASK_MGMT command (CMD48) separately to clear device's queue.	
		0	Programming 0 Has No Effect
		1	Clears All the Tasks in the Controller
0 (R/W)	HALT	Halt Request and Resume. The EMSI_CQ_CTL.HALT bit provides a halt request and resume.	
		0	Software writes 0 to this bit to exit from the halt state and resume CQE activity.
		1	Software writes 1 to the EMSI_CQ_CTL.HALT bit when it wants to acquire software control over the eMMC bus and to disable CQE from issuing command on the bus. For example, issuing a Discard Task command (CMDQ_TASK_MGMT). When the software writes 1, CQE completes the ongoing task (if any in progress). After the task is completed and the CQE is in idle state, CQE does not issue new commands and indicates to the software by setting the EMSI_CQ_CTL.HALT bit to 1. The software can poll on the EMSI_CQ_CTL.HALT bit until it is set (=1) and only then send commands on the eMMC bus.

Device Pending Tasks Register

The EMSI_CQ_DPT register maintains the list of tasks that are queued into device and are awaiting execution completion.

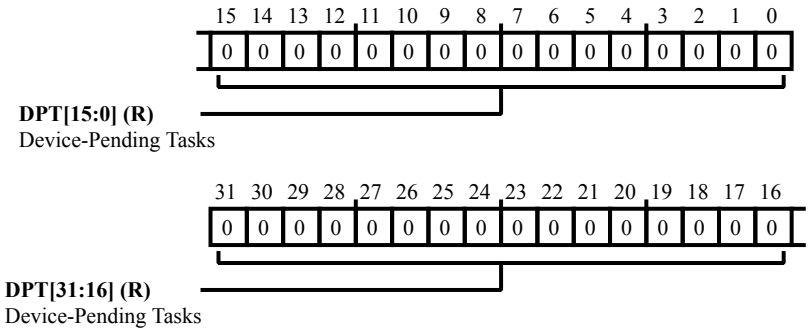

Figure 18-62: EMSI_CQ_DPT Register Diagram

Table 18-40: EMSI_CQ_DPT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	DPT	Device-Pending Tasks. Each of the 32 bits are bit mapped to the 32 tasks. - Bit-N(1): Task-N has been successfully queued into the device and is awaiting execution - Bit-N(0): Task-N is not yet queued Bit n of this register is set if and only if QUEUED_TASK_PARAMS (CMD44) and QUEUED_TASK_ADDRESS (CMD45) were sent for this specific task and if this task has not been executed. The controller sets the EMSI_CQ_DPT.DPT bit after receiving a successful response for CMD45. CQE clears the EMSI_CQ_DPT.DPT bit after the task has completed execution. Software reads this register in the task-discard procedure to determine if the task is queued in the device.

Device Queue Status Register

The EMSI_CQ_DQSTAT register stores the most recent value of the device's queue status.

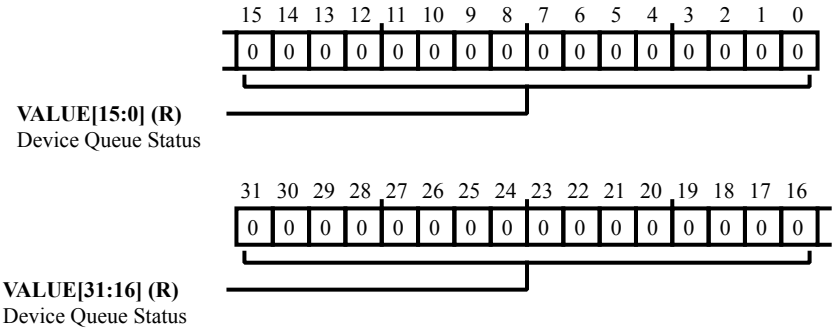

Figure 18-63: EMSI_CQ_DQSTAT Register Diagram

Table 18-41: EMSI_CQ_DQSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Device Queue Status. Each of the EMSI_CQ_DQSTAT.VALUE bits are bit mapped to the 32 tasks as follows: - Bit-N(1): Device has marked task N as ready for execution - Bit-N(0): Task-N is not ready for execution. This task may be pending in the device or not submitted. The eMSI controller updates this register with response of the device queue status command.

Command Queuing Interrupt Coalescing Register

The EMSI_CQ_IC register controls and configures the interrupt coalescing feature.

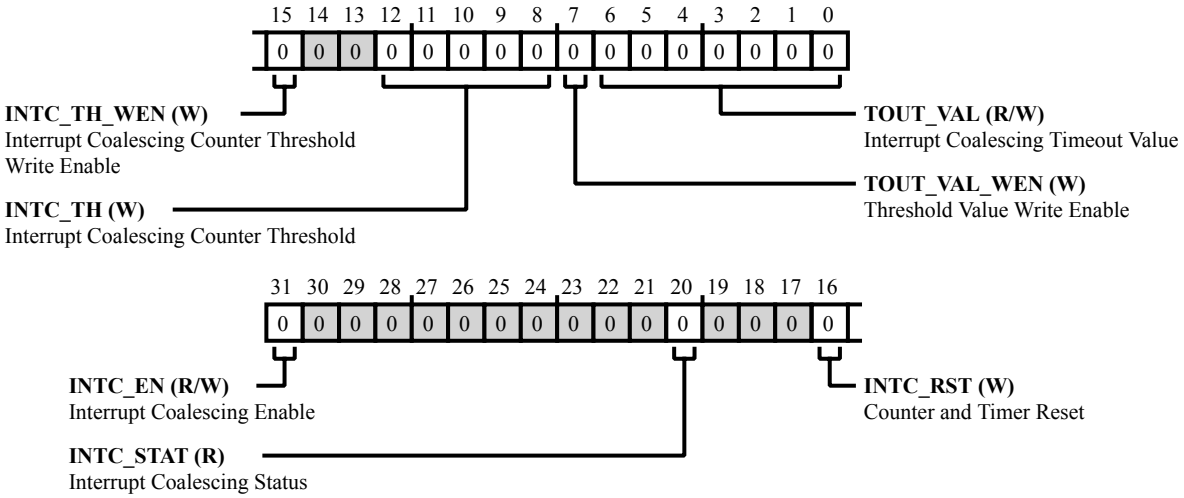

Figure 18-64: EMSI_CQ_IC Register Diagram

Table 18-42: EMSI_CQ_IC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	INTC_EN	Interrupt Coalescing Enable.	
		0	Interrupt Coalescing Mechanism is Disabled (Default)
		1	Interrupt Coalescing Mechanism is Active. Interrupts are Counted and Timed, and Coalesced Interrupts are Generated
20 (R/NW)	INTC_STAT	Interrupt Coalescing Status. The EMSI_CQ_IC.INTC_STAT bit indicates to the software whether any tasks (with INT=0) have completed and counted towards interrupt coalescing (that is, this is set if and only if INTC counter > 0).	
		0	INT0 Task Completions Have Not Occurred Since Last Counter Reset (INTC Counter == 0)
		1	At Least One INT0 Task Completion Has Been Counted (INTC Counter > 0)
16 (RX/W)	INTC_RST	Counter and Timer Reset. When the host driver writes 1 to the EMSI_CQ_IC.INTC_RST, the interrupt coalescing timer and counter are reset.	
		0	No Effect
		1	Interrupt Coalescing Timer and Counter are Reset

Table 18-42: EMSI_CQ_IC Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (RX/W)	INTC_TH_WEN	Interrupt Coalescing Counter Threshold Write Enable. When software writes 1 to the `EMSI_CQ_IC.INTC_TH_WEN` bit, the value `EMSI_CQ_IC.INTC_TH` is updated with the contents written on the same cycle.	
		0	Clears INTC_TH_WEN
		1	Sets INTC_TH_WEN
12:8 (RX/W)	INTC_TH	Interrupt Coalescing Counter Threshold. Software uses the `EMSI_CQ_IC.INTC_TH` field to configure the number of task completions (only tasks with INT=0 in the task descriptor), which are required in order to generate an interrupt. Counter Operation: As data transfer tasks with INT=0 complete, they are counted by CQE. The counter is reset by software during the interrupt service routine. The counter stops counting when it reaches the value configured in `EMSI_CQ_IC.INTC_TH`, and generates interrupt. - 0x0: Interrupt coalescing feature disabled - 0x1: Interrupt coalescing interrupt generated after 1 task when INT=0 completes - 0x2: Interrupt coalescing interrupt generated after 2 tasks when INT=0 completes - ..... - 0x1f: Interrupt coalescing interrupt generated after 31 tasks when INT=0 completes To write to this field, the `EMSI_CQ_IC.INTC_TH_WEN` bit must be set during the same write operation.	
7 (RX/W)	TOUT_VAL_WEN	Threshold Value Write Enable. When software writes 1 to the `EMSI_CQ_IC.TOUT_VAL_WEN` bit, the value in the `EMSI_CQ_IC.TOUT_VAL` bit field is updated with the contents written on the same cycle.	
		0	Clears TOUT_VAL_WEN
		1	Sets TOUT_VAL_WEN

Table 18-42: EMSI_CQ_IC Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
6:0 (R/W)	TOUT_VAL	Interrupt Coalescing Timeout Value. Software uses the `EMSI_CQ_IC.TOUT_VAL` field to configure the maximum time allowed between the completion of a task on the bus and the generation of an interrupt. Timer Operation: The timer is reset by software during the interrupt service routine. It starts running when the first data transfer task with INT=0 is completed, after the timer was reset. When the timer reaches the value configured in ICTOVAL field, it generates an interrupt and stops. The timer's unit is equal to 1024 clock periods of the clock whose frequency is specified in the `EMSI_CQ_CAP.ITCFVAL` bit field. - 0x0: Timer is disabled. Timeout-based interrupt is not generated - 0x1: Timeout on 01x1024 cycles of timer clock frequency - 0x2: Timeout on 02x1024 cycles of timer clock frequency - ..... - 0x7f: Timeout on 127x1024 cycles of timer clock frequency In order to write to this field, the `EMSI_CQ_IC.TOUT_VAL_WEN` bit must be set at the same write operation.

Command Queuing Interrupt Status Register

The EMSI_CQ_ISTAT register indicates pending interrupts that require service. Each bit in this register is asserted in response to a specific event, only if the respective bit is set in the EMSI_CQ_ISTAT_EN register.

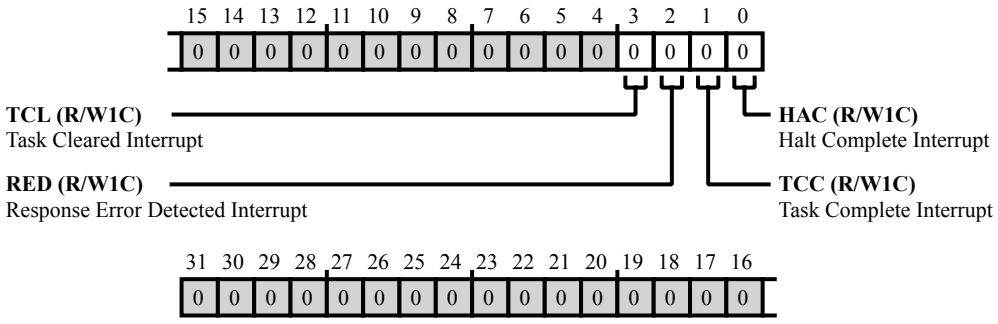

Figure 18-65: EMSI_CQ_ISTAT Register Diagram

Table 18-43: EMSI_CQ_ISTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W1C)	TCL	Task Cleared Interrupt. The EMSI_CQ_ISTAT.TCL bit is asserted (if EMSI_CQ_ISTAT_EN.TCL =1) when a task clear operation is completed by the CQE. The completed task clear operation is either an individual task clear (by writing EMSI_CQ_TCLR) or clearing of all tasks (by writing EMSI_CQ_CTL). A value of 1 clears this status bit.	
		0	TCL Interrupt is Not Set
		1	TCL Interrupt is Set
2 (R/W1C)	RED	Response Error Detected Interrupt. The EMSI_CQ_ISTAT.RED status bit is asserted (if EMSI_CQ_ISTAT_EN.RED =1) when a response is received with an error bit set in the device status field. Configure the EMSI_CQ_RMEM register to identify the device status bit fields that may trigger an interrupt and that are masked. A value of 1 clears this status bit.	
		0	RED Interrupt is Not Set
		1	RED Interrupt is Set

Table 18-43: EMSI_CQ_ISTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W1C)	TCC	Task Complete Interrupt. The EMSI_CQ_ISTAT.TCC status bit is asserted (if EMSI_CQ_ISTAT_EN.TCC =1) when at least one of the following conditions are met: - A task is completed and the INT bit is set in its Task Descriptor - Interrupt caused by Interrupt Coalescing logic due to timeout - Interrupt Coalescing logic reached the configured threshold A value of 1 clears this status bit.	
		0	TCC Interrupt is Not Set
		1	TCC Interrupt is Set
0 (R/W1C)	HAC	Halt Complete Interrupt. The EMSI_CQ_ISTAT.HAC status bit is asserted (only if EMSI_CQ_ISTAT_EN.HAC =1) when the EMSI_CQ_CTL.HALT bit transitions from 0 to 1 indicating that the eMSI controller has completed its current ongoing task and has entered the halt state. A value of 1 clears this status bit.	
		0	HAC Interrupt is Not Set
		1	HAC Interrupt is Set

Command Queuing Interrupt Status Enable Register

The EMSI_CQ_ISTAT_EN register enables and disables the reporting of the corresponding interrupt status to the host software in the EMSI_CQ_ISTAT register. When a bit is set (1) and the corresponding interrupt condition is active, then the bit in the EMSI_CQ_ISTAT register is asserted. Interrupt sources that are disabled (when 0) are not indicated in the EMSI_CQ_ISTAT register. This register is bit-index matched to the EMSI_CQ_ISTAT register.

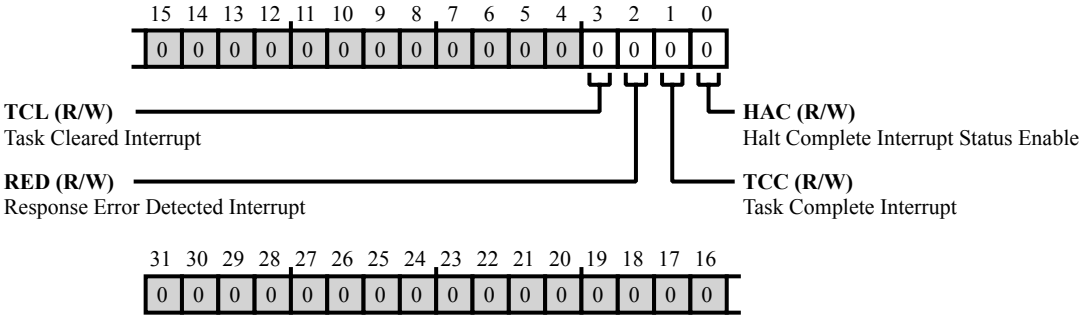

Figure 18-66: EMSI_CQ_ISTAT_EN Register Diagram

Table 18-44: EMSI_CQ_ISTAT_EN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	TCL	Task Cleared Interrupt. Task cleared interrupt status enable.	
		0	CQIS.TCL is Disabled
		1	CQIS.TCL is Set When Its Interrupt Condition is Active
2 (R/W)	RED	Response Error Detected Interrupt. Response error detected interrupt status enable.	
		0	CQIS.RED is Disabled
		1	CQIS.RED is Set When Its Interrupt Condition is Active
1 (R/W)	TCC	Task Complete Interrupt. Task complete interrupt status enable.	
		0	CQIS.TCC is Disabled
		1	CQIS.TCC is Set When Its Interrupt Condition is Active

Table 18-44: EMSI_CQ_ISTAT_EN Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	HAC	Halt Complete Interrupt Status Enable.	
		0	CQIS.HAC is Disabled
		1	CQIS.HAC is Set When Its Interrupt Condition is Active

Command Queuing Interrupt Signal Enable Register

The EMSI_CQ_ISTAT_INTEN register enables and disables the generation of interrupts to host software. When a bit is set and the corresponding bit in EMSI_CQ_ISTAT is set, then an interrupt is generated. This register is bit-index matched to the EMSI_CQ_ISTAT register.

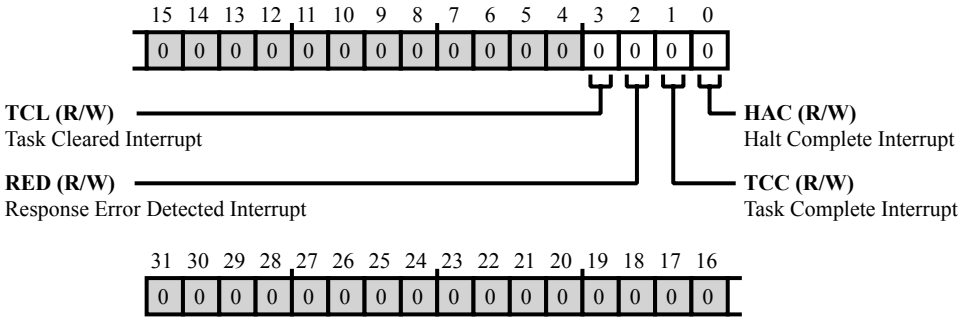

Figure 18-67: EMSI_CQ_ISTAT_INTEN Register Diagram

Table 18-45: EMSI_CQ_ISTAT_INTEN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	TCL	Task Cleared Interrupt. Task cleared interrupt signal enable.	
		0	CQIS.TCL Interrupt Signal Generation is Disabled
		1	CQIS.TCL Interrupt Signal Generation is Active
2 (R/W)	RED	Response Error Detected Interrupt. Response error detected interrupt signal enable.	
		0	CQIS.RED Interrupt Signal Generation is Disabled
		1	CQIS.RED Interrupt Signal Generation is Active
1 (R/W)	TCC	Task Complete Interrupt. Task complete interrupt signal enable.	
		0	CQIS.TCC Interrupt Signal Generation is Disabled
		1	CQIS.TCC Interrupt Signal Generation is Active
0 (R/W)	HAC	Halt Complete Interrupt. Halt complete interrupt signal enable.	
		0	CQIS.HAC Interrupt Signal Generation is Disabled
		1	CQIS.HAC Interrupt Signal Generation is Active

Command Response Mode Error Mask Register

The EMSI_CQ_RMEM register controls the generation of the response error detect (RED) interrupt. Only the bits enabled here can contribute to RED.

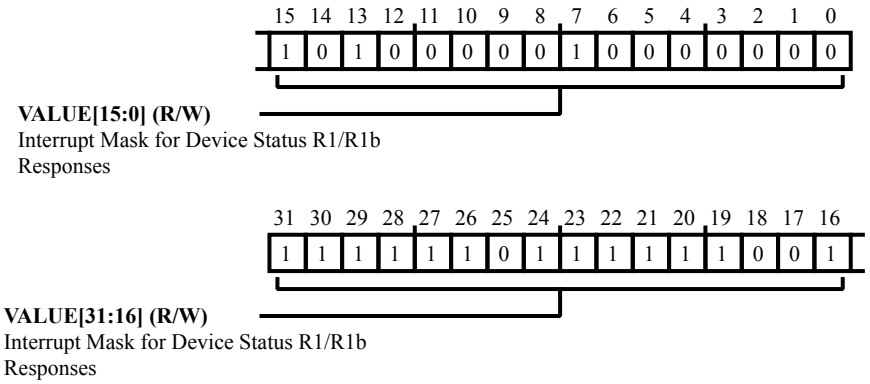

Figure 18-68: EMSI_CQ_RMEM Register Diagram

Table 18-46: EMSI_CQ_RMEM Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Interrupt Mask for Device Status R1/R1b Responses. The EMSI_CQ_RMEM.VALUE bits are bit-mapped to the device response. The EMSI_CQ_RMEM.VALUE bits are used as an interrupt mask on the device status field that is received in R1/R1b responses. - 1: When a R1/R1b response is received, with a bit i in the device status set, a RED interrupt is generated. - 0: When a R1/R1b response is received, bit i in the device status is ignored. The reset value of this register is set to trigger an interrupt on all "Error" type bits in the device status. Note: Responses to CMD13 (SQS) encode the QSR so that they are ignored by this logic.

CQ Send Status Configuration 1 Register

The EMSI_CQ_SSCFG1 register is used for removing an outstanding task in the CQE. The register controls when SEND_QUEUE_STATUS commands are sent.

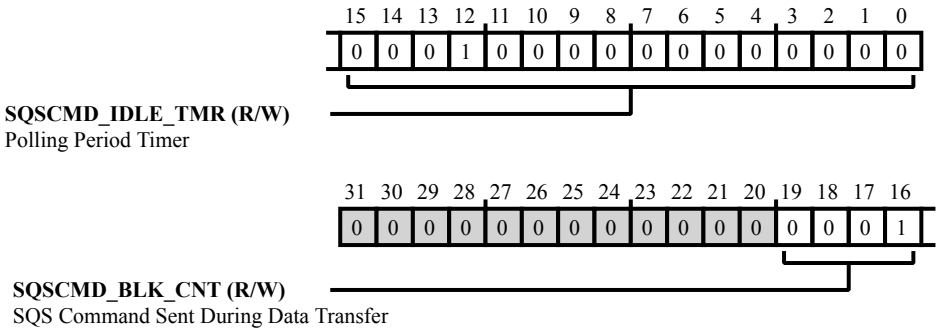

Figure 18-69: EMSI_CQ_SSCFG1 Register Diagram

Table 18-47: EMSI_CQ_SSCFG1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
19:16 (R/W)	SQSCMD_BLK_CNT	SQS Command Sent During Data Transfer. The EMSI_CQ_SSCFG1.SQSCMD_BLK_CNT field indicates when SQS CMD is sent while data transfer is in progress. A value of 'n' indicates that CQE sends status command on the CMD line, during the transfer of data block BLOCK_CNT-n, on the data lines, where BLOCK_CNT is the number of blocks in the current transaction. - 0x0: SEND_QUEUE_STATUS (CMD13) command is not sent during the transaction. Instead, it is sent only when the data lines are idle. - 0x1: SEND_QUEUE_STATUS command is to be sent during the last block of the transaction. - 0x2: SEND_QUEUE_STATUS command when last 2 blocks are pending. - 0x3: SEND_QUEUE_STATUS command when last 3 blocks are pending. - ..... - 0xf: SEND_QUEUE_STATUS command when last 15 blocks are pending. The EMSI_CQ_SSCFG1.SQSCMD_BLK_CNT bits should be programmed only when EMSI_CQ_CFG.CQ_EN is = 0.

Table 18-47: EMSI_CQ_SSCFG1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	SQSCMD_IDLE_TMR	Polling Period Timer. The `EMSI_CQ_SSCFG1.SQSCMD_IDLE_TMR` bit field configures the polling period to be used when using periodic SEND_QUEUE_STATUS (CMD13) polling. Periodic polling is used when tasks are pending in the device, but no data transfer is in progress. When a SEND_QUEUE_STATUS response indicates that no task is ready for execution, the CQE counts the configured time until it issues the next SEND_QUEUE_STATUS. Timer units are clock periods of the clock whose frequency is specified in the `EMSI_CQ_CAP.ITCFVAL` bits. The minimum value is 0001h (1 clock period) and the maximum value is FFFFh (65535 clock periods). For example, a `EMSI_CQ_CAP.ITCFVAL` field value of 0 indicates a 19.2 MHz clock frequency (period = 52.08 ns). If the setting in `EMSI_CQ_SSCFG1.SQSCMD_IDLE_TMR` is 1000h, the calculated polling period is 4096*52.08 ns= 213.33 ns. The value in this field should be programmed only when `EMSI_CQ_CFG.CQ_EN` = 0.

CQ Send Status Configuration 2 Register

The EMSI_CQ_SSCFG2 register is used for configuring the RCA field in SEND_QUEUE_STATUS command argument.

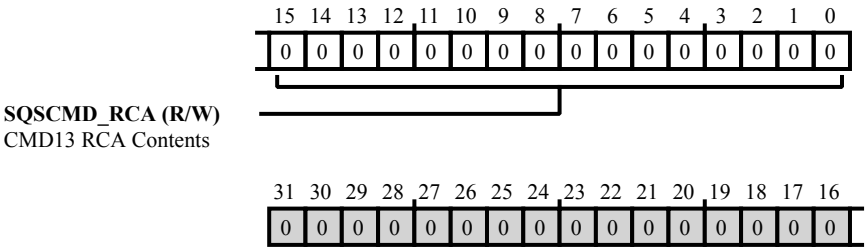

Figure 18-70: EMSI_CQ_SSCFG2 Register Diagram

Table 18-48: EMSI_CQ_SSCFG2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	SQSCMD_RCA	CMD13 RCA Contents. The EMSI_CQ_SSCFG2.SQSCMD_RCA bit field provides CQE with the contents of the 16-bit RCA field in SEND_QUEUE_STATUS (CMD13) command argument. The CQE copies this field to bits 31:16 of the argument when transmitting the SEND_ QUEUE_STATUS (CMD13) command.

Command Queuing Task Clear Register

The EMSI_CQ_TCLR register is used for removing an outstanding task in the CQE. The register must be used only when the CQE is in a halt state.

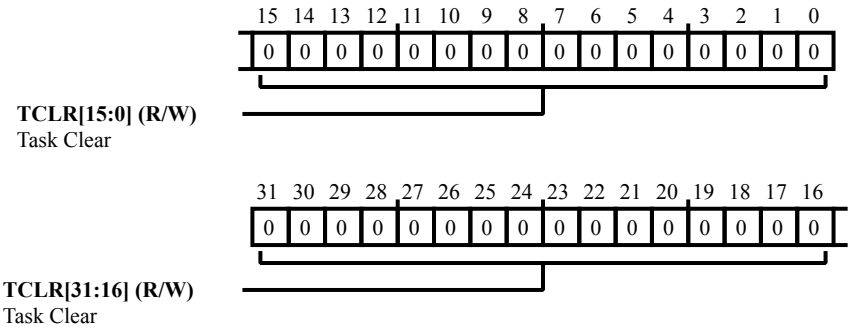

Figure 18-71: EMSI_CQ_TCLR Register Diagram

Table 18-49: EMSI_CQ_TCLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	TCLR	Task Clear. Writing 1 to bit n of the EMSI_CQ_TCLR.TCLR bit field orders the CQE to clear a task that the software has previously issued. This bit can only be written when the CQE is in the halt state as indicated in the EMSI_CQ_CTL.HALT bit. When software writes 1 to a bit in this register, CQE updates the value to 1, and starts clearing the data structures related to the task. The CQE clears the bit fields (sets a value of 0) in the EMSI_CQ_TCLR register and in the EMSI_CQ_TDBR register once the clear operation is complete. Software must poll on this register until it is cleared to verify that a clear operation was done.

Command Queuing Task Completion Notification Register

The EMSI_CQ_TCN register is used by the CQE to notify software about completed tasks.

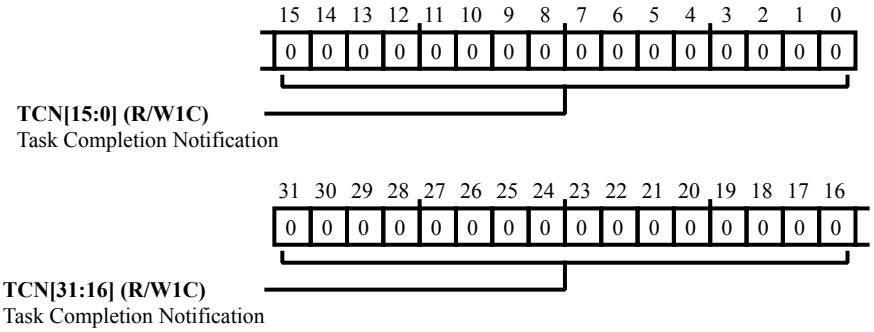

Figure 18-72: EMSI_CQ_TCN Register Diagram

Table 18-50: EMSI_CQ_TCN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W1C)	TCN	Task Completion Notification. Each of the EMSI_CQ_TCN.TCN bits are bit mapped to the 32 tasks. - Bit-N(1): Task-N has completed execution (with success or errors) - Bit-N(0): Task-N has not completed, could be pending or not submitted. On task completion, software may read this bit field to know tasks that have completed. After reading this register, software may clear the relevant bit fields by writing 1 to the corresponding bits.

Command Queuing DoorBell Register

The EMSI_CQ_TDBR register, causes software to trigger the CQE to process a new task.

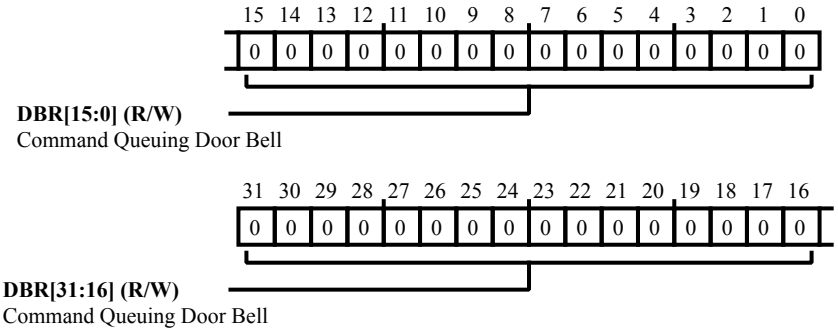

Figure 18-73: EMSI_CQ_TDBR Register Diagram

Table 18-51: EMSI_CQ_TDBR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	DBR	Command Queuing Door Bell. The software configures EMSI_CQ_TDL_BADDR and enables EMSI_CQ_TDBR EMSI_CQ_CFG CQE in CQCFG before using this register. Writing 1 to bit n of this register triggers the CQE to start processing the task encoded in slot n of the TDL. Writing 0 by the software does not have any impact on the hardware, and does not change the value of the register bit. The CQE always processes tasks according to the order submitted to the list by write transactions. The CQE processes data transfer tasks by reading the task descriptor and sending QUEUED_TASK_PARAMS (CMD44) and QUEUED_TASK_ADDRESS (CMD45) commands to the device. CQE processes DCMD tasks (in slot #31, when enabled) by reading the task descriptor, and generating the command encoded by its index and argument. The corresponding bit is cleared to 0 by CQE in one of the following events: - A task execution is completed (with success or error). - The task is cleared using EMSI_CQ_TCLR register. - All tasks are cleared using EMSI_CQ_CTL register. - CQE is disabled using EMSI_CQ_CFG register. Software may initiate multiple tasks at the same time (batch submission) by writing 1 to multiple bits of this register in the same transaction. In the case of batch submission, CQE processes the tasks in order of the task index, starting with the lowest index. If one or more tasks in the batch are marked with QBR, the ordering of execution is based on said processing order.

Command Queuing Task Descriptor List Base Address Register

The EMSI_CQ_TDL_BADDR register is used for configuring the lower 32 bits of the byte address of the head of the Task Descriptor List in the host memory.

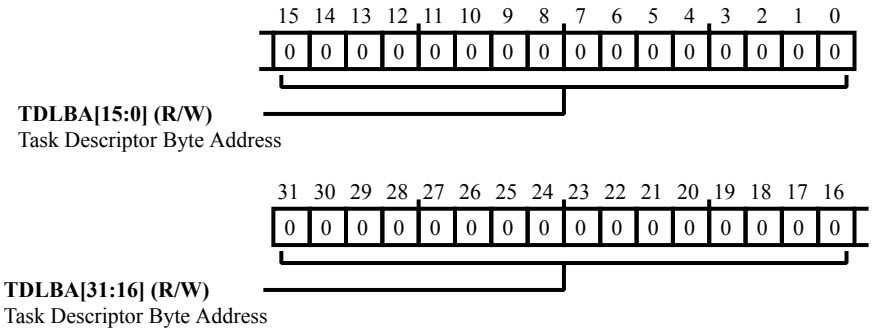

Figure 18-74: EMSI_CQ_TDL_BADDR Register Diagram

Table 18-52: EMSI_CQ_TDL_BADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	TDLBA	Task Descriptor Byte Address. The EMSI_CQ_TDL_BADDR.TDLBA bit field stores the LSB bits (31:0) of the byte address of the head of the task descriptor List in system memory. The size of the task descriptor list is 32 x (task descriptor size + transfer descriptor size) as configured by the host driver. This address is set on 1 KB boundary. The lower 10 bits of this register are cleared (=0) by the software and are ignored by CQE.

CQ Task Error Information Register

The EMSI_CQ_TERRINFO register is updated by the CQE when an error occurs on data or a command related to a task activity. When such an error is detected by the CQE or indicated by the eMSI controller, the CQE stores task IDs and indices of commands that were executed on the command line and data lines when the error occurred in this register.

Software must use this information in the error recovery procedure.

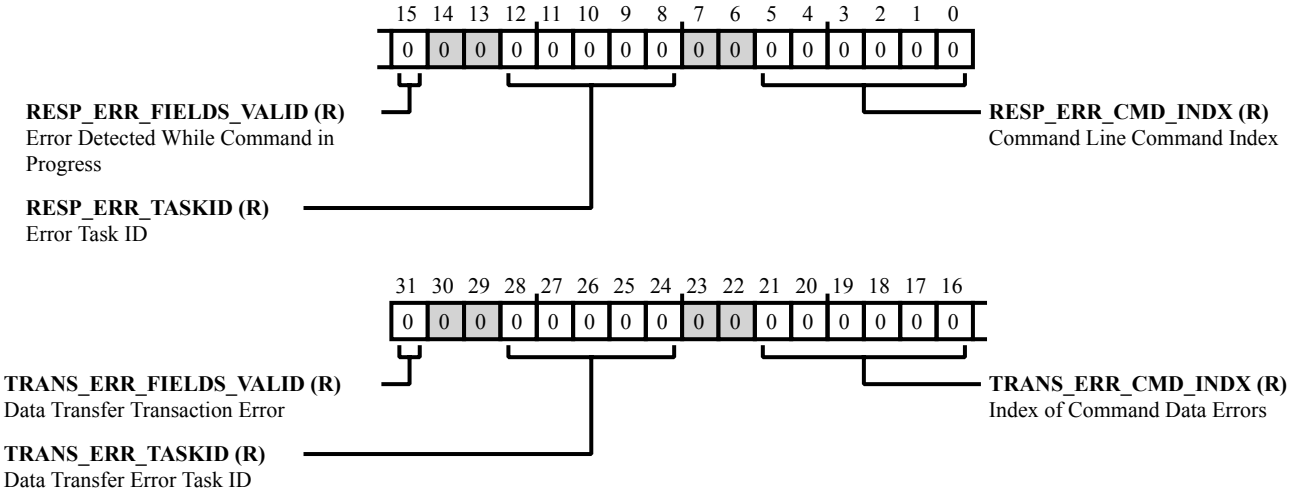

Figure 18-75: EMSI_CQ_TERRINFO Register Diagram

Table 18-53: EMSI_CQ_TERRINFO Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/NW)	TRANS_ERR_FIELDS_VALID	Data Transfer Transaction Error. The EMSI_CQ_TERRINFO.TRANS_ERR_FIELDS_VALID bit is updated when an error is detected while a data transfer transaction was in progress.	
		0	Ignore Contents of TRANS_ERR_TASKID and TRANS_ERR_CMD_INDX
		1	Data Transfer Related Error Detected. Check Contents of TRANS_ERR_TASKID and TRANS_ERR_CMD_INDX Fields
28:24 (R/NW)	TRANS_ERR_TASKID	Data Transfer Error Task ID. The EMSI_CQ_TERRINFO.TRANS_ERR_TASKID bit field captures the ID of the task that was executed and whose data transfer has errors.	
21:16 (R/NW)	TRANS_ERR_CMD_INDX	Index of Command Data Errors. The EMSI_CQ_TERRINFO.TRANS_ERR_CMD_INDX bit field captures the index of the command that was executed and whose data transfer has errors.	

Table 18-53: EMSI_CQ_TERRINFO Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/NW)	RESP_ERR_FIELDS_VALID	Error Detected While Command in Progress. The `EMSI_CQ_TERRINFO.RESP_ERR_FIELDS_VALID` bit is updated when an error is detected while a command transaction was in progress.	
		0	Ignore Contents of RESP_ERR_TASKID and RESP_ERR_CMD_INDX
		1	Response-related Error is Detected. Check Contents of RESP_ERR_TASKID and RESP_ERR_CMD_INDX Fields
12:8 (R/NW)	RESP_ERR_TASKID	Error Task ID. The `EMSI_CQ_TERRINFO.RESP_ERR_TASKID` bit field captures the ID of the task which was executed on the command line when the error occurred.	
5:0 (R/NW)	RESP_ERR_CMD_INDX	Command Line Command Index. The `EMSI_CQ_TERRINFO.RESP_ERR_CMD_INDX` bits capture the index of the command that was executed on the command line when the error occurred.	

EMSI Control 1 Register

The EMSI_CTL1 register is used to control the operation of the eMSI controller. This register is applicable for eMMC mode.

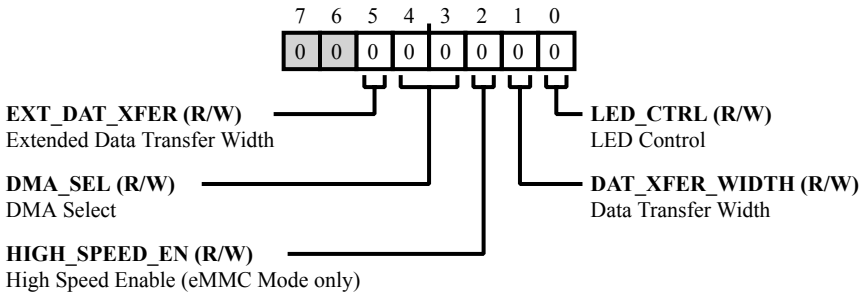

Figure 18-76: EMSI_CTL1 Register Diagram

Table 18-54: EMSI_CTL1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (R/W)	EXT_DAT_XFER	Extended Data Transfer Width. The EMSI_CTL1.EXT_DAT_XFER bit controls 8-bit bus width mode of an eMMC device.	
		0	Bus Width is Selected by the Data Transfer Width
		1	8-bit Bus Width
4:3 (R/W)	DMA_SEL	DMA Select. The EMSI_CTL1.DMA_SEL bit field is used to select the DMA type. When EMSI_CTL2.HOST_VER4_EN =1: - 0x0: SDMA is selected - 0x1: Reserved - 0x2: ADMA2 is selected - 0x3: ADMA2 or ADMA3 is selected When EMSI_CTL2.HOST_VER4_EN =0: - 0x0: SDMA is selected - 0x1: Reserved - 0x2: 32-bit Address ADMA2 is selected	
		0	SDMA is Selected
		1	Reserved
		2	ADMA2 is Selected
		3	ADMA2 or ADMA3 is Selected

Table 18-54: EMSI_CTL1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W)	HIGH_SPEED_EN	High Speed Enable (eMMC Mode only). In eMMC mode, the `EMSI_CTL1.HIGH_SPEED_EN` bit is used to determine the selection of the preset value for high speed mode. This bit is set = 1 when the eMSI bus clock is 0-50MHz. This bit is cleared = 0 when the eMSI bus clock frequency is 0-25MHz.	
		0	Normal Speed Mode (eMSI bus clock frequency 0-25 MHz)
		1	High Speed Mode (eMSI bus clock frequency 0-50 MHz)
1 (R/W)	DAT_XFER_WIDTH	Data Transfer Width. For eMMC mode,the `EMSI_CTL1.DAT_XFER_WIDTH` bit selects the data transfer width of the eMSI controller. The host driver sets it to match the data width of the eMMC device.	
		0	1-bit Mode
		1	4-bit Mode
0 (R/W)	LED_CTRL	LED Control. The `EMSI_CTL1.LED_CTRL` bit is used to caution the user not to remove the card while the eMMC card is being accessed. The value is reflected on the EMSI_LED_CONTROL signal. The `EMSI_CTL1.LED_CTRL` bit can be set to 1 by host driver at the start of data transfer and cleared when data transfer is complete.	
		0	LED Off
		1	LED On

EMSI Control 2 Register

The EMSI_CTL2 register is used to control how the eMSI controller operates. This register is applicable for eMMC mode.

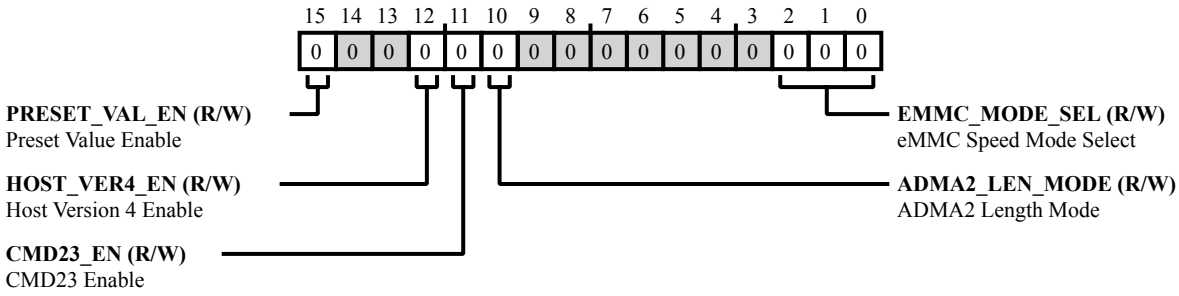

Figure 18-77: EMSI_CTL2 Register Diagram

Table 18-55: EMSI_CTL2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	PRESET_VAL_EN	Preset Value Enable. The EMSI_CTL2.PRESET_VAL_EN bit enables automatic selection of the eMSI bus clock frequency using the preset value registers. When the EMSI_CTL2.PRESET_VAL_EN bit is set, the eMSI bus clock frequency generation (frequency select) is performed by the controller. These values are selected from the set of preset value registers based on the selected speed mode.	
		0	eMSI bus clock controlled by Host Driver
		1	Automatic Selection by Preset Value are Enabled
12 (R/W)	HOST_VER4_EN	Host Version 4 Enable. The EMSI_CTL2.HOST_VER4_EN bit selects either Version 3.00 compatible mode or Version 4 mode. The functions of the following fields are modified for Host Version 4 mode. - SDMA Address: SDMA uses the EMSI_ADMA_ADDR_LO register instead of the EMSI_SDMA_ADDR register - ADMA2/ADMA3 selection: ADMA3 is selected by DMA select in the EMSI_CTL1 register - 32-bit Block Count: the EMSI_SDMA_ADDR register is modified to the 32-bit Block Count register Note: It is recommended not to program ADMA3 integrated descriptor address registers, and command queuing registers (if applicable) while operating in host version less than 4 mode (EMSI_CTL2.HOST_VER4_EN = 0).	
		0	Version 3.00 Compatible Mode
		1	Version 4 Mode

Table 18-55: EMSI_CTL2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W)	CMD23_EN	CMD23 Enable. If the device supports CMD23, the `EMSI_CTL2.CMD23_EN` bit is set (=1). The `EMSI_CTL2.CMD23_EN` bit is used to select Auto CMD23 or Auto CMD12 for ADMA3 data transfer.	
		0	Auto CMD23 is Disabled
		1	Auto CMD23 is Enabled
10 (R/W)	ADMA2_LEN_MODE	ADMA2 Length Mode. The `EMSI_CTL2.ADMA2_LEN_MODE` bit selects ADMA2 Length mode to be either 16-bit or 26-bit.	
		0	16-bit Data Length Mode
		1	26-bit Data Length Mode
2:0 (R/W)	EMMC_MODE_SEL	eMMC Speed Mode Select. In eMMC mode, the `EMSI_CTL2.EMMC_MODE_SEL` bits are used to select the speed mode.	
		0	Legacy
		1	High Speed SDR
		2	Reserved
		3	Reserved
		4	High Speed DDR
		5	Reserved
		6	Reserved
		7	Reserved

SD Host Controller Specification Version

The EMSI_HOST_CNTRL_VERS register is used to indicate the supported SD host controller specification version number.

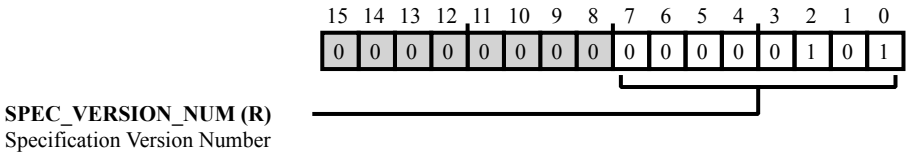

Figure 18-78: EMSI_HOST_CNTRL_VERS Register Diagram

Table 18-56: EMSI_HOST_CNTRL_VERS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
7:0 (R/NW)	SPEC_VERSION_NUM	Specification Version Number. The EMSI_HOST_CNTRL_VERS.SPEC_VERSION_NUM bits indicate the SD host controller specification version. The upper and lower 4-bits indicate the version. Values 0x06-0xFF are reserved.	
		0	SD Host Controller Specification Version 1.00
		1	SD Host Controller Specification Version 2.00
		2	SD Host Controller Specification Version 3.00
		3	SD Host Controller Specification Version 4.00
		4	SD Host Controller Specification Version 4.10
		5	SD Host Controller Specification Version 4.20

eMMC Control Register

The EMSI_EMMC_CTL register is used to control the eMMC operation.

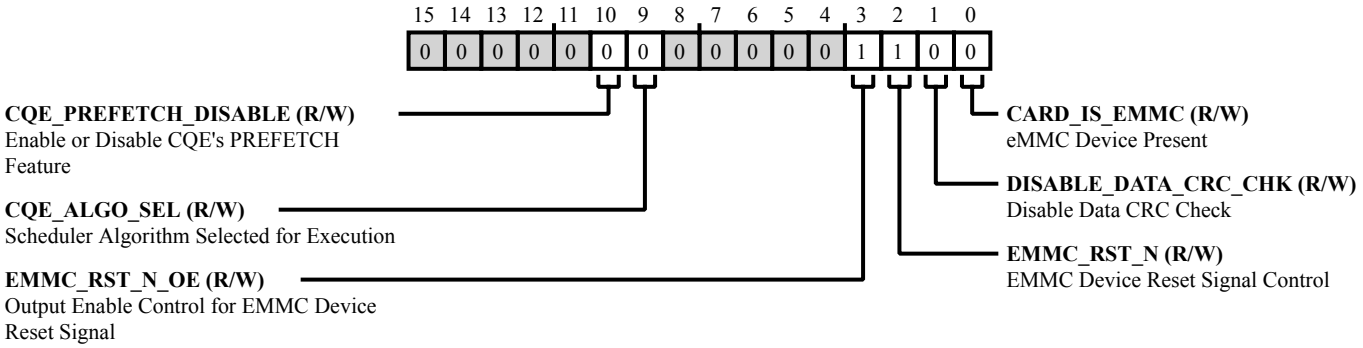

Figure 18-79: EMSI_EMMC_CTL Register Diagram

Table 18-57: EMSI_EMMC_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
10 (R/W)	CQE_PREFETCH_DISABLE	Enable or Disable CQE's PREFETCH Feature. The EMSI_EMMC_CTL.CQE_PREFETCH_DISABLE bit field allows software to disable the CQE's data prefetch feature when set (=1).	
		0	CQE Can Prefetch Data for Successive WRITE Transfers and Pipeline Successive READ Transfers
		1	Prefetch for WRITE and Pipeline for READ are Disabled
9 (R/W)	CQE_ALGO_SEL	Scheduler Algorithm Selected for Execution. The EMSI_EMMC_CTL.CQE_ALGO_SEL bit selects the algorithm used for selecting one of the many ready tasks for execution.	
		0	Priority Based Reordering with FCFS to Resolve Equal Priority Tasks
		1	First Come First Serve, in the Order of DBR Rings
3 (R/W)	EMMC_RST_N_OE	Output Enable Control for EMMC Device Reset Signal. The EMSI_EMMC_CTL.EMMC_RST_N_OE bit field controls the devise reset for EMMC devices.	
		0	eMMC_rst_n_oe is 0
		1	eMMC_rst_n_oe is 1

Table 18-57: EMSI_EMMC_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W)	EMMC_RST_N	EMMC Device Reset Signal Control. The `EMSI_EMMC_CTL.EMMC_RST_N` register field controls the RST signal of the eMSI controller.	
		0	Reset to eMMC device asserted (active Low)
		1	Reset to eMMC device is deasserted
1 (R/W)	DISABLE_DATA_CRC_CHK	Disable Data CRC Check. The `EMSI_EMMC_CTL.DISABLE_DATA_CRC_CHK` bit controls masking of CRC16 error for card write in eMMC mode. This is useful in bus testing (CMD19) for an eMMC device. In bus testing, an eMMC card does not send CRC status for a block, which may generate CRC error. This CRC error can be masked using the `EMSI_EMMC_CTL.DISABLE_DATA_CRC_CHK` bit during bus testing.	
		0	DATA CRC Check is Enabled
		1	DATA CRC Check is Disabled
0 (R/W)	CARD_IS_EMMC	eMMC Device Present. The `EMSI_EMMC_CTL.CARD_IS_EMMC` bit indicates the type of device connected. An application programs the `EMSI_EMMC_CTL.CARD_IS_EMMC` bit based on the device connected to the eMSI controller.	
		0	Card Connected to the eMSI controller is a Non-eMMC Card
		1	Card Connected to the eMSI controller is an eMMC card

Error Interrupt Status Register

The EMSI_ERR_STAT register indicates error occurred during eMMC transactions. Writing a 1 clears the bit and writing a 0 retains the bit unchanged. Signals defined in this register can be enabled by the Error Interrupt Status Enable register, but not by the EMSI_ERR_STAT_INTEN register. More than one status can be cleared with a single register write. This register is applicable for eMMC mode.

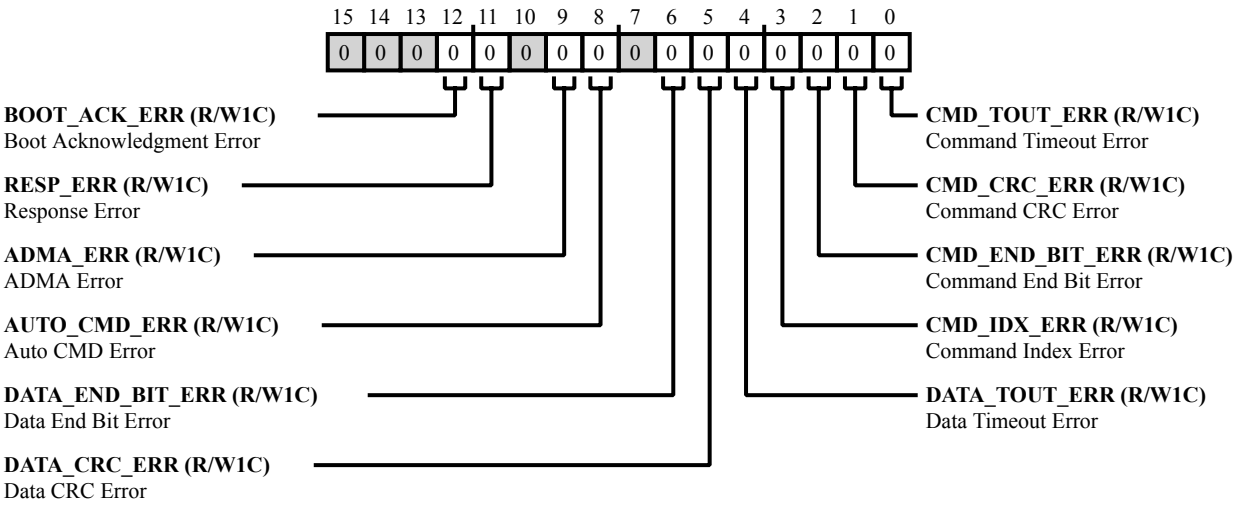

Figure 18-80: EMSI_ERR_STAT Register Diagram

Table 18-58: EMSI_ERR_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W1C)	BOOT_ACK_ERR	Boot Acknowledgment Error. The EMSI_ERR_STAT.BOOT_ACK_ERR bit is set when there is a timeout for boot acknowledgment or when detecting boot ack status having a value other than 010. This is applicable only when boot acknowledgment is expected in eMMC mode.	
		0	No Error
		1	Error
11 (R/W1C)	RESP_ERR	Response Error. Host Version 4.00 supports a response error check function to avoid overhead of response error check by the host driver during DMA execution. If the EMSI_TRNSFRMODE.RESP_ERR_CHK_EN =1, the eMSI controller checks R1 response. If an error is detected in a response, the EMSI_ERR_STAT.RESP_ERR bit is set (=1).This is applicable in eMMC mode.	
		0	No Error
		1	Error

Table 18-58: EMSI_ERR_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W1C)	ADMA_ERR	ADMA Error. The EMSI_ERR_STAT.ADMA_ERR bit is set when the eMSI controller detects error during ADMA-based data transfer. The error could be due to following reasons: - Error response received from System bus - ADMA3, ADMA2 Descriptors invalid - CQE Task or Transfer descriptors invalid When the error occurs, the state of the ADMA is saved in the ADMA Error Status register. In eMMC CQE mode: The eMSI controller generates this Interrupt when it detects an invalid descriptor data (Valid=0) at the ST_FDS state. An ADMA error state in the ADMA error status indicates that an error has occurred in ST_FDS state. The host driver may find that Valid bit is not set at the error descriptor.	
		0	No Error
		1	Error
8 (R/W1C)	AUTO_CMD_ERR	Auto CMD Error. This error status is used by Auto CMD12 and Auto CMD23 in eMMC mode. The EMSI_ERR_STAT.AUTO_CMD_ERR bit is set when detecting that any of the bits D00 to D05 in Auto CMD Error Status register has changed from 0 to 1. D07 is effective in case of Auto CMD12. The Auto CMD error status register is valid while the EMSI_ERR_STAT.AUTO_CMD_ERR bit is set (=1) and may be cleared by clearing the EMSI_ERR_STAT.AUTO_CMD_ERR bit.	
		0	No Error
		1	Error
6 (R/W1C)	DATA_END_BIT_ERR	Data End Bit Error. The EMSI_ERR_STAT.DATA_END_BIT_ERR bit is set in eMMC mode either when detecting a 0 at the end bit position of read data that uses the DAT line or at the end bit position of the CRC status.	
		0	No Error
		1	Error
5 (R/W1C)	DATA_CRC_ERR	Data CRC Error. The EMSI_ERR_STAT.DATA_CRC_ERR bit is set in eMMC mode when detecting a CRC error when transferring read data which uses the DAT line, when detecting the write CRC status having a value of other than 010, or on a write CRC status timeout.	
		0	No Error
		1	Error

Table 18-58: EMSI_ERR_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/W1C)	DATA_TOUT_ERR	Data Timeout Error. The EMSI_ERR_STAT.DATA_TOUT_ERR bit is set in eMMC mode when detecting one of the following timeout conditions: - Busy timeout for R1b type - Busy timeout after Write CRC status - Write CRC Status timeout - Read Data timeout	
		0	No Error
		1	Time Out
3 (R/W1C)	CMD_IDX_ERR	Command Index Error. The EMSI_ERR_STAT.CMD_IDX_ERR bit is set if a command index error occurs in the command response in eMMC mode.	
		0	No Error
		1	Error
2 (R/W1C)	CMD_END_BIT_ERR	Command End Bit Error. The EMSI_ERR_STAT.CMD_END_BIT_ERR bit is set when detecting that the end bit of a command response is 0 in eMMC mode.	
		0	No Error
		1	End Bit Error Generated
1 (R/W1C)	CMD_CRC_ERR	Command CRC Error. Command CRC Error is generated in eMMC mode for following two cases. - The eMSI controller detects a CMD line conflict by monitoring the CMD line when a command is issued. If the eMSI controller drives the CMD line to 1 level, but detects 0 level on the CMD line at the next eMSI bus clock edge, then the eMSI controller aborts the command (stop driving CMD line) and set the EMSI_ERR_STAT.CMD_CRC_ERR bit to 1. The command timeout error is also set (=1) to distinguish a CMD line conflict. - If a response is returned and the command timeout error is clear (=0) (indicating no timeout), the EMSI_ERR_STAT.CMD_CRC_ERR bit is set (=1) when detecting a CRC error in the command response.	
		0	No Error
		1	CRC Error Generated

Table 18-58: EMSI_ERR_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W1C)	CMD_TOUT_ERR	Command Timeout Error. In eMMC mode,the `EMSI_ERR_STAT.CMD_TOUT_ERR` bit is set only if no response is returned within 64 eMSI bus clock cycles from the end bit of the command. If the eMSI controller detects a CMD line conflict, along with Command CRC Error bit, the `EMSI_ERR_STAT.CMD_TOUT_ERR` bit is set (=1), without waiting for 64 eMSI bus clock cycles.	
		0	No Error
		1	Time Out

Error Interrupt Status Enable Register

The EMSI_ERR_STAT_EN register sets the interrupt status for error interrupt status register (EMSI_ERR_STAT) when the corresponding bit in EMSI_ERR_STAT_EN is set (=1). This register is applicable for eMMC mode.

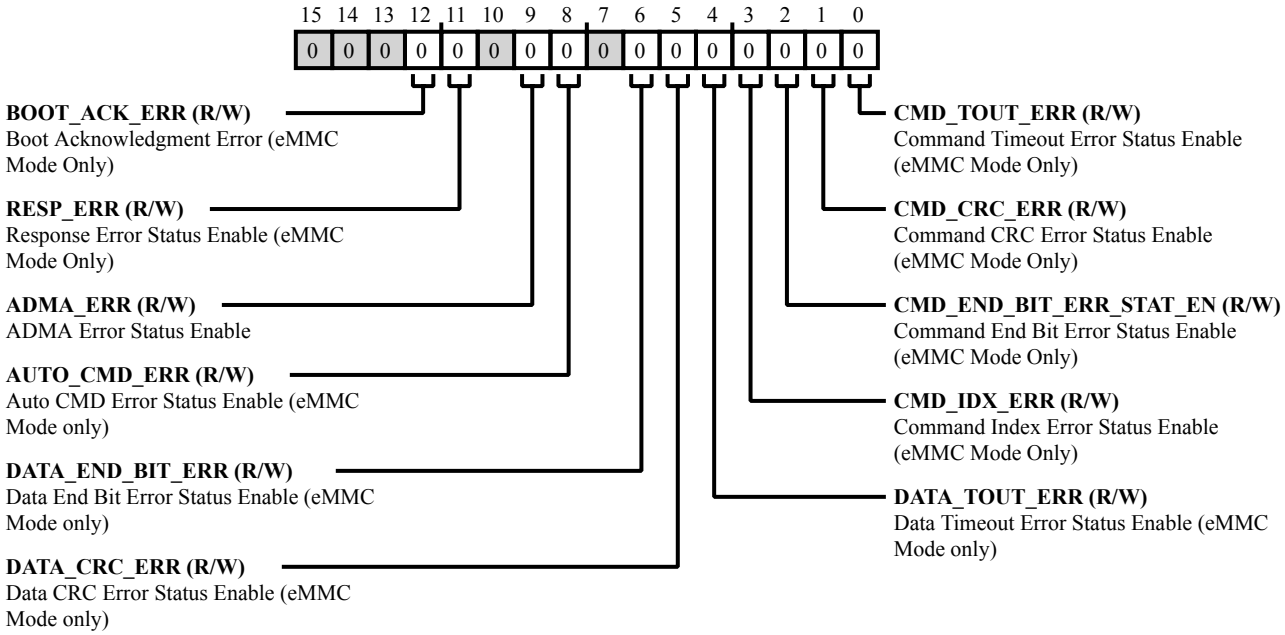

Figure 18-81: EMSI_ERR_STAT_EN Register Diagram

Table 18-59: EMSI_ERR_STAT_EN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W)	BOOT_ACK_ERR	Boot Acknowledgment Error (eMMC Mode Only). When the EMSI_ERR_STAT_EN.BOOT_ACK_ERR bit is set (=1), it enables setting the corresponding error in the EMSI_ERR_STAT register.	
		0	Masked
		1	Enabled
11 (R/W)	RESP_ERR	Response Error Status Enable (eMMC Mode Only). When the EMSI_ERR_STAT_EN.RESP_ERR bit is set (=1), it enables setting the corresponding error in the EMSI_ERR_STAT register.	
		0	Masked
		1	Enabled

Table 18-59: EMSI_ERR_STAT_EN Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W)	ADMA_ERR	ADMA Error Status Enable. When the EMSI_ERR_STAT_EN.ADMA_ERR bit is set (=1), it enables setting the corresponding error in the EMSI_ERR_STAT register.	
		0	Masked
		1	Enabled
8 (R/W)	AUTO_CMD_ERR	Auto CMD Error Status Enable (eMMC Mode only). When the EMSI_ERR_STAT_EN.AUTO_CMD_ERR bit is set (=1), it enables setting the corresponding error in the EMSI_ERR_STAT register.	
		0	Masked
		1	Enabled
6 (R/W)	DATA_END_BIT_ERR	Data End Bit Error Status Enable (eMMC Mode only). When the EMSI_ERR_STAT_EN.DATA_END_BIT_ERR bit is set (=1), it enables setting the corresponding error in the EMSI_ERR_STAT register.	
		0	Masked
		1	Enabled
5 (R/W)	DATA_CRC_ERR	Data CRC Error Status Enable (eMMC Mode only). When the EMSI_ERR_STAT_EN.DATA_CRC_ERR bit is set (=1), it enables setting the corresponding error in the EMSI_ERR_STAT register.	
		0	Masked
		1	Enabled
4 (R/W)	DATA_TOUT_ERR	Data Timeout Error Status Enable (eMMC Mode only). When the EMSI_ERR_STAT_EN.DATA_TOUT_ERR bit is set (=1), it enables setting the corresponding error in the EMSI_ERR_STAT register.	
		0	Masked
		1	Enabled
3 (R/W)	CMD_IDX_ERR	Command Index Error Status Enable (eMMC Mode Only). When the EMSI_ERR_STAT_EN.CMD_IDX_ERR bit is set (=1), it enables setting the corresponding error in the EMSI_ERR_STAT register.	
		0	Masked
		1	Enabled

Table 18-59: EMSI_ERR_STAT_EN Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W)	CMD_END_BIT_ERR_STAT_EN	Command End Bit Error Status Enable (eMMC Mode Only). When the `EMSI_ERR_STAT_EN.CMD_END_BIT_ERR_STAT_EN` bit is set (=1), it enables setting the corresponding error in the `EMSI_ERR_STAT` register.	
		0	Masked
		1	Enabled
1 (R/W)	CMD_CRC_ERR	Command CRC Error Status Enable (eMMC Mode Only). When the `EMSI_ERR_STAT_EN.CMD_CRC_ERR` bit is set (=1), it enables setting the corresponding error in the `EMSI_ERR_STAT` register.	
		0	Masked
		1	Enabled
0 (R/W)	CMD_TOUT_ERR	Command Timeout Error Status Enable (eMMC Mode Only). When the `EMSI_ERR_STAT_EN.CMD_TOUT_ERR` bit is set (=1), it enables setting the corresponding error in the `EMSI_ERR_STAT` register.	
		0	Masked
		1	Enabled

Error Interrupt Signal Enable Register

The EMSI_ERR_STAT_INTEN register is used to select the interrupt status that is notified to the core as an interrupt. All status bits share the same 1-bit interrupt line. Setting any of these bits to 1 enables the interrupt. This register is applicable for eMMC mode.

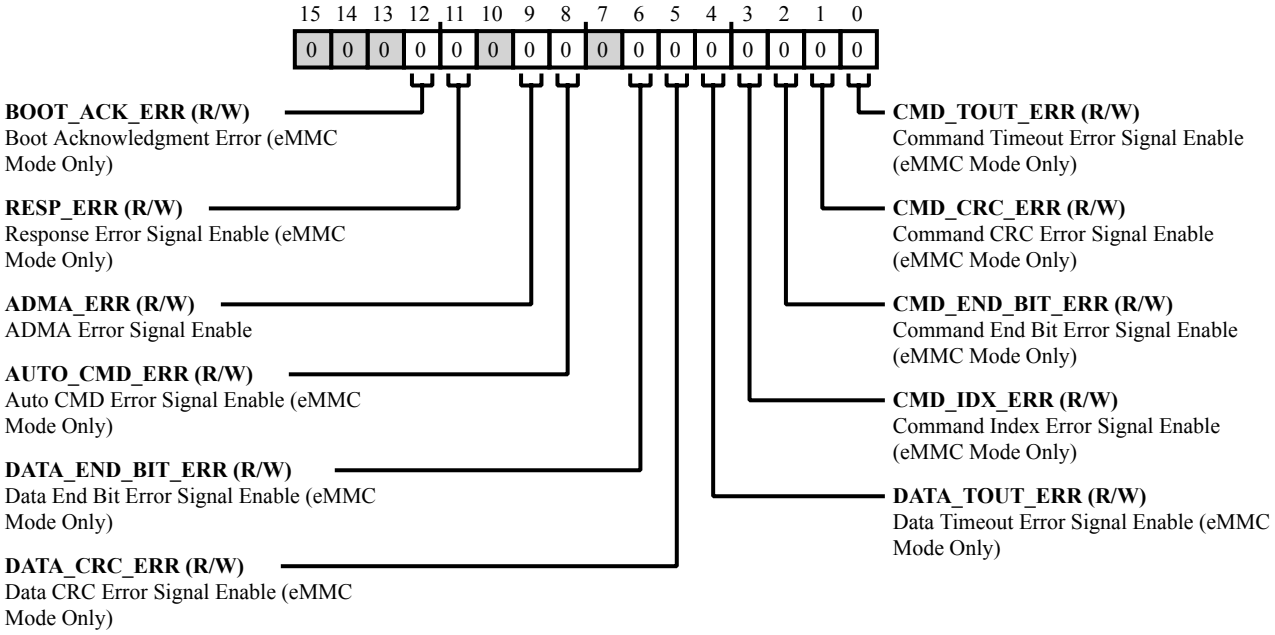

Figure 18-82: EMSI_ERR_STAT_INTEN Register Diagram

Table 18-60: EMSI_ERR_STAT_INTEN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W)	BOOT_ACK_ERR	Boot Acknowledgment Error (eMMC Mode Only). When the EMSI_ERR_STAT_INTEN.BOOT_ACK_ERR bit is set (=1), it enables generating an interrupt signal when the boot acknowledgment error in the EMSI_ERR_STAT register is set.	
		0	Masked
		1	Enabled
11 (R/W)	RESP_ERR	Response Error Signal Enable (eMMC Mode Only). When the EMSI_ERR_STAT_INTEN.RESP_ERR bit is set (=1), it enables generating an interrupt signal error in the corresponding bit in the EMSI_ERR_STAT register.	
		0	Masked
		1	Enabled

Table 18-60: EMSI_ERR_STAT_INTEN Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W)	ADMA_ERR	ADMA Error Signal Enable. When the EMSI_ERR_STAT_INTEN.ADMA_ERR bit is set (=1), it enables generating an interrupt signal error in the corresponding bit in the EMSI_ERR_STAT register.	
		0	Masked
		1	Enabled
8 (R/W)	AUTO_CMD_ERR	Auto CMD Error Signal Enable (eMMC Mode Only). When the EMSI_ERR_STAT_INTEN.AUTO_CMD_ERR bit is set (=1), it enables generating an interrupt signal error in the corresponding bit in the EMSI_ERR_STAT register.	
		0	Masked
		1	Enabled
6 (R/W)	DATA_END_BIT_ERR	Data End Bit Error Signal Enable (eMMC Mode Only). When the EMSI_ERR_STAT_INTEN.DATA_END_BIT_ERR bit is set (=1), it enables generating an interrupt signal error in the corresponding bit in the EMSI_ERR_STAT register.	
		0	Masked
		1	Enabled
5 (R/W)	DATA_CRC_ERR	Data CRC Error Signal Enable (eMMC Mode Only). When the EMSI_ERR_STAT_INTEN.DATA_CRC_ERR bit is set (=1), it enables generating an interrupt signal error in the corresponding bit in the EMSI_ERR_STAT register.	
		0	Masked
		1	Enabled
4 (R/W)	DATA_TOUT_ERR	Data Timeout Error Signal Enable (eMMC Mode Only). When the EMSI_ERR_STAT_INTEN.DATA_TOUT_ERR bit is set (=1), it enables generating an interrupt signal error in the corresponding bit in the EMSI_ERR_STAT register.	
		0	Masked
		1	Enabled

Table 18-60: EMSI_ERR_STAT_INTEN Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	CMD_IDX_ERR	Command Index Error Signal Enable (eMMC Mode Only). When the EMSI_ERR_STAT_INTEN.CMD_IDX_ERR bit is set (=1), it enables generating an interrupt signal error in the corresponding bit in the EMSI_ERR_STAT register.	
		0	No Error
		1	Error
2 (R/W)	CMD_END_BIT_ERR	Command End Bit Error Signal Enable (eMMC Mode Only). When the EMSI_ERR_STAT_INTEN.CMD_END_BIT_ERR bit is set (=1), it enables generating an interrupt signal error in the corresponding bit in the EMSI_ERR_STAT register.	
		0	Masked
		1	Enabled
1 (R/W)	CMD_CRC_ERR	Command CRC Error Signal Enable (eMMC Mode Only). When the EMSI_ERR_STAT_INTEN.CMD_CRC_ERR bit is set (=1), it enables generating an interrupt signal error in the corresponding bit in the EMSI_ERR_STAT register.	
		0	Masked
		1	Enabled
0 (R/W)	CMD_TOUT_ERR	Command Timeout Error Signal Enable (eMMC Mode Only). When the EMSI_ERR_STAT_INTEN.CMD_TOUT_ERR bit is set (=1), it enables generating an interrupt signal error in the corresponding bit in the EMSI_ERR_STAT register.	
		0	Masked
		1	Enabled

Force Event Register for Auto CMD Error Status Register

The EMSI_FRC_AUTOCMDSTAT register is not a physically implemented but is an address at which the Auto CMD Error Status register (EMSI_AUTOCMD_STAT) can be written.This register is applicable for an eMMC mode. Setting a bit in this register sets the corresponding bit in the EMSI_AUTOCMD_STAT register.

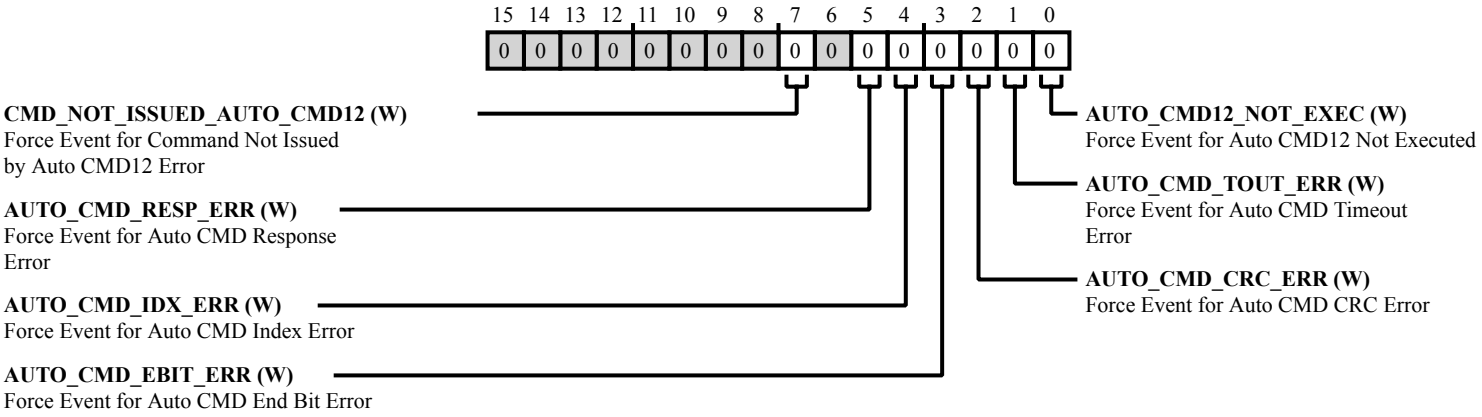

Figure 18-83: EMSI_FRC_AUTOCMDSTAT Register Diagram

Table 18-61: EMSI_FRC_AUTOCMDSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (RX/W)	CMD_NOT_ISSUED_AUTO_CMD12	Force Event for Command Not Issued by Auto CMD12 Error. Setting the EMSI_FRC_AUTOCMDSTAT.CMD_NOT_ISSUED_AUTO_CMD12 bit sets the corresponding bit in the EMSI_AUTOCMD_STAT register.	
		0	Not Affected
		1	Command Not Issued by Auto CMD12 Error Status is Set
5 (RX/W)	AUTO_CMD_RESP_ERR	Force Event for Auto CMD Response Error. Setting the EMSI_FRC_AUTOCMDSTAT.AUTO_CMD_RESP_ERR bit sets the corresponding bit in the EMSI_AUTOCMD_STAT register.	
		0	Not Affected
		1	Auto CMD Response Error Status is Set
4 (RX/W)	AUTO_CMD_IDX_ERR	Force Event for Auto CMD Index Error. Setting the EMSI_FRC_AUTOCMDSTAT.AUTO_CMD_IDX_ERR bit sets the corresponding bit in the EMSI_AUTOCMD_STAT register.	
		0	Not Affected
		1	Auto CMD Index Error Status is Set

Table 18-61: EMSI_FRC_AUTOCMDSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (RX/W)	AUTO_CMD_EBIT_ERR	Force Event for Auto CMD End Bit Error. Setting the EMSI_FRC_AUTOCMDSTAT.AUTO_CMD_EBIT_ERR bit sets the corresponding bit in the EMSI_AUTOCMD_STAT register.	
		0	Not Affected
		1	Auto CMD End Bit Error Status is Set
2 (RX/W)	AUTO_CMD_CRC_ERR	Force Event for Auto CMD CRC Error. Setting the EMSI_FRC_AUTOCMDSTAT.AUTO_CMD_CRC_ERR bit sets the corresponding bit in the EMSI_AUTOCMD_STAT register.	
		0	Not Affected
		1	Auto CMD CRC Error Status is Set
1 (RX/W)	AUTO_CMD_TOUT_ERR	Force Event for Auto CMD Timeout Error. Setting the EMSI_FRC_AUTOCMDSTAT.AUTO_CMD_TOUT_ERR bit sets the corresponding bit in the EMSI_AUTOCMD_STAT register.	
		0	Not Affected
		1	Auto CMD Timeout Error Status is Set
0 (RX/W)	AUTO_CMD12_NOT_EXEC	Force Event for Auto CMD12 Not Executed. Setting the EMSI_FRC_AUTOCMDSTAT.AUTO_CMD12_NOT_EXEC bit sets the corresponding bit in the EMSI_AUTOCMD_STAT register.	
		0	Not Affected
		1	Auto CMD12 Not Executed Status is Set

Force Event Register for Error Interrupt Status

The EMSI_FRC_ERRSTAT register is not physically implemented but is an address at which the error interrupt status register (EMSI_ERR_STAT) can be written. The effect of a write to this address is reflected in the (EMSI_ERR_STAT) register if the corresponding bit of the error interrupt status enable register (EMSI_ERR_STAT_EN) is set. This register is applicable for an eMMC mode.

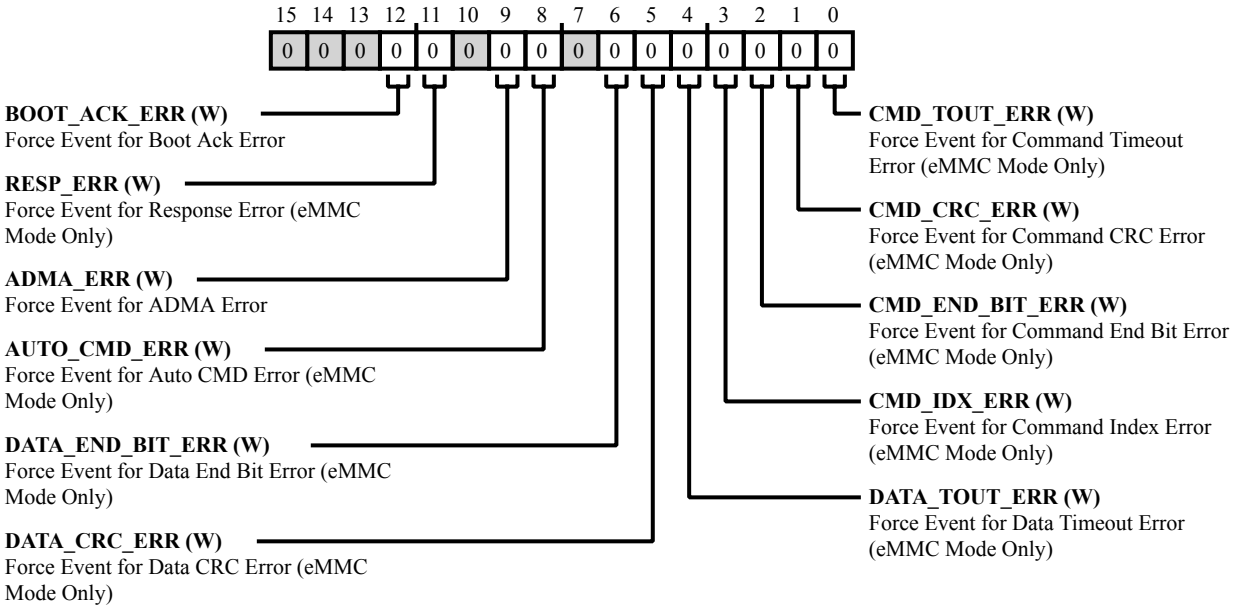

Figure 18-84: EMSI_FRC_ERRSTAT Register Diagram

Table 18-62: EMSI_FRC_ERRSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (RX/W)	BOOT_ACK_ERR	Force Event for Boot Ack Error. A write to the EMSI_FRC_ERRSTAT.BOOT_ACK_ERR address is reflected in the EMSI_ERR_STAT register if the corresponding bit of the EMSI_ERR_STAT_EN register is set.	
		0	Not Affected
		1	Boot Ack Error Status is Set
11 (RX/W)	RESP_ERR	Force Event for Response Error (eMMC Mode Only). A write to the EMSI_FRC_ERRSTAT.RESP_ERR address is reflected in the EMSI_ERR_STAT register if the corresponding bit of the EMSI_ERR_STAT_EN register is set.	
		0	Not Affected
		1	Response Error Status is Set

Table 18-62: EMSI_FRC_ERRSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (RX/W)	ADMA_ERR	Force Event for ADMA Error. A write to the EMSI_FRC_ERRSTAT.ADMA_ERR address is reflected in the EMSI_ERR_STAT register if the corresponding bit of the EMSI_ERR_STAT_EN register is set.	
		0	Not Affected
		1	ADMA Error Status is Set
8 (RX/W)	AUTO_CMD_ERR	Force Event for Auto CMD Error (eMMC Mode Only). A write to the EMSI_FRC_ERRSTAT.AUTO_CMD_ERR address is reflected in the EMSI_ERR_STAT register if the corresponding bit of the EMSI_ERR_STAT_EN register is set.	
		0	Not Affected
		1	Auto CMD Error Status is Set
6 (RX/W)	DATA_END_BIT_ERR	Force Event for Data End Bit Error (eMMC Mode Only). A write to the EMSI_FRC_ERRSTAT.DATA_END_BIT_ERR address is reflected in the EMSI_ERR_STAT register if the corresponding bit of the EMSI_ERR_STAT_EN register is set.	
		0	Not Affected
		1	Data End Bit Error Status is Set
5 (RX/W)	DATA_CRC_ERR	Force Event for Data CRC Error (eMMC Mode Only). A write to the EMSI_FRC_ERRSTAT.DATA_CRC_ERR address is reflected in the EMSI_ERR_STAT register if the corresponding bit of the EMSI_ERR_STAT_EN register is set.	
		0	Not Affected
		1	Data CRC Error Status is Set
4 (RX/W)	DATA_TOUT_ERR	Force Event for Data Timeout Error (eMMC Mode Only). A write to the EMSI_FRC_ERRSTAT.DATA_TOUT_ERR address is reflected in the EMSI_ERR_STAT register if the corresponding bit of the EMSI_ERR_STAT_EN register is set.	
		0	Not Affected
		1	Data Timeout Error Status is Set

Table 18-62: EMSI_FRC_ERRSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (RX/W)	CMD_IDX_ERR	Force Event for Command Index Error (eMMC Mode Only). A write to the EMSI_FRC_ERRSTAT.CMD_IDX_ERR address is reflected in the EMSI_ERR_STAT register if the corresponding bit of the EMSI_ERR_STAT_EN register is set.	
		0	Not Affected
		1	Command Index Error Status is Set
2 (RX/W)	CMD_END_BIT_ERR	Force Event for Command End Bit Error (eMMC Mode Only). A write to the EMSI_FRC_ERRSTAT.CMD_END_BIT_ERR address is reflected in the EMSI_ERR_STAT register if the corresponding bit of the EMSI_ERR_STAT_EN register is set.	
		0	Not Affected
		1	Command End Bit Error Status is Set
1 (RX/W)	CMD_CRC_ERR	Force Event for Command CRC Error (eMMC Mode Only). A write to the EMSI_FRC_ERRSTAT.CMD_CRC_ERR address is reflected in the EMSI_ERR_STAT register if the corresponding bit of the EMSI_ERR_STAT_EN register is set.	
		0	Not Affected
		1	Command CRC Error Status is Set
0 (RX/W)	CMD_TOUT_ERR	Force Event for Command Timeout Error (eMMC Mode Only). A write to the EMSI_FRC_ERRSTAT.CMD_TOUT_ERR address is reflected in the EMSI_ERR_STAT register if the corresponding bit of the EMSI_ERR_STAT_EN register is set.	
		0	Not Affected
		1	Command Timeout Error Status is Set

Interrupt Status Register

The EMSI_ISTAT register reflects the interrupt status. This register is applicable for eMMC mode.

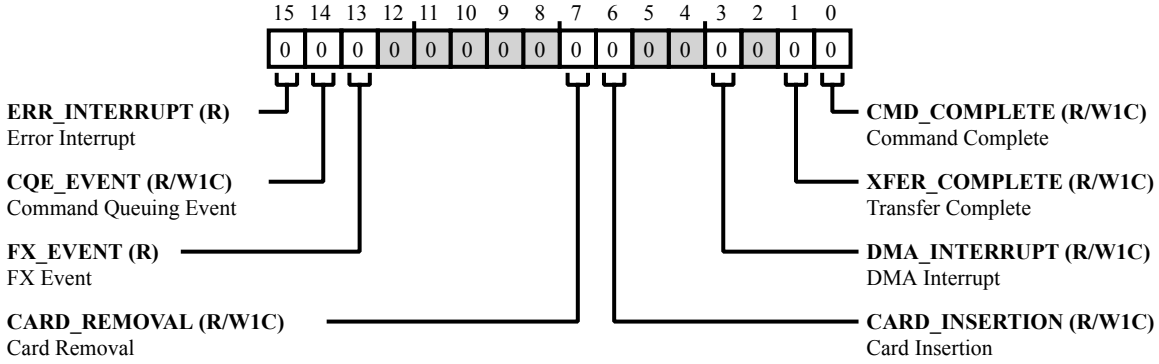

Figure 18-85: EMSI_ISTAT Register Diagram

Table 18-63: EMSI_ISTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/NW)	ERR_INTERRUPT	Error Interrupt. The EMSI_ISTAT.ERR_INTERRUPT bit is set if any bit in the EMSI_ERR_STAT register are set.	
		0	No Error
		1	Error
14 (R/W1C)	CQE_EVENT	Command Queuing Event. The EMSI_ISTAT.CQE_EVENT status bit is set if command queuing related event has occurred in eMMC mode. Read the EMSI_CQ_ISTAT/EMSI_CQ_TERRINFO registers for more details.	
		0	No Event
		1	Command Queuing Event is Detected
13 (R/NW)	FX_EVENT	FX Event. The EMSI_ISTAT.FX_EVENT status bit is set when R[14] of the response register is set (=1) and response type R1 is cleared (=0) in the EMSI_TRNSFRMODE register. This interrupt is used with the response check function.	
		0	No Event
		1	FX Event is Detected

Table 18-63: EMSI_ISTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W1C)	CARD_REMOVAL	Card Removal. The EMSI_ISTAT.CARD_REMOVAL bit is set if the card inserted in the present state register changes from 1 to 0.	
		0	Card State Stable or Debouncing
		1	Card Removed
6 (R/W1C)	CARD_INSERTION	Card Insertion. The EMSI_ISTAT.CARD_INSERTION bit is set if the card inserted in the present state register changes from 0 to 1.	
		0	Card State Stable or Debouncing
		1	Card Inserted
3 (R/W1C)	DMA_INTERRUPT	DMA Interrupt. The EMSI_ISTAT.DMA_INTERRUPT bit is set if the eMSI controller detects the SDMA Buffer Boundary during transfer. In case of ADMA, by setting the Int field in the descriptor table, the eMSI controller generates this interrupt. This interrupt is not generated after a transfer complete.	
		0	No DMA Interrupt
		1	DMA Interrupt is Generated
1 (R/W1C)	XFER_COMPLETE	Transfer Complete. The EMSI_ISTAT.XFER_COMPLETE bit is set when a read/write transfer and a command with status busy is completed.	
		0	Not Complete
		1	Command Execution is Completed
0 (R/W1C)	CMD_COMPLETE	Command Complete. In an eMMC Mode, the EMSI_ISTAT.CMD_COMPLETE bit is set when the end bit of a response except for Auto CMD12 and Auto CMD23. This interrupt is not generated when the EMSI_TRNSFRMODE.RESP_INT_DIS bit is set (=1).	
		0	No Command Complete
		1	Command Complete

Interrupt Status Enable Register

The EMSI_ISTAT_EN register enables/masks the interrupt status for the corresponding bit in the interrupt status register (EMSI_ISTAT) register. This register is applicable for eMMC mode.

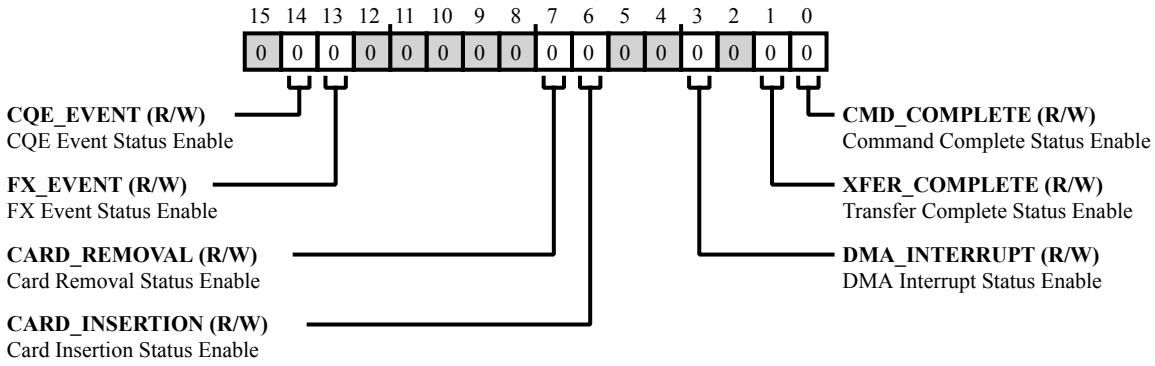

Figure 18-86: EMSI_ISTAT_EN Register Diagram

Table 18-64: EMSI_ISTAT_EN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
14 (R/W)	CQE_EVENT	CQE Event Status Enable. The EMSI_ISTAT_EN.CQE_EVENT bit, when set (=1), enables the interrupt status for the corresponding bit in the EMSI_ISTAT register.	
		0	Masked
		1	Enabled
13 (R/W)	FX_EVENT	FX Event Status Enable. The EMSI_ISTAT_EN.FX_EVENT bit is added from Version 4.10.	
		0	Masked
		1	Enabled
7 (R/W)	CARD_REMOVAL	Card Removal Status Enable. The EMSI_ISTAT_EN.CARD_REMOVAL bit, when set (=1), enables the interrupt status for the corresponding bit in the EMSI_ISTAT register.	
		0	Masked
		1	Enabled
6 (R/W)	CARD_INSERTION	Card Insertion Status Enable. The EMSI_ISTAT_EN.CARD_INSERTION bit, when set (=1), enables the interrupt status for the corresponding bit in the EMSI_ISTAT register.	
		0	Masked
		1	Enabled

Table 18-64: EMSI_ISTAT_EN Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	DMA_INTERRUPT	DMA Interrupt Status Enable. The `EMSI_ISTAT_EN.DMA_INTERRUPT` bit, when set (=1), enables the interrupt status for the corresponding bit in the `EMSI_ISTAT` register.	
		0	Masked
		1	Enabled
1 (R/W)	XFER_COMPLETE	Transfer Complete Status Enable. The `EMSI_ISTAT_EN.XFER_COMPLETE` bit, when set (=1), enables the interrupt status for the corresponding bit in the `EMSI_ISTAT` register.	
		0	Masked
		1	Enabled
0 (R/W)	CMD_COMPLETE	Command Complete Status Enable. The `EMSI_ISTAT_EN.CMD_COMPLETE` bit, when set (=1), enables the interrupt status for the corresponding bit in the `EMSI_ISTAT` register.	
		0	Masked
		1	Enabled

Interrupt Signal Enable Register

The EMSI_ISTAT_INTEN register is used to select the interrupt status that is indicated to the core as the interrupt. All these status bits share the same 1-bit interrupt line. Setting any of these bits to 1 enables interrupt generation. This register is applicable for eMMC mode.

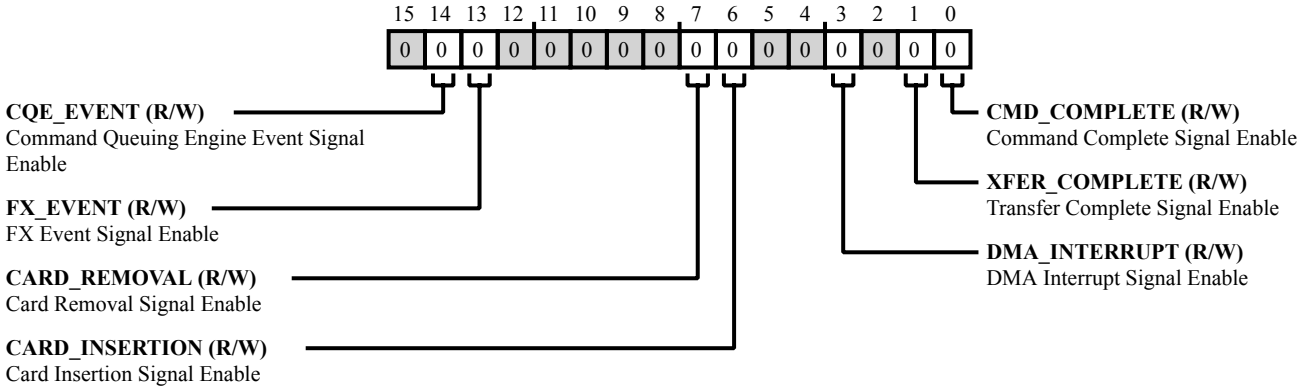

Figure 18-87: EMSI_ISTAT_INTEN Register Diagram

Table 18-65: EMSI_ISTAT_INTEN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
14 (R/W)	CQE_EVENT	Command Queuing Engine Event Signal Enable. When the EMSI_ISTAT_INTEN.CQE_EVENT bit is set (=1) it selects the interrupt status that is indicated to the core.	
		0	Masked
		1	Enabled
13 (R/W)	FX_EVENT	FX Event Signal Enable. When the EMSI_ISTAT_INTEN.FX_EVENT bit is set (=1) it selects the interrupt status that is indicated to the core.	
		0	Masked
		1	Enabled
7 (R/W)	CARD_REMOVAL	Card Removal Signal Enable. When the EMSI_ISTAT_INTEN.CARD_REMOVAL bit is set (=1) it selects the interrupt status that is indicated to the core.	
		0	Masked
		1	Enabled

Table 18-65: EMSI_ISTAT_INTEN Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6 (R/W)	CARD_INSERTION	Card Insertion Signal Enable. When the `EMSI_ISTAT_INTEN.CARD_INSERTION` bit is set (=1) it selects the interrupt status that is indicated to the core.	
		0	Masked
		1	Enabled
3 (R/W)	DMA_INTERRUPT	DMA Interrupt Signal Enable. When the `EMSI_ISTAT_INTEN.DMA_INTERRUPT` bit is set (=1) it selects the interrupt status that is indicated to the core.	
		0	Masked
		1	Enabled
1 (R/W)	XFER_COMPLETE	Transfer Complete Signal Enable. When the `EMSI_ISTAT_INTEN.XFER_COMPLETE` bit is set (=1) it selects the interrupt status that is indicated to the core.	
		0	Masked
		1	Enabled
0 (R/W)	CMD_COMPLETE	Command Complete Signal Enable. When the `EMSI_ISTAT_INTEN.CMD_COMPLETE` bit is set (=1) it selects the interrupt status that is indicated to the core.	
		0	Masked
		1	Enabled

Preset Value for Default Speed

The EMSI_PRESET_DS register defines preset value for default speed mode in SD mode.

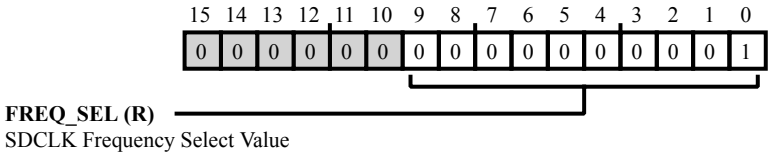

Figure 18-88: EMSI_PRESET_DS Register Diagram

Table 18-66: EMSI_PRESET_DS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
9:0 (R/NW)	FREQ_SEL	SDCLK Frequency Select Value. The EMSI_PRESET_DS.FREQ_SEL bits configure the 10-bit preset value that is set in the EMSI_CLK_CTL.FREQ_SEL bit field.

Preset Value for HSDDR

The EMSI_PRESET_HSDDR register defines the preset value for high speed DDR speed mode in eMMC mode.

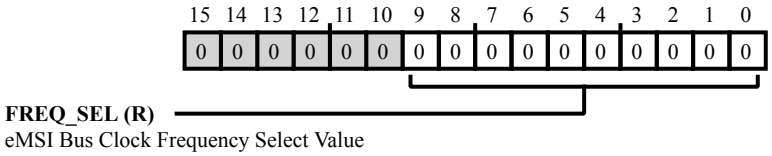

Figure 18-89: EMSI_PRESET_HSDDR Register Diagram

Table 18-67: EMSI_PRESET_HSDDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
9:0 (R/NW)	FREQ_SEL	eMSI Bus Clock Frequency Select Value. The EMSI_PRESET_HSDDR.FREQ_SEL bits specify a 10-bit preset value that must be set in the EMSI_CLK_CTL.FREQ_SEL bit field, as described by an eMSI system.

Preset Value for HSSDR

The EMSI_PRESET_HSSDR register defines the preset value for high speed SDR speed mode in eMMC mode.

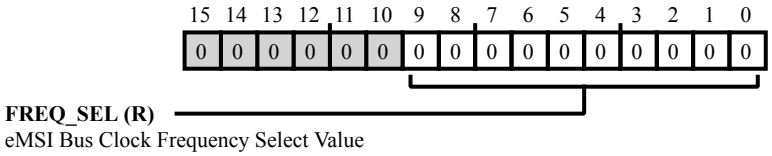

Figure 18-90: EMSI_PRESET_HSSDR Register Diagram

Table 18-68: EMSI_PRESET_HSSDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
9:0 (R/NW)	FREQ_SEL	eMSI Bus Clock Frequency Select Value. The EMSI_PRESET_HSSDR.FREQ_SEL bits specify a 10-bit preset value that must be set in the EMSI_CLK_CTL.FREQ_SEL bit field, as described by a eMSI system.

Preset Value for Initialization

The EMSI_PRESET_INIT register defines Preset Value for Initialization in eMMC mode.

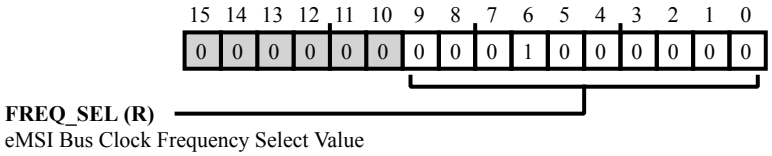

Figure 18-91: EMSI_PRESET_INIT Register Diagram

Table 18-69: EMSI_PRESET_INIT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
9:0 (R/NW)	FREQ_SEL	eMSI Bus Clock Frequency Select Value. The EMSI_PRESET_INIT.FREQ_SEL bits configure the 10-bit preset value that is set in the EMSI_CLK_CTL.FREQ_SEL bit field. The value should be written manually in the EMSI_CLK_CTL.FREQ_SEL bit field for eMSI bus clock initialization.

Preset Value for Legacy Mode

The EMSI_PRESET_LEGACY register defines the preset value for legacy speed mode in eMMC mode.

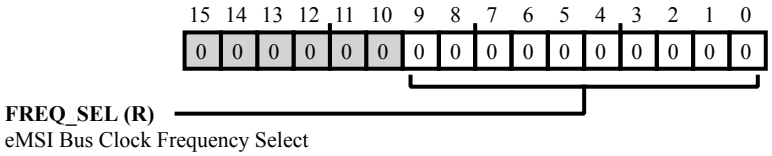

Figure 18-92: EMSI_PRESET_LEGACY Register Diagram

Table 18-70: EMSI_PRESET_LEGACY Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
9:0 (R/NW)	FREQ_SEL	eMSI Bus Clock Frequency Select. The EMSI_PRESET_LEGACY.FREQ_SEL bits specify a 10-bit preset value that must be set in the EMSI_CLK_CTL.FREQ_SEL bit field, as described by a eMSI system.

Present State Register

The EMSI_PSTATE register indicates the present status of the eMSI controller. This register is applicable for eMMC mode.

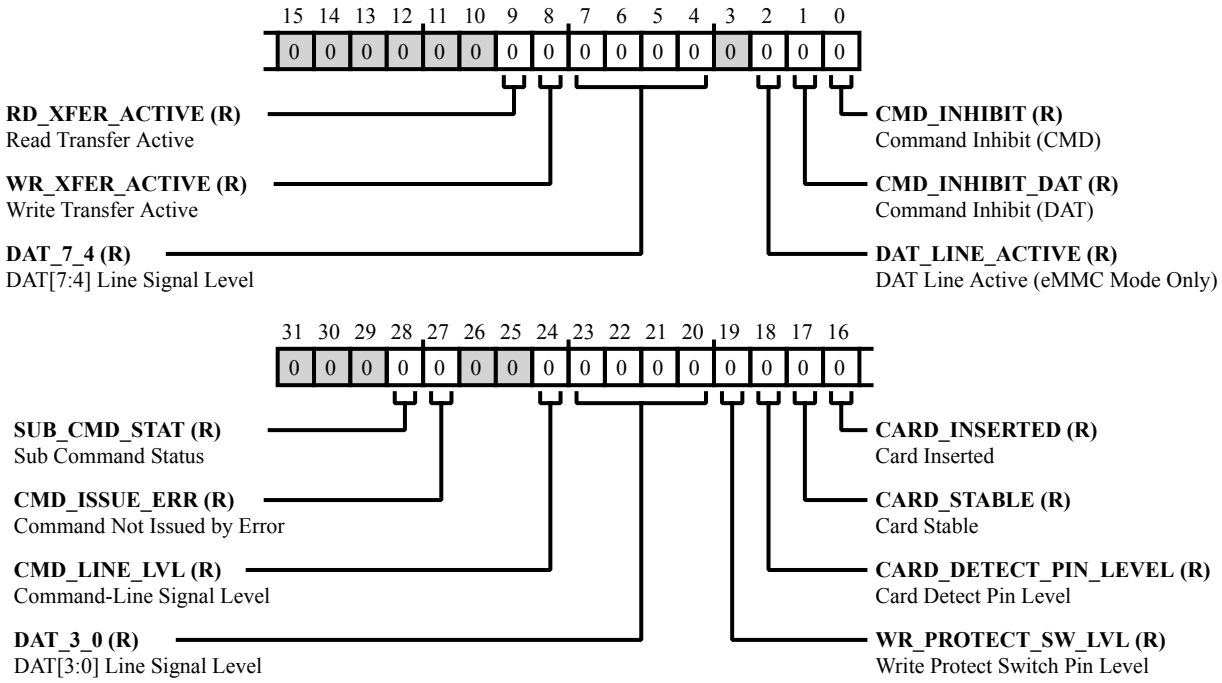

Figure 18-93: EMSI_PSTATE Register Diagram

Table 18-71: EMSI_PSTATE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
28 (R/NW)	SUB_CMD_STAT	Sub Command Status. The EMSI_PSTATE.SUB_CMD_STAT bit is used to distinguish between a main command and a sub command status.	
		0	Main Command Status
		1	Sub Command Status
27 (R/NW)	CMD_ISSUE_ERR	Command Not Issued by Error. The EMSI_PSTATE.CMD_ISSUE_ERR bit is set if a command cannot be issued after setting the command register due to an error except the Auto CMD12 error.	
		0	No Error for Issuing a Command
		1	Command Cannot Be Issued

Table 18-71: EMSI_PSTATE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
24 (R/NW)	CMD_LINE_LVL	Command-Line Signal Level. The EMSI_PSTATE.CMD_LINE_LVL bit is used to check the CMD line level to recover from errors and for debugging. The EMSI_PSTATE.CMD_LINE_LVL field reflect the value of the CMD signal.	
23:20 (R/NW)	DAT_3_0	DAT[3:0] Line Signal Level. The EMSI_PSTATE.DAT_3_0 bit is used to check the DAT line level to recover from errors and for debugging.	
19 (R/NW)	WR_PROTECT_SW_LVL	Write Protect Switch Pin Level. The EMSI_PSTATE.WR_PROTECT_SW_LVL bit is supported only for memory and combo cards. The EMSI_PSTATE.WR_PROTECT_SW_LVL bit reflects the synchronized value of the WP signal.	
		0	Write Protected
		1	Write Enabled
18 (R/NW)	CARD_DE-TECT_PIN_LEVEL	Card Detect Pin Level. The EMSI_PSTATE.CARD_DETECT_PIN_LEVEL bit reflects the inverse synchronized value of the CD signal.	
		0	No Card Present
		1	Card Present
17 (R/NW)	CARD_STABLE	Card Stable. The EMSI_PSTATE.CARD_STABLE bit indicates the stability of the Card Detect Pin Level. A card is not detected if the EMSI_PSTATE.CARD_STABLE bit is set (=1) and the value of the EMSI_PSTATE.CARD_INSERTED bit is 0.	
		0	Reset or Debouncing
		1	No Card or Inserted
16 (R/NW)	CARD_INSERTED	Card Inserted. The EMSI_PSTATE.CARD_INSERTED bit indicates whether a card has been inserted. The eMSI controller debounces this signal so that the host driver need not wait for it to stabilize.	
		0	Reset, Debouncing, or No Card
		1	Card Inserted
9 (R/NW)	RD_XFER_ACTIVE	Read Transfer Active. The EMSI_PSTATE.RD_XFER_ACTIVE bit indicates whether a read transfer is active for eMMC mode.	
		0	No Valid Data
		1	Transferring Data

Table 18-71: EMSI_PSTATE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/NW)	WR_XFER_ACTIVE	Write Transfer Active. The EMSI_PSTATE.WR_XFER_ACTIVE status indicates whether a write transfer is active for eMMC mode.	
		0	No Valid Data
		1	Transferring Data
7:4 (R/NW)	DAT_7_4	DAT[7:4] Line Signal Level. The EMSI_PSTATE.DAT_7_4 bit is used to check the DAT line level to recover from errors and for debugging.	
2 (R/NW)	DAT_LINE_ACTIVE	DAT Line Active (eMMC Mode Only). The EMSI_PSTATE.DAT_LINE_ACTIVE bit indicates whether one of the DAT lines on the eMMC bus is in use. In the case of read transactions, the EMSI_PSTATE.DAT_LINE_ACTIVE bit indicates whether a read transfer is executing on the eMMC bus. In the case of write transactions, the EMSI_PSTATE.DAT_LINE_ACTIVE bit indicates whether a write transfer is executing on the eMMC bus. For a command with busy, this status indicates whether the command executing busy is executing on an eMMC bus.	
		0	DAT Line Inactive
		1	DAT Line Active
1 (R/NW)	CMD_INHIBIT_DAT	Command Inhibit (DAT). The EMSI_PSTATE.CMD_INHIBIT_DAT bit is applicable for eMMC mode and is generated if either DAT line active or read transfer active is set (=1). If the EMSI_PSTATE.CMD_INHIBIT_DAT bit is cleared (=0) it indicates that the eMSI controller can issue subsequent eMMC commands.	
		0	Can Issue Command Which Used DAT Line
		1	Cannot Issue Command Which Used DAT Line

Table 18-71: EMSI_PSTATE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/NW)	CMD_INHIBIT	Command Inhibit (CMD). The `EMSI_PSTATE.CMD_INHIBIT` bit indicates the following : For eMMC mode, if the `EMSI_PSTATE.CMD_INHIBIT` bit is cleared (=0) it indicates that the CMD line is not in use and the eMSI controller can issue an eMMC command using the CMD line. The `EMSI_PSTATE.CMD_INHIBIT` bit is set when the command register is written. The `EMSI_PSTATE.CMD_INHIBIT` bit is cleared when the command response is received. The `EMSI_PSTATE.CMD_INHIBIT` bit is not cleared by the response of auto CMD12/23 but cleared by the response of read/write command.	
		0	eMSI Controller is Ready to Issue a Command
		1	eMSI Controller is Not Ready to Issue a Command

Response Register 0

The EMSI_RESP0 register stores 39-08 bits of the Response Field for an eMMC mode. The response for an eMMC command can be a maximum of 128 bits. These 128 bits are segregated into four 32-bit registers, EMSI_RESP0-3.

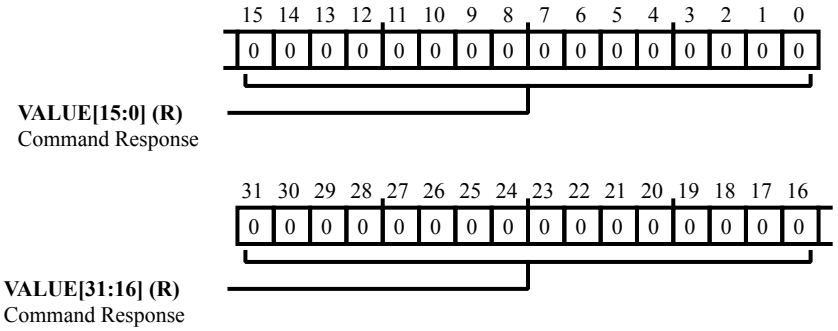

Figure 18-94: EMSI_RESP0 Register Diagram

Table 18-72: EMSI_RESP0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Command Response. The EMSI_RESP0.VALUE bits reflect 39-8 bits of eMMC Response Field. Note: For Auto CMD, the 32-bit response (bits 39-8 of the Response Field) is updated in the EMSI_RESP3 register.

Response Register 1

The EMSI_RESP1 register stores bits 71-40 of the Response Field for eMMC mode. This register is used to store the response from the eMMC device. The response can be a maximum of 128 bits. These 128 bits are segregated into four 32-bit registers EMSI_RESP0-3.

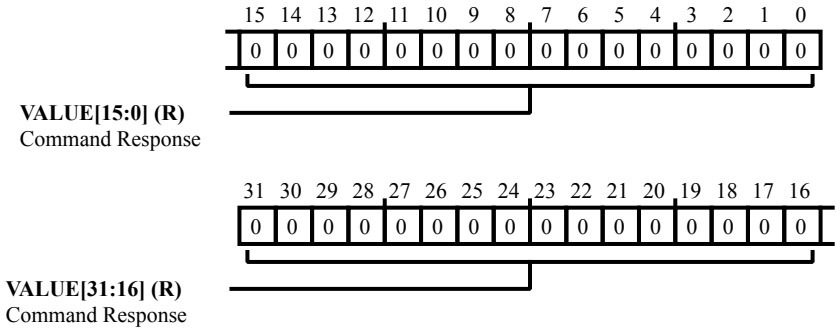

Figure 18-95: EMSI_RESP1 Register Diagram

Table 18-73: EMSI_RESP1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Command Response. The EMSI_RESP1.VALUE bits reflect bits 71-40 of the eMMC Response Field.

Response Register 2

The EMSI_RESP2 register stores 103-72 bits of the Response Field for an eMMC mode. The response for eMMC command can be a maximum of 128 bits. These 128 bits are segregated into four 32-bit registers: EMSI_RESP0-3

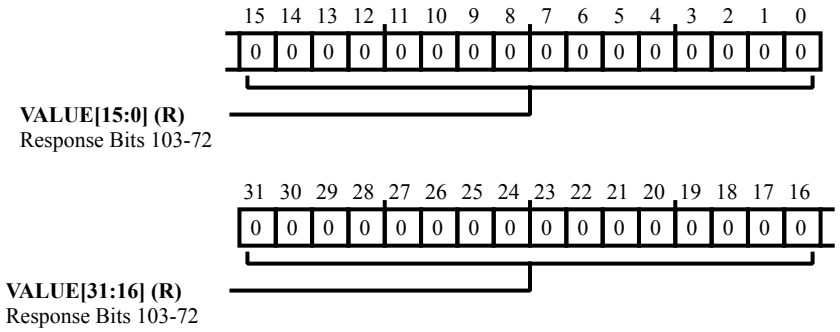

Figure 18-96: EMSI_RESP2 Register Diagram

Table 18-74: EMSI_RESP2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Response Bits 103-72. The EMSI_RESP2.VALUE bit field stores bits 103-72 of the Response Field for eMMC mode. The response for eMMC command can be a maximum of 128 bits.

Response Register 3

The EMSI_RESP3 register stores bits 135-104 of the Response Field for an eMMC mode. The eMMC response can be a maximum of 128 bits. These 128 bits are segregated into four 32-bit registers: EMSI_RESP0-3.

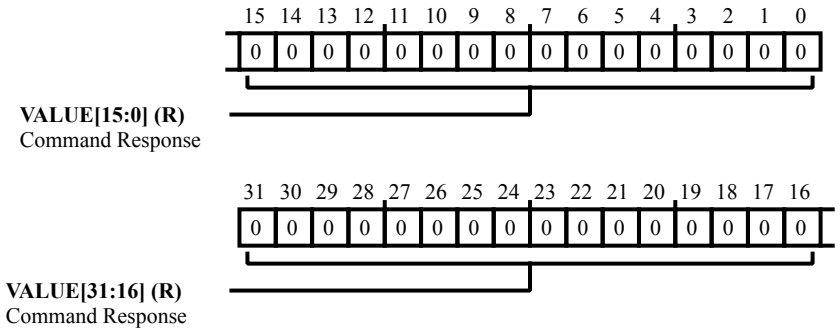

Figure 18-97: EMSI_RESP3 Register Diagram

Table 18-75: EMSI_RESP3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Command Response. These bits reflect bits 135-104 of eMMC Response Field. Note: For Auto CMD, this register also reflects the 32-bit response (bits 39-8 of the Response Field).

SDMA System Address Register

The EMSI_SDMA_ADDR register is used to configure a 32-bit block count or a SDMA system address based on the Host Version 4 Enable bit in the EMSI_CTL2 register. This register is applicable for eMMC mode.

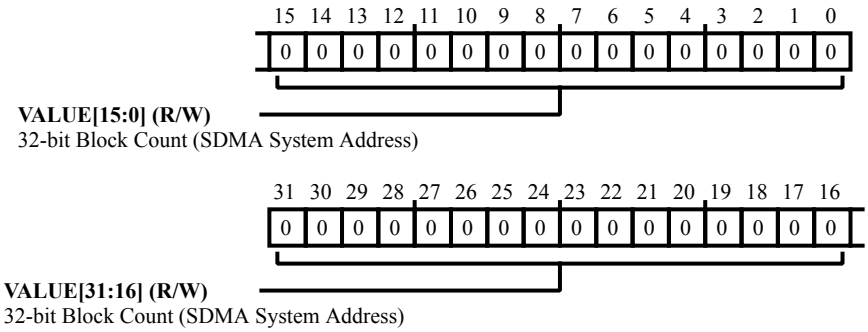

Figure 18-98: EMSI_SDMA_ADDR Register Diagram

Table 18-76: EMSI_SDMA_ADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	32-bit Block Count (SDMA System Address). The `EMSI_SDMA_ADDR.VALUE` bit field contains the system memory address for an SDMA transfer in the 32-bit addressing mode (Host Version 4 Enable = 0). When the eMSI controller stops a SDMA transfer, this bit field points to the system address of the next contiguous data position. It can be accessed only if no transaction is executing. Reading this register during data transfers may return an invalid value. 32-bit Block Count (Host Version 4 Enable = 1): From the SD Host Controller Version 4.10 specification, this register is redefined as 32-bit block count. The eMSI controller decrements the block count of this register for every block transfer and the data transfer stops when the count reaches zero. Following are the values for BLOCKCNT_SDMASA: - 0xFFFF_FFFF: 4G - 1 Block - ... - 0x0000_0002: 2 Blocks - 0x0000_0001: 1 Block - 0x0000_0000: Stop Count Note: - For Host Version 4 Enable = 0, the host driver does not program the system address in this register while operating in ADMA mode. The system address must be programmed in the ADMA System Address register. - For Host Version 4 Enable = 0, the host driver programs a non-zero 32-bit block count value in this register when Auto CMD23 is enabled for ADMA modes. Auto CMD23 cannot be used with SDMA. - This register must be programmed with a non-zero value for data transfer if the 32-bit block count register is used instead of the 16-bit block count register.

Software Reset Register

The EMSI_SWRST register is used to generate a reset pulse by writing 1 to each bit of this register. After completing the reset, the eMSI controller clears each bit. As it takes some time to complete a software reset, the host driver confirms that these bits are 0. This register is applicable for eMMC mode.

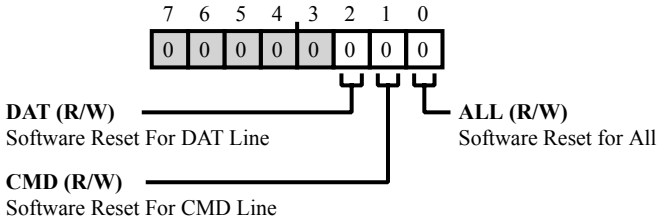

Figure 18-99: EMSI_SWRST Register Diagram

Table 18-77: EMSI_SWRST Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W)	DAT	Software Reset For DAT Line. The EMSI_SWRST.DAT bit is used in eMMC mode and it resets only a part of the data circuit and the DMA circuit is also reset. The following registers and bits are cleared by the EMSI_SWRST.DAT bit: Present state register • Read transfer active • Write transfer active • DAT line active • Command Inhibit (DAT) Normal Interrupt status register • DMA interrupt • Transfer complete.	
		0	Work
		1	Reset

Table 18-77: EMSI_SWRST Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W)	CMD	Software Reset For CMD Line. The EMSI_SWRST.CMD bit resets only a part of the command circuit to be able to issue a command. This reset is effective only for a command issuing circuit (including response error statuses related to Command Inhibit (CMD) control) and does not affect the data transfer circuit. The eMSI controller can continue data transfer even after this reset is executed while handling subcommand-response errors. The following registers and bits are cleared by the EMSI_SWRST.CMD bit: - Present State register: Command Inhibit (CMD) bit - Interrupt Status register: Command Complete bit - Error Interrupt Status: Response error statuses related to Command Inhibit (CMD) bit	
		0	Work
		1	Reset
0 (R/W)	ALL	Software Reset for All. This reset affects the entire eMSI controller. During its initialization, the host driver sets (=1) the EMSI_SWRST.ALL bit to reset the eMSI controller. All registers are reset except the capabilities register. If the EMSI_SWRST.ALL bit is set (=1), the host driver must issue reset command and reinitialize the card.	
		0	Work
		1	Reset

Timeout Control Register

The EMSI_TO_CTL register is used to set the Data Timeout Counter value for an eMMC mode according to the timer clock defined by the capabilities register, while initializing the eMSI controller.

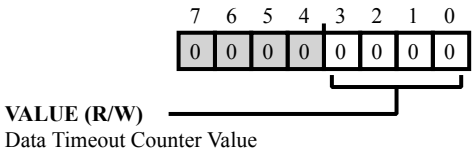

Figure 18-100: EMSI_TO_CTL Register Diagram

Table 18-78: EMSI_TO_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
3:0 (R/W)	VALUE	Data Timeout Counter Value. The EMSI_TO_CTL.VALUE value determines the interval by which DAT line time-outs are detected. The timeout clock frequency is generated by dividing the base clock TMCLK value by this value. When setting this register, prevent inadvertent timeout events by clearing the EMSI_ERR_STAT_EN.DATA_TOUT_ERR bit. The values for these bits are: - 0xF: Reserved - 0xE: TMCLK x 2^{27} - ..... - 0x1: TMCLK x 2^{14} - 0x0: TMCLK x 2^{13} Note: During a boot operating in an eMMC mode, an application must configure the boot data timeout value (approximately 1 sec) in the EMSI_TO_CTL.VALUE bit.

Transfer Mode Register

The EMSI_TRNSFRMODE register is used to control the operation of data transfers for an eMMC mode. The host driver sets this register before issuing a command that transfers data.

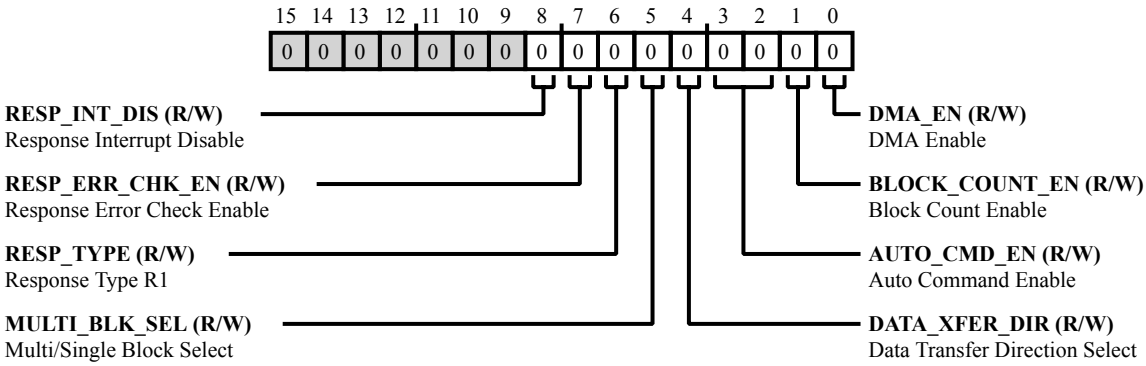

Figure 18-101: EMSI_TRNSFRMODE Register Diagram

Table 18-79: EMSI_TRNSFRMODE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W)	RESP_INT_DIS	Response Interrupt Disable. The eMSI controller supports the response check function to avoid overhead of response error check by the host driver. Only a response type of R1 can be checked by the controller. If the host driver checks the response error, set the EMSI_TRNSFRMODE.RESP_INT_DIS bit to 0 and wait for command complete interrupt and then check the response register. If the eMSI controller checks the response error, set the EMSI_TRNSFRMODE.RESP_INT_DIS bit = 1 and set the EMSI_TRNSFRMODE.RESP_ERR_CHK_EN bit = 1. The command complete interrupt is disabled by the EMSI_TRNSFRMODE.RESP_INT_DIS bit regardless of the command complete signal enable.	
		0	Response Interrupt is Enabled
		1	Response Interrupt is Disabled

Table 18-79: EMSI_TRNSFRMODE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	RESP_ERR_CHK_EN	Response Error Check Enable. The eMSI controller supports the response check function to avoid overhead of response error checking by host driver. Response types of only R1 can be checked by the controller. If the eMSI controller checks the response error, set the `EMSI_TRNSFRMODE.RESP_ERR_CHK_EN` bit = 1 and set the `EMSI_TRNSFRMODE.RESP_INT_DIS` bit = 1. If an error is detected, the Response Error interrupt is generated in the `EMSI_ERR_STAT` register. Note: Response error check must not be enabled for any response type other than R1.	
		0	Response Error Check is Disabled
		1	Response Error Check is Enabled
6 (R/W)	RESP_TYPE	Response Type R1. The `EMSI_TRNSFRMODE.RESP_TYPE` bit selects R1 as a response type when the Response Error Check is selected. Error statuses checked in R1: - OUT_OF_RANGE - ADDRESS_ERROR - BLOCK_LEN_ERROR - WP_VIOLATION - CARD_IS_LOCKED - COM_CRC_ERROR - CARD_ECC_FAILED - CC_ERROR - ERROR	
		0	R1 (eMMC)
		1	Reserved
5 (R/W)	MULTI_BLK_SEL	Multi/Single Block Select. The `EMSI_TRNSFRMODE.MULTI_BLK_SEL` bit is set when issuing multiple-block transfer commands using the DAT line. If the `EMSI_TRNSFRMODE.MULTI_BLK_SEL` bit is cleared (=0) it is not necessary to set the block count register.	
		0	Single Block
		1	Multiple Block

Table 18-79: EMSI_TRNSFRMODE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/W)	DATA_XFER_DIR	Data Transfer Direction Select. The EMSI_TRNSFRMODE.DATA_XFER_DIR bit defines the direction of DAT line data transfers. The EMSI_TRNSFRMODE.DATA_XFER_DIR bit is set (=1) by the host driver to transfer data from the eMMC device to the eMSI controller and it is cleared (=0) for all other commands.	
		0	Write (Host to Card)
		1	Read (Card to Host)
3:2 (R/W)	AUTO_CMD_EN	Auto Command Enable. The EMSI_TRNSFRMODE.AUTO_CMD_EN bit field determines the use of Auto Command functions.	
		0	Auto Command Disabled
		1	Auto CMD12 Enable
		2	Auto CMD23 Enable
		3	Auto CMD Auto Select
1 (R/W)	BLOCK_COUNT_EN	Block Count Enable. The EMSI_TRNSFRMODE.BLOCK_COUNT_EN bit is used to enable the block count register, which is relevant for multiple block transfers. If the EMSI_TRNSFRMODE.BLOCK_COUNT_EN bit is cleared (=0), the block count register is disabled, which is useful in executing an infinite transfer.	
		0	Disable
		1	Enable
0 (R/W)	DMA_EN	DMA Enable. The EMSI_TRNSFRMODE.DMA_EN bit enables the DMA functionality. If the EMSI_TRNSFRMODE.DMA_EN bit is set (=1), a DMA operation begins when the host driver writes to the Command register (or EMSI_ADMA_DESADDR_LO for ADMA3). The program can select one of the DMA modes by using DMA Select in the EMSI_CTL1 register.	
		0	No Data Transfer or Non-DMA Data Transfer
		1	DMA Data Transfer

EMSI Version

The EMSI_VER_ID register reflects the current release number of the eMSI controller.

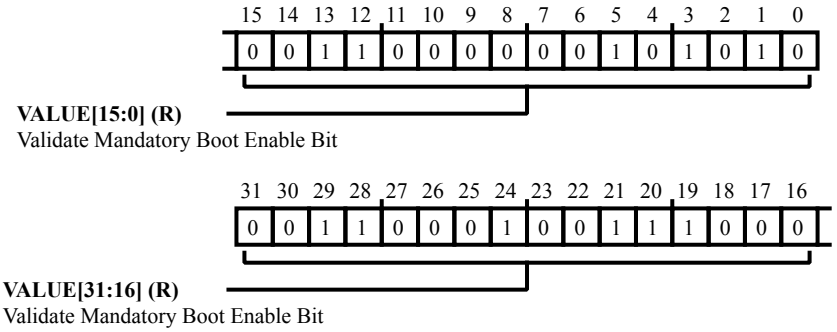

Figure 18-102: EMSI_VER_ID Register Diagram

Table 18-80: EMSI_VER_ID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Validate Mandatory Boot Enable Bit. The EMSI_VER_ID.VALUE bit field indicates the eMSI controller current release number that is read by an application. An application reading this register in conjunction with the register, gathers details of the current release.

EMSI Version Type

The EMSI_VER_TYPE register reflects the current release type of the eMSI controller.

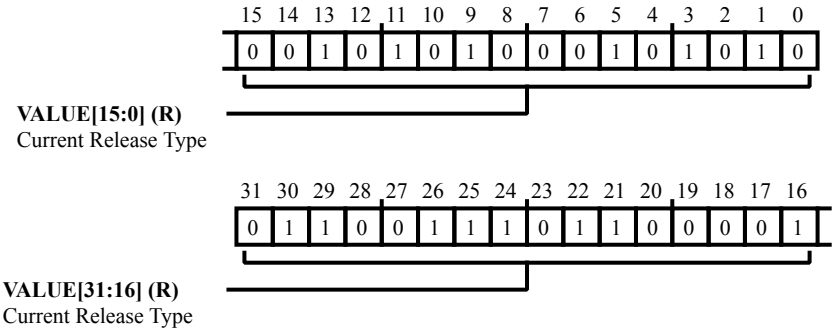

Figure 18-103: EMSI_VER_TYPE Register Diagram

Table 18-81: EMSI_VER_TYPE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Current Release Type. This field indicates the eMSI controller current release type that is read by an application. An application reading this register in conjunction with the register, gathers details of the current release.

Wakeup Control Register

The EMSI_WU_CTL register is mandatory for the Host Controller, but the wakeup functionality depends on the Host Controller system hardware and software. The Host Driver maintains voltage on the SD Bus by setting the SD Bus Power to 1 in the Power Control Register, while a wakeup event through the Card Interrupt is desired.

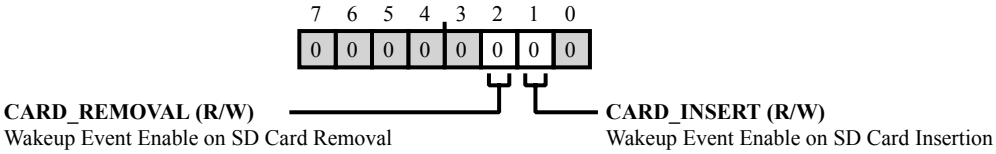

Figure 18-104: EMSI_WU_CTL Register Diagram

Table 18-82: EMSI_WU_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W)	CARD_REMOVAL	Wakeup Event Enable on SD Card Removal. The EMSI_WU_CTL.CARD_REMOVAL bit enables wakeup event through Card Removal assertion in the Normal Interrupt Status register. For the SDIO card, Wake Up Support (FN_WUS) in the Card Information Structure (CIS) register does not affect the EMSI_WU_CTL.CARD_REMOVAL bit.	
		0	Disable
		1	Enable
1 (R/W)	CARD_INSERT	Wakeup Event Enable on SD Card Insertion. The EMSI_WU_CTL.CARD_INSERT bit enables wakeup event through Card Insertion assertion in the Normal Interrupt Status register. FN_WUS (Wake Up Support) in CIS does not affect the EMSI_WU_CTL.CARD_INSERT bit.

		1	Enable

19 Link Port (LP)

Link ports allow the processor to connect to other processors or peripheral link ports using a simple communication protocol for high-speed parallel data transfer. This peripheral allows various I/O peripheral interconnection schemes to I/O peripheral devices as well as co-processing and multiprocessing schemes.

The link ports of the processor support 8-bit wide data transfers. The link port pins are multiplexed in the GPIO ports. For information on processor multiplexing, see the data sheet for the specific processor.

Link ports can operate independently and simultaneously, allowing glueless high-speed connectivity of up to four external processors.

NOTE: Reference to CLKO8 in this chapter can be considered as OCLK_0.

LP Features

All link ports are identical in their design and have the following common features.

- Bidirectional ports with eight data signals (`LP_D0` - `LP_D7`), an acknowledge signal (`LP_ACK`), and a clock signal (`LP_CLK`).
- Provide high-speed, point-to-point data transfers to other processors, allowing different types of interconnections between multiple processors.
- Pack data into 32-bit words. The processor can directly read this data or transfer it through DMA to or from on-chip memory.
- Support for data buffering through a 2-deep FIFO for transmit and a 4-deep FIFO for receive.
- Programmable clock and acknowledge based handshake mechanism for efficient communication.
- A dedicated DMA channel.
- Support for data transfer in 2-bit mode (DDR/non-DDR only) and 4-bit mode (DDR/non-DDR)

LP Functional Description

This section provides a description of the link port, including a list of its registers and a functional block diagram.

ADSP-SC59x LP Register List

The Link Port LP is an 8-bit wide parallel port that can connect to another processor's LP or another LP-compatible device. This port allows a variety of interconnection schemes to I/O peripheral devices as well as co-processing and multiprocessing schemes. A set of registers governs LP operations. For more information on LP functionality, see the LP register descriptions.

Block Diagram

The ***Link Port Block Diagram*** shows the block diagram of a link port.

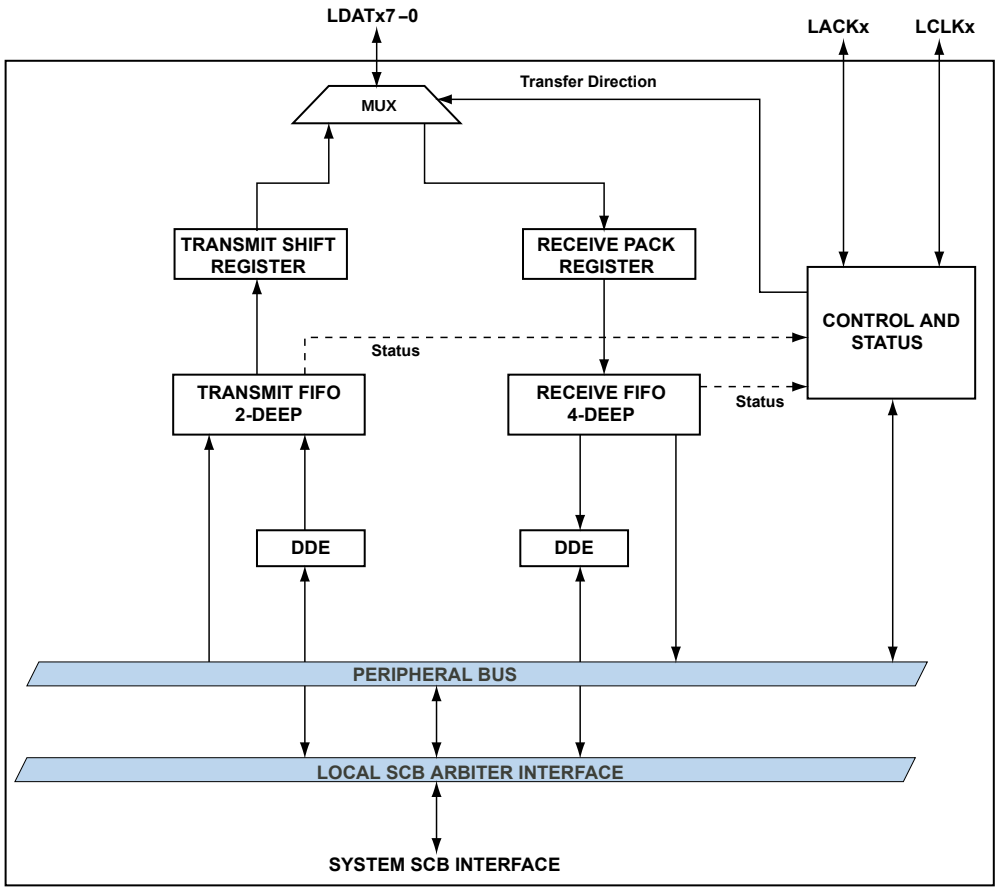

Figure 19-1: Link Port Block Diagram

External Connections

As shown in the ***Link Port Pin Connections*** figure, a link port has eight data lines (LP_D0 – LP_D7), a clock line (LP_CLK), and an acknowledge line (LP_ACK). A link port can act as either a transmitter or a receiver but not both at the same time.

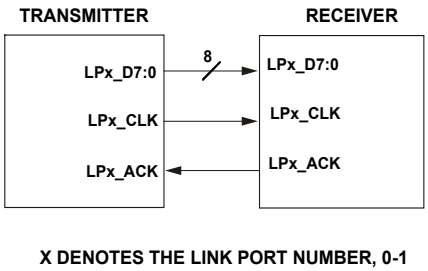

Figure 19-2: Link Port Pin Connections

Use external pull-downs for the LP_CLK and LP_ACK pins so that the link port can enable the transmitter and receiver, irrespective of the state of the other.

Internal Blocks

As shown in the block diagram, the link ports have independent modules for transmit and receive. If enabled as transmitter, the link port uses a 2 deep 32-bit FIFO. If enabled as a receiver, the port uses a 4 deep 32-bit FIFO. The core MMR access bus interfaces with these FIFOs. The distributed DMA engines (DDE) use the system cross bar (SCB) interface to access the FIFO. The link port uses the LP_CTL.TRAN bit to determine whether the module is enabled for transmit or receive operation.

Architectural Concepts

The following sections describe the architectural concepts of the link port.

- Link Port Protocol
- FIFO Buffers
- Handshake for Link Port Enable Process
- Clocking
- Multi-Processor Connectivity

Link Port Protocol (SC59x)

A link port transmitted word consists of 4 bytes and the communication proceeds as follows.

1. The transmitter asserts the link port clock (LP_CLK) with each byte of data. The receiver uses the falling edge of LP_CLK driven by the transmitter to latch the byte.
2. When the receiver is ready to accept another word in the receive buffer it asserts the acknowledge signal, LP_ACK.

3. The transmitter samples LP_ACK driven by the receiver at the beginning of each word transmission. If LP_ACK is deasserted, then the transmitter does not transmit the next word.
4. The transmitter leaves LP_CLK high and continues to drive the first byte of the next word until LP_ACK is asserted.
5. When this assertion occurs, the transmitter drives LP_CLK low. The transmission of the next word starts. If the transmit buffer is empty, LP_CLK remains low until the buffer refills, regardless of the state of LP_ACK.

The LP_ACK signal can deassert when it anticipates that the buffer could fill. The receiver reasserts the LP_ACK signal as soon as the internal DMA grant signal has occurred or the core reads the receive buffer. Either of these actions frees a buffer location.

NOTE: The LP_ACK signal inhibits transmission of the next word and not of the current byte.

The LP_ACK signal provides a handshake between the receiver and transmitter in the following configurations.

- When configured as a transmitter, the port drives both the data and the clock while LP_ACK is three-stated. In this mode, LP_CLK is always synchronous with OCLK_0.
- When configured as a receiver, the link port drives the acknowledge signal and the data and clock lines are three-stated. In this case, the external LP_CLK signal can either be synchronous or asynchronous with OCLK_0.
- When the link port is disabled, the data, clock, and acknowledge signals are three-stated.

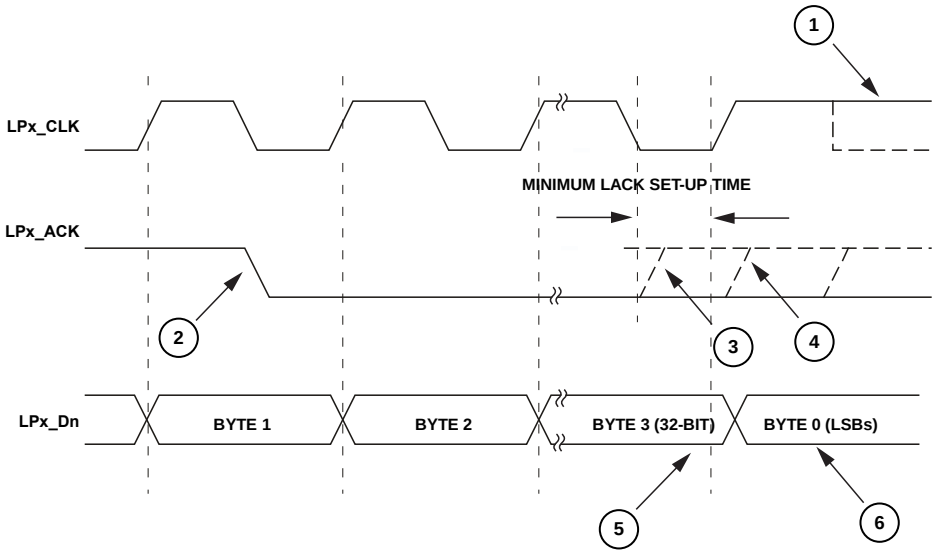

Figure 19-3: Link Port Communication and Handshake Waveform

The following list describes the stages shown in the ***Link Port Communication and Handshake Waveform*** figure.

1. LP_CLK stays high at byte 0 when LP_ACK is sampled low on the previous LP_CLK rising edge. LP_CLK high indicates a stall.
2. The LP_ACK signal can deassert after byte 0.

3. The LP_ACK signal reasserts as soon as the link buffer is not full (depending on Rx FIFO conditions).
4. The transmitter samples LP_ACK to determine whether to transmit the next word.
5. The receiver accepts the remaining word even if LP_ACK is deasserted. The transmitter does not send the following word.
6. Transmission of data for next word is held until LP_ACK is asserted.

The transmitter samples the LP_ACK signal. If the signal is high, the transmitter gives out the falling edges of LP_CLK for data sampling. The LP_ACK signal is first sampled at the rising edge of OCLK_0. One more OCLK_0 stage synchronizes the signal further. This synchronized signal is given to the subsequent logic. The LP_CLK falling edge is aligned with OCLK_0 falling edge in a 1:1 clock ratio mode and with the OCLK_0 rising edge for the rest of the clock ratios. The following figures explain how the synchronization is maintained between the LP_ACK and LP_CLK signals.

In the following figure, synchronizing time is guaranteed to be 1.5 OCLK_0 cycles.

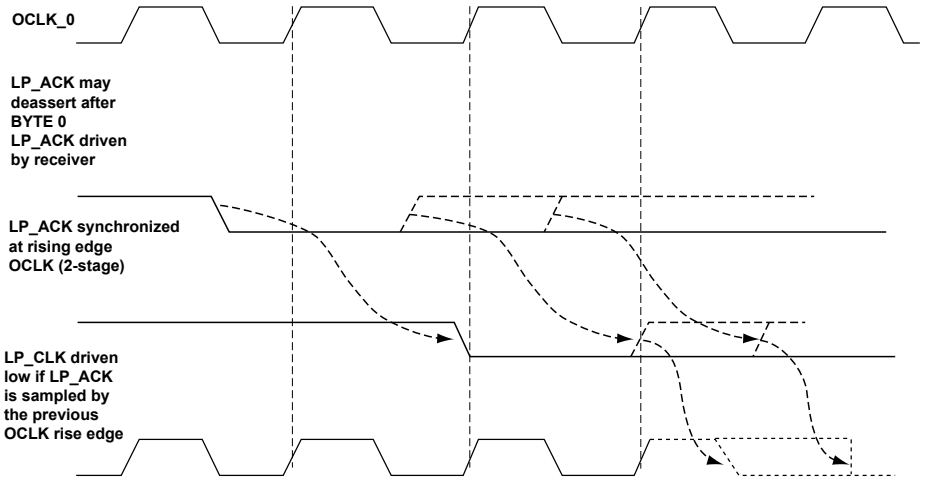

Figure 19-4: LP_ACK Synchronization for OCLK_0:LP_CLK=1:1

In the following figure, synchronizing time is guaranteed to be 2 OCLK_0 cycles.

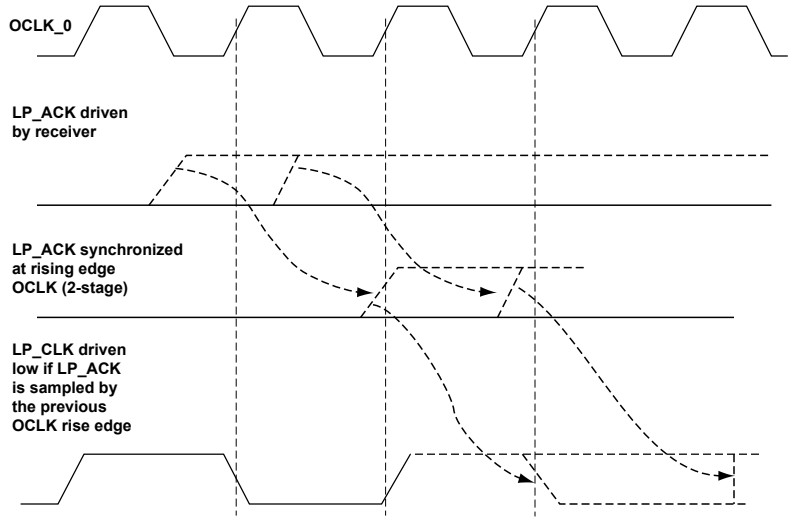

Figure 19-5: LP_ACK Synchronization for OCLK_0 LP_CLK=1:2, 1:4 and Up

The link port uses the value programmed in the LP_DIV register at the transmitter to determine the frequency of the link port clock (LP_CLK). However, the signal appearing on the LP_CLK pin is also dependent on the status of the LP_ACK pin driven by the receiver. The ***Relationship Between Internal Link Port Clock and Link Port Clock at the Pins*** figure shows this relationship.

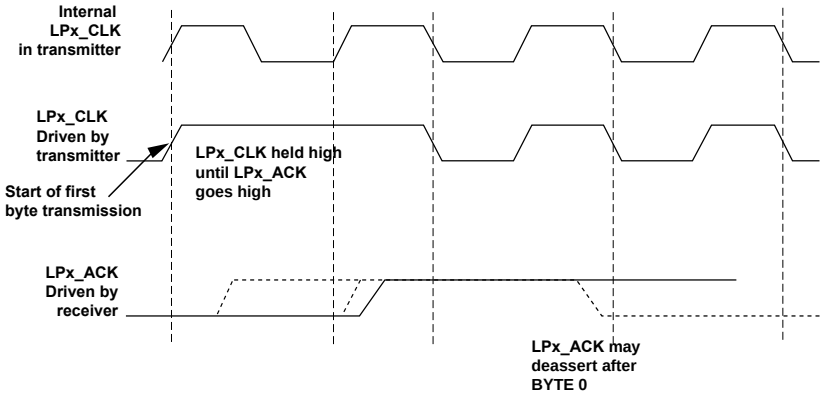

Figure 19-6: Relationship Between Internal Link Port Clock and Link Port Clock at the Pins

FIFO Buffers

When a link port is configured as transmitter, the link port uses a 2-deep FIFO buffer. A shift register unpacks the single 32-bit word to four 8-bit data bytes. As the FIFO has space for more data, the link port makes a new DMA request. If the FIFO becomes empty, the LP_CLK signal is deasserted. The core can access FIFO through the LP_TX register.

The core or DMA makes three writes (2-stage FIFO and 1 shift register) to the transmit buffer before it signals a full condition. The link port uses the LP_STAT.FFST bit field to reflect the status of the FIFO but not the shift register full or empty condition. However, the program can poll the LP_STAT.LPBS bit to discover whether the link

port is driving data from the shift register to the pins. The LP_STAT.LPBS bit is also set when receiver has held off transmission by driving LP_ACK low.

NOTE: When the 2-deep FIFO and the output shift-register overflow, any further write to the link port buffer overwrites the input stage of the FIFO.

NOTE: The core can also read the transmit FIFO through the data LP_TX register.

NOTE: If the transmitter is disabled while performing writes to the transmit FIFO, a FIFO full condition is signaled after two writes.

The transmit buffer registers have shadow registers. Using these shadow registers, both stages of the 2-deep FIFO can be read without updating the status registers. The LP_TXIN_SHDW register corresponds to the input stage of the FIFO. The LP_TXOUT_SHDW register corresponds to the output stage of the FIFO as shown in the ***Transmit FIFO path*** figure.

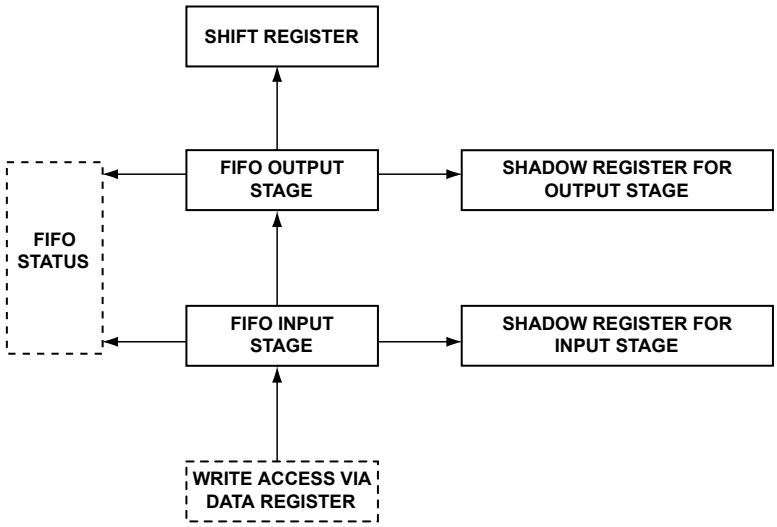

Figure 19-7: Transmit FIFO path

When a link port is configured as receiver, data transfers to the core or DMA from the full 4-deep receive FIFO. An internal packing register packs data to 32 bits. Four reads can occur from the receive buffer by the core or DMA before it signals an empty condition. The link port uses the LP_STAT.FFST bits to reflect the status of the 4-deep read buffer FIFO. The core can access this FIFO through the LP_RX register.

NOTE: When receive FIFO overflows (LP_STAT.ROVF bit=1), any further data from the transmitter is lost. Only the data retained in the receive FIFO can be retrieved further.

The receiver drives the LP_ACK output signal low, after the first byte of data for the next-to-last empty slot (in the 4-deep FIFO) is received. This functionality prevents data loss due to the transmitter starting transmission of the next word before the LP_ACK signal reaches the transmitter. (The timing is due to the larger delay in synchronization.) This functionality guarantees that even after allowing for the extra synchronization cycle in the transmitter and receiver, there is no overflow in the receive FIFO. The ***LACK Generation Based on Receive FIFO Status*** figure

shows how FIFO slots influence the acknowledge signal generation. The grayed sections show received data. The white sections show empty locations where the decision to pull LP_ACK high is taken.

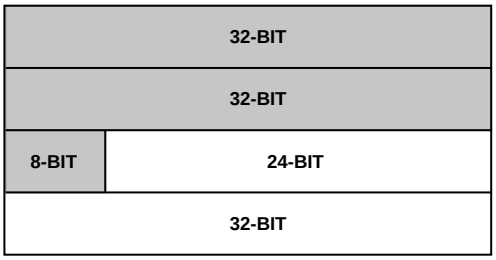

Figure 19-8: LACK Generation Based on Receive FIFO Status

NOTE: The link port uses a 4-deep receive FIFO only under a worst case situation, as mentioned. In all other cases, respond as if the FIFO has only a 3-deep stage. The LP_ACK signal is pulled high before the last stage of the FIFO.

The link port has memory-mapped buffers for both receive and transmit operations. A JTAG-based emulator can read the FIFO which can cause unexpected problems in data transfers. This activity can only happen during an emulation event (typically hitting a breakpoint or single-stepping). The emulator issues core reads through JTAG. To work around this issue, see the tools documentation for more information.

Handshake for Link Port Enable Process

In a link port-based system, the transmitter and the receiver can be enabled at different times. Use external pull-downs for the LP_CLK and LP_ACK signals.

If the receiver is enabled before the transmitter, the external pull-down holds the LP_CLK signal of the transmitter low. The receiver is held off. The receiver can wait for a rising edge on the LP_CLK signal to assert its receive service request interrupt. This rising edge occurs only when transmitter starts driving the first data on to the bus, after the application enables it.

If the transmitter is enabled before the receiver, the external pull-down holds the LP_ACK signal of the receiver low. Transmission is held off. Refer to the ***Enable the Transmitter Before the Receiver*** figure. The transmitter can wait for a rising edge on the LP_ACK signal to assert its transmit service request interrupt. This rising edge is asserted as soon as the receiver is enabled after the hardware drives the LP_ACK high.

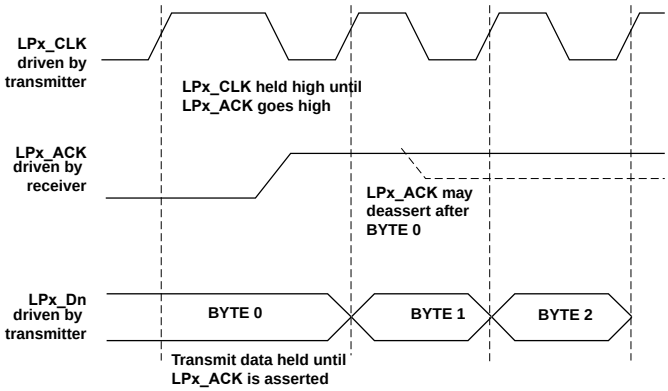

Figure 19-9: Enable the Transmitter Before the Receiver

NOTE: Service request interrupts or status are asserted only when the link port (receiver or transmitter) is disabled.

Clocking

The link port clock (LP_CLK) is derived from the internal system clock (OCLK_0). The link port clock to system clock ratio can be configured in the LP_DIV register. This value applies to the transmitter only. The receiver can operate at any asynchronous frequency up to the maximum frequency, independent of the ratio programmed. The following formula describes the relationship between the frequency of the link port clock, the OCLK_0 frequency, and the LP_DIV value.

- $f_{LP_CLK} = f_{OCLK_0}$< or = $f_{LP_CLK\text{-}MAX}$ if DIV = 0
- $f_{LP_CLK} = f_{OCLK_0}/(2 \times DIV)$ if DIV > 0

Where: f_{LP_CLK} = link clock frequency, $f_{LP_CLK\text{-}MAX}$ = link clock maximum frequency, and f_{OCLK0_0} = system clock frequency.

While programming the LP_DIV register to select the clock ratio, ensure that the LP_CLK frequency does not exceed the maximum frequency supported for the device. For supported frequencies, see the product-specific data sheet.

NOTE: The Drive Strength (DS) value must be changed to b(010) for the LPCLK pin to operate the link port at the maximum frequency of 125 MHz. Refer the PADS_PORTB0_DS and PADS_PORTC0_DS register bit descriptions for details.

Multi-Processor Connectivity

Link ports can operate independently, allowing glueless connection with external processors. Link ports have dedicated DMA channels, allowing independent data transfers. The following group of figures shows some examples of different bus connection topology that can be used in multi-processor system design. The inter-connection methods are not limited to these examples.

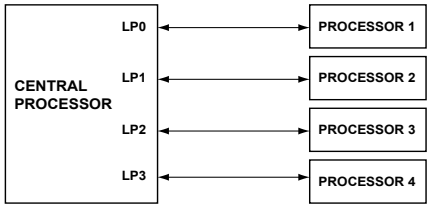

Figure 19-10: Central Processor-Based Model

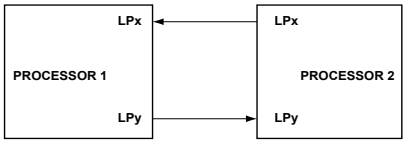

Figure 19-11: Link Port Full-Duplex Transfer Model

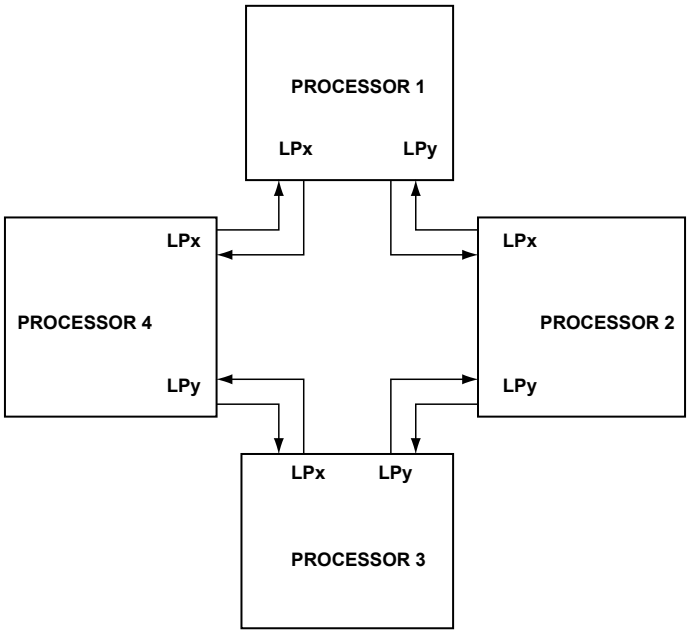

Figure 19-12: Link Port Ring Model

The link port protocol does not include built-in support for multiple requesters. However, there can be situations where multiple devices try to become the bus requester at the same time. Multi-requester conflicts can be resolved using token passing. In token passing, the token is a software flag that passes between processors.

At reset, the token is set to reside in the link port of one device, making it the requester and the transmitter. When a receiver (completer) wants to become the requester, it can assert its `LP_ACK` signal to get the attention of the requester. The requester knows, through the software protocol, whether to respond with actual data or whether the token is requested. If the requester wishes to give up the token, it can send back a user-defined token release word and thereafter clear its token flag.

Simultaneously, the completer sets its token and can thereafter transmit. The token release word can be any user-defined value. Because the transmitter and receiver expect a code word, this word does not need to be exclusive of

normal data transmission. If the requester wishes to give up the token, it can send back a user-defined token release word and thereafter clear its token flag. Simultaneously, the completer examines the data sent back and if it is the token release word, the completer sets its token, and can thereafter transmit.

The link port protocol includes handshake mechanism to inform the other end of transfer (transmit or receive) of an enable instance. However, it does not support handshakes to inform a disabled instance, while a chunk of data transfers. The application must assume the disabled state of the other end and take appropriate action.

For example, in a multi-processing environment, a receiver did not read its full FIFO for an extended time due to internal bus arbitrations. The transmitter can require software or a peripheral timer-based timeout to inform the application that the `LP_ACK` signal is low for an extended period.

LP Operating Modes

The link port does not have particular modes of operation, as the peripheral is based on a simple protocol. The following sections explain the data transfer modes, using the core and using DMA.

- Core Data Transfers
- DMA Data Transfers

LP Data Transfer Modes

This section describes link port DMA and core data transfers.

Core Data Transfers

If DMA is disabled for a link port buffer, the processor core can write or read internal FIFO buffers as a memory-mapped register through the MMR access bus. To avoid FIFO overflow or underflow, the core can access the FIFO registers in one of the following ways.

- Access link port registers using an interrupt service routine (ISR) mapped to the data request interrupt of the link port. The interrupt request remains high only when the FIFO is accessible (when the FIFO is not full in transmit mode and not empty in receive mode).
- Poll the FIFO status bits of the `LP_STAT` register. Write to the transmit FIFO if not full or read from the receive FIFO if not empty.

DMA Data Transfers

Dedicated DMA channels are available for each link port. DMA-related activity is explained in the following steps.

1. Data Receive – Once the DMA channel and link port module are configured and enabled, the external device begins writing data to the FIFO through the data pins of the link port. The FIFO detects this activity and in turn sends a DMA request. After the request is granted, the DMA transfer progresses until the FIFO is empty.
2. Data Transmit – Once the DMA channel and link port module are configured and enabled, setting the `LP_CTL.EN` bit automatically asserts a DMA request when the transmit FIFO is empty. After the request is granted, DMA fills the FIFO. The external device begins reading data from the FIFO through the data pins of

the link port. The FIFO detects that there is room in the buffer and asserts another DMA request, continuing the process.

LP Event Control

This section describes how the link port uses interrupts and status signals.

Interrupt Signals

Each link port has two dedicated interrupt lines registered with the system event controller—a data request interrupt and a status interrupt. Data request interrupts are asserted based on FIFO conditions for data transfer. Status interrupts are asserted when a service request status or an overflow status is set. The following list explains each of these interrupts.

- ***Data Request Interrupt.*** Asserted if the FIFO is not full in transmission mode and the FIFO is not empty in reception mode. This functionality serves as a core triggered interrupt in non-DMA mode and as the DMA interrupt request in DMA mode. Generation of this interrupt is based on the `LP_STAT.FFST` (status bit of the link port buffer).
- ***Link Port Transmit Service Request Interrupt (LTRQ)***. Allow a disabled link port to generate an interrupt when an external access is attempted. When a link port is configured as transmitter, the transmit service request interrupt is enabled by setting the `LP_CTL.TRQMSK` bit. When set, an external receiver can indicate to the disabled transmitter that it must receive data through the connected link port. The receiver does so by driving a high level on the `LP_ACK` line. When the `LP_ACK` of the disabled transmitter link port is detected high, a `LP_STAT.LTRQ` interrupt is generated. The transmitter can enable itself for data transfer with the receiver. The link port needs a pull-down on `LP_ACK` for this feature to function properly.
- ***Link Port Receive Service Request Interrupt (LRRQ)***. When a link port is configured as receiver, this interrupt is enabled by setting the `LP_CTL.RRQMSK` bit. When set, an external transmitter can indicate to the disabled receiver that it must receive data through the connected link port. The transmitter does so by driving out the first data. When the `LP_CLK` of the disabled receiver link port is detected high, a `LP_STAT.LRRQ` interrupt is generated. The receiver can further enable itself for data transfer with the transmitter. The link port needs a pull-down on the `LP_CLK` signal for this feature to function properly.
- ***Link Port Receive Overflow Interrupt (LPOVF)***. Generated when the receiver FIFO overflows and is enabled by setting the `LP_CTL.ROVFMSK` bit. This interrupt can happen if the transmitter continues to transmit data even though the receiver has deasserted `LP_ACK` signal causing the receive FIFO to overflow.

Enabling Link Port Interrupts

A data request interrupt is fed to the system event controller directly and can be controlled separately from the application.

To mask the interrupt, set the mask bits in `LP_CTL` register corresponding to service interrupts and the overflow interrupt. These interrupts are OR'ed and fed to the SIC as a single `LP_STAT` interrupt. These interrupts are latched and stored in the associated bits of `LP_STAT` register. If an `LP_STAT` interrupt occurs, in the ISR, programs

can read the LP_STAT register bits to determine the type of interrupt. These bits are write-one-to-clear (W1C); writing one to the bit resets the bit and disables the corresponding interrupt.

Status and Error Signals

This section explains the various status signals in the LP_STAT register.

- ***Transfer Status signals***. The link port uses the bus status bit (LP_STAT.LPBS) to give the status of the bus condition (busy or idle) when the link port is configured as transmitter. The LP_STAT.LPBS is high if the link port drives data into the link port pins. Programs can poll this bit after polling the LP_STAT.FFST bit to disable the link port safely.

  The link buffer status (LP_STAT.FFST) field directly indicates the status of the FIFO (including empty or full conditions) during data transfer. Software can poll this field in the LP_STAT register before writing to the FIFO (in case of transmission) or reading from the FIFO (in case of reception). The LP_STAT.FFST bit is automatically cleared when the link port is disabled.

- ***Transfer Request Status signals***. The link port uses the receive request status (LP_STAT.LRRQ) bit to indicate that an external receiver wants to receive data (in case the link port is a disabled transmitter). The link port uses the transmit request status (LP_STAT.LTRQ) bit to indicate that an external transmitter wants to send data (in case the link port is a disabled receiver). Software can poll these bits to enable the transmitter or receiver accordingly.

- ***Error Status signals***. In receive mode 32-bit data is received in four chunks of 8-bit data. This data is then packed to a single 32-bit data before loading the FIFO. The link buffer error status (LP_STAT.LPACK) bit is high during this packing process and goes low after packing.

  The link port overflow status (LP_STAT.ROVF) bit is set when the receive FIFO overflows. This event can occur if the transmitter continues to transmit data even though the receiver has deasserted LP_ACK causing the receiver FIFO to overflow.

LP Programming Model

The following sections provide information on configuring the operating mode and enabling the link ports.

- Setting Up a DMA Transmit Operation
- Setting Up a DMA Receive Operation
- Setting Up a Core Transmit Operation
- Setting Up a Core Receive Operation

Setting Up a DMA Transmit Operation

This following procedure describes the typical steps for configuring the link ports in DMA transmit mode.

1. Enable the link port pins in the GPIO port mux using the appropriate PORT_FER and PORT_MUX registers.

2. Configure the drive strength value to b(010) for the link port clock pins to operate the link port at maximum frequency (PADS_PORTB0_DS and PADS_PORTC0_DS registers).
3. Install interrupt handlers for DMA and for transfer status (service request interrupt).
4. Configure the link port to transmit by setting the LP_CTL bit and enable the transmit request interrupt mask by setting the LP_CTL.TRQMSK bit.
5. Program the link port clock divider by writing a value to the LP_DIV register.
6. If using DMA stop mode or auto buffer mode, program the appropriate DMA registers.

   ADDITIONAL INFORMATION: An example configuration is: DMA_ADDRSTART, DMA_XCNT, DMA_XMOD, and DMA_CFG registers (Stop/Auto, DMA_CFG.PSIZE =1, DMA_CFG.MSIZE =4, interrupt generation and memory read).
7. Wait for the link port receiver (connected externally) to be enabled. The application can wait for the transmit service request interrupt to assert.
8. Clear the transmit service request interrupt status by writing 1 to the LP_STAT.LTRQ bit.
9. Enable DMA by setting the DMA_CFG.EN bit.
10. Enable the link port by setting the LP_CTL.EN bit.
11. Wait for DMA to assert a transfer completion interrupt.
12. Clear the DMA interrupt source by writing 1 to the DMA_STAT.IRQDONE bit.

Setting Up a DMA Receive Operation

This section describes the typical steps for using the link ports in DMA receive mode.

1. Enable the link port pins in GPIO port mux using the appropriate PORT_FER and PORT_MUX registers.
2. Install interrupt handlers for DMA and for transfer status (service request interrupt).
3. Configure the link port for reception (clear the LP_CTL.TRAN bit) and enable the receive request interrupt mask by setting the LP_CTL.RRQMSK bit.
4. If using DMA stop mode or auto buffer mode, program the DMA registers.

   ADDITIONAL INFORMATION: An example configuration is: DMA_ADDRSTART, DMA_XCNT, DMA_XMOD, and DMA_CFG registers (Stop/Auto, DMA_CFG.PSIZE=1, DMA_CFG.MSIZE=4, interrupt generation and memory write).
5. If using DMA array mode or list mode, create DMA configuration data structures filled with components.

   ADDITIONAL INFORMATION: An example configuration is: DMA_ADDRSTART, DMA_XCNT, DMA_XMOD, and DMA_CFG registers (Array/List, DMA_CFG.PSIZE =1, DMA_CFG.MSIZE =4, interrupt generation, memory write and fetch =4/5) and DMA_DSCPTR_NXT register (if list mode). Further, program

DMA configuration register (Array/List, DMA_CFG.PSIZE =1, DMA_CFG.MSIZE =4, Memory Write and Fetch =4/5) and program the DMA_DSCPTR_NXT register (if list mode).

6. Wait for the link port transmitter (connected externally) to be enabled with subsequent data transmission. The application can wait for the receive service request interrupt to assert.
7. Clear the receive service request interrupt status by writing 1 to the LP_STAT.LRRQ bit.
8. Enable DMA by setting the DMA_CFG.EN bit.
9. Enable the link port by setting the LP_CTL.EN bit.
10. Wait for DMA to assert the transfer complete interrupt.
11. Clear the DMA interrupt source by writing 1 to the DMA_STAT.IRQDONE bit of the DMA status register.

Setting Up a Core Transmit Operation

This section describes the typical steps for using the link ports in processor core based transmission.

1. Enable the link port pins in the GPIO port mux using the appropriate PORT_FER and PORT_MUX registers.
2. Configure the drive strength value to b(010) for the link port clock pins to operate the link port at maximum frequency (PADS_PORTB0_DS and PADS_PORTC0_DS registers).
3. Install interrupt handlers for data transfer and for transfer status (service request interrupt). The interrupt handlers for data transfer are the same source or ID as the DMA interrupt line in the SEC.
4. Configure the link port for transmission by setting the LP_CTL.TRAN bit) and enable the transmit request interrupt mask by setting the LP_CTL.TRQMSK bit).
5. Program the link port clock divider by writing a value in to the LP_DIV register.
6. Wait for the link port receiver (connected externally) to be enabled. The application can wait for a transmit service request interrupt to assert.
7. Clear the transmit service request interrupt status by writing 1 to the LP_STAT.LTRQ bit.
8. Enable the link port by setting the LP_CTL.EN bit.
9. The data request interrupt is asserted whenever there is free space in the FIFO. The application can write to the LP_TX register based on the FIFO conditions (half or empty) reflected in the LP_STAT.FFST bit field.

Setting Up a Core Receive Operation

This section describes the typical steps for using the link ports in processor core-based reception.

1. Enable the link port pins in the GPIO port mux using the appropriate PORT_FER and PORT_MUX registers.
2. Install interrupt handlers for data transfer and for transfer status (service request interrupt). The interrupt handlers for data transfer are the same source or ID as the DMA interrupt line in the SEC).

3. Configure link port for reception (clear LP_CTL.TRAN bit). Enable the receive request interrupt mask bit (set LP_CTL.RRQMSK).
4. Wait for the link port transmit (connected externally) to be enabled with subsequent transmission of data. The application can wait for receive service request interrupt to be asserted.
5. Clear the receive service request interrupt status by writing 1 to the LP_STAT.LRRQ bit.
6. Enable the link port by setting the LP_CTL.EN bit.
7. The data request interrupt is asserted whenever there is free space in the FIFO. The application can read from the LP_RX register based on the FIFO conditions (1 or 2 or 3 data available) which is reflected in the LP_STAT.FFST bit field.

ADSP-SC59x LP Register Descriptions

Link Port (LP) contains the following registers.

Table 19-6: ADSP-SC59x LP Register List

Name	Description
LP_CTL	Control Register
LP_DIV	Clock Divider Value Register
LP_RX	Receive Buffer Register
LP_STAT	Status Register
LP_TX	Transmit Buffer Register
LP_TXIN_SHDW	Shadow Input Transmit Buffer Register
LP_TXOUT_SHDW	Shadow Output Transmit Buffer Register

Control Register

The LP_CTL register provides LP interrupt masking, selection of transfer direction, and link port enable.

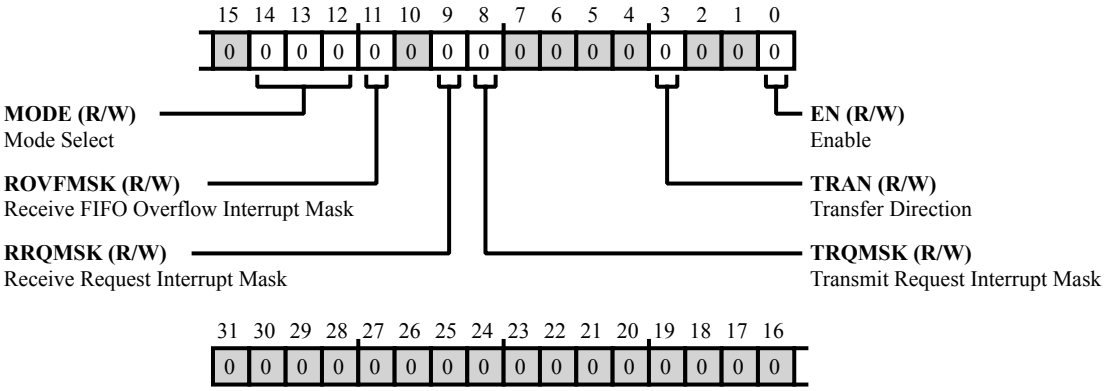

Figure 19-13: LP_CTL Register Diagram

Table 19-7: LP_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
14:12 (R/W)	MODE	Mode Select. The LP_CTL.MODE field indicates the mode of operation: Single Data Rates (SDR) of 2 bit and 4 bit, Double Data Rates (DDR) of 2 bit, 4 bit, and 8 bit. Note that the LRRQ interrupt is not supported in DDR mode. The LP receiver must be enabled by the user before starting the LP transmitter. For LP DDR mode, the value of LP DDR clock should be twice that of LP clock. CDU CLKO9 is used for the LP DDR clock.	
		0	8 bit SDR. The default mode. (D0, D1, D2, D3, D4, D5, D6 and D7 data pins used)
		1	4 bit SDR. (D0, D1, D2 and D3 data pins are used)
		2	2 bit SDR. (D0 and D1 data pins are used)
		4	8 bit DDR. (D0, D1, D2, D3, D4, D5, D6 and D7 data pins are used)
		5	4 bit DDR. (D0, D1, D2 and D3 data pins are used)
		6	2 bit DDR. (D0 and D1 data pins are used)
11 (R/W)	ROVFMSK	Receive FIFO Overflow Interrupt Mask.	
		0	Mask Disable Receive FIFO Overflow Interrupt
		1	Unmask Enable Receive FIFO Overflow Interrupt

Table 19-7: LP_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W)	RRQMSK	Receive Request Interrupt Mask. Link Port Receive Request Mask	
		0	Mask Disable Receive Request interrupt.
		1	Unmask Enable Receive Request interrupt.
8 (R/W)	TRQMSK	Transmit Request Interrupt Mask. Link Port Transmit Request Mask	
		0	Mask Disable Transmit Request interrupt.
		1	Unmask Enable Transmit Request interrupt.
3 (R/W)	TRAN	Transfer Direction. The `LP_CTL.TRAN` bit selects the transfer direction as transmit (if set) or receive (if cleared) for link buffer.	
		0	Receive Direction transfer is receive
		1	Transmit Direction transfer is transmit
0 (R/W)	EN	Enable. The `LP_CTL.EN` enables or disables the link port. When the processor disables the port (`LP_CTL.EN` transitions from high to low), the processor clears the corresponding `LP_STAT` bits.	
		0	Disable Disable linkport
		1	Enable linkport Enable linkport

Clock Divider Value Register

The LP_DIV register selects the divisor for ratio between the internal LP clock (LCLK) and system clock (CLKO8). This programming is applicable only for the transmitter. The receiver can operate at any asynchronous frequency up to the maximum frequency independent of the ratio programmed.

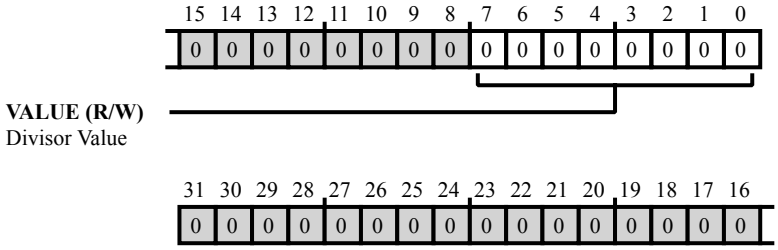

Figure 19-14: LP_DIV Register Diagram

Table 19-8: LP_DIV Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	VALUE	Divisor Value. The LP_DIV.VALUE bits select the clock divider (relating the LP' internally generated clock (LCLK) to the system clock (CLKO8). The LP_DIV.VALUE should be programmed prior to LP enable. For LP_DIV.VALUE = 0, LCLK = CLKO8 For LP_DIV.VALUE = xxxxxxxx, LCLK = CLKO8 / (2 x DIV)

Receive Buffer Register

The LP_RX register buffers the receive data flow through the LP. The receive buffer is a four-location deep FIFO. In the receive buffer, data is transferred to the core or DMA from the receive FIFO where an internal register does the packing. This packing register is not software accessible. For more information on LP buffer features and operations, see the LP functional description.

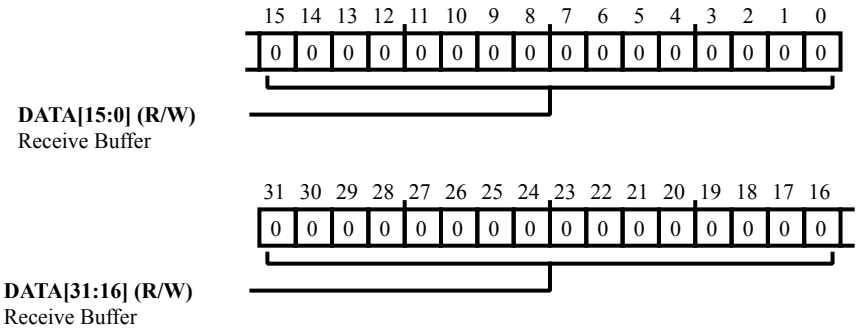

Figure 19-15: LP_RX Register Diagram

Table 19-9: LP_RX Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	DATA	Receive Buffer.

Status Register

The LP_STAT register provides status information on link port interrupts, FIFO, buses, and receive/transmit requests.

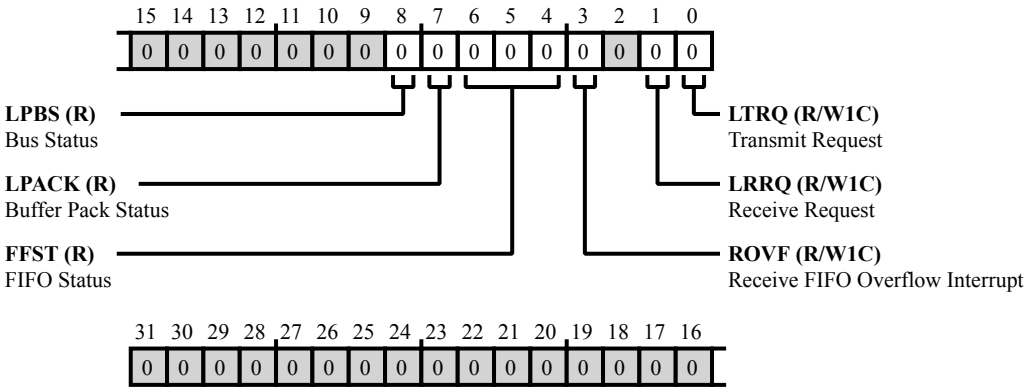

Figure 19-16: LP_STAT Register Diagram

Table 19-10: LP_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/NW)	LPBS	Bus Status. The LP_STAT.LPBS bit indicates the LPDAT bus status. LP_STAT.LPBS is kept high if data is being driven by the link port into the LP_D[n] pins.	
		0	Link port bus is idle
		1	Link port bus is busy
7 (R/NW)	LPACK	Buffer Pack Status. The LP_STAT.LPACK bit indicates packing status. In receive mode, 32-bit data is received in 4 blocks of 8-bit data. Then, the data is packed to get a single 32-bit data before loading the FIFO. The LP_STAT.LPACK bit is high during this packing process and goes low after packing. In transmit mode, 32-bit data in the FIFO is unpacked to 4 blocks of 8-bit data before sending. The LP_STAT.LPACK is high during unpacking.	
		0	Packing Complete Packing done
		1	Packing Incomplete Packing is in progress
6:4 (R/NW)	FFST	FIFO Status. The LP_STAT.FFST bits indicate the FIFO status. These bits are cleared when the LP is disabled.	
		0	TX - Empty; RX - Empty Link buffer (TX OR RX) empty

Table 19-10: LP_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		1	TX - Reserved ; RX - Has 1 data word RX has 1 word of data. TX reserved
		2	TX - Reserved; RX - Has 2 data words RX has 2 word of data. TX reserved.
		3	TX - Reserved; RX - Has 3 data words RX has 3 word of data. TX reserved.
		4	TX - One Word; RX -Has 4 data words RX has 4 word of data. TX 1 word of data.
		5	Reserved
		6	TX - FIFO Full; RX - Reserved RX reserved. TX reserved.
		7	Reserved
3 (R/W1C)	ROVF	Receive FIFO Overflow Interrupt. This interrupt is generated when the receiver FIFO overflows. This overflow may happen if the transmitter continues to transmit data even though the receiver has de-asserted the LP_ACK pin.	
1 (R/W1C)	LRRQ	Receive Request. The LP generates this interrupt when the LP_CLK pin of a disabled link port (the receiver) is forced high by another link port (the transmitter). Note that the LRRQ interrupt is not supported in DDR mode.	
0 (R/W1C)	LTRQ	Transmit Request. The LP generates this interrupt when the LP_ACK pin of a disabled link port (the transmitter) is forced high by another link port (the receiver).	

Transmit Buffer Register

The LP_TX register buffers the transmit data flow through the LP. The transmit buffer is two words deep. In the transmit buffer, the input stage of the FIFO is used to accept core data or DMA data from internal memory, and the data is transferred to the link port interface from the output stage of the FIFO. The output stage performs the unpacking in the transmit buffer. The least significant byte is transmitted first. As each word is unpacked and transmitted, the next location in FIFO becomes available and a new DMA request is made if DMA is enabled. If the register becomes empty, the LP asserts the LP_CLK signal. For more information on LP buffer features and operations, see the LP functional description.

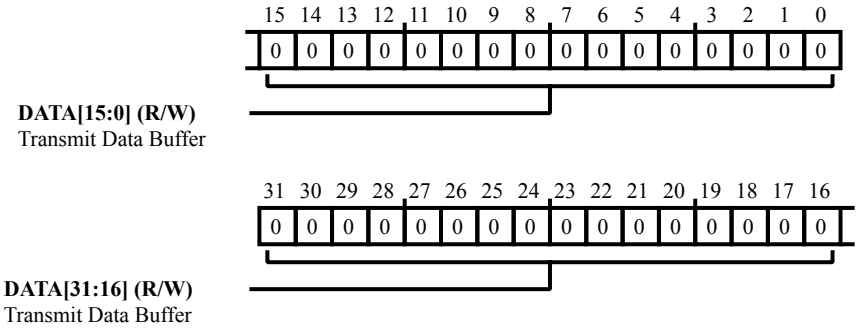

Figure 19-17: LP_TX Register Diagram

Table 19-11: LP_TX Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	DATA	Transmit Data Buffer.

Shadow Input Transmit Buffer Register

The LP_TXIN_SHDW register contains the same data as the input stage of the transmit buffer. Read of this shadow transmit buffer does not update the LP_STAT register.

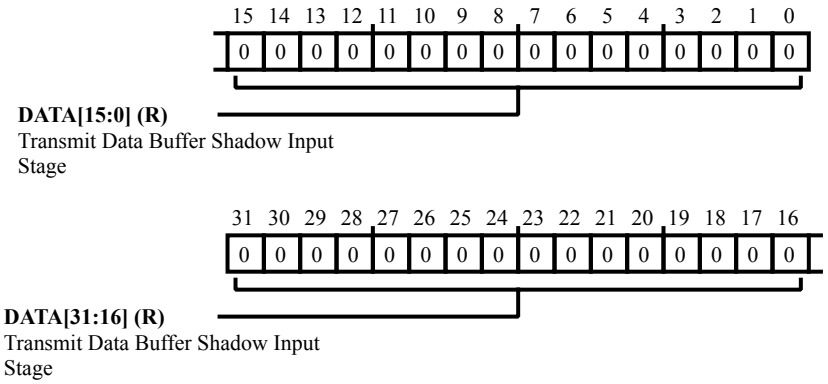

Figure 19-18: LP_TXIN_SHDW Register Diagram

Table 19-12: LP_TXIN_SHDW Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	DATA	Transmit Data Buffer Shadow Input Stage.

Shadow Output Transmit Buffer Register

The LP_TXOUT_SHDW register contains the same data as the output stage of the transmit buffer. Read of this shadow transmit buffer does not update the LP_STAT register.

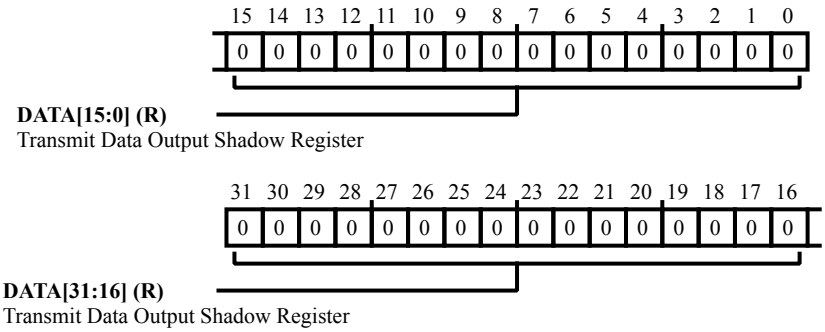

Figure 19-19: LP_TXOUT_SHDW Register Diagram

Table 19-13: LP_TXOUT_SHDW Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	DATA	Transmit Data Output Shadow Register.

20 Pulse Density Modulation (PDM) Microphone Interface

The pulse density modulation (PDM) microphone interface converts digital PDM microphone data to I^2S/TDM format. The microphone data in I^2S/TDM format is then routed internally to the SPORT/ASRC or externally via the DAI pins. Each DAI unit has one PDM interface.

PDM Features

The PDM interface includes the following features:

- Four channels of PDM audio inputs from digital microphones
- 16×, 32×, or 64× decimation ratio of PDM to pulse code modulation (PCM) audio data
- 24-bit resolution to support high sound pressure level (SPL) microphones
- 126 dB A-weighted SNR
- 4 kHz to 192 kHz output sampling rate
- Bit clock rates of 64×, 128×, 192×, 256×, 384×, or 512× the output sampling rate

  NOTE: Refer to the product data sheet for the maximum BCLK frequency.
- Automatic PDM clock generation
- Target I^2S or TDM output interface
- Supports up to 16 TDM slots
- Configurable TDM slot routing and sizes

PDM Functional Description

The following are the typical connections for the PDM module:

- PDM interface–PDM clock (PDM_CLK0) and PDM data (PDM_DAT0 and PDM_DAT1) are typically routed to DAI pins via the Signal Routing Unit (SRU) which is in turn connected to a PDM data source, for example, PDM microphones.
- Target I^2S/TDM interface –Bit clock (BCLK), frame sync (LRCLK), and serial data (SDATA) signals are typically routed internally to the SPORT using the SRU for the microphone data to reach memory in PCM format.
- Control registers–All PDM related control registers are included in the DAI MMR system.

ADSP-SC59x PDM Register List

Pulse Density Modulation interface block

Table 20-1: ADSP-SC59x PDM Register List

Name	Description
PDM_CTL0	PDM Control Register
PDM_HPF_CTL	High Pass Filter Control Register
PDM_RESET	Software Reset Register
PDM_SP_CTL0	Serial Port Control0 Register
PDM_SP_CTL1	Serial Port Control1 Register

PDM Block Diagram

The *PDM Interface Block Diagram* figure illustrates the interconnection of PDM block in the DAI subsystem.

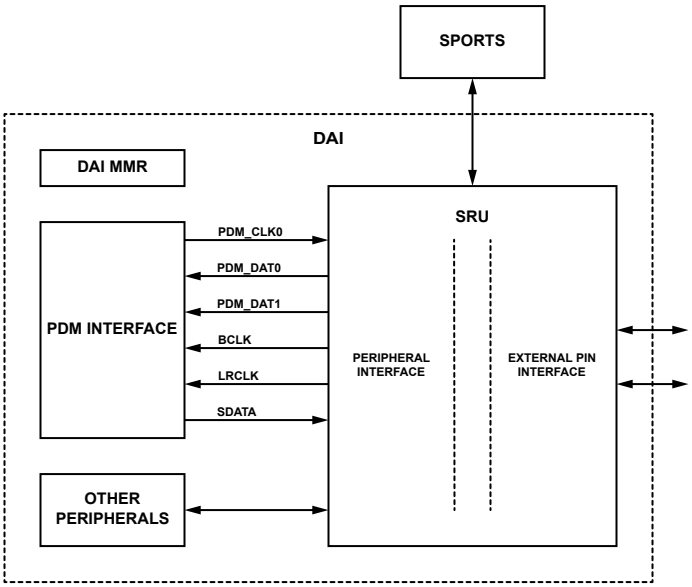

Figure 20-1: PDM Interface Block Diagram

PDM Architectural Concepts

The PDM interface provides up to four channels of decimation from a 1-bit PDM source to a 24-bit PCM audio stream. The down sampling ratio is typically 64 × f_S, where f_S is the PCM output sampling rate. The down sampling ratio can also be set at 32 × f_S or 16 × f_S, to facilitate higher output sampling rates. All channels decimate at the same ratio. The 24-bit down-sampled PCM audio data is output via standard stereo (I^2S, left justified, right justified) or TDM format. The input sources for the PDM interface can be any device that has a target PDM output, such as a digital microphone.

Internally, there are four channels. The *PDM Channel Mapping* table details the mapping of the PDM_DATx input pins to the internal channels. If a channel is not in use, the associated PDM_DATx pin can be disabled to save power.

Table 20-2: PDM Channel Mapping

Input Pin	PDM_CLK Edge	Internal Channel
PDM_DAT0	Falling	0
PDM_DAT0	Rising	1
PDM_DAT1	Falling	2
PDM_DAT1	Rising	3

PDM Initialization and Clocking

After I^2S clocks are applied, there are 16 full frame sync cycles of initialization time before the PDM clocks start. Once the PDM clocks start running, 48 additional frame sync cycles elapse before the PDM data is driven on the SDATA pin.

During normal operation, if the bit clock or frame sync is removed then the PDM clock output stops immediately and the PDM interface enters a lower power state. If the clocks resume, the PDM interface relocks to the bit clock and frame sync signals and adjusts the PDM clock output accordingly. The length of time before the PDM clock outputs resume is 4 frames ± 1 frame to lock to the incoming signal. If the format of the clock signals change, the PDM interface detects this change at the end of the frame and stops the PDM clock outputs. Then, the device reconfigures and resumes sending PDM clocks with no user intervention. Again, the PDM clock outputs resume after 4 frames ±1 frame to lock to the incoming signal.

The PDM interface requires a clock rate that is a minimum of 64× the frame sync sample rate. Bit clock rates of 128×, 192×, 256×, 384×, and 512× the frame sync rate are also supported. The PDM interface automatically detects the ratio between the bit clock and frame sync signals and generates a PDM clock output at 64 × the frame synce rate by default. If lower decimation ratios are selected in the `PDM_CTL0` register, the PDM output clock rate corresponds to the configuration set in the `PDM_CTL0.DEC_RATIO` bit field. The minimum sampling rate is 4 kHz and the maximum sampling rate is 192 kHz. The PDM clock range is 256 kHz to 6.144 MHz. Internally, all processing is done at the PDM clock rate.

SPORT Interface

The PDM interface supports I^{2}S and TDM serial output formats. It supports up to 16 TDM slots, with slot widths of 16, 24, or 32-bits. Internal channels are connected to output slots by configuring the appropriate channel slot bit fields in the PDM_SP_CTL1 register. By default, each channel is routed to the slot with the same number. For example, the reset value of the PDM_SP_CTL1.CH3_SLOT bit field is 0x0011, connecting channel 3 to slot 3.

Each channel has a drive select bit: PDM_SP_CTL1.CH0_DRV, PDM_SP_CTL1.CH1_DRV, PDM_SP_CTL1.CH2_DRV, or PDM_SP_CTL1.CH3_DRV. If the drive select bit is set to one, the channel is driven on the serial port in the appropriate output slot; and if it is cleared to zero, the channel does not drive (tristate high impedance mode). Note that this feature is useful only when the SPORT data is driven out of the processor via a DAI pin buffer and not when the data is routed internally to the SPORT or ASRC. To use this feature, tie the PDMx_SDATA_OE_O signal to the DAIx_PBENxx_I signal of the DAI pin buffer.

It is possible to erroneously configure more than one channel to drive on a single TDM slot. There is no cross-checking of register settings to prevent this configuration, but it will not damage the device. In this case, only the data from the lowest channel number is driven into the slot and the data from the higher channels will not be driven.

The PDM_SP_CTL0.SAI_MODE bit configures the SPORT interface mode. The two modes are stereo and TDM. The primary difference between these two modes is the format of the frame sync clock that is expected and the polarity of the active edge of the clock.

With the PDM_SP_CTL0.SAI_MODE bit and the PDM_SP_CTL0.LRCLK_POL bit set to zero, the serial port is in stereo mode with the clock polarity set to normal. In this mode, there must be only two channels of data sent. The frame starts with the falling edge of the frame sync, with an expected cycle of 50% high and 50% low. Channel 0 sends out data when the clock is low. As soon as the frame sync goes high the data from channel 0 stops and channel 1 begins sending data. Both edges of the frame sync clock are used. If the duty cycle is not 50/50, there may be errors in the resulting data. In this mode of operation, the PDM interface does not expect 32-bit clock transitions for each channel. All bit clock to frame sync ratios are supported.

With the PDM_SP_CTL0.SAI_MODE bit set to one and the PDM_SP_CTL0.LRCLK_POL bit set to zero, the serial port is in TDM mode with the clock polarity set to normal. In this mode, it can transmit anywhere from one channel to as many as four channels spread out across 16 data slots in TDM-16 format.

The PDM interface supports bit clock rates of 64×, 128×, 192×, 256×, 384×, or 512× the output sampling rate. The BCLK frequency however, must not exceed the maximum value specified in the data sheet. These bit clock rates are combined with the three different TDM slot sizes of 16-bit, 24-bit, or 32-bit slots, selected by the PDM_SP_CTL0.CH0_SLOT_WIDTH bit field. Note that as soon as the next frame sync edge is detected, the PDM interface restarts from slot 0 and any unreceived data from the previous frame is lost. This is how to achieve unusual TDM formats like TDM-5 or TDM-10. In addition, there is only support for TDM-16 or less for placing data into a TDM slot. Data cannot be placed into slots above 16, however it is possible to configure the PDM interface to tristate all unused TDM slots, which includes all the slots above the first 16 slots for modes that have more than 16 slots.

In TDM mode, the frame sync is expected to be a positive going pulse that is at least one-bit clock period wide. A falling edge is not necessary, it is only important that the signal is low long enough to meet the timing specification for a read before transitioning from low to high. The frame starts with the rising edge of this pulse. The data is clocked out according to the slot width and using the data format specified in the PDM_SP_CTL0 register. The PDM interface continues to send data until all active channels are sent and then the device waits for the next frame sync clock edge to start sending the next set of frame samples.

In TDM-8 format, when the PDM interface is set to output channel 0 through channel 3 into slot 0 to slot 3, the PDM interface can tristate for the remainder of the frame. This allows another PDM to output four channels onto slot 4 through slot 7. These slots do not have to be consecutive, and the two devices can be configured to interleave their respective data. The serial port can be set up to drive only when there is data to drive into a data slot. If all eight channels are not in use, configuring the drive select bit in the PDM_SP_CTL1 for the unused channels will assign those slots to drive or tristate in the TDM data stream. Note that this feature is useful only when the SPORT data is driven out of the chip via a DAI pin buffer and not when the data is routed internally to the SPORT or ASRC. To use this feature, tie the PDMx_SDATA_OE_O signal to the DAIx_PBENxx_I signal of the DAI pin buffer.

To invert the IRCLK polarity, set the PDM_SP_CTL0.LRCLK_POL bit to one. With inverted clock polarity in stereo mode, channel 0 is sent out when the frame sync is high, so the start of the frame is a low to high transition. With inverted clock polarity in TDM mode, the frame sync pulse is negative, so the frame starts with the high to low transition.

Configure the PDM_SP_CTL0.DATA_FORMAT bit field to align data within the 32-bit data slot. There is support for left justified mode, delayed by one-bit clock period; and right justified modes for 24-bit, 20-bit, and 16-bit data word sizes.

SPORT Timing

The *Stereo Mode* figure is a timing diagram for I²S mode with 24-bit data.

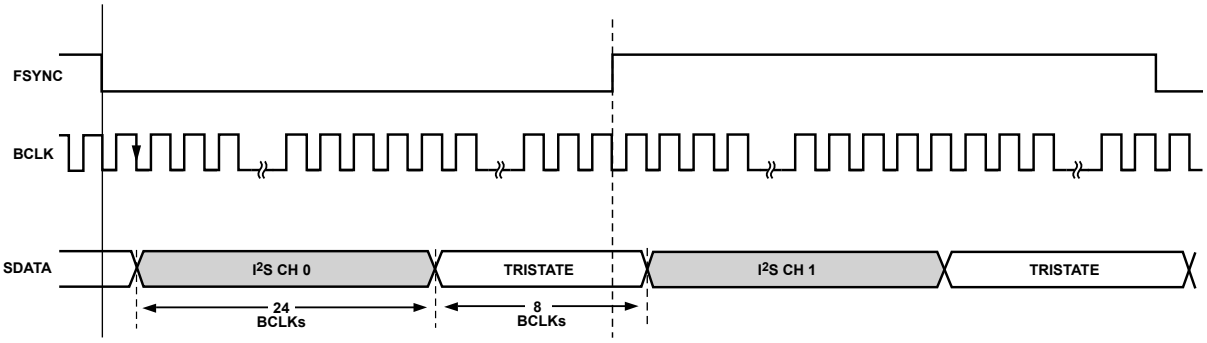

Figure 20-2: Stereo Mode

The *TDM4 Mode Four Channel* figure is a timing diagram for TDM4 mode with default channel assignments, 24-bit data, and 32-bit slots, and normal polarity clocks.

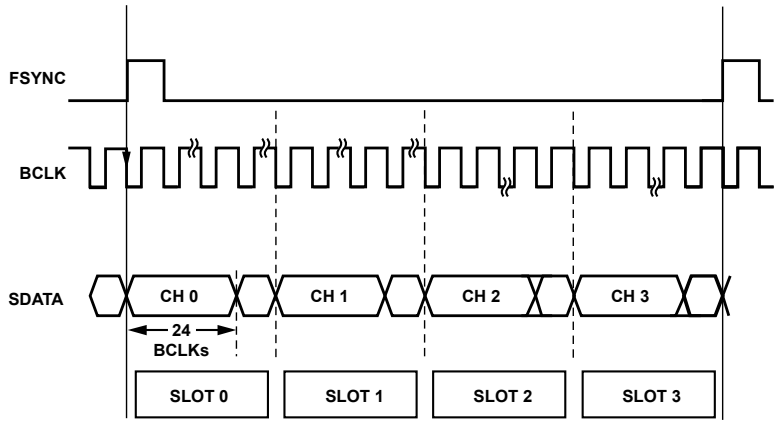

Figure 20-3: TDM4 Four Channel

The ***TDM4 Mode Two Channel*** figure is a timing diagram that shows TDM4 mode with only two channels enabled, 24-bit data delayed by zero BCLK, 32-bit slots, and normal polarity clocks.

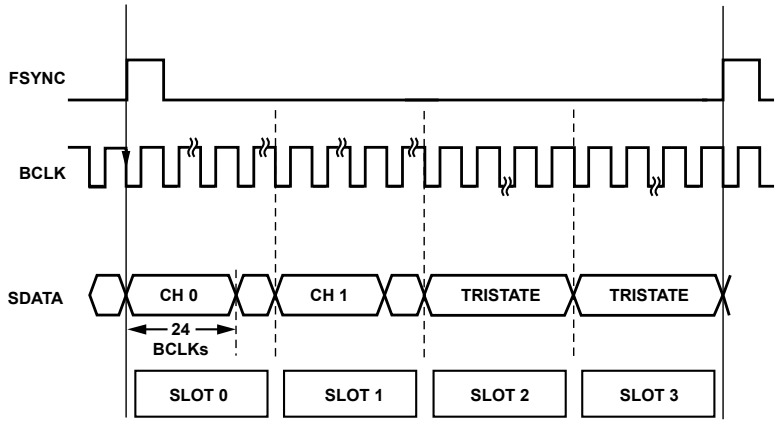

Figure 20-4: TDM4 Two Channel

The ***TDM8 Mode Four Channel*** figure is a timing diagram that shows TDM8 mode with all the four channels enabled, 24-bit data delayed by zero BCLK, 32-bit slots, and normal polarity clocks.

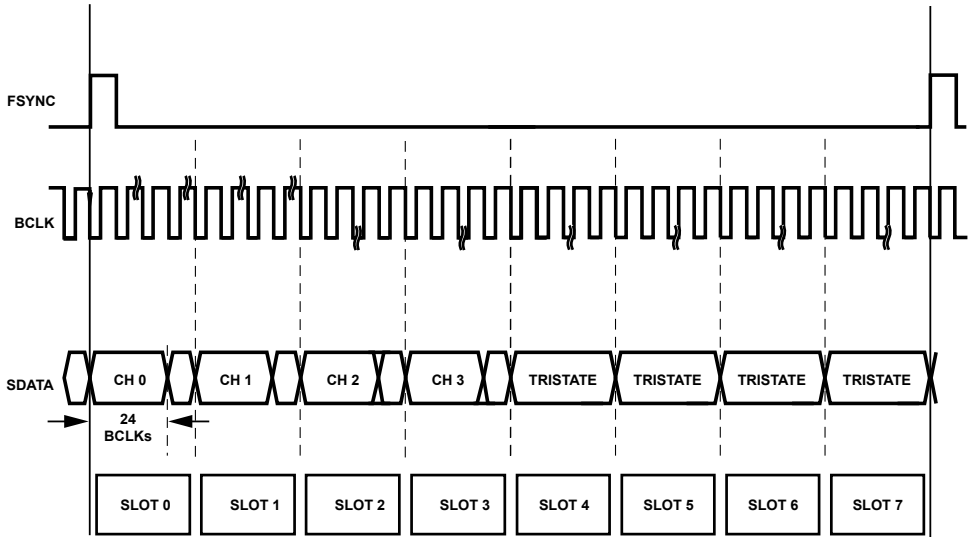

Figure 20-5: TDM8 Four Channels

The *TDM2 Mode Two Channel* figure is a timing diagram that shows TDM2 mode with two channels enabled, 24-bit data delayed by one BCLK, 32-bit slots, and normal polarity clocks.

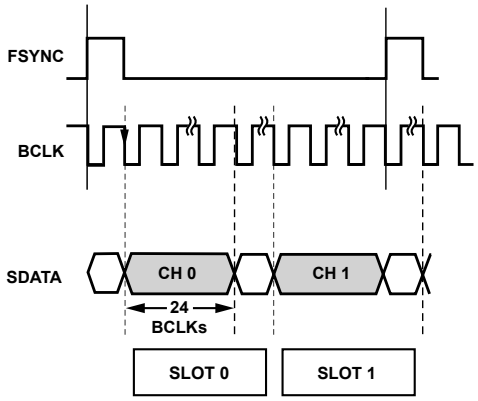

Figure 20-6: TDM2 Two Channels

High Pass Filter

There is a first order high-pass filter in the signal path. It is disabled by default and can be enabled by setting the `PDM_HPF_CTL.EN` bit. To adjust the cutoff frequency, configure the `PDM_HPF_CTL.FC` bit field. The settings are relative to the output sampling rate.

The *HPF Cutoff Frequency Selection* table shows the setting and the cutoff frequency for common sampling rates.

Table 20-3: HPF Cutoff Frequency Selections

PDM_HPF_CTL.HPF_FC	Multiplication Factor	48 kHz Sampling Rate Cutoff Frequency (Hz)	32 kHz Sampling Rate Cutoff Frequency (Hz)
0101	0.00505	242.4	161.6
1001	0.00251	120.48	80.32

Table 20-3: HPF Cutoff Frequency Selections (Continued)

PDM_HPF_CTL.HPF_FC	Multiplication Factor	48 kHz Sampling Rate Cutoff Frequency (Hz)	32 kHz Sampling Rate Cutoff Frequency (Hz)
0111	0.00125	60	40

1111	0.00000468	0.23328	0.15552

PDM Programming Model

The following section provides information on configuring the PDM interface.

Configuring the PDM Interface

Use the following steps to configure the PDM interface:

Optional high pass filter configuration:

- Configure the `PDM_HPF_CTL` register to enable the high pass filter using the `PDM_HPF_CTL.EN` bit and set the cutoff frequency by programming the `PDM_HPF_CTL.FC` bit field.

1. Configure `PDM_SP_CTL0` register to set the following parameters:
    a. SPORT mode (Stereo/TDM) with the `PDM_SP_CTL0.SAI_MODE` bit
    b. SPORT data format (BCLK delay) with `PDM_SP_CTL0.DATA_FORMAT` bit field
    c. SPORT slot width (16, 24, or 32 bits) with `PDM_SP_CTL0.CH0_SLOT_WIDTH` bit field – applicable only for the TDM mode
    d. BCLK capture edge (rising/falling) with the `PDM_SP_CTL0.BCLK_POL` bit
    e. LRCLK polarity (normal/inverted) with the `PDM_SP_CTL0.LRCLK_POL` bit
2. Configure the `PDM_SP_CTL1` register to set the following parameters:
    a. PDM to SPORT channel slot mapping with serial port channel slot bit fields (CHx_SLOT)
    b. To select if the PDM channel will get driven to the associated SPORT channel slot with the serial port channel drive select bit (CHx_DRV).

3. Configure the PDM_CTL0 register to configure the decimation ratio with the PDM_CTL0.DEC_RATIO bit field and finally enable the PDM clock with the PDM_CTL0.CLK0_EN bit.

Software Reset

The PDM_RESET.SOFT bit is set to perform a soft reset of the PDM block. Setting this bit resets internal bit clock counters and audio data, but it does not reset the PDM register settings. This bit is self-clearing.

ADSP-SC59x PDM Register Descriptions

Pulse Density Modulation interface block (PDM) contains the following registers.

Table 20-4: ADSP-SC59x PDM Register List

Name	Description
PDM_CTL0	PDM Control Register
PDM_HPF_CTL	High Pass Filter Control Register
PDM_RESET	Software Reset Register
PDM_SP_CTL0	Serial Port Control0 Register
PDM_SP_CTL1	Serial Port Control1 Register

PDM Control Register

The PDM_CTL0 register (read/write) controls the channel activation, clock enable and Decimation ratio.

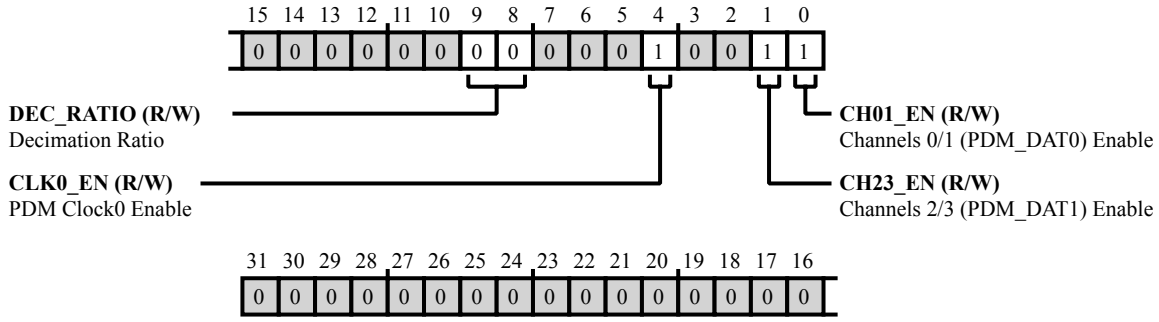

Figure 20-7: PDM_CTL0 Register Diagram

Table 20-5: PDM_CTL0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
9:8 (R/W)	DEC_RATIO	Decimation Ratio.	
		0	64 times decimation
		1	32 times decimation
		2	16 times decimation
4 (R/W)	CLK0_EN	PDM Clock0 Enable.	
		0	PDM_CLK0 output disabled
		1	PDM_CLK0 output enabled
1 (R/W)	CH23_EN	Channels 2/3 (PDM_DAT1) Enable.	
		0	PDM channels 2/3 disabled
		1	PDM channels 2/3 enabled
0 (R/W)	CH01_EN	Channels 0/1 (PDM_DAT0) Enable.	
		0	PDM channels 0/1 disabled
		1	PDM channels 0/1 enabled

High Pass Filter Control Register

The PDM_HPF_CTL register (read/write) controls the High Pass Filter.

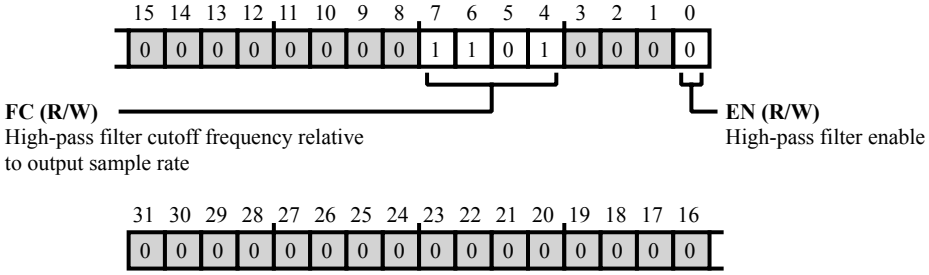

Figure 20-8: PDM_HPF_CTL Register Diagram

Table 20-6: PDM_HPF_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration

		12	0.0000389
		13	0.0000194
		14	0.00000971
		15	0.00000486
0 (R/W)	EN	High-pass filter enable.	
		0	High Pass Filter Off
		1	High Pass Filter On

Software Reset Register

The PDM_RESET register (read/write) controls the software reset operations.

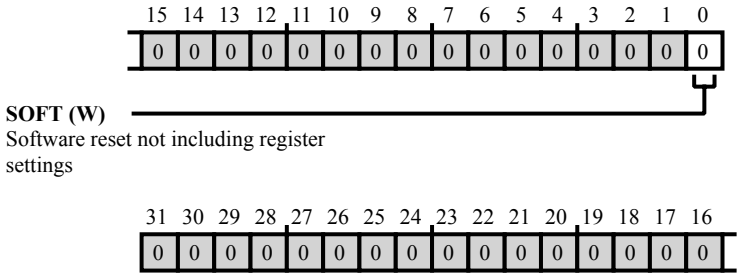

Figure 20-9: PDM_RESET Register Diagram

Table 20-7: PDM_RESET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (RX/W)	SOFT	Software reset not including register settings.	
		0	N/A
		1	Write once to soft reset

Serial Port Control0 Register

The PDM_SP_CTL0 register (read/write) controls serial port mode, data format and slot width.

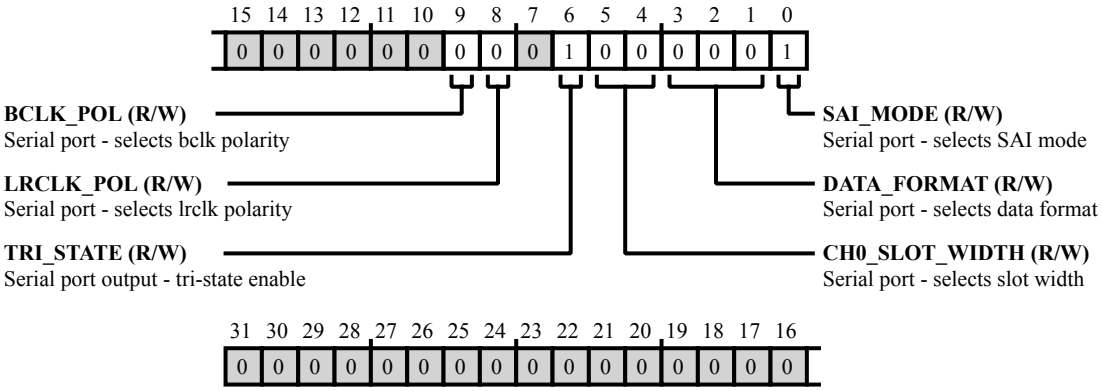

Figure 20-10: PDM_SP_CTL0 Register Diagram

Table 20-8: PDM_SP_CTL0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W)	BCLK_POL	Serial port - selects bclk polarity.	
		0	Capture on rising edge
		1	Capture on falling egde
8 (R/W)	LRCLK_POL	Serial port - selects lrclk polarity.	
		0	Normal Polarity
		1	Inverted Polarity
6 (R/W)	TRI_STATE	Serial port output - tri-state enable.	
		0	tri-state disabled
		1	tri-state enabled
5:4 (R/W)	CH0_SLOT_WIDTH	Serial port - selects slot width.	
		0	32 BCLK's per slot
		1	16 BCLK's per slot
		2	24 BCLK's per slot
3:1 (R/W)	DATA_FORMAT	Serial port - selects data format.	
		0	Typical I2S mode, delay by 1
		1	Left Justified,delay by 0
		2	Delay by 8
		3	Delay by 12

21 Universal Serial Bus Controller (USBC)

The USB OTG controller provides a low-cost connectivity solution for consumer mobile devices such as cell phones, digital still cameras, and MP3 players. It allows these devices to transfer data using a point-to-point USB connection without the need for a personal computer host.

The USB controller can operate in a traditional USB device-only mode as well as the host mode presented in the On-The-Go (OTG) supplement to the USB 2.0 specification.

USBC Features

The USB OTG controller provides the following features:

- Complies with the On-The-Go Supplement to the USB 2.0 Specification (revision 2.0)
- Supports high speed (HS, 480 Mbps), full speed (FS, 12 Mbps) and low speed (LS, 1.5 Mbps) rates
- Provides scatter/gather DMA mode access support on the application side
- Provides ULPI interface support on the MAC PHY
- Supports up to 12 bidirectional endpoints including control endpoint 0
- Supports Session Request Protocol (SRP)
- Supports Host Negotiation Protocol (HNP)
- Supports up to 16 host channels. In host mode, when the number of device endpoints to be supported is more than the number of host channels, software can reprogram the channels to support up to 127 devices, each having 32 endpoints (IN + OUT), for a maximum of 4,064 endpoints.
- Includes automatic ping capabilities
- Supports the keep-alive in low speed mode and SOFs in high and full speed modes

The application interface uses the bus to support the following:

- Bus completer interface for accessing Control and Status Registers (CSRs). (Access to FIFO and queues is not supported).
    - Bus requester interface for data FIFO access

  - Supports 32-bit data on the AHB bus
  - Supports little endian mode
  - Supports INCR4, INCR8, INCR16, INCR, and single transfers on the bus completer interface
  - Supports error and okay bus responses on the bus requester interface. The bus completer interface supports only an okay response. An error response is generated on the bus completer interface when the transfer size (HSIZE) is not equal to 32 bits.
  - Software-selectable bus burst type on bus requester interface in DMA mode
- When INCR4 is chosen, the core uses INCR/INCR4 or single
- When INCR8 is chosen, the core normally uses INCR8. However, at the beginning and at the end of a transfer, it can use INCR or single, depending on the size of the transfer.
- When INCR16 is chosen, the core normally uses INCR16. However, at the beginning and at the end of a transfer, it can use INCR or single, depending on the size of the transfer.
- Handles the fixed burst address alignment. For example, INCR16 is used only when lower addresses [5:0] are all 0.
- Generates bus busy cycles on the bus requester interface
- Supports the 1KB boundary breakup

The MAC PHY interface supports the ULPI interface and 8-bit SDR or 4-bit DDR

The system memory architecture has the following features:

- Supports internal DMA mode for the system memory architecture
- Provides descriptor-based scatter/gather DMA operation

Supports Non-DWORD alignment:

- In host mode, supports scatter/gather DMA mode, IN and OUT transfers - Non-DWORD alignment of buffer addresses
- In device mode, supports scatter/gather DMA mode, IN and OUT transfers - Non-DWORD alignment of buffer addresses

NOTE: Non-DWORD alignment support is available only for buffer addresses and not for descriptors.

The internal memory features:

- Support for a dedicated transmit FIFO for each of the device IN endpoints. Each FIFO can hold multiple packets.
- An interface for remote memory support used to signal the core of a DMA write complete event on the system
- Support for packet-based, dynamic FIFO memory allocation for endpoints for small FIFOs, and flexible, efficient use of RAM.

- Support to change the FIFO memory size of an endpoint during transfers
- Support for endpoint FIFO sizes that are not powers of 2, to allow the use of contiguous memory locations.
- Optional support for transmit and receive thresholding in DMA mode (in device mode). Thresholding and threshold length are selectable through global registers.

USBC Functional Description

The USB OTG controller includes the following interfaces:

- *Bus completer and data RAM* – the bus completer provides the microcontroller with read and write access to the CSRs of the core. The data RAM interface connects to single port RAM (SPRAM) for transaction data storage which is 4096 deep.
- *USB 2.0 PHYs and serial transceiver* – The USB OTG core supports the ULPI PHY interface (Revision 1.1). The ULPI PHY is unidirectional, with 8-bit SDR (single data rate).
- Internal DMA controller (bus requester) – enables the core to act as a requester on the bus to transfer data to and from the bus.
- PHY control interfaces to ULPI PHY registers.
- Descriptor-based scatter/gather DMA controller for device and host mode. (Descriptor-based congruent-sequential DMA is not supported).
- The core supports the scatter/gather DMA operation in both device and host mode.

NOTE: Hubs (split transfers) are not supported in the host scatter/gather DMA mode of operation. Split transfers are supported only in host buffer DMA (internal DMA) mode of operation.

ADSP-SC59x USBC Register List

The Universal Serial Bus Controller (USBC) is a multi-point high-speed dual-role USB 2.0-compliant controller. The USB controller can operate in a traditional USB peripheral-only mode as well as the host mode presented in the On- The-Go (OTG) supplement to the USB 2.0 Specification. A set of registers governs USBC operations. For more information on USBC functionality, see the USB controller register descriptions.

USBC Block Diagram

The ***USBC Block Diagram*** shows the USB OTG controller in a typical system.

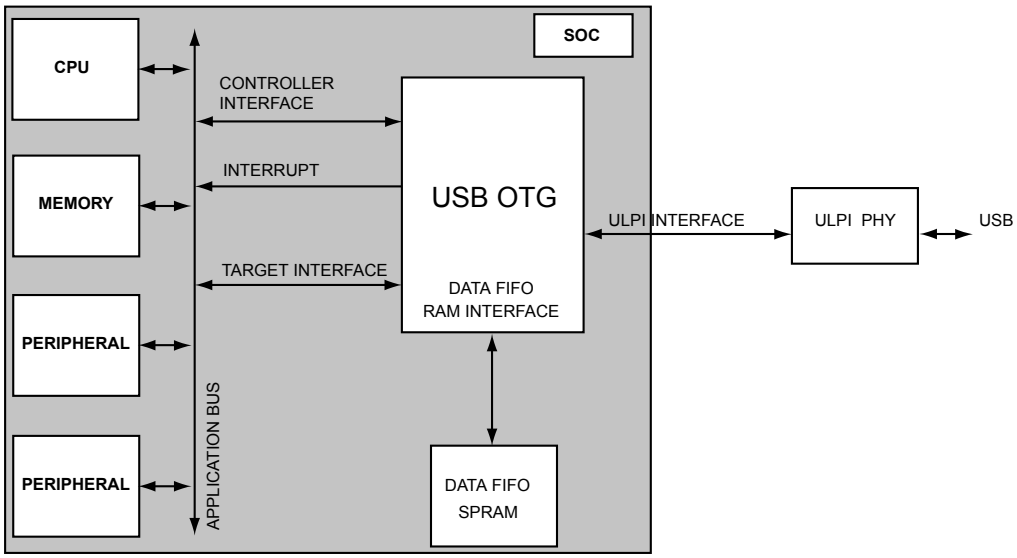

Figure 21-1: USBC Block Diagram

USBC Definitions

A list of common USB terms and their definitions as used in this specification and based on the USB controller follows:

'A' Device

The USB device with a mini-A plug inserted into its receptacle. The A device always supplies power to VBUS.

'B' Device

The USB device with a standard-B or mini-B plug inserted into its receptacle. The B device starts a session as the peripheral.

Bidirectional endpoint

An endpoint that can concurrently support both receive and transfer packets.

Control endpoint

An endpoint used only for transfer of USB control packets for setup and configuration. In all USB devices, the control endpoint refers to the bidirectional endpoint 0.

Dual role device

A USB device that can operate either as the USB host in an OTG session or as a traditional USB peripheral.

Endpoint

A single physical communication channel for USB, implemented as a FIFO and control logic for that endpoint. Each endpoint has an associated USB transfer type, maximum packet size, bandwidth requirement, endpoint number, and (often) a fixed transfer direction.

Frame

A regular, fixed 1 ms (LS and FS) / 125 us timeslot that can contain several transactions. The transfer type determines the permissible transactions for a given endpoint.

HNP

Host negotiation protocol. Part of the USB OTG supplement that allows the host function to be transferred between two connected dual role devices.

Packet

The lowest level of data exchange on USB. The transfer type and buffer size of the USB peripheral determine the size.

PHY

The PHY is a transceiver circuit that implements the physical layer of USB. For full speed USB OTG, this circuit includes line drivers and receivers, pull-up, or pull-down resistors as well as device ID and VBUS level detection.

Session

A period during which USB transfers take place within an OTG connection. The A device (drives VBUS) or B device (initiates SRP) can initiate this period. VBUS is powered during a session.

SRP

Session request protocol. Part of the USB OTG supplement that allows a B device to turn on VBUS and initiate a USB session.

Transaction

Collection of one or more packets in sequence

Transfer

Collection of one or more transactions in sequence

Unidirectional endpoint

Endpoint with its direction fixed in a single direction (for example, it can only receive packets from the USB) in both host and peripheral modes.

Transmit and Receive FIFOs

A transmit and receive FIFO interface on the USB OTG core is used to move data in and out of the data FIFO RAM. These movements are classified as periodic (for isochronous and interrupt transfers) or non-periodic (for bulk and control transfers). The interface has

- A single receive FIFO for all host IN and device OUT transfers
- Dedicated Tx FIFO for each IN endpoint for periodic /non-periodic device IN transfers

DDR Mode

The ULPI PHY can be unidirectional or bidirectional, either with 8-bit SDR or 4-bit DDR mode. In the USBC module, the selection of SDR and DDR modes is software configurable. In SDR mode, data is transferred on D0-D7 of the ULPI bus. In DDR mode, data is transferred only on D0-D3 (4-bit wide) of ULPI bus. In SDR mode, DATA[3:0] pins are synchronized to the rising edge of the clock. In DDR mode, DATA[3:0] are synchronized to both the rising and falling edges of the clock; DATA[7:4] pins can be left unconnected. DDR mode helps to reduce the board traces.

All 4-bit DDR mode timing and operations adhere to the ULPI specification for 4-bit data mode.

To configure the USB controller into DDR mode, software must set (=1) the USBC_CFG.DDRSEL bit before starting any ULPI transmission. All USB/ULPI features, operations, and register settings remain the same for SDR and DDR modes.

NOTE: Ensure that the USB PHY is also configured to DDR mode before configuring the USB controller to DDR mode.

Restrictions

The USBC modules has some restrictions for response time and thresholding.

Response Time Restriction

For the controller as a device, there is a worst-case response time for any tokens that follow an isochronous OUT transaction. This worst-case response time depends on the bus clock frequency. The controller registers are in the bus domain; the controller does not accept another token before updating these register values. The worst case is for any token following an isochronous OUT. For an isochronous transaction, there is no handshake, and the next token can come sooner than expected. When the bus clock is the same as the PHY clock, this worst-case value is seven PHY clocks. When the bus clock is faster, this value is smaller.

If this worst-case condition occurs:

- For bulk/interrupt tokens, the controller responds with a NAK and drops the isochronous and setup tokens. The host interprets this event as a time-out condition for SETUP and retries the SETUP packet.
- For isochronous transfers, the controller sets the USBC_ISTAT.INCOMPLP interrupt to inform the application that isochronous IN/OUT packets were dropped.

At the system level, this limitation can reduce the performance of the device controller because the controller drops or sends NAK to the token which is sent by the host too close to end of the preceding isochronous OUT token. For bulk, interrupt, and control transactions, the system recovers as the host retires the token; the transactions will eventually complete. For isochronous transactions, the host proceeds to the next transaction scheduled for the next interval.

A significant performance degradation occurs in the following cases:

- The device is connected to a host which is capable of consistently sending a token within 88-96 bit times, that is, six to seven PHY clocks from the end of the preceding isochronous OUT token.
- The device is connected to a host through multiple layers of hubs such that the interpacket gap between an isochronous OUT token and the following token shrinks to less than seven PHY clocks.

However, the system does not stop responding or enter an unrecoverable state. It has been observed that the USB host implementation is unable to send tokens with the worst-case inter-packet gap of 88-96 bit times.

Thresholding

When enabling thresholding, the bus must run at 60 MHz or faster. Do not enable the `USBC_THR_CTL_D.RXTHREN` bit because it may cause issues in the RxFIFO (especially during error conditions such as Rx error and babble).

USBC Architectural Concepts

The USB controller operates in either of two USB operation modes (device or host mode) at a given time.

In device mode, the USB controller encodes, decodes, checks, and directs all USB packets sent and received, responding appropriately to host requests. Data is transferred from the processor core memory into the Tx FIFOs of the device onto USB as IN packets. In the other direction, USB OUT packets are received into the Rx FIFOs (having been sent from the host) and transferred to system memory for processing or storage. In peripheral mode, the USB controller acts as a completer device to another USB host; either a personal computer or another OTG host controller.

When operating in host mode, the USB controller uses simple hosting capabilities to requester point-to-point connections with another USB peripheral, initiating transfers on the bus for the peripheral to respond. USB IN packets are received into the Rx FIFOs for transfer into the processor core memory. Data written into Tx FIFOs is transmitted onto the bus as USB OUT packets. In this mode, the USB controller encodes, decodes, and checks USB packets sent and received. The controller automatically schedules isochronous and interrupt transfers from the endpoint buffers. It performs one transaction every *n* frames, where n represents the polling interval programmed for the endpoint.

Any of the endpoints can be programmed to be written to or read from using the DMA requester channels. This configuration provides the most efficient means of transferring data between the controller and on-chip memory.

The USB provides two top-level maskable interrupts, each of which can be sourced from any or all transmit endpoint status, receive endpoint status, or global USB status.

The RAM interface of the USB controller supports a single block of synchronous single-port RAM used to buffer the USB packets.

ATTENTION: Check the processor data sheet for requirements regarding minimum system clock frequency needed for proper USB operation.

System Level Architecture

The following sections describe the system level architecture.

Bus Interface Unit (BIU)

The bus interface unit (BIU) includes the completer bus interface unit (BIUS) and the requester bus interface unit (BIUM).

Requester Bus Interface Unit (BIUM)

The internal DMA controller translates internal DMA requests into bus requester requests. The DMA address, transfer count, and packet count registers reside in the CSR block. The address of the selected channel is given as an input to the internal DMA controller. The BIUM converts the internal DMA request cycles into bus cycles. Characteristics of this interface include the following:

- Fully AMBA 2.0-compliant bus requester —No restrictions
- SINGLE, INCR, INC4, INC8, or INC8 burst types. When INC4, INC8, or INC16 is chosen, SINGLE and INCR cycles can happen due to a split, retry, or early termination.

  The USBC core uses INCR in the following scenarios:

  - Remaining data transfers (when the data length is not a direct multiple of the burst length, the remaining data is sent using INCR burst type).
- Handles bus ERROR condition
- Inserts busy cycle when needed by the application
- Handles bus 1 KB boundary breaking
- Data bus and address bus (of the bus requester) are 32 bits wide. The USBC core generates transfer with HSIZE = 2 (DWORD) and 0 (BYTE).

Completer Bus Interface Unit (BIUS)

The bus completer interface unit converts bus cycles to CSR write/read, data FIFO read/write, and DFIFO push/pop signals. DFIFO read and write access is made available only for testing purposes. The read, write, push, and pop signals are active high for one clock.

The wait states for different accesses are:

- Zero wait states on writes to the CSR, except when the state machine is busy with a previous push to DFIFO or write data RAM
- Zero wait states on pushes to DFIFO, one additional wait state when the USB accesses the FIFO RAM
- Zero wait states on debug writes to DFIFO, one additional wait state when the USB accesses the FIFO RAM
- One wait state on reads to CSR registers
- One initial wait state on NSEQ pop access and no subsequent wait states on NSEQ/SEQ back-to-back pops to DFIFO; one additional wait state when the USB accesses the FIFO RAM.
- Two wait states on software debug reads to DFIFO, one additional wait state when the USB accesses the FIFO RAM (debug access to DFIFO is not optimized to save area)

The BIUS is:

- Fully AMBA 2.0 compliant bus completer with no restrictions
- Supports INCR4, INCR8, INCR16, INCR and SINGLE transfers

- Supports busy and early terminations
- CSR and DFIFO reads/writes must always be 32-bit; 8- and 16-bit write accesses commit unknown values to the DFIFO.
- Generates OKAY responses only
- Does not generate SPLIT, RETRY, or ERROR responses

To make the software transparent to the hardware implementation, one 4 KB region is mapped to each device endpoint or host channel. The controller has:

- One common Rx FIFO, used in host and device modes
- Separate IN endpoint transmit FIFO for each device mode IN endpoints in a dedicated transmit FIFO operation
- The FIFO SPRAM is also used for storing some register values to save gates. In scatter/gather DMA mode, four SPRAM locations (four 35-bit words) are reserved for this reason.
- In DMA mode, one SPRAM location (one 35-bit word) is used for storing the DMA address

  Within the controller:

- Writes to any non-periodic IN endpoint or OUT channel are mapped to the non-periodic Tx FIFO

In device mode, a write access to an IN endpoint is mapped to the corresponding endpoint Tx FIFO. The `USBC_CTL_IEP0_D`[30:27] field maps an endpoint to a specific device periodic FIFO).

When `USBC_CTL_IEP[n]_D.TXFNUM` = 0, the endpoint is mapped to a common non-periodic Tx FIFO. Otherwise, it is mapped to the FIFO number selected by these fields. Hardware maintains the non-periodic Tx queue and host mode Tx periodic queues for internal operation. For debugging, software can read the top of the queue information. Because the read domain of these queues is in the PHY domain, no debug pop access is provided to these queues, saving area; access is provided only to the top of the queue.

NOTE: In device mode, each periodic IN endpoint has a separate buffer allocated, holding only one packet at a time. Therefore, there is no device mode periodic queue. Limiting to one packet shrinks the individual FIFO controller, saving area.

The ***Host FIFO Address Mapping*** figure shows FIFO mapping in host mode.

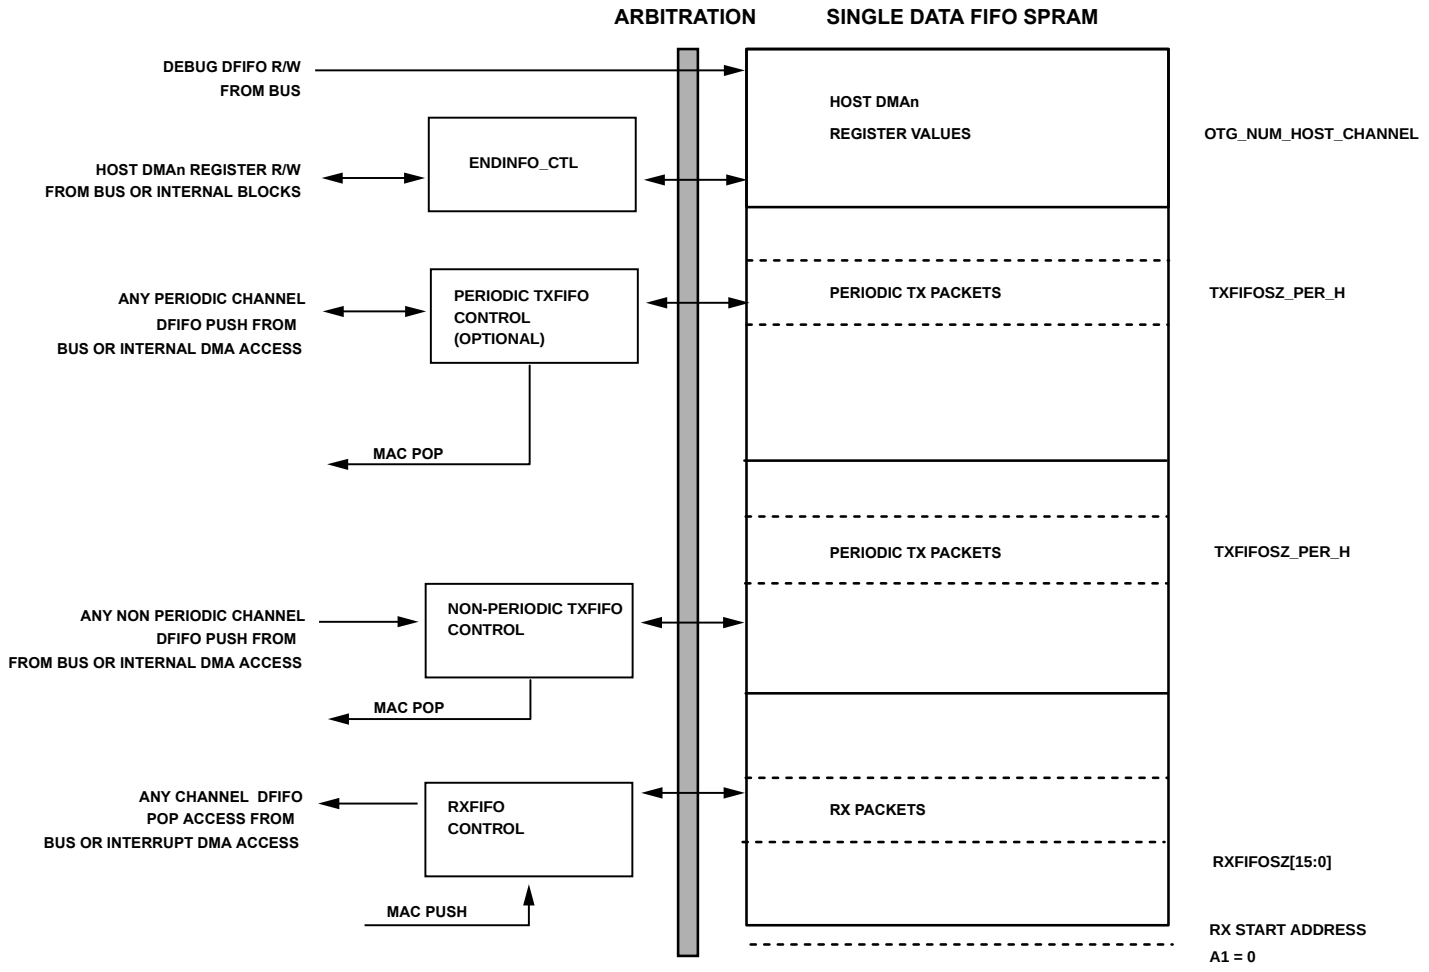

Figure 21-2: Host FIFO Address Mapping

The ***Device FIFO Address Mapping*** figure shows FIFO mapping in device mode.

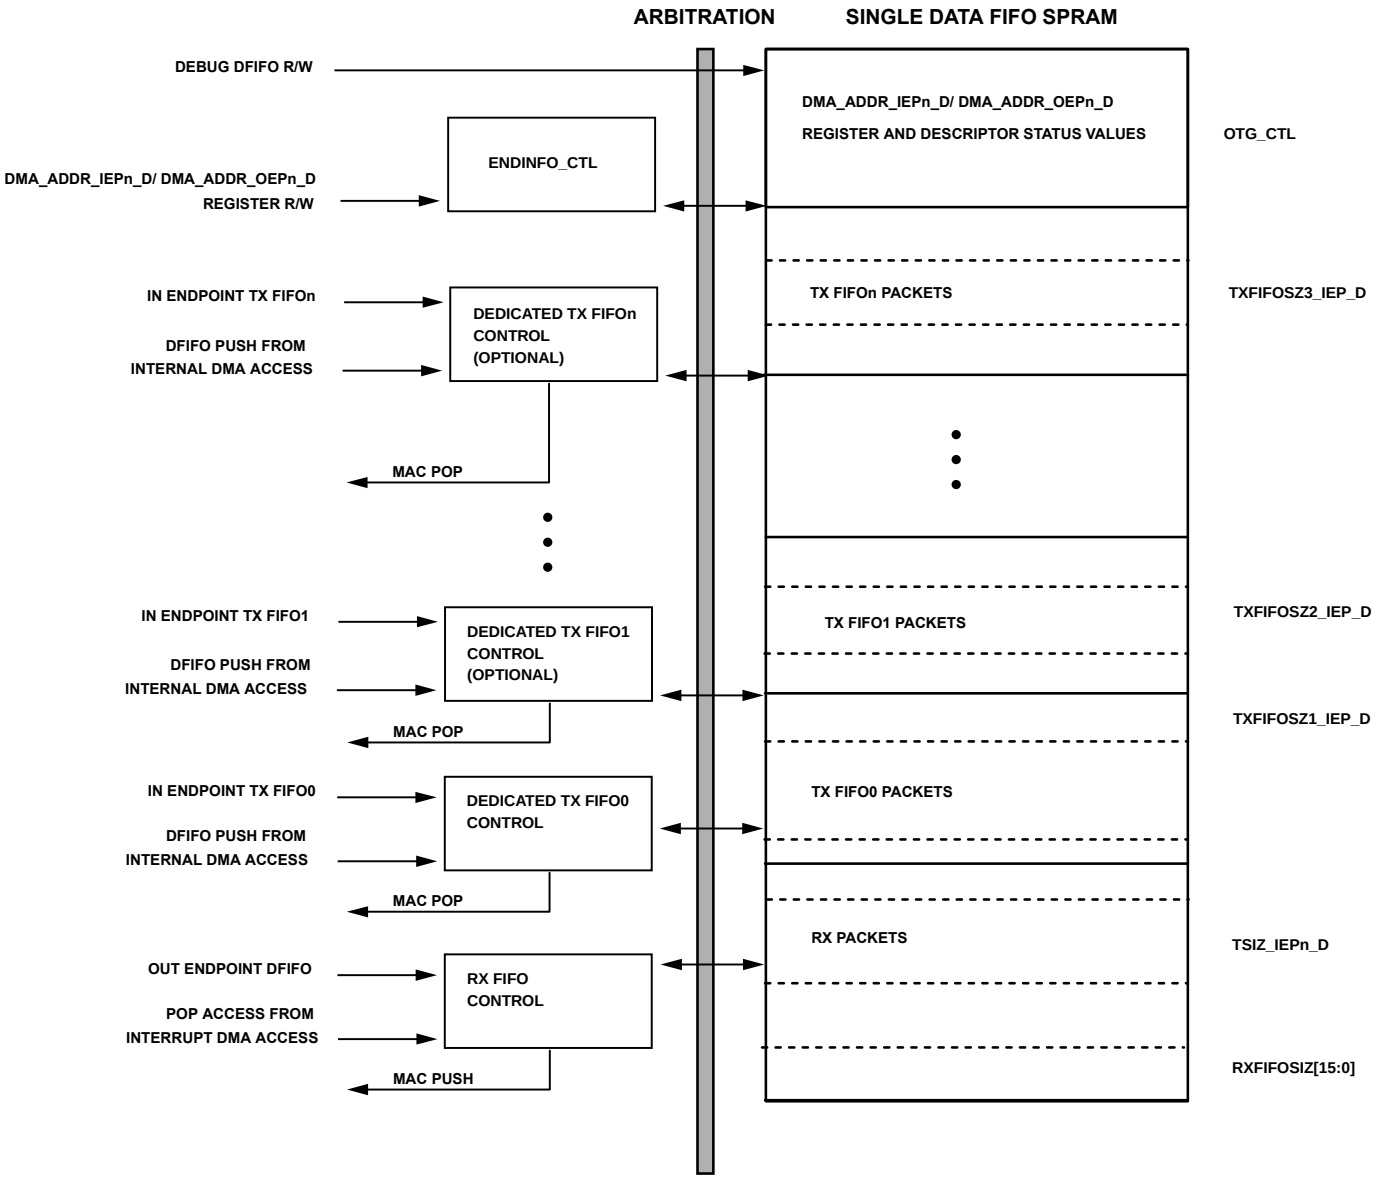

Figure 21-3: Device FIFO Address Mapping

Internal DMA Controller

The USB OTG provides an internal DMA mode of operation. The internal DMA controller has two modes of operation: buffer DMA mode and scatter/gather DMA mode.

The *USBC Internal DMA Control Block Diagram* shows the internal DMA controller mode.

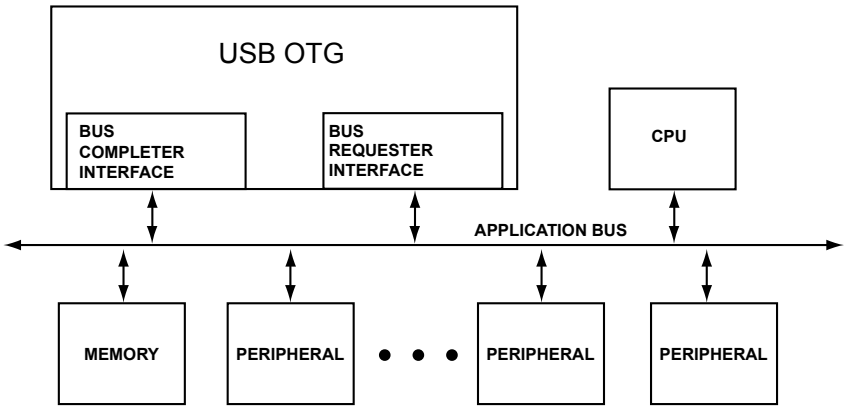

Figure 21-4: USBC Internal DMA Control Block Diagram

Host Architecture

The host uses one transmit FIFO for all non-periodic OUT transactions. The transmit FIFO is used as a transmit buffer to hold the data (payload of the transmit packet) to be transmitted over the USB port. The host pipes the USB transactions through request queues. Each entry in the request queue holds the IN or OUT channel number along with other information to perform a transaction on the USB. The order in which the requests are written into the queue determines the sequence of transactions on the USB. The host processes the non-periodic request queue, at the beginning of each (micro) frame.

The host uses one receive FIFO for all non-periodic transactions. The FIFO is used as a receive buffer to hold the received data (payload of the received packet) from the USB until it is transferred to system memory. The status of each packet received also goes into the FIFO. The status entry holds the IN channel number (along with other information such as received byte count and validity status) to perform a transaction on the bus.

The ***System Level Host BIU Block Diagram*** shows the bus interface architecture of the USB OTG controller in host mode.

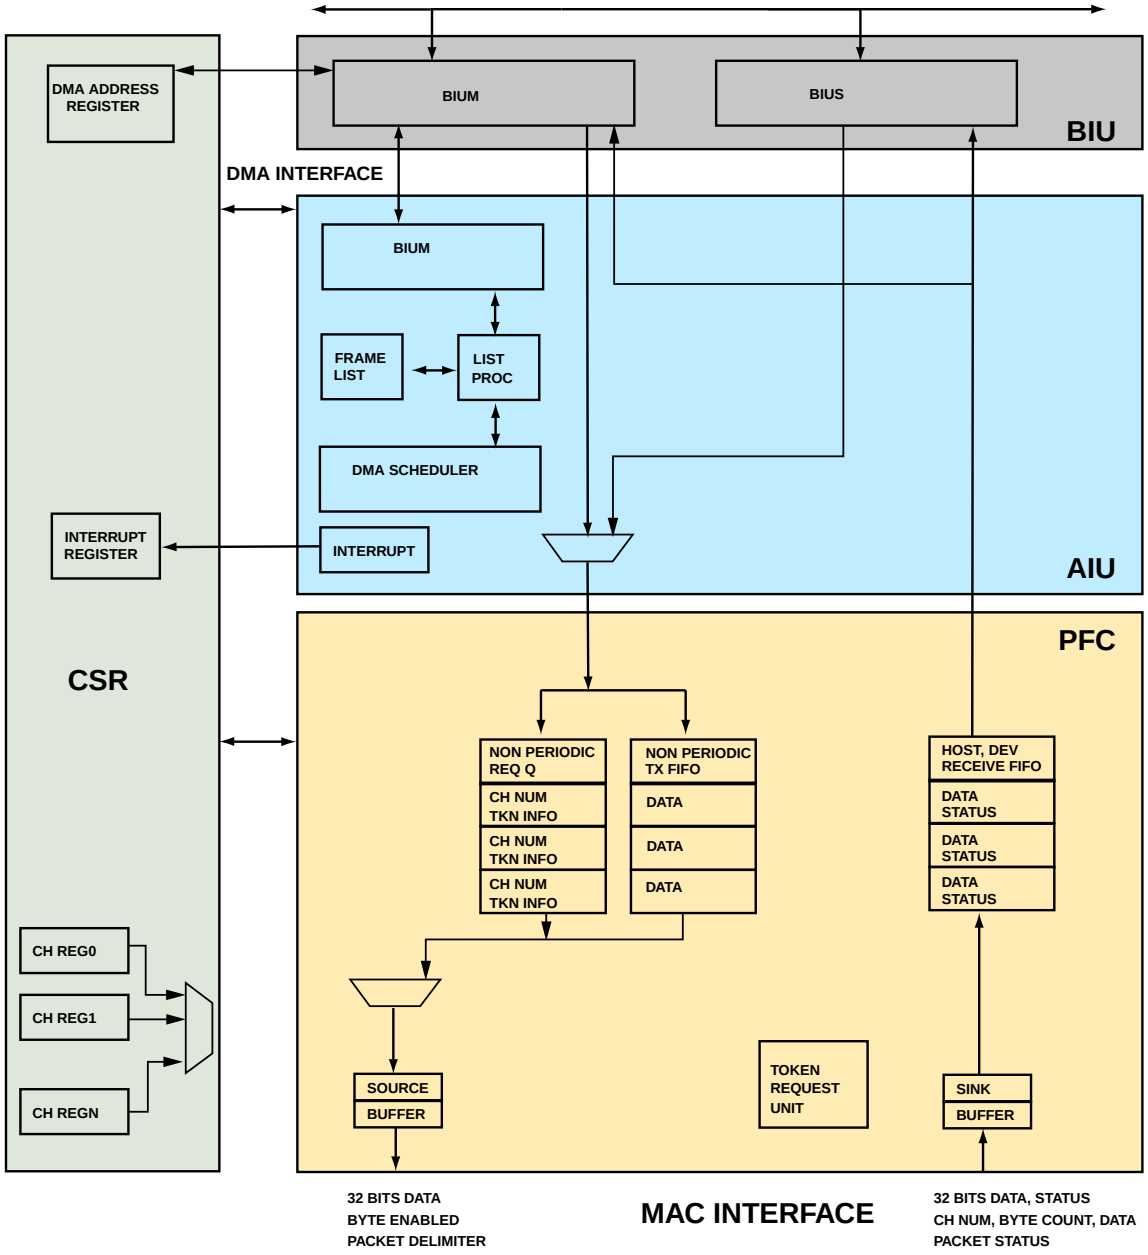

Figure 21-5: System Level Host BIU Block Diagram

Device Architecture

In device mode, the USB OTG core uses a dedicated transmit FIFO operation or a single receive FIFO. The ***System Level Device BIU Block Diagram*** shows the bus interface architecture of the USB OTG controller in device mode.

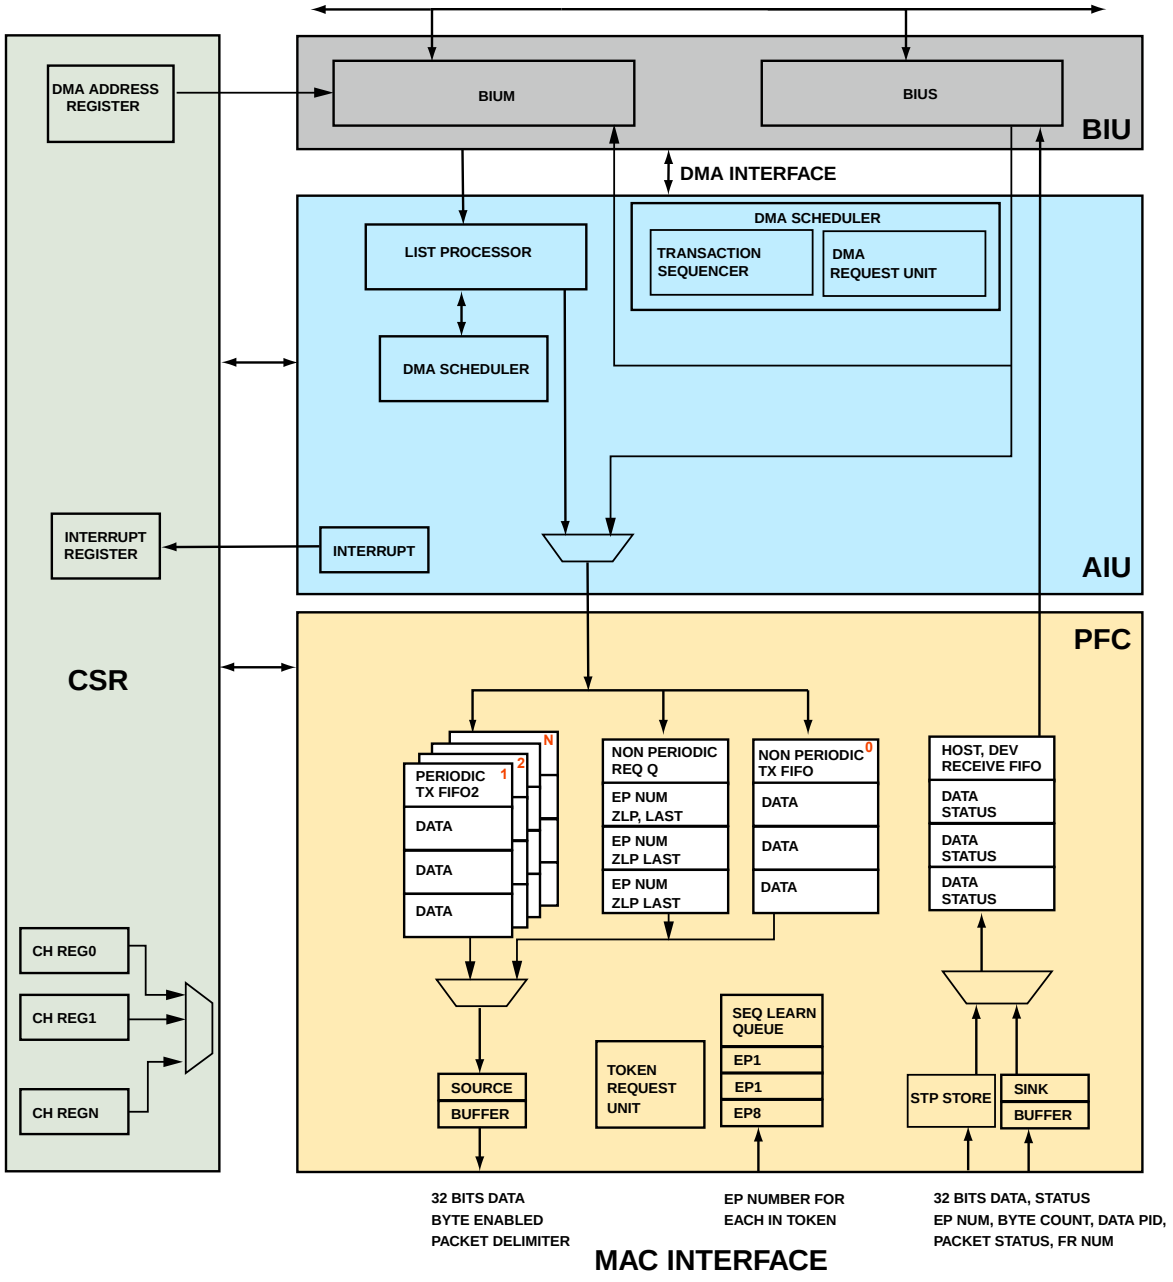

Figure 21-6: System Level Device BIU Block Diagram

Dedicated Transmit FIFO Operation

In a dedicated transmit FIFO operation, the USB OTG core uses individual transmit FIFOs for each IN endpoint. The core also supports thresholding in the transmit and receive directions when DMA mode is selected. For transmit mode, there are separate controls to enable thresholding for isochronous and non-isochronous transfers. Support is also provided for two different threshold values for the bus and the MAC on the transmit side.

When thresholding is enabled, the core can be configured to have a less-than-one packet sized FIFO. The core internally handles an underrun condition during transmit and corrupts the packet (inverts the CRC) on the USB.

During a receive operation with thresholding, when a packet ends up in a FIFO overflow condition, the core NAKs the OUT packet and internally rewinds the pointers. When thresholding is enabled, the best practice is to have a FIFO size two times the threshold value. If packet transmission results in an underrun condition (eventually resulting in packet corruption on the USB), the host can time out the endpoint after three consecutive errors.

Single Receive FIFO Operation

The OTG device uses a single receive FIFO to receive data for all the OUT endpoints. The receive FIFO holds the status of the received data packet, such as byte count, data PID, and the validity of the received data. The DMA or the application reads the data out of the receive FIFO as it is received.

Control and Status Registers (CSR)

The CSR block resides in the bus clock domain and contains all registers except the power and clock gating control register (`USBC_PWR_CTL`) and the core interrupt register (`USBC_ISTAT`[31:29]). These register bits must be active in power down mode, and hence are implemented in the BIUS module. The bus completer interface unit can write and read registers, and the core can set or reset the interrupt and status bits. The interrupts have priority over bus completer interface updates. For example, when a bus completer interface access tries to clear an interrupt bit when the core is setting the same interrupt bit, the interrupt bit is set, and the bus write to that bit is ignored.

Because the core does not check byte enables, all register accesses are 32 bits.

Even though bus completer writes have only the granularity of byte writes, each interrupt bit in an interrupt register is controlled separately. Thus, the bus completer interface can clear an interrupt bit when the core is setting a different interrupt bit, but no read modify byte write (which could cause erroneous interrupt behaviors) is performed.

All implemented registers are 32 bits wide, and only those registers required by the configuration are implemented. For example, when the core is configured for only two endpoints, then registers corresponding to endpoints 3–15 are not implemented. In addition, because the core can be only be either in host or device mode at a given time, the host and device registers use the same physical registers to save area. Writes to unimplemented registers are ignored and reads from them return an unknown value. Cycles complete gracefully with an OK response. When device mode registers are accessed during host mode and conversely, the mode mismatch interrupt (`USBC_ISTAT.MODEMIS`) is set, write data is ignored, and read data returns an unknown value.

Application Interface Unit (AIU)

The application Interface Unit (AIU) consists of the following interfaces:

- Bus requester
- Bus completer
- Packet FIFO controller
- Control and status registers

The AIU is responsible for the following functions.

- Generating and writing the delimiter (byte enables and last DWORD indicator) into the transmit FIFOs (based on FIFO number) for transmit packets in device (IN) and host (OUT) modes
- Writing a token into the request queue (periodic/non-periodic) for transmit transactions in device and host modes
- Writing a token into the request queue for receive (IN) transactions (only in host mode)
- Selecting the periodic or non-periodic request queue based on the type of transaction. When the channel or endpoint type indicates a periodic transaction, the periodic queue is selected.
- Generating interrupts for both transmit and receiving operations in device and host modes
- Address decoding for selecting the appropriate transmit FIFOs and queues
- Generating DMA interface signals to access an internal DMA controller for data transfer
- Round-robin arbitration among periodic and non-periodic channels and endpoints. Higher priority is always given to periodic channels or endpoints .
- Transmit/receive threshold handling (when transmit thresholding is enabled)
- Rewinding logic for DMA address and transfer size during an underrun or overflow condition (when thresholding is enabled)

DMA Scheduler (DSCH)

The DSCH is responsible for interfacing to an internal DMA. It controls the transfer of data packets between the system memory and the OTG core.

The DMA scheduler includes the following:

- *Arbiter* – This logic provides the sequence in which the channels/endpoints are to be processed in DMA mode. In host mode, the arbiter provides round-robin arbitration among periodic and non-periodic channels. Periodic channels are processed with higher priority.

  In device mode, when a threshold is enabled, the priority is as follows:

  1. Any transmit endpoint which is active on the USB
  2. Any receive data in a receive FIFO
  3. Round-robin arbitration on periodic transmit endpoints
  4. Round-robin arbitration on non-periodic transmit endpoints. In device mode when thresholding is not enabled, round robin arbitration is used for periodic and non-periodic IN endpoints with priority given to periodic IN endpoints.

- *DMA Request State Machine* – The state machine is responsible for the following:
  - Requesting the internal DMA for data fetch (from system memory to transmit FIFO, one maximum packet size or last packet size at a time)

- Writing the OUT request token into the request queue at the end of data fetch in host mode.
- Writing the IN request token into the request queue in host mode
- Requesting the internal DMA for data update (from the receive FIFO to system memory, one maximum packet size or last packet size at a time)
- Writing the request queue for ping, complete split, zero-length packet, or disable channel requests for the host

Periodic FIFO Control (PFC)

The PFC includes periodic and non-periodic transmit FIFOs and an endpoint information controller.

Periodic Transmit Data FIFO

The periodic transmit data FIFO stores periodic transmit data. There are different periodic FIFO structures in device and host modes.

Device Mode

There are no periodic or non-periodic FIFOs. FIFOs are implemented based on the number of IN endpoints and the application chooses a specific FIFO for an IN endpoint when enabling an endpoint. The following periodic IN endpoint characteristics remain valid in a dedicated transmit FIFO operation:

- The BIUS or the DMA interface unit writes data into a dedicated FIFO; the MAC reads the data from it.
- Each FIFO holds data for a single periodic IN endpoint. For high-bandwidth endpoints, this FIFO can hold in a single micro frame only the data to be transmitted, which can be no more than three maximum-packet-size packets.
- A whole packet must be in the FIFO before it can be transmitted on the USB, when thresholding is not enabled.
- When thresholding is enabled, the core starts transmitting on the USB in response to an IN token, when there is at least one MAC threshold amount of data available in the FIFO. For high-bandwidth periodic IN endpoints, the core can transmit one packet that is already available in the FIFO, while a second packet is being pushed into the FIFO.

Host Mode

Host mode periodic OUT transfers are not supported.

Non-Periodic Transmit Data FIFO

The non-periodic transmit data FIFO stores the data to be transmitted on all non-periodic IN endpoints in device mode and OUT channels in host mode. A non-periodic request queue associated with this FIFO stores endpoint or channel-related information.

- The BIUS or the DMA interface unit writes data to this FIFO; the MAC reads this data from it.

- In device mode, for each data packet in the data FIFO, there is a corresponding endpoint number and IN data packet type information entry in the request queue.
- In host mode, for each data packet in the data FIFO, there is a corresponding channel number and token-related control information entry in the request queue.
- The request queue also holds IN token entries in host mode (even though there is no associated data in the data FIFO).
- The depth of the non-periodic request queue is eight packets; it is implemented using flip-flops.
- Since dynamic FIFO sizing is enabled, the data FIFO RAM size and start address must be programmed in the CSRs.
- The data FIFO is 35 bits wide:
    - Bits [34:32]: A 4-bit byte enable, and a 1-bit packet delimiter are encoded into 3 bits and stored in external RAM. This reduces the data width in the external data RAM.
    - Encoding is as follows:
        - 3'b100: Last DWORD of the packet, all 4 bytes are valid
        - 3'b011: Last DWORD of the packet, bytes 0, 1, and 2 are valid
        - 3'b010: Last DWORD of the packet, bytes 0, and 1 are valid
        - 3'b001: Last DWORD of the packet, only byte 0 is valid
        - 3'b111: Non-last DWORD of a packet, all 4 bytes are valid
- Bits [31:0]: Data
- The request queue is 7 bits wide:
    - Host Mode:
        - Bits [6:3]: Channel number
        - Bits [2:0]: Token-related control information
    - Device Mode:
        - Bits [6:3]: IN endpoint number
        - Bit [2]: Not used
        - Bit [1]: Indicates a zero-length data packet
        - Bit [0]: Not used

Dedicated Transmit FIFO Operation

In host mode, the FIFO architecture is the same as in non-periodic transmit FIFO operation.

In device mode, there are no periodic or non-periodic FIFOs. FIFOs are implemented based on the number of IN endpoints (OTG_NUM_IN_EPS) (`USBC_HWCFG2.NDEVEPS`), and the application chooses a specific FIFO for an IN endpoint when it enables an endpoint. The following non-periodic IN endpoint characteristics remain valid in dedicated transmit FIFO mode:

- There are no queues associated with device mode FIFOs.
- If dynamic FIFO sizing is enabled, the data FIFO RAM size and the start address must be programmed in the CSRs
- The data FIFO is 35 bits wide. Bits 31:0 are data, and bits 34:32 are byte enables and packet delimiter encoding.

  Bits 34:32 are decoded below:

  - 3'b100 - Last DWORD of the packet, all 4 bytes valid
  - 3'b011 - Last DWORD of the packet, bytes 0, 1, 2 valid
  - 3'b010 - Last DWORD of the packet, bytes 0, 1 are valid
  - 3'b001 - Last DWORD of the packet, only byte 0 is valid
  - 3'b111 - Non last DWORD of a packet, all 4 bytes valid. 4-bit byte enables and 1-bit packet delimiter are encoded into 3 bits before storing into the external RAM. This reduces the data width in the external data RAM .

Receive Data FIFO

This FIFO stores data and status received on all OUT endpoints in device mode and all IN endpoints in host mode.

- The MAC writes data into this FIFO, and the BIUS or DMA interface unit reads this data from it.
- This FIFO can hold multiple OUT packets belonging to different endpoints or channels
- For each data OUT packet received on the USB, there is an associated status that indicates the byte count, packet status, and endpoint or channel number of the received packet.
- Data packets received with errors are flushed, so the BIUS and DMA interface unit never receive a corrupted data packet.
- Setup data packets received by the MAC in device mode are also written to the receive FIFO.
- Space is reserved in the receive data FIFO to store setup packets and related status information, based on the control endpoint supported by the device. The core never uses this reserved space to store any other type of data. This ensures that there is always enough space in the receive data FIFO to store setup data packets.
- If the device supports n endpoints, (4 * n + 6) DWORDs of space are allocated for receiving setup data packets. The extra 6 DWORDs are allocated to accommodate any back-to-back setup data packets sent by the USB host.
- The data FIFO is 35 bits wide:

- Bits [34:32]: Unused
- Bits [31:0]: data word
- Device mode status:
  - Bits [24:21]: 4 LSBs of the frame number in which the packet was received
  - Bits [20:17]: Packet status
  - Bits [16:15]: Data PID
  - Bits [14:4]: Byte count
  - Bits [3:0]: Endpoint number
- Host mode status:
  - Bits [20:17]: Packet status
  - Bits [16:15]: Data PID
  - Bits [14:4]: Byte count
  - Bits [3:0]: Channel number

Endpoint Information Controller (EPINFO_CTL)

The EPINFO_CTL manages the stored values in the last few locations of the SPRAM. The SPRAM Allocation table shows the space allocated for scatter/gather DMA.

Table 21-3: PRAM Allocation

Mode	SPRAM Space Allocation (EP_LOC_CNT)
Host	Four locations per channel are used in SPRAM to store the base descriptor address, current descriptor address, current buffer pointer, and the status quadlet. For example, if there are ten channels, the last forty locations are reserved for storing these values.
Device	Four locations per endpoint direction are used in SPRAM to store the base descriptor address, current descriptor address, current buffer pointer and the status quadlet. The application writes data to the base descriptor address. When the application reads the location where it wrote the base descriptor address, it receives the current descriptor address. For example, if there are ten bidirectional endpoints, the last 80 locations are reserved for storing these values.

Media Access Controller (MAC)

The Media Access Controller (MAC) module handles USB transactions, and device, host, and OTG protocols. This section discusses the MAC components, transaction and protocol handling.

MAC Components

The *MAC Block Diagram* shows the major MAC module components.

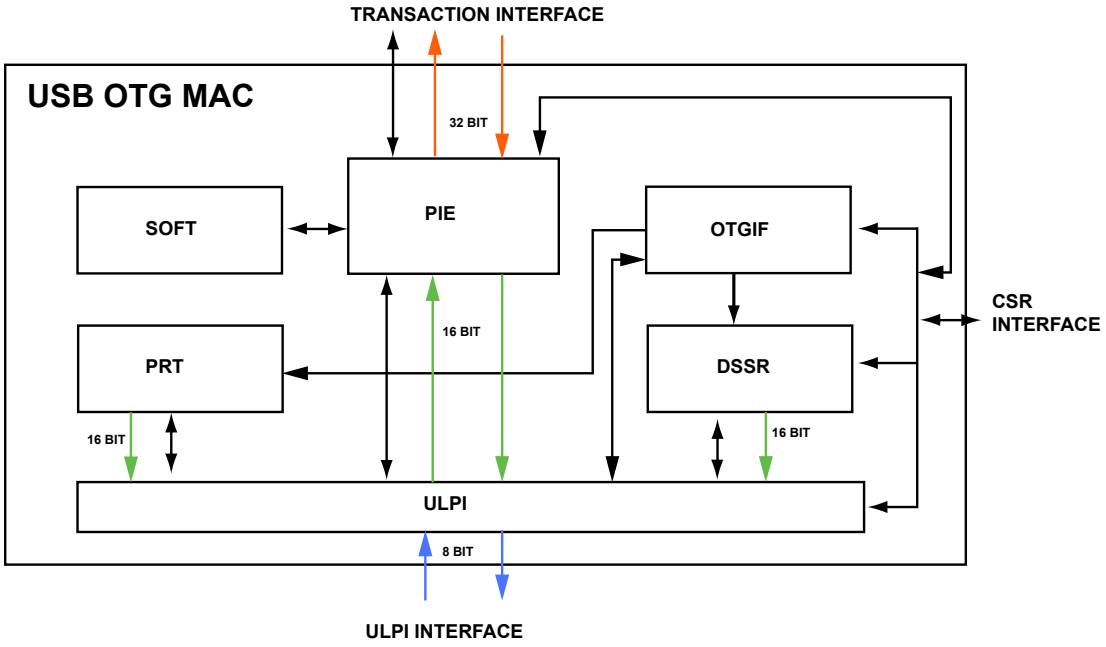

Figure 21-7: MAC Block Diagram

The MAC major blocks include

- *Device Speed enumeration, Suspend, and Resume block (DSSR)* – This block performs the speed enumeration, suspend, resume, and remote wakeup functions. The DSSR block is only active in device mode.
- *Parallel Interface Engine (PIE)* –This block is responsible for token, data, and handshake packet generation and reception, and PID and CRC checking and generation. It generates handshake and data packets based on data integrity and on CSR control and FIFO status information. The PIE also handles the data transfer to and from the FIFO, and the status update to the PFC and AIU.
- *SOF tracker (SOFT)* – This block tracks SOF packets and generates SOF interrupts in device mode. It handles missing SOFs and delayed SOFs to keep the frame number synchronization between the host and the device.
- *Port (PRT)* – The port block is only active in host mode. It is responsible for connect and disconnect detection, USB reset and speed enumeration, suspend and resume generation, remote wakeup detection, SOF generation, and high-speed test mode handling.
- *OTG Interface (OTGIF)* – The OTG interface block handles SRP and HNP. These OTG protocols are implemented either through the regular ULPI interface or the I^2C interface (for USB 1.1 serial transceivers only).
- *ULPI Interface* – The block converts data widths for the 8-bit PHY interface and multiplexes output signals to the PHY from multiple blocks.

USB Transaction Handling

The USB handles transactions differently in device and host modes.

Device Mode

In device mode, the MAC decodes and checks the integrity of token packets as it receives them from the host. If the received token is a valid OUT or setup token, the MAC waits and checks the PID of the following data packet. It then writes the data to the Rx FIFO (when it is available). After the packet is completed, the MAC checks the data integrity, sends the appropriate handshake when required to the host, and writes the transaction status to the receiving status queue. When the OUT token is received and the Rx FIFO is not available, the MAC sends the host a NAK handshake. If the received token is a valid ping token, the MAC sends the appropriate handshake, based on the FIFO status and CSR control information. When an IN token is received and the data is available in the FIFO, the MAC reads the data, builds the data packet, and sends it. It waits for a handshake packet, if any, from the host, and then updates the transaction status to the PFC. When an IN token is received and the data is not available in the FIFO, the MAC sends the host a NAK handshake.

Host Mode

In host mode, the MAC receives a token request from the AIU to start a USB transaction. After receiving a token request, the MAC builds ,and sends the requested token packet. For OUT or setup transactions, the MAC reads data from the Tx FIFO, builds and sends a data packet. It waits for a handshake packet, if any, from the device, and updates the transaction status to the AIU. For an IN or ping transaction, the MAC waits for a data or handshake packet from the device. If it receives a handshake packet, the MAC updates the status to the AIU. When it receives a data packet with the correct PID, the MAC writes the data into the Rx FIFO, checks the integrity of the data, sends a handshake packet, when required, to the device, then updates the status to the AIU.

Host Protocol Handling

In host mode, the MAC detects the device connect and disconnect, handles the USB reset and speed enumeration process, initiates USB suspend and resume, detects remote wakeup, generates SOF packets, and handles high-speed test modes.

Device Protocol Handling

In device mode, the MAC handles the USB reset sequence and speed enumeration process to determine the USB operating speed. The MAC detects USB suspend and resume signaling from the host, initiates remote wakeup, handles soft connect and disconnect, decodes and tracks SOF packets, plus handles high-speed test modes.

OTP Protocol Handling

The MAC handles Host Negotiation Protocol (HNP) for host and peripheral role swapping. It handles the Session Request Protocol (SRP), which allows an A-device to turn off VBUS to save power when the USB bus is used. It also provides a means for a B-device to request the A-device to activate VBUS.

USBC Programming Model

Programming the USB includes initializing and connecting the host and device cores and initializing the endpoint.

Program the Host Core

The following sections describe how to program the host core.

Initialize the Host

To initialize the USBC core as host, the application must perform the following steps:

1. Program the USBC_IMSK.PRTINT bit to unmask the PDM_HPF_CTL.FC bits.
2. Program the USBC_CFG_H register to select the full-speed host or high-speed host.
3. Program USBC_PORT_CTL_H.PWR =1. This configuration drives VBUS on the USB.
4. Wait for the USBC_PORT_CTL_H.CONNDET interrupt. This interrupt indicates that a device is connected to the port.
5. Program USBC_PORT_CTL_H.RST=1. This configuration starts the reset process.
6. Wait at least 10 ms for the reset process to complete.
7. Program USBC_PORT_CTL_H.RST=0.
8. Wait for the USBC_PORT_CTL_H.ENCHNG interrupt.
9. Read the USBC_PORT_CTL_H.SPD field to get the enumerated speed.
10. Program the USBC_FIR_H register with a value corresponding to the selected PHY clock.
11. Program the USBC_RXFIFOSZ register to select the size of the RxFIFO.
12. Program the USBC_TXFIFOSZ_NP register to select the size and the start address of the non-periodic FIFO.

    ADDITIONAL INFORMATION: To communicate with devices, the application must initialize and enable at least one channel. At this point, the host is up and running and the port register begins to report device disconnects, etc. The port is active with the start of frame (SOF) packets occurring downstream of the enabled port.

Connect the Host

Complete the following steps to connect the host:

1. Connect the USB cable the host port; the core triggers the USBC_ISTAT.CONIDSTSCHNG interrupt.
2. When the host application detects the interrupt, the application can perform one of the following actions:
   a. Turn on VBUS by setting USBC_PORT_CTL_H.PWR = 1, or
   b. Wait for SRP signaling from the device to turn on VBUS

3. The PHY indicates VBUS power-on by asserting the UTMI_VBUSVALID signal.
4. The host core detects the device connection and triggers the host port interrupt (USBC_ISTAT.PRTINT) to the application.
5. The application reads the USBC_PORT_CTL_H register to check whether the USBC_PORT_CTL_H.CONNDET bit is set (=1).

Disconnect the Host

The host disconnection process depends on the configuration. Complete the following steps to disconnect the host:

1. When the device is disconnected from the USB cable (but the cable is still connected to the USB host), the core triggers the USBC_ISTAT.DISCONINT (disconnect detected) interrupt.
2. The host application can either to turn off the VBUS by programming USBC_PORT_CTL_H.PWR = 0, or, if the VBUS is controlled externally, the core does not switch off the VBUS.

Program the Device Core

The following sections describe how to initialize and connect the device core.

Initialize the Device

The application must meet the following conditions to set up the device core to handle traffic:

- In completer mode, the USBC_IMSK.NPTXFEMP and USBC_IMSK.RXFLVL bits must be cleared (=0)
- In DMA mode, the USBC_IMSK.NPTXFEMP and USBC_IMSK.RXFLVL interrupts must be masked.

The application must perform the following steps to initialize the core at device on, power on, or after a mode change from host to device.

1. Program the following fields in USBC_CFG_D register:
    a. USBC_CFG_D.DESCDMA–(applicable only when USBC_AHB_CFG.DMAEN parameter is set (=1))
    b. USBC_CFG_D.SPD–device speed
    c. USBC_CFG_D.NZSTSOUTHSHK–non-zero length status OUT handshake
    d. USBC_CFG_D.PERFRINT–periodic frame interval (when periodic endpoints are supported)
2. Program the device threshold control register. This operation is required only when using DMA mode and thresholding.
3. Clear (=0) the USBC_CTL_D.SFTDISCON bit. The core issues a connect after this bit is cleared.
4. Program the USBC_IMSK register to unmask the following interrupts.
    a. USB reset

b. Enumeration done

c. Early suspend

d. USB suspend

e. SOF

5. Wait for the USBC_ISTAT.USBRST interrupt; it indicates that a reset has been detected on the USB and lasts for about 10 ms. On receiving this interrupt, the application must perform the steps described in Initialize upon USB Reset.

6. Wait for the USBC_ISTAT.ENUMDONE interrupt. This interrupt indicates the end of reset on the USB. On receiving this interrupt, the application must read the USBC_ISTAT_D register to determine the enumeration speed and perform the steps described in Initialize upon Enumeration Completion.

   At this point, the device is ready to accept SOF packets and perform control transfers on control endpoint 0. To communicate with devices, the application must initialize and enable at least one channel. The host is up and running and the port register begins to report device disconnects, etc. The port is active with SOFs occurring downstream of the enabled port.

Connect the Device

The device connection process depends on an active VBUS and a connection to the USB cable.

VBUS is Active and the Device is Connected

When VBUS is active and the device is connected to the USB cable, there is no SRP from the device. The device connection flow is as follows:

1. The device triggers the USBC_ISTAT.SESREQINT interrupt bit.
2. The device application programs the required bits in the USBC_CFG_D register.
3. When the host drives reset, the device triggers USBC_ISTAT.USBRST upon detecting the reset. The host then follows the USB 2.0 enumeration sequence.

VBUS is Off and the Device is Connected

When VBUS is off and the device is connected to the USB cable, the device initiates SRP in OTG revision 1.3 mode. The device connection flow is as follows:

1. The application initiates SRP by writing to the USBC_OTG_CTL.SESREQ bit. The USBC core perform data-line pulsing followed by VBUS pulsing.
2. The host starts a new session by turning on VBUS, indicating SRP success. The USBC core interrupts the application by setting (=1) the USBC_OTG_CTL.SESREQSCS bit.
3. The application reads the USBC_OTG_CTL.SESREQ bit and programs the required bits in USBC_CFG_D register.

4. When the host drives reset, the device triggers the USBC_ISTAT.USBRST upon detecting the reset. The host then follows the USB 2.0 enumeration sequence.

Disconnect the Device

The device session ends when the USB cable is disconnected or VBUS is switched off by the host. The device disconnect flow depends the OTG mode.

Case 1:

- When the USB cable is unplugged or the VBUS is switched off by the host, the device core triggers the USBC_ISTAT.OTGINT interrupt bit.
- When the device application detects the USBC_ISTAT.OTGINT interrupt, it checks that the USBC_OTG_IRQ.SESENDDET (session end detected) bit is set (=1).

Case 2:

- When the USB cable is unplugged or the VBUS is switched off by the host, the device core triggers the USBC_ISTAT.USBRST interrupt bit.
- When the device application detects the USBC_ISTAT.USBRST bit, the application sets a timeout check for SET ADDRESS Control Xfer from the host.
- When application does not receive SET ADDRESS Control Xfer from the host before the timeout period, it is treated as a device disconnection.

Initialize the Endpoint

The following sections describe how to initialize the endpoint upon USB reset and after enumeration.

Initialize upon USB Reset

This section describes what the application must do when it detects a USB reset.

1. Set the NAK bit for all OUT endpoints.
    a. USBC_CTL_OEP[n]_D.SNAK = 1 (for all OUT endpoints)
2. Unmask the following interrupt bits.
    a. USBC_IMSK_D.INEP0 = 1 (control 0 IN endpoint)
    b. USBC_IMSK_D.OUTEP0 = 1 (control 0 OUT endpoint)
    c. USBC_IMASK_OEP_D.SETUP = 1
    d. USBC_IMASK_OEP_D.XFERCOMPL = 1
    e. USBC_IMASK_IEP_D.XFERCOMPL = 1
    f. USBC_IMASK_IEP_D.TIMEOUT = 1

3. To transmit or receive data, the device must initialize registers as specified in the Initialize the Device section
4. Set up the data FIFO RAM for each of the FIFOs (only if dynamic FIFO sizing is enabled).
   - Program the USBC_RXFIFOSZ register, to be able to receive control OUT data and setup data. If thresholding is not enabled, at a minimum, this must be equal to 1 max packet size of control endpoint 0 + 2 DWORDs (for the status of the control OUT data packet) + 10 DWORDs (for setup packets). If thresholding is enabled, at a minimum, this must be equal to 2*(USBC_THR_CTL_D.RXTHRLEN/4 + 1) + 2 DWORDs (for the status of the control OUT data packet) + 10 DWORDs (for setup packets)
   - Program the USBC_TXFIFOSZ_NP register in shared FIFO operation or dedicated FIFO size register (depending on the FIFO number chosen) in Dedicated FIFO operation, to be able to transmit control IN data. At a minimum, this must be equal to 1 max packet size of control endpoint 0. If thresholding is enabled, this can be programmed to less than one max packet size.
5. Reset the device address field in device configuration register (USBC_CFG_D.ADDR)
6. (This step is not required if you are using scatter/gather DMA mode). Program the following fields in the endpoint-specific registers for the control OUT endpoint 0 to receive a SETUP packet.
   - USBC_TSIZ_OEP0_D.SUPCNT = 3 (to receive up to three back-to-back SETUP packets)
   - In DMA mode, USBC_DMA_ADDR_OEP0_D register with a memory address to store any SETUP packets received

   At this point, all initialization required to receive SETUP packets is done, except for enabling control OUT endpoint 0 in DMA mode.

Initialize upon Enumeration Completion

This section describes what the application must do when it detects an enumeration done interrupt.

1. On the enumeration done interrupt (USBC_ISTAT.ENUMDONE), read the USBC_STAT_D.ENUMSPD to determine the enumeration speed.
2. Program the USBC_CTL_IEP0_D.MPS field to set the maximum packet size. This step configures control endpoint 0. The maximum packet size for a control endpoint depends on the enumeration speed
3. In DMA mode, program the USBC_CTL_OEP0_D register to enable control OUT endpoint 0, to receive a SETUP packet. In scatter/gather DMA mode, the descriptors must be set up in memory before enabling the endpoint.
   a. USBC_CTL_OEP0_D.EPENA = 1
4. Unmask the SOF interrupt.

   The device is ready to receive SOF packets and is configured to perform control transfers on control endpoint 0.

OTG Programming

OTG programming includes host negotiating protocols for the A device and B device.

A Device Host Negotiation

The host negotiation protocol (HNP) switches the USB host role from the A device to the B device. The application must set the USBC_CFG.HNPCAP bit to enable the USBC core to perform the protocol as an A device.

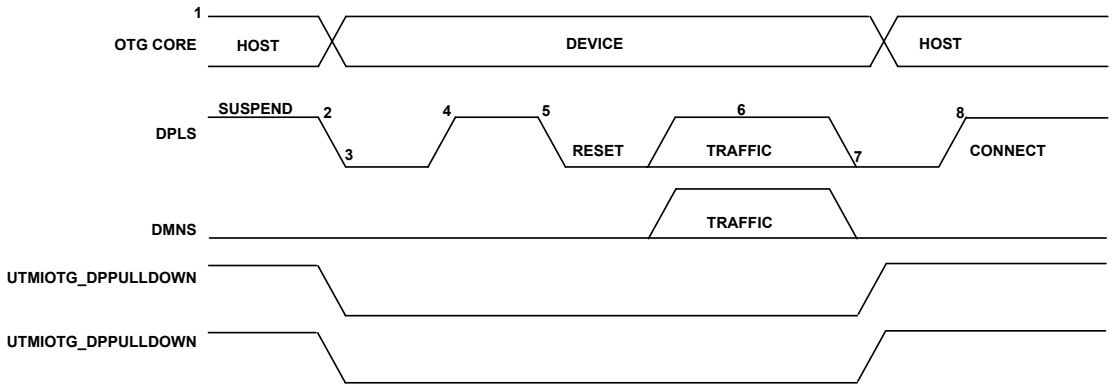

Figure 21-8: A Device HNP

The protocol completes the following sequence:

1. The USBC core sends the B device a SetFeature b_hnp_enable descriptor to enable HNP support. The ACK response of the B device indicates that the device supports HNP. (The application must set the USBC_OTG_CTL.HNPEN bit to indicate to the USBC core that the B device supports HNP).

2. When it has finished using the bus, the application suspends by writing to the USBC_PORT_CTL_H.SUSP bit.

3. When the B device detects a USB suspend operation and disconnects; the operation indicates the initial condition for the HNP. The B device initiates the HNP only when it must switch to the host role; otherwise, the bus continues to be suspended.

The USBC core sets the host negotiation detected interrupt bit (USBC_ISTAT.OTGINT), indicating the start of HNP.

The USBC core deasserts the UTMIOTG_DPPULLDOWN and UTMIOTG_DMPULLDOWN signals to indicate a device role. The PHY enable the D+ pull-up resistor indicates a connect for B device.

The application must read the USBC_OTG_CTL.CURMOD bit to determine the device mode operation.

4. The B device detects the connection, issues a USB reset, and enumerates the USBC core for data traffic.

5. The B device continues the host role, initiating traffic, and suspends the bus when the operation is complete.

The USBC core sets the USBC_ISTAT.ERLYSUSP bit after 3 ms of bus idleness.

6. In negotiated mode, the USBC core detects the suspend, disconnects, and switches back to the host role. The USBC core asserts the UTMIOTG_DPPULLDOWN and UTMIOTG_DMPULLDOWN signals to indicate its assumption of the host role.

7. The USBC core sets the USBC_ISTAT.CONIDSTSCHNG bit. The application must read the USBC_OTG_CTL.CONIDSTS bit to determine the USBC core operation as an A device. This indicates the completion of the HNP to the application. The application must read the USBC_OTG_CTL.CURMOD bit to determine host mode operation.

8. The B device connects, completing the HNP process.

B Device Host Negotiation

The host negotiation protocol (HNP) switches the USB host role from the B device to the A device. The application must set the USBC_CFG.HNPCAP bit to enable the USBC core to perform HNP as a B device.

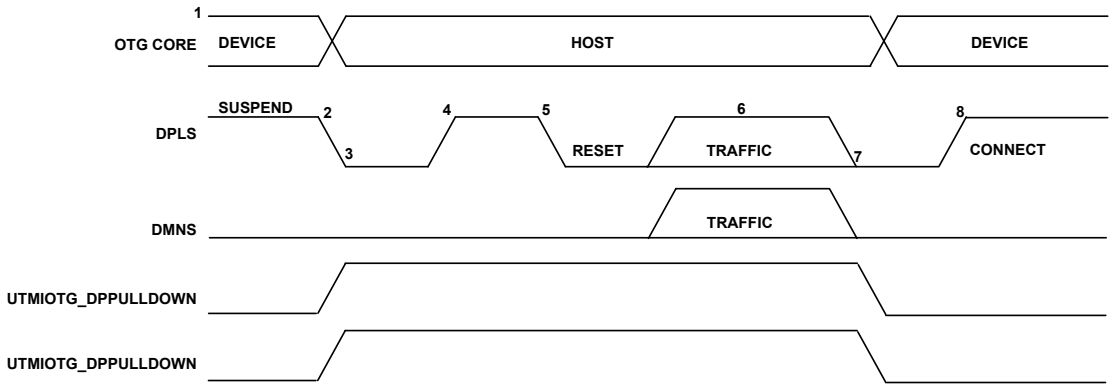

Figure 21-9: B Device HNP

1. The A device sends the SetFeature b_hnp_enable descriptor to enable HNP support. The USBC core ACK response indicates that it supports HNP. (The application must set the USBC_OTG_CTL.HNPEN bit to indicate HNP support).

The application sets the USBC_OTG_CTL.HNPREQ bit to indicate to the USBC core to initiate HNP.

2. When it has finished using the bus, the A device suspends by writing to the USBC_PORT_CTL_H.SUSP bit.

The USBC core sets the USBC_ISTAT.ERLYSUSP bit after 3 ms of bus idleness. Following this, the USBC core sets the USBC_ISTAT.ERLYSUSP bit.

The USBC core disconnects and the A device detects SE0 on the bus, indicating HNP. The USBC core asserts the UTMIOTG_DPPULLDOWN and UTMIOTG_DMPULLDOWN signals to indicate its assumption of the host role.

The A device responds by activating its D+ pull-up resistor within 3 ms of detecting SE0. The USBC core detects this as a connect.

The USBC core sets the USBC_OTG_IRQ.HNEGSSTSCHG bit, indicating the HNP status. The application must read the USBC_OTG_IRQ.HNEGSSTSCHG bit to determine host negotiation success. The application must read the USBC_ISTAT.CURMOD bit to determine host mode operation.

3. Program the USBC_PORT_CTL_H.PWR = 1 to drive VBUS on the USB.

4. Wait for the USBC_PORT_CTL_H.CONNDET interrupt. This indicates that a device is connected to the port.

5. The application sets the reset bit (USBC_PORT_CTL_H.RST) and the USBC core issues a USB reset and enumerates the A-device for data traffic.

6. Wait for the USBC_PORT_CTL_H.ENCHNG interrupt.

7. The USBC core continues the host role of initiating traffic, and when done, suspends the bus by writing the USBC_PORT_CTL_H.SUSP bit.

8. In negotiated mode, when the A device detects a suspend, it disconnects and switches back to the host role. The USBC core deasserts the UTMIOTG_DPPULLDOWN and UTMIOTG_DMPULLDOWN signals to indicate the assumption of the device role.

9. The application must read the USBC_ISTAT.CURMOD bit to determine the host mode operation.

10. The USBC core connects, completing the HNP process.

ADSP-SC59x USBC Register Descriptions

USB Controller (USBC) contains the following registers.

Table 21-4: ADSP-SC59x USBC Register List

Name	Description
USBC_ISTAT_D	Device All Endpoint Interrupt Status Register
USBC_IMSK_D	Device All Endpoint Interrupt Mask Register
USBC_CFG_D	Device Configuration Register
USBC_CTL_D	Device Control Register
USBC_CTL_IEP0_D	Device Control IN Endpoint 0 Control Register
USBC_CTL_IEP[n]_D	Device Control IN Endpoint n Control Register
USBC_DMA_ADDR_IEP0_D	Device Control IN Endpoint 0 DMA Address Register
USBC_DMA_BADDR_IEP0_D	Device IN Endpoint 0 Buffer Address Register
USBC_DMA_BADDR_IEP[n]_D	Device Control IN Endpoint n DMA Buffer Address Register
USBC_DMA_ADDR_IEP[n]_D	Device Control IN Endpoint n DMA Address Register
USBC_IMSK_IEP_FEMPT_D	Device IN Endpoint FIFO Empty Interrupt Mask Register
USBC_ISTAT_IEP0_D	Device Control IN Endpoint 0 Interrupt Control Register

Table 21-4: ADSP-SC59x USBC Register List (Continued)

Name	Description
USBC_ISTAT_IEP[n]_D	Device Control IN Endpoint n Interrupt Control Register
USBC_IMASK_IEP_D	Device IN Endpoint Common Interrupt Mask Register
USBC_TSIZ_IEP0_D	Device Control IN Endpoint 0 Transfer Size Register
USBC_TSIZ_IEP[n]_D	Device Control IN Endpoint n Transfer Size Register
USBC_TXFIFOSZ1_IEP_D	Device IN Endpoint 1 Transmit FIFO Size Register
USBC_TXFIFOSZ2_IEP_D	Device IN Endpoint 2 Transmit FIFO Size Register
USBC_TXFIFOSZ3_IEP_D	Device IN Endpoint 3 Transmit FIFO Size Register
USBC_CTL_OEP0_D	Device OUT Endpoint 0 Control Register

USBC_HWCFG3	User Hardware Configuration 3 Register
USBC_HWCFG4	User Hardware Configuration 4 Register
USBC_IMSK	Interrupt Mask Register

Table 21-4: ADSP-SC59x USBC Register List (Continued)

Name	Description
USBC_ISTAT	Interrupt Status Register
USBC_TXFIFOSZ_NP	Non-periodic Transmit FIFO Size Register
USBC_TXFIFO_STAT_NP	Non-periodic Transmit FIFO/Queue Status Register
USBC_OTG_CTL	OTG Control and Status Register
USBC_OTG_IRQ	OTG Interrupt Register
USBC_PHYIF_CTL	PHY Interface Control Register
USBC_RST_CTL	Reset Register
USBC_RXFIFOSZ	Receive FIFO Size Register
USBC_RXDATA_STAT	Receive Status Read/Pop Register
USBC_RXDBG_STAT	Receive Status Debug Read Register
USBC_MODID	Module ID Register
USBC_CFG	USB Configuration Register
USBC_ISTAT_H	Host All Channels Interrupt Register
USBC_IMSK_H	Host All Channels Interrupt Mask Register
USBC_CHAR[n]_H	Host Channel n Characteristics Register
USBC_DMA_BADDR[n]_H	Host Channel n DMA Buffer Address Register
USBC_DMA_ADDR[n]_H	Host Channel n DMA Address Register
USBC_CFG_H	Host Configuration Register
USBC_IMSK[n]_H	Host Channel n Interrupt Mask Register
USBC_ISTAT[n]_H	Host Channel n Interrupt Status Register
USBC_SPLT_CTL[n]_H	Host Channel n Split Control Register
USBC_TSIZ[n]_H	Host Channel n Transfer Size Register
USBC_FIR_H	Host Frame Interval Register
USBC_FL_BADDR_H	Host Frame List Base Address Register
USBC_FNUM_H	Host Frame Number/Frame Time Remaining Register
USBC_PORT_CTL_H	Host Port Control and Status Register
USBC_TXFIFOSZ_PER_H	Host Periodic Transmit FIFO Size Register
USBC_PWR_CTL	Power and Clock Gating Control Register

Device All Endpoint Interrupt Status Register

When a significant event occurs on an endpoint, the USBC_ISTAT_D register interrupts the application using the USBC_ISTAT.OEPINT or USBC_ISTAT.IEPINT register. There is one interrupt bit per endpoint, up to a maximum of 12 bits for OUT endpoints and 12 bits for IN endpoints. For a bidirectional endpoint, the corresponding IN and OUT interrupt bits are used.

Bits in this register are set and cleared when the application sets and clears bits in the corresponding Device Endpoint n Interrupt register (USBC_ISTAT_IEP[n]_D/ USBC_ISTAT_OEP[n]_D).

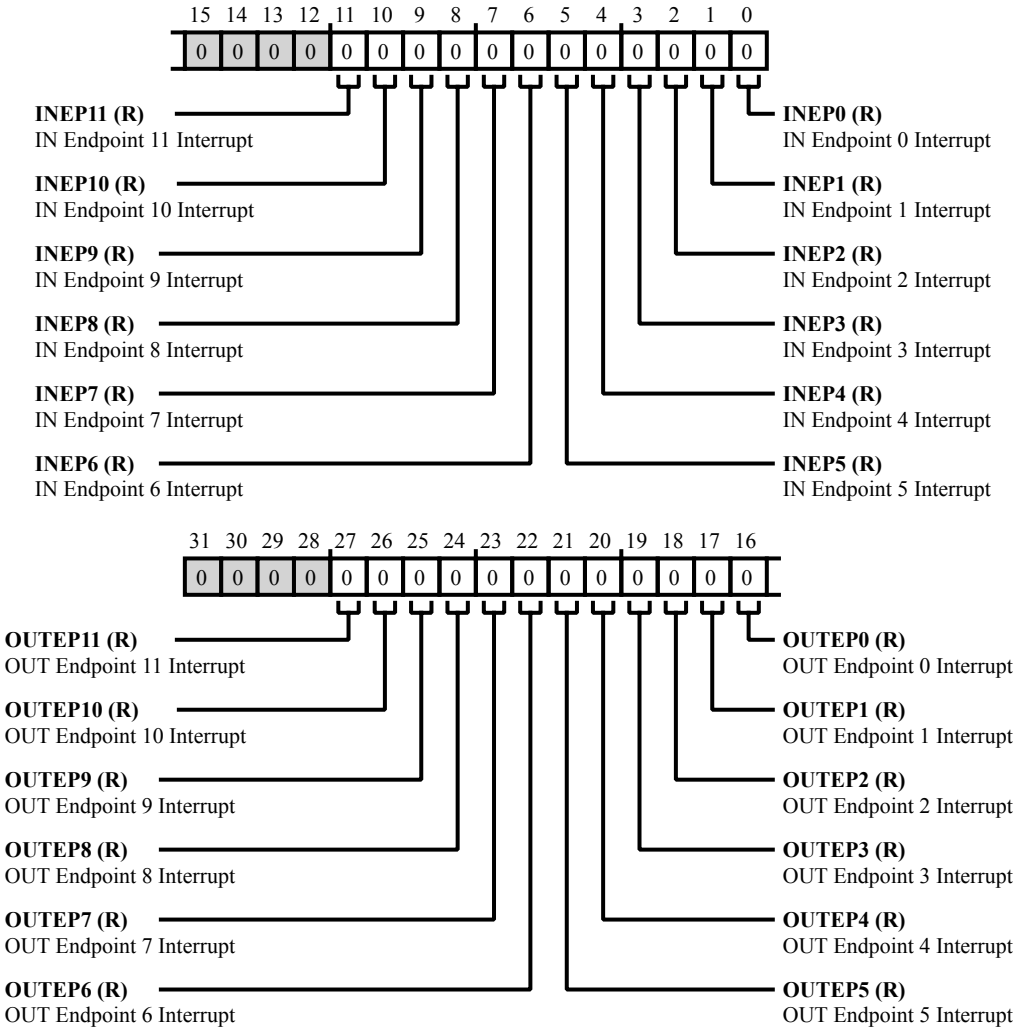

Figure 21-10: USBC_ISTAT_D Register Diagram

Table 21-5: USBC_ISTAT_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
27 (R/NW)	OUTEP11	OUT Endpoint 11 Interrupt. The `USBC_ISTAT_D.OUTEP11` bit enables the interrupt request for the OUT endpoint.
26 (R/NW)	OUTEP10	OUT Endpoint 10 Interrupt. The `USBC_ISTAT_D.OUTEP10` bit enables the interrupt request for the OUT endpoint.
25 (R/NW)	OUTEP9	OUT Endpoint 9 Interrupt. The `USBC_ISTAT_D.OUTEP9` bit enables the interrupt request for the OUT endpoint.
24 (R/NW)	OUTEP8	OUT Endpoint 8 Interrupt. The `USBC_ISTAT_D.OUTEP8` bit enables the interrupt request for the OUT endpoint.
23 (R/NW)	OUTEP7	OUT Endpoint 7 Interrupt. The `USBC_ISTAT_D.OUTEP7` bit enables the interrupt request for the OUT endpoint.
22 (R/NW)	OUTEP6	OUT Endpoint 6 Interrupt. The `USBC_ISTAT_D.OUTEP6` bit enables the interrupt request for the OUT endpoint.
21 (R/NW)	OUTEP5	OUT Endpoint 5 Interrupt. The `USBC_ISTAT_D.OUTEP5` bit enables the interrupt request for the OUT endpoint.
20 (R/NW)	OUTEP4	OUT Endpoint 4 Interrupt. The `USBC_ISTAT_D.OUTEP4` bit enables the interrupt request for the OUT endpoint.
19 (R/NW)	OUTEP3	OUT Endpoint 3 Interrupt. The `USBC_ISTAT_D.OUTEP3` bit enables the interrupt request for the OUT endpoint.
18 (R/NW)	OUTEP2	OUT Endpoint 2 Interrupt. The `USBC_ISTAT_D.OUTEP2` bit enables the interrupt request for the OUT endpoint.
17 (R/NW)	OUTEP1	OUT Endpoint 1 Interrupt. The `USBC_ISTAT_D.OUTEP1` bit enables the interrupt request for the OUT endpoint.
16 (R/NW)	OUTEP0	OUT Endpoint 0 Interrupt. The `USBC_ISTAT_D.OUTEP0` bit enables the interrupt request for the OUT endpoint.

Table 21-5: USBC_ISTAT_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
11 (R/NW)	INEP11	IN Endpoint 11 Interrupt. The `USBC_ISTAT_D.INEP11` bit enables the interrupt request for the IN endpoint.
10 (R/NW)	INEP10	IN Endpoint 10 Interrupt. The `USBC_ISTAT_D.INEP10` bit enables the interrupt request for the IN endpoint.
9 (R/NW)	INEP9	IN Endpoint 9 Interrupt. The `USBC_ISTAT_D.INEP9` bit enables the interrupt request for the IN endpoint.
8 (R/NW)	INEP8	IN Endpoint 8 Interrupt. The `USBC_ISTAT_D.INEP8` bit enables the interrupt request for the IN endpoint.
7 (R/NW)	INEP7	IN Endpoint 7 Interrupt. The `USBC_ISTAT_D.INEP7` bit enables the interrupt request for the IN endpoint.
6 (R/NW)	INEP6	IN Endpoint 6 Interrupt. The `USBC_ISTAT_D.INEP6` bit enables the interrupt request for the IN endpoint.
5 (R/NW)	INEP5	IN Endpoint 5 Interrupt. The `USBC_ISTAT_D.INEP5` bit enables the interrupt request for the IN endpoint.
4 (R/NW)	INEP4	IN Endpoint 4 Interrupt. The `USBC_ISTAT_D.INEP4` bit enables the interrupt request for the IN endpoint.
3 (R/NW)	INEP3	IN Endpoint 3 Interrupt. The `USBC_ISTAT_D.INEP3` bit enables the interrupt request for the IN endpoint.
2 (R/NW)	INEP2	IN Endpoint 2 Interrupt. The `USBC_ISTAT_D.INEP2` bit enables the interrupt request for the IN endpoint.
1 (R/NW)	INEP1	IN Endpoint 1 Interrupt. The `USBC_ISTAT_D.INEP1` bit enables the interrupt request for the IN endpoint.
0 (R/NW)	INEP0	IN Endpoint 0 Interrupt. The `USBC_ISTAT_D.INEP0` bit enables the interrupt request for the IN endpoint.

Device All Endpoint Interrupt Mask Register

The USBC_IMSK_D register works with the USBC_ISTAT_D register to interrupt the application when an event occurs on a device endpoint. However, the USBC_ISTAT_D register bit that corresponds to the interrupt is still set.

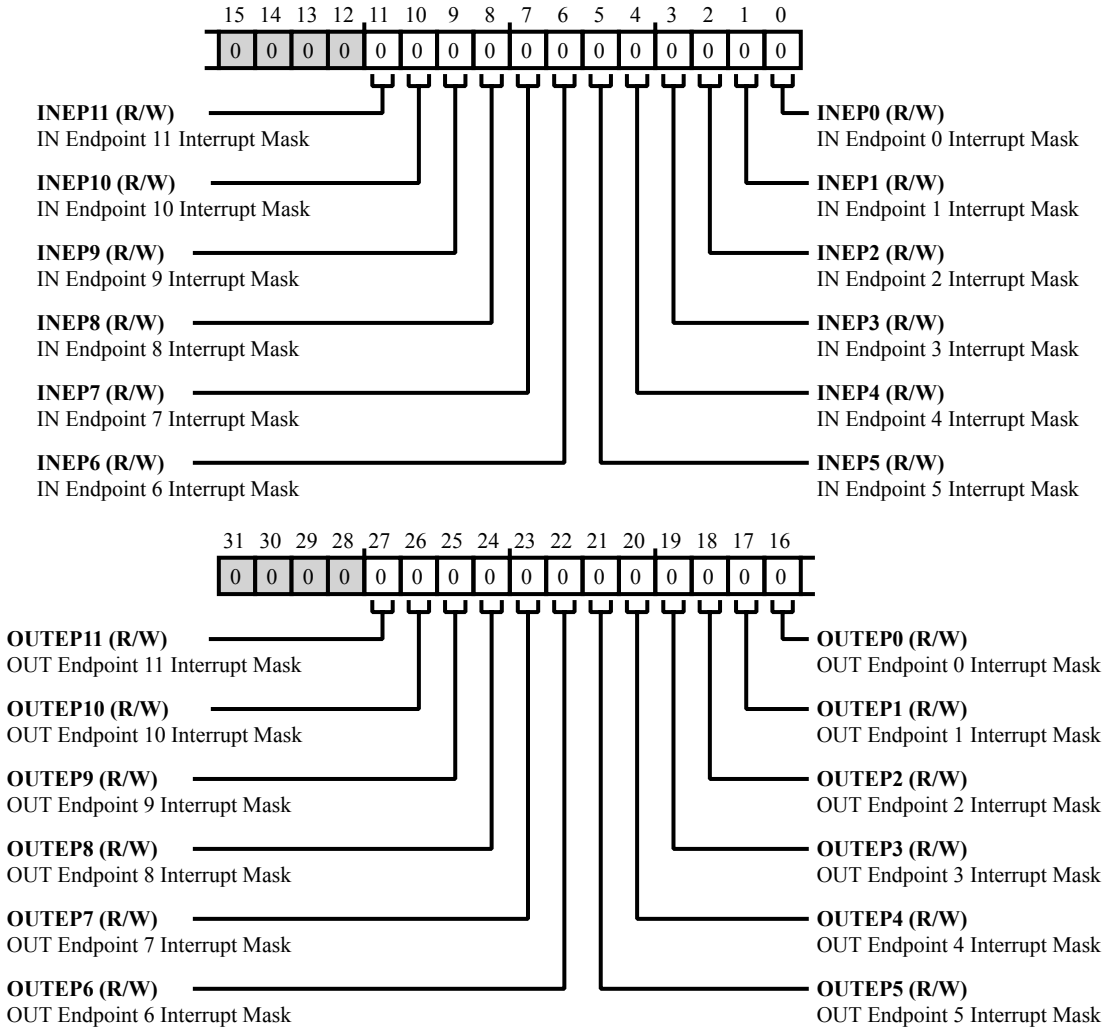

Figure 21-11: USBC_IMSK_D Register Diagram

Table 21-6: USBC_IMSK_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
27 (R/W)	OUTEP11	OUT Endpoint 11 Interrupt Mask. The USBC_IMSK_D.OUTEP11 bit unmasks (enables) or masks (disables) the interrupt request for the OUT endpoint.

Table 21-6: USBC_IMSK_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
26 (R/W)	OUTEP10	OUT Endpoint 10 Interrupt Mask. The `USBC_IMSK_D.OUTEP10` bit unmasks (enables) or masks (disables) the interrupt request for the OUT endpoint.
25 (R/W)	OUTEP9	OUT Endpoint 9 Interrupt Mask. The `USBC_IMSK_D.OUTEP9` bit unmasks (enables) or masks (disables) the interrupt request for the OUT endpoint.
24 (R/W)	OUTEP8	OUT Endpoint 8 Interrupt Mask. The `USBC_IMSK_D.OUTEP8` bit unmasks (enables) or masks (disables) the interrupt request for the OUT endpoint.
23 (R/W)	OUTEP7	OUT Endpoint 7 Interrupt Mask. The `USBC_IMSK_D.OUTEP7` bit unmasks (enables) or masks (disables) the interrupt request for the OUT endpoint.
22 (R/W)	OUTEP6	OUT Endpoint 6 Interrupt Mask. The `USBC_IMSK_D.OUTEP6` bit unmasks (enables) or masks (disables) the interrupt request for the OUT endpoint.
21 (R/W)	OUTEP5	OUT Endpoint 5 Interrupt Mask. The `USBC_IMSK_D.OUTEP5` bit unmasks (enables) or masks (disables) the interrupt request for the OUT endpoint.
20 (R/W)	OUTEP4	OUT Endpoint 4 Interrupt Mask. The `USBC_IMSK_D.OUTEP4` bit unmasks (enables) or masks (disables) the interrupt request for the OUT endpoint.
19 (R/W)	OUTEP3	OUT Endpoint 3 Interrupt Mask. The `USBC_IMSK_D.OUTEP3` bit unmasks (enables) or masks (disables) the interrupt request for the OUT endpoint.
18 (R/W)	OUTEP2	OUT Endpoint 2 Interrupt Mask. The `USBC_IMSK_D.OUTEP2` bit unmasks (enables) or masks (disables) the interrupt request for the OUT endpoint.
17 (R/W)	OUTEP1	OUT Endpoint 1 Interrupt Mask. The `USBC_IMSK_D.OUTEP1` bit unmasks (enables) or masks (disables) the interrupt request for the OUT endpoint.
16 (R/W)	OUTEP0	OUT Endpoint 0 Interrupt Mask. The `USBC_IMSK_D.OUTEP0` bit unmasks (enables) or masks (disables) the interrupt request for the OUT endpoint.

Table 21-6: USBC_IMSK_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
11 (R/W)	INEP11	IN Endpoint 11 Interrupt Mask. The `USBC_IMSK_D.INEP11` bit unmasks (enables) or masks (disables) the interrupt request for the IN endpoint.
10 (R/W)	INEP10	IN Endpoint 10 Interrupt Mask. The `USBC_IMSK_D.INEP10` bit unmasks (enables) or masks (disables) the interrupt request for the IN endpoint.
9 (R/W)	INEP9	IN Endpoint 9 Interrupt Mask. The `USBC_IMSK_D.INEP9`bit unmasks (enables) or masks (disables) the interrupt request for the IN endpoint.
8 (R/W)	INEP8	IN Endpoint 8 Interrupt Mask. The `USBC_IMSK_D.INEP8`bit unmasks (enables) or masks (disables) the interrupt request for the IN endpoint.
7 (R/W)	INEP7	IN Endpoint 7 Interrupt Mask. The `USBC_IMSK_D.INEP7` bit unmasks (enables) or masks (disables) the interrupt request for the IN endpoint.
6 (R/W)	INEP6	IN Endpoint 6 Interrupt Mask. The `USBC_IMSK_D.INEP6` bit unmasks (enables) or masks (disables) the interrupt request for the IN endpoint.
5 (R/W)	INEP5	IN Endpoint 5 Interrupt Mask. The `USBC_IMSK_D.INEP5` bit unmasks (enables) or masks (disables) the interrupt request for the IN endpoint.
4 (R/W)	INEP4	IN Endpoint 4 Interrupt Mask. The `USBC_IMSK_D.INEP4` bit unmasks (enables) or masks (disables) the interrupt request for the IN endpoint.
3 (R/W)	INEP3	IN Endpoint 3 Interrupt Mask. The `USBC_IMSK_D.INEP3` bit unmasks (enables) or masks (disables) the interrupt request for the IN endpoint.
2 (R/W)	INEP2	IN Endpoint 2 Interrupt Mask. The `USBC_IMSK_D.INEP2` bit unmasks (enables) or masks (disables) the interrupt request for the IN endpoint.
1 (R/W)	INEP1	IN Endpoint 1 Interrupt Mask. The `USBC_IMSK_D.INEP1` bit unmasks (enables) or masks (disables) the interrupt request for the IN endpoint.

Table 21-6: USBC_IMSK_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
0 (R/W)	INEP0	IN Endpoint 0 Interrupt Mask. The `USBC_IMSK_D.INEP0` bit unmasks (enables) or masks (disables) the interrupt request for the IN endpoint.

Device Configuration Register

The USBC_CFG_D register configures the core in device mode after power-on or after certain control commands or enumeration. Do not make changes to this register after initial programming.

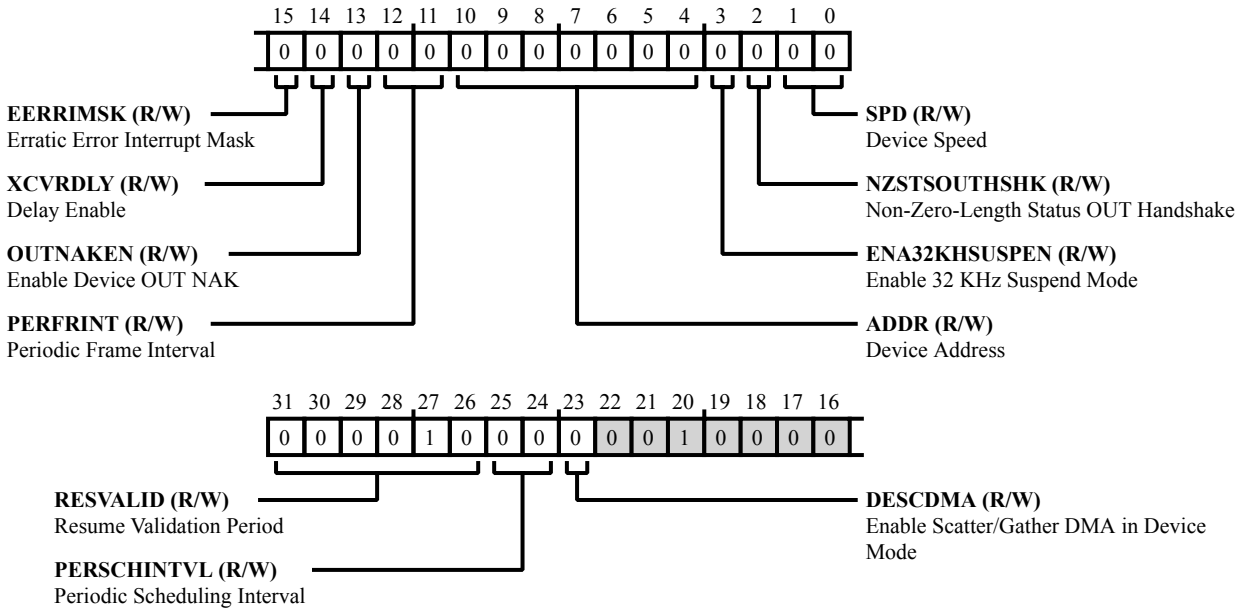

Figure 21-12: USBC_CFG_D Register Diagram

Table 21-7: USBC_CFG_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:26 (R/W)	RESVALID	Resume Validation Period. The USBC_CFG_D.RESVALID field controls the resume period when the core resumes after suspend. The core counts for USBC_CFG_D.RESVALID clock cycles to detect a valid resume. The USBC_CFG_D.RESVALID field is effective only when USBC_CFG_D.ENA32KHSUSPEN is set.

Table 21-7: USBC_CFG_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
25:24 (R/W)	PERSCHINTVL	Periodic Scheduling Interval. The USBC_CFG_D.PERSCHINTVL field must be programmed for scatter/gather DMA mode. The USBC_CFG_D.PERSCHINTVL field specifies the amount of time the internal DMA engine must allocate for fetching periodic IN endpoint data. Based on the number of periodic endpoints, this value must be specified as 25, 50, or 75% of (micro)frame. When any periodic endpoints are active, the internal DMA engine allocates the specified amount of time in fetching periodic IN endpoint data. When no periodic endpoints are active, the internal DMA engine services the non-periodic endpoints and ignores this field. After the specified time within a (micro)frame, the DMA switches to fetching for non-periodic endpoints.	
		0	25% of microframe
		1	50% of microframe
		2	75% of microframe
		3	Reserved
23 (R/W)	DESCDMA	Enable Scatter/Gather DMA in Device Mode. When the scatter/gather DMA option is selected during configuration, the application can set the USBC_CFG_D.DESCDMA bit during initialization to enable the scatter/gather DMA operation. Note: This bit must be modified only once after a reset. The following combinations are available for programming: Slave mode: USBC_AHB_CFG.DMAEN=0, USBC_CFG_D.DESCDMA=0 Invalid: USBC_AHB_CFG.DMAEN=0, USBC_CFG_D.DESCDMA=1 Buffered DMA mode: USBC_AHB_CFG.DMAEN=1, USBC_CFG_D.DESCDMA=0 Scatter/gather DMA mode: USBC_AHB_CFG.DMAEN=1, USBC_CFG_D.DESCDMA=1	
15 (R/W)	EERRIMSK	Erratic Error Interrupt Mask. The USBC_CFG_D.EERRIMSK bit unmasks (enables) or masks (disables) the interrupt request for early suspend on erratic error.	
14 (R/W)	XCVRDLY	Delay Enable. The USBC_CFG_D.XCVRDLY bit enables or disables the delay between xcvr_sel and txvalid during device chirp.	

Table 21-7: USBC_CFG_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
13 (R/W)	OUTNAKEN	Enable Device OUT NAK. The `USBC_CFG_D.OUTNAKEN` bit enables setting NAK for bulk OUT endpoints after the transfer is completed for device mode descriptor DMA. The `USBC_CFG_D.OUTNAKEN` bit is one time programmable after reset like any other `USBC_CFG_D` register bits.	
		0	Disable
		1	Enable
12:11 (R/W)	PERFRINT	Periodic Frame Interval. The `USBC_CFG_D.PERFRINT` field indicates the time within a (micro)frame at which the application must be notified using the end of periodic frame interrupt. This can be used to determine when all the isochronous traffic for that (micro)frame is complete.	
		0	80% of the microframe interval
		1	85% of the microframe interval
		2	90% of the microframe interval
		3	95% of the microframe interval
10:4 (R/W)	ADDR	Device Address. The `USBC_CFG_D.ADDR` field must be programmed after every SetAddress control command.	
3 (R/W)	ENA32KHSUSPEN	Enable 32 KHz Suspend Mode. The `USBC_CFG_D.ENA32KHSUSPEN` bit can be set only when the FS PHY interface is selected. Otherwise, this bit needs to be cleared. If the FS PHY interface is chosen and this bit is set, the PHY clock during suspend must be switched from 48 MHz to 32 KHz.	
2 (R/W)	NZSTSOUTHSHK	Non-Zero-Length Status OUT Handshake. The `USBC_CFG_D.NZSTSOUTHSHK` field selects the handshake that the core sends upon receiving a non-zero length data packet during the OUT transaction of a control transfer's status stage.	
		0	Send the received OUT packet to the application (zero length or non-zero-length) and send a handshake based on the NAK and STALL bits for the endpoint in the Device Endpoint Control register.
		1	Send a STALL handshake on a nonzero-length status OUT transaction and do not send the received OUT packet to the application.

Table 21-7: USBC_CFG_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1:0 (R/W)	SPD	Device Speed. The `USBC_CFG_D.SPD` bit indicates the speed at which the application requires the core to enumerate, or the maximum speed the application can support. However, the actual bus speed is determined only after the connect sequence is completed, and is based on the speed of the USB host to which the core is connected.	
		0	High Speed USB 2.0. PHY clock is 30 Mhz or 60 Mhz.
		1	Full Speed USB 2.0. PHY clock is 30 Mhz or 60 Mhz.
		2	Low Speed USB 1.1 Transceiver clock is 6 Mhz.
		3	Full Speed USB 1.1. Transceiver clock is 48 MHz.

Device Control Register

In device mode, the USBC_CTL_D register controls global functions such as wakeup and soft disconnect.

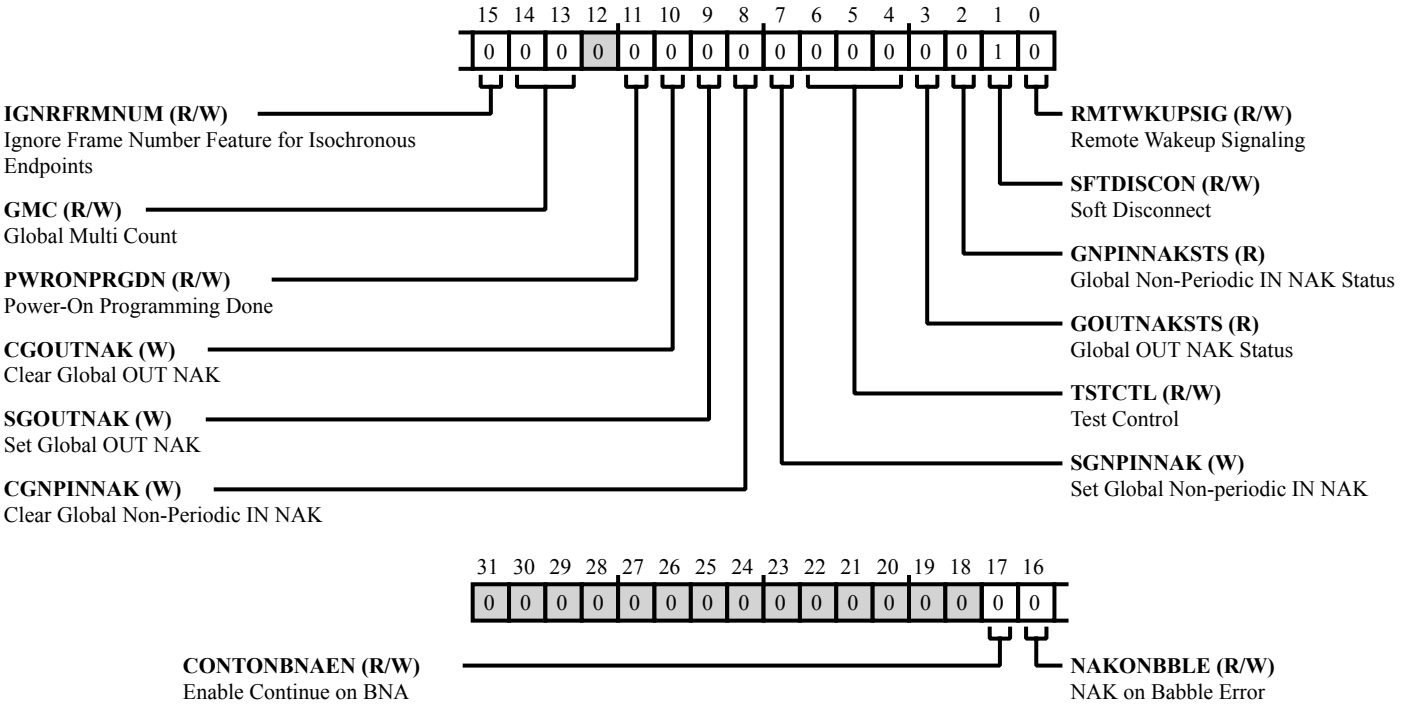

Figure 21-13: USBC_CTL_D Register Diagram

Table 21-8: USBC_CTL_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/W)	CONTONBNAEN	Enable Continue on BNA. The USBC_CTL_D.CONTONBNAEN bit enables the core to continue on BNA for bulk OUT endpoints. With this feature enabled, when a bulk OUT or INTR OUT endpoint receives a BNA interrupt, the core starts processing the descriptor that caused the BNA interrupt after the endpoint re-enables the endpoint. After receiving a BNA interrupt, the core disables the endpoint. When the endpoint is re-enabled by the application, the core starts processing from the DOEPDMA descriptor or from the descriptor that received the BNA interrupt. The USBC_CTL_D.CONTONBNAEN bit is a one-time programmable after reset bit (like the other USBC_CTL_D register bits).	
		0	Process from the DOEPDMA descriptor
		1	Process from the descriptor that received the BNA interrupt

Table 21-8: USBC_CTL_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
16 (R/W)	NAKONBBLE	NAK on Babble Error. When set (=1), the USBC_CTL_D.NAKONBBLE bit enables NAK automatically on babble (NakOnBble). The core sets NAK automatically for the endpoint on which babble is received.
15 (R/W)	IGNRFRMNUM	Ignore Frame Number Feature for Isochronous Endpoints. The USBC_CTL_D.IGNRFRMNUM bit controls the Periodic Transfer Interrupt (PTI) feature. When USBC_CTL_D.IGNRFRMNUM is set (=1), the core transmits the packets only in the frame number in which they are intended to be transmitted. When USBC_CTL_D.IGNRFRMNUM is cleared, the core ignores the frame number, sending packets immediately as the packets are ready. Note: Do not set (=1) the USBC_CTL_D.IGNRFRMNUM bit when the core is operating in threshold mode. This feature does not apply to high speed, high bandwidth transfers. When the USBC_CTL_D.IGNRFRMNUM bit is set (=1), there must be only one packet per descriptor. In scatter/gather DMA mode, if USBC_CTL_D.IGNRFRMNUM bit is enabled, the packets are not flushed when a ISOC IN token is received for an elapsed frame. In PTI mode, the application receive a transfer complete interrupt after transfers for multiple (micro)frames are completed.
14:13 (R/W)	GMC	Global Multi Count. The USBC_CTL_D.GMC field indicates the number of packets to be serviced for the endpoint before moving to the next endpoint. It applies only to non-periodic endpoints. The USBC_CTL_D.GMC bit must be programmed only once after initialization. The value of this field automatically changes to 2'h1 when USBC_CFG_D.DESCDMA = 1. 0 Invalid 1 1 packet 2 2 packets 3 3 packets
11 (R/W)	PWRONPRGDN	Power-On Programming Done. Th USBC_CTL_D.PWRONPRGDN bit indicates that register programming is completed after a wakeup from power down mode.
10 (RX/W)	CGOUTNAK	Clear Global OUT NAK. A write to the USBC_CTL_D.CGOUTNAK field clears the global OUT NAK.

Table 21-8: USBC_CTL_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (RX/W)	SGOUTNAK	Set Global OUT NAK. A write to the `USBC_CTL_D.SGOUTNAK` field sets the global OUT NAK. The application uses this bit to send a NAK handshake on all OUT endpoints. The application must set the this bit only after making sure that the `USBC_ISTAT.GOUTNAKEFF` bit is cleared (=0).	
8 (RX/W)	CGNPINNAK	Clear Global Non-Periodic IN NAK. A write to the `USBC_CTL_D.CGNPINNAK` field clears the global non-periodic IN NAK.	
7 (RX/W)	SGNPINNAK	Set Global Non-periodic IN NAK. A write to the `USBC_CTL_D.SGNPINNAK` field sets the global non-periodic IN NAK. The application uses this bit to send a NAK handshake on all non-periodic IN endpoints. The core can also set this bit when a timeout condition is detected on a non-periodic endpoint in shared FIFO operation. The application must set this bit only after ensuring that after making sure that the `USBC_ISTAT.GINNAKEFF` bit is cleared (=0).	
6:4 (R/W)	TSTCTL	Test Control. The `USBC_CTL_D.TSTCTL` field indicates the test mode state.	
		0	Test mode disabled
		1	Test_J mode. In this mode, the USB controller transmits a continuous J on the bus.
		2	Test_K mode. In this mode, the USB controller transmits a continuous K on the bus.
		3	Test_SE0 NAK mode
		4	Test_Packet mode
		5	Test_Force_Enable mode
3 (R/NW)	GOUTNAKSTS	Global OUT NAK Status. The `USBC_CTL_D.GOUTNAKSTS` bit indicates whether a handshake is sent based on the FIFO status and the NAK and STALL bit settings or sends a NAK handshake on all packets, except on SETUP transactions. No data is written to the RxFIFO (irrespective of space availability). All isochronous OUT packets are dropped	
		0	Send handshake
		1	Send NAK handshake

Table 21-8: USBC_CTL_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/NW)	GNPINNAKSTS	Global Non-Periodic IN NAK Status. The `USBC_CTL_D.GNPINNAKSTS` bit indicates whether a handshake is sent out based on the data availability in the transmit FIFO or an NAK handshake is sent out on all non-periodic IN endpoints, irrespective of the data availability in the transmit FIFO.	
		0	Handshake based on available data
		1	NAK Handshake
1 (R/W)	SFTDISCON	Soft Disconnect. The `USBC_CTL_D.SFTDISCON` bit signals the controller to do a soft disconnect. As long as this bit is set, the host does not see that the device is connected, and the device does not receive signals on the USB. The core stays in the disconnected state until the application clears this bit. The following is the minimum duration under various conditions for which this bit must be set for the USB host to detect a device disconnect. To accommodate clock jitter, it is recommended that the application adds some extra delay to the specified minimum duration. For high speed, if the device state is suspended, the minimum duration is 1 ms + 2.5 us. If the device state is idle, the minimum duration is 3 ms + 2.5 us. If the device state is not idle or suspended (performing transactions), the minimum duration 125 us For full speed/low speed, if the device state is suspended, the minimum duration is 1 ms + 2.5 us. if the device state is idle, the minimum duration is 2.5 us. if the device state is not idle or suspended (performing transactions), the minimum duration 125 us. Note: This bit can be also used for ULPI/FS serial interfaces. This bit is not impacted by a soft reset.	
		0	Normal Operation When this bit is cleared after a soft disconnect, the controller generates a device connect event to the USB host. When the device is reconnected, the USB host restarts device enumeration.
		1	The controller generates a device disconnect event to the USB host.

Table 21-8: USBC_CTL_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
0 (R/W)	RMTWKUPSIG	Remote Wakeup Signaling. When the `USBC_CTL_D.RMTWKUPSIG` bit is set (=1), the core initiates remote signaling to wake up the USB host. The application must set this bit to instruct the core to exit the suspend state. As specified in the USB 2.0 specification, the application must clear this bit 1-15 ms after setting it. If LPM is enabled and the core is in the L1 (sleep) state, when the application sets this bit, the core initiates L1 remote signaling to wake up the USB host. The application must set this bit to instruct the core to exit the sleep state. As specified in the LPM specification, the hardware automatically clears the `USBC_CTL_D.RMTWKUPSIG` bit 50 ms after being set by the application.

Device Control IN Endpoint 0 Control Register

In device mode, the USBC_CTL_IEP0_D register controls IN endpoint 0.

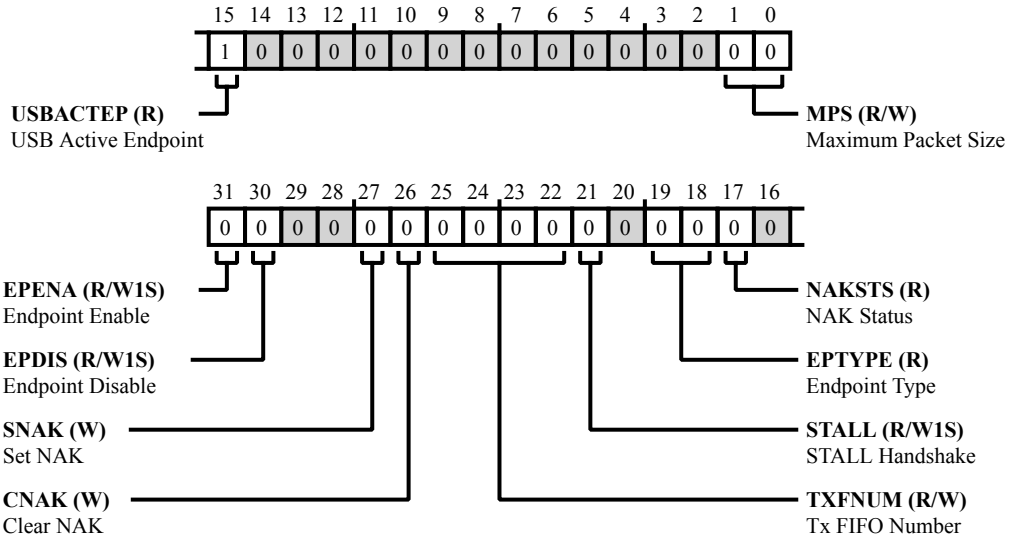

Figure 21-14: USBC_CTL_IEP0_D Register Diagram

Table 21-9: USBC_CTL_IEP0_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W1S)	EPENA	Endpoint Enable. The USBC_CTL_IEP0_D.EPENA bit indicates that the descriptor structure and data buffer with data ready for transmission is configured.
30 (R/W1S)	EPDIS	Endpoint Disable. The application sets the USBC_CTL_IEP0_D.EPDIS bit to stop transmitting data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the endpoint disabled interrupt before treating the endpoint as disabled. The core clears the USBC_CTL_IEP0_D.EPDIS bit before setting the endpoint disabled interrupt. The application must set this bit only if endpoint enable is already set for this endpoint.
27 (RX/W)	SNAK	Set NAK. A write to the USBC_CTL_IEP0_D.SNAK bit sets the NAK bit for the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also set this bit for an endpoint after a SETUP packet is received on that endpoint.
26 (RX/W)	CNAK	Clear NAK. A write to the USBC_CTL_IEP0_D.CNAK bit clears the NAK bit for the endpoint.

Table 21-9: USBC_CTL_IEP0_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
25:22 (R/W)	TXFNUM	Tx FIFO Number. The `USBC_CTL_IEP0_D.TXFNUM` field indicates the FIFO number that is assigned to the IN endpoint.	
21 (R/W1S)	STALL	STALL Handshake. The application sets (=1) the `USBC_CTL_IEP0_D.STALL` bit, and the core clears (=0) it, when a SETUP token is received for the endpoint. If a NAK bit, the global non-periodic IN NAK, or global OUT NAK is set along with this bit, the `USBC_CTL_IEP0_D.STALL` bit takes priority.	
19:18 (R/NW)	EPTYPE	Endpoint Type. The `USBC_CTL_IEP0_D.EPTYPE` bit is hardcoded to 00 for control.	
17 (R/NW)	NAKSTS	NAK Status. When the `USBC_CTL_IEP0_D.NAKSTS` bit is set, either by the application or core, the core stops transmitting data, even when there is data available in the TxFIFO. Irrespective of the bit configuration, the core always responds to SETUP data packets with an ACK handshake.	
		0	Core is transmitting non-NAK handshakes based on FIFO status
		1	Core is transmitting NAK handshakes on the endpoint
15 (R/NW)	USBACTEP	USB Active Endpoint. The `USBC_CTL_IEP0_D.USBACTEP` bit is always set (= 1), indicating that control endpoint 0 is active in all configurations and interfaces.	
1:0 (R/W)	MPS	Maximum Packet Size. The `USBC_CTL_IEP0_D.MPS` field indicates the maximum packet size (in bytes) for the current logical endpoint. The field applies to IN and OUT endpoints.	
		0	64 bytes
		1	32 bytes
		2	16 bytes
		3	8 bytes

Device Control IN Endpoint n Control Register

In device mode, the `USBC_CTL_IEP[n]_D` register controls IN endpoint n.

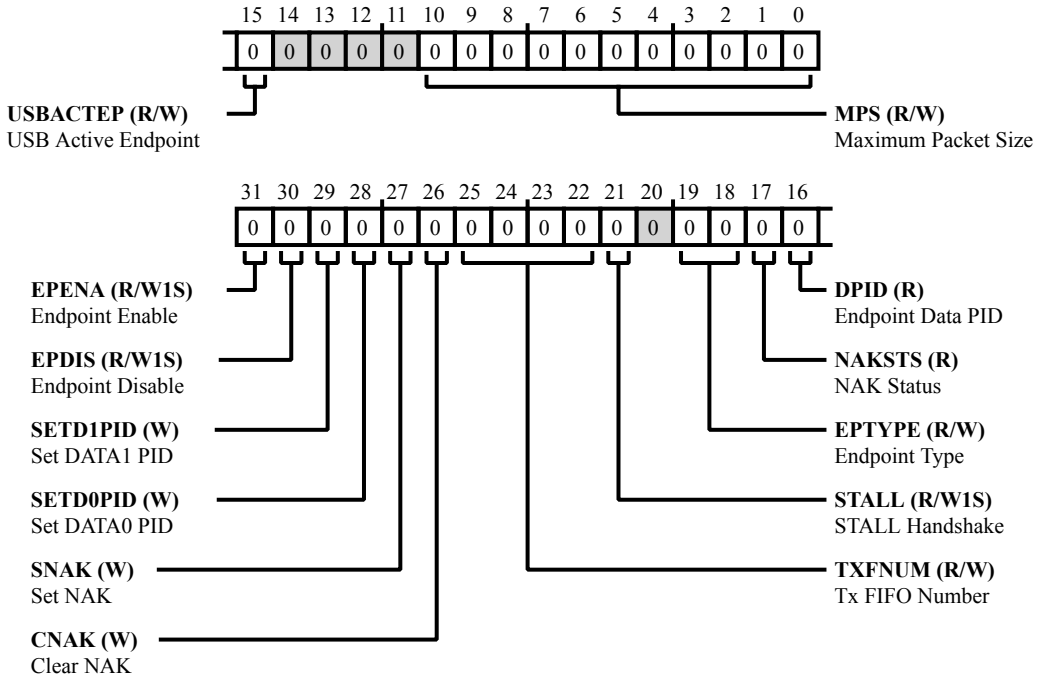

Figure 21-15: USBC_CTL_IEP[n]_D Register Diagram

Table 21-10: USBC_CTL_IEP[n]_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W1S)	EPENA	Endpoint Enable. When scatter/gather DMA mode is enabled for IN endpoints, the `USBC_CTL_IEP[n]_D.EPENA` bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. For OUT endpoints, it indicates that the descriptor structure and data buffer to receive data is set up. When scatter/gather DMA mode is enabled, such as for buffer-pointer based DMA mode: For IN endpoints, the `USBC_CTL_IEP[n]_D.EPENA` bit indicates that data is ready to be transmitted on the endpoint. For OUT endpoints, the `USBC_CTL_IEP[n]_D.EPENA` bit indicates that the application has allocated the memory to start receiving data from the USB. The core clears the `USBC_CTL_IEP[n]_D.EPENA` bit before setting any of the following interrupts on this endpoint: SETUP Phase Done, Endpoint Disabled, Transfer Completed. Note: For control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory.

Table 21-10: USBC_CTL_IEP[n]_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
30 (R/W1S)	EPDIS	Endpoint Disable. The application sets the USBC_CTL_IEP[n]_D.EPDIS bit to stop transmitting data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the endpoint disabled interrupt before treating the endpoint as disabled. The core clears the USBC_CTL_IEP[n]_D.EPDIS bit before setting the endpoint disabled interrupt. The application must set this bit only if endpoint enable is already set for this endpoint. The USBC_CTL_IEP[n]_D.EPDIS bit applies to IN and OUT endpoints.
29 (RX/W)	SETD1PID	Set DATA1 PID. The USBC_CTL_IEP[n]_D.SETD1PID bit applies to interrupt and bulk IN and OUT endpoints only.The USBC_CTL_IEP[n]_D.SETD1PID bit applies to both for scatter/gather DMA mode and non scatter/gather DMA mode. Writing to the USBC_CTL_IEP[n]_D.SETD1PID bit sets the Endpoint Data PID (DPID) field in this register to DATA1. In non scatter/gather DMA mode, set odd (micro)frame (SetOddFr). SetOddFr applies to isochronous IN and OUT endpoints only. Writing to the USBC_CTL_IEP[n]_D.SETD1PID bit sets the even and odd (micro)Frame (EO_FrNum) field to odd (micro)frame. The USBC_CTL_IEP[n]_D.SETD1PID bit is not applicable for scatter/gather DMA mode for isochronous endpoints.
28 (RX/W)	SETD0PID	Set DATA0 PID. The USBC_CTL_IEP[n]_D.SETD0PID bit applies to interrupt/bulk IN and OUT endpoints only. A write to the USBC_CTL_IEP[n]_D.SETD0PID bit sets the endpoint data PID (DPID) field in this register to DATA0. The USBC_CTL_IEP[n]_D.SETD0PID bit applies to both scatter/gather DMA mode and non-scatter/gather DMA mode. In non-scatter/gather DMA mode: Set even (micro)frame (SetEvenFr) SetEvenFr applies to isochronous IN and OUT endpoints only. A write to the USBC_CTL_IEP[n]_D.SETD0PID bit sets the even/odd (micro)frame (EO_FrNum) field to even (micro)frame. When scatter/gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure.
27 (RX/W)	SNAK	Set NAK. A write to the USBC_CTL_IEP[n]_D.SNAK bit sets the NAK bit for the endpoint. Using the USBC_CTL_IEP[n]_D.SNAK bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also set this bit for an endpoint after a SETUP packet is received on that endpoint.

Table 21-10: USBC_CTL_IEP[n]_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
26 (RX/W)	CNAK	Clear NAK. A write to the `USBC_CTL_IEP[n]_D.CNAK` bit clears the NAK bit for the endpoint.	
25:22 (R/W)	TXFNUM	Tx FIFO Number. The `USBC_CTL_IEP[n]_D.TXFNUM` field indicates the FIFO number that is assigned to the IN endpoint. Each active IN endpoint must be programmed to a separate FIFO number. This field is valid only for IN endpoints.	
21 (R/W1S)	STALL	STALL Handshake. The `USBC_CTL_IEP[n]_D.STALL` bit indicates a handshake stall. The application sets (=1) the `USBC_CTL_IEP[n]_D.STALL` bit to stall all tokens from the USB host to this endpoint. If a NAK, global non-periodic IN NAK, or global OUT NAK bit is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. The `USBC_CTL_IEP[n]_D.STALL` bit applies to non-control, non-isochronous IN and OUT endpoints only. The application can only set the `USBC_CTL_IEP[n]_D.STALL` bit, and the core clears it, when a SETUP token is received for this endpoint. Irrespective of the bit configuration, the core always responds to SETUP data packets with an ACK handshake.	
19:18 (R/W)	EPTYPE	Endpoint Type. The `USBC_CTL_IEP[n]_D.EPTYPE` bit indicates the transfer type supported by this logical endpoint.	
		0	Control
		1	Isochronous
		2	Bulk
		3	Interrupt

Table 21-10: USBC_CTL_IEP[n]_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/NW)	NAKSTS	NAK Status. When the `USBC_CTL_IEP[n]_D.NAKSTS` bit is set, either by the application or core, the core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. For non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. For isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of the bit configuration, the core always responds to SETUP data packets with an ACK handshake.	
		0	Core is transmitting non-NAK handshakes based on the FIFO status
		1	Core is transmitting NAK handshakes on the endpoint
16 (R/NW)	DPID	Endpoint Data PID. The `USBC_CTL_IEP[n]_D.DPID` field applies to interrupt/bulk IN and OUT endpoints only. The `USBC_CTL_IEP[n]_D.DPID` field indicates the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1 The `USBC_CTL_IEP[n]_D.DPID` field applies to both scatter/gather DMA mode and non-scatter/gather DMA mode. Even/Odd (Micro)Frame (EO_FrNum) In non-scatter/gather DMA mode, the `USBC_CTL_IEP[n]_D.DPID` field applies to isochronous IN and OUT endpoints only. The `USBC_CTL_IEP[n]_D.DPID` field indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro)frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 0: Even (micro)frame 1: Odd (micro)frame When scatter/gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure.	

Table 21-10: USBC_CTL_IEP[n]_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W)	USBACTEP	USB Active Endpoint. `USBC_CTL_IEP[n]_D.USBACTEP` bit indicates whether this endpoint is active in the current configuration and interface. The core clears the `USBC_CTL_IEP[n]_D.USBACTEP` bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit.
10:0 (R/W)	MPS	Maximum Packet Size. The `USBC_CTL_IEP[n]_D.MPS` field indicates the maximum packet size (in bytes) for the current logical endpoint. This value is in bytes.

Device Control IN Endpoint 0 DMA Address Register

In device mode, the USBC_DMA_ADDR_IEP0_D register indicates the DWORD-aligned start address of the external memory for storing or fetching endpoint data. This register is incremented on every bus transaction.

When scatter/gather DMA mode is not enabled, the USBC_DMA_ADDR_IEP0_D register indicates the start address.

When scatter/gather DMA mode is enabled, the USBC_DMA_ADDR_IEP0_D register indicates the base pointer for the descriptor list.

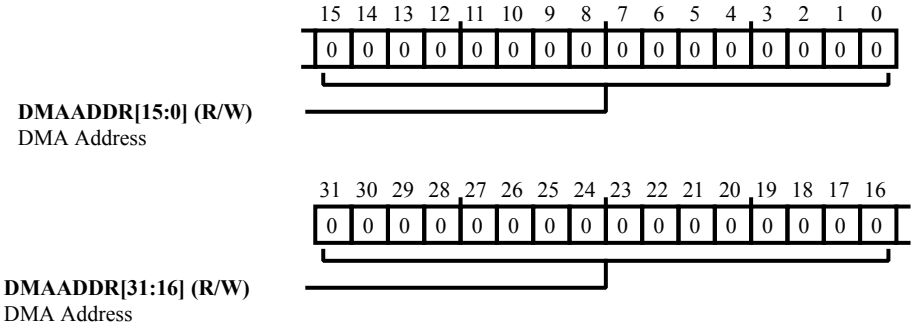

Figure 21-16: USBC_DMA_ADDR_IEP0_D Register Diagram

Table 21-11: USBC_DMA_ADDR_IEP0_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	DMAADDR	DMA Address. This USBC_DMA_ADDR_IEP0_D.DMAADDR field holds the start address of the external memory for storing or fetching endpoint data. Note: For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten.

Device IN Endpoint 0 Buffer Address Register

In device mode, the USBC_DMA_BADDR_IEP0_D register indicates the buffer address for IN endpoint 0. It is updated when the data transfer for the endpoint 0 is in progress.

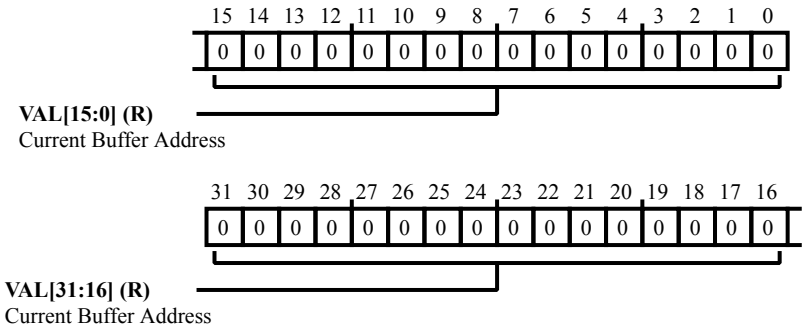

Figure 21-17: USBC_DMA_BADDR_IEP0_D Register Diagram

Table 21-12: USBC_DMA_BADDR_IEP0_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VAL	Current Buffer Address. The USBC_DMA_BADDR_IEP0_D.VAL field holds the current buffer address.

Device Control IN Endpoint n DMA Buffer Address Register

In device mode, the USBC_DMA_BADDR_IEP[n]_D register indicates the buffer address for IN endpoint n. It is updated when the data transfer for the corresponding endpoint is in progress.

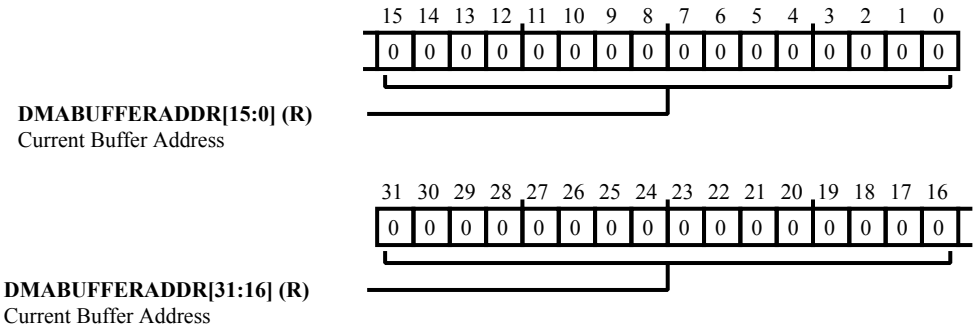

Figure 21-18: USBC_DMA_BADDR_IEP[n]_D Register Diagram

Table 21-13: USBC_DMA_BADDR_IEP[n]_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	DMABUFFERADDR	Current Buffer Address. The USBC_DMA_BADDR_IEP[n]_D.DMABUFFERADDR field holds the current buffer address. This field is present only in scatter/gather DMA mode. Otherwise, this field is reserved.

Device Control IN Endpoint n DMA Address Register

The USBC_DMA_ADDR_IEP[n]_D register indicates the DWORD-aligned start address of the external memory for storing or fetching endpoint data. This register is incremented on every bus transaction.

When scatter/gather DMA mode is not enabled, the USBC_DMA_ADDR_IEP[n]_D register indicates the start address.

When scatter/gather DMA mode is enabled, the USBC_DMA_ADDR_IEP[n]_D register indicates the base pointer for the descriptor list.

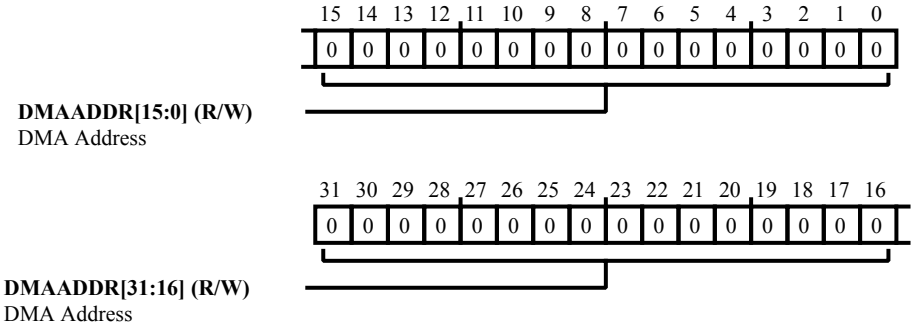

Figure 21-19: USBC_DMA_ADDR_IEP[n]_D Register Diagram

Table 21-14: USBC_DMA_ADDR_IEP[n]_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	DMAADDR	DMA Address. The USBC_DMA_ADDR_IEP[n]_D.DMAADDR field holds the start address of the external memory for storing or fetching endpoint data. Note: For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten.

Device IN Endpoint FIFO Empty Interrupt Mask Register

The USBC_IMSK_IEP_FEMPT_D register is valid only in dedicated FIFO operation (OTG_EN_DED_TX_FIFO = 1). This register is used to control the IN endpoint FIFO empty interrupt generation.

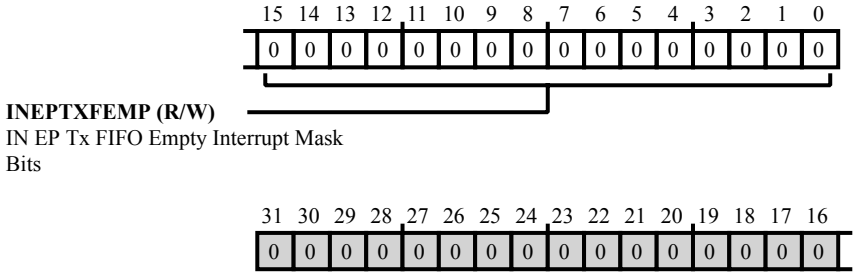

Figure 21-20: USBC_IMSK_IEP_FEMPT_D Register Diagram

Table 21-15: USBC_IMSK_IEP_FEMPT_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	INEPTXFEMP	IN EP Tx FIFO Empty Interrupt Mask Bits. The USBC_IMSK_IEP_FEMPT_D.INEPTXFEMP field acts as mask bits for the TXFEMP interrupt in the USBC_ISTAT_IEP[n]_D register; one bit per IN Endpoint. For example, bit 0 for IN endpoint 0, bit 15 for IN endpoint 15.

Device Control IN Endpoint 0 Interrupt Control Register

The USBC_ISTAT_IEP0_D register indicates the status of an endpoint with respect to USB- and bus-related events. The application must read this register when USBC_ISTAT.OEPINT or USBC_ISTAT.IEPINT is set. Before the application can read this register, it must first read the USBC_ISTAT_D register to get the exact endpoint number for the Device Endpoint n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the USBC_ISTAT_D and USBC_ISTAT registers.

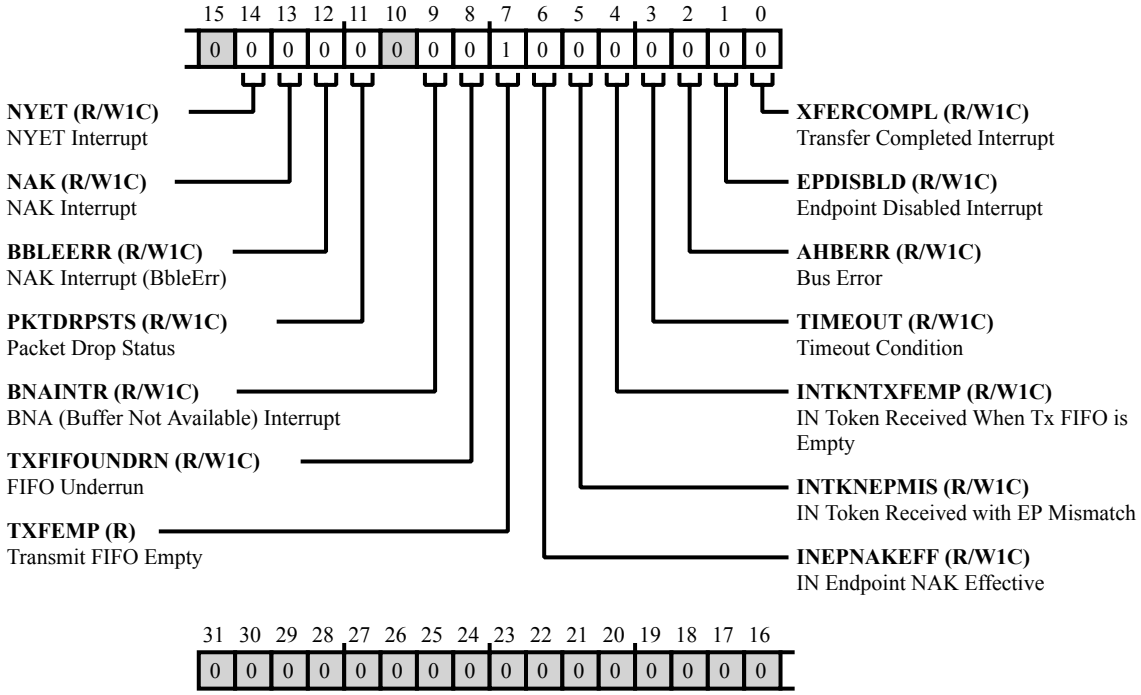

Figure 21-21: USBC_ISTAT_IEP0_D Register Diagram

Table 21-16: USBC_ISTAT_IEP0_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
14 (R/W1C)	NYET	NYET Interrupt. The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint.
13 (R/W1C)	NAK	NAK Interrupt. The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints, the interrupt gets generated when a zero length packet is transmitted due to unavailability of data in the Tx FIFO.
12 (R/W1C)	BBLEERR	NAK Interrupt (BbleErr). The core generates the NAK interrupt when babble is received for the endpoint.

Table 21-16: USBC_ISTAT_IEP0_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
11 (R/W1C)	PKTDRPSTS	Packet Drop Status. The USBC_ISTAT_IEP0_D.PKTDRPSTS bit indicates to the application that an ISOC OUT packet has been dropped. The USBC_ISTAT_IEP0_D.PKTDRPSTS bit does not have an associated mask bit and does not generate an interrupt. The USBC_ISTAT_IEP0_D.PKTDRPSTS bit is valid in non scatter/gather DMA mode when periodic transfer interrupt feature is selected.
9 (R/W1C)	BNAINTR	BNA (Buffer Not Available) Interrupt. The core generates this interrupt when the descriptor accessed is not ready for the core to process, such as host busy or DMA done.
8 (R/W1C)	TXFIFOUNDRN	FIFO Underrun. The USBC_ISTAT_IEP0_D.TXFIFOUNDRN bit applies to IN endpoints only. The core generates this interrupt when it detects a transmit FIFO underrun condition in threshold mode for this endpoint.
7 (R/NW)	TXFEMP	Transmit FIFO Empty. This interrupt is asserted when the Tx FIFO for this endpoint is either half or completely empty. The half or completely empty status is determined by the USBC_AHB_CFG.NPTXFELVL bit. The USBC_ISTAT_IEP0_D.TXFEMP bit is valid only for IN endpoints.
6 (R/W1C)	INEPNAKEFF	IN Endpoint NAK Effective. The USBC_ISTAT_IEP0_D.INEPNAKEFF bit applies to periodic IN endpoints only. The USBC_ISTAT_IEP0_D.INEPNAKEFF bit can be cleared when the application clears the IN endpoint NAK by writing to the USBC_CTL_IEP[n]_D.CNAK bit. This interrupt indicates that the core has sampled the NAK bit. Set (either by the application or by the core). The interrupt indicates that the IN endpoint NAK bit set by the application has taken effect in the core. This interrupt does not guarantee that a NAK handshake is sent on the USB. A STALL bit takes priority over a NAK bit.
5 (R/W1C)	INTKNEPMIS	IN Token Received with EP Mismatch. The USBC_ISTAT_IEP0_D.INTKNEPMIS bit indicates that the data in the top of the non-periodic Tx FIFO belongs to an endpoint other than the one for which the IN token was received. This interrupt is asserted on the endpoint for which the IN token was received. The USBC_ISTAT_IEP0_D.INTKNEPMIS bit applies to non-periodic IN endpoints only.

Table 21-16: USBC_ISTAT_IEP0_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
4 (R/W1C)	INTKNTXFEMP	IN Token Received When Tx FIFO is Empty. The USBC_ISTAT_IEP0_D.INTKNTXFEMP bit indicates that an IN token was received when the associated Tx FIFO (periodic/non-periodic) was empty. This interrupt is asserted on the endpoint for which the IN token was received. The USBC_ISTAT_IEP0_D.INTKNTXFEMP bit applies to non-periodic IN endpoints only.
3 (R/W1C)	TIMEOUT	Timeout Condition. The USBC_ISTAT_IEP0_D.TIMEOUT bit indicates that the core has detected a timeout condition on the USB for the last IN token on this endpoint. In shared TX FIFO mode, the USBC_ISTAT_IEP0_D.TIMEOUT bit applies to non-isochronous IN endpoints only. In dedicated FIFO mode, the USBC_ISTAT_IEP0_D.TIMEOUT bit applies only to control IN endpoints. In scatter/gather DMA mode, the timeout interrupt is not asserted.
2 (R/W1C)	AHBERR	Bus Error. The USBC_ISTAT_IEP0_D.AHBERR bit bus error during a bus read/write. It applies only in internal DMA mode. The application can read the corresponding endpoint DMA address register to get the error address. The USBC_ISTAT_IEP0_D.AHBERR bit applies to IN and OUT endpoints.
1 (R/W1C)	EPDISBLD	Endpoint Disabled Interrupt. The USBC_ISTAT_IEP0_D.EPDISBLD bit indicates that the endpoint is disabled per the application's request. The USBC_ISTAT_IEP0_D.EPDISBLD bit applies to IN and OUT endpoints.
0 (R/W1C)	XFERCOMPL	Transfer Completed Interrupt. The USBC_ISTAT_IEP0_D.XFERCOMPL field applies to IN and OUT endpoints. When scatter/gather DMA mode is enabled: For IN endpoints, the USBC_ISTAT_IEP0_D.XFERCOMPL field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. For OUT endpoints, the USBC_ISTAT_IEP0_D.XFERCOMPL field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is set. When scatter/gather DMA mode is disabled, the USBC_ISTAT_IEP0_D.XFERCOMPL field indicates that the programmed transfer is complete on the bus as well as on the USB, for this endpoint.

Device Control IN Endpoint n Interrupt Control Register

The USBC_ISTAT_IEP[n]_D register indicates the status of an endpoint with respect to USB- and bus-related events. This register exists for endpoint [n] when the USBC_HWCFG.EPDIR bit is 0 or 1 for that endpoint.

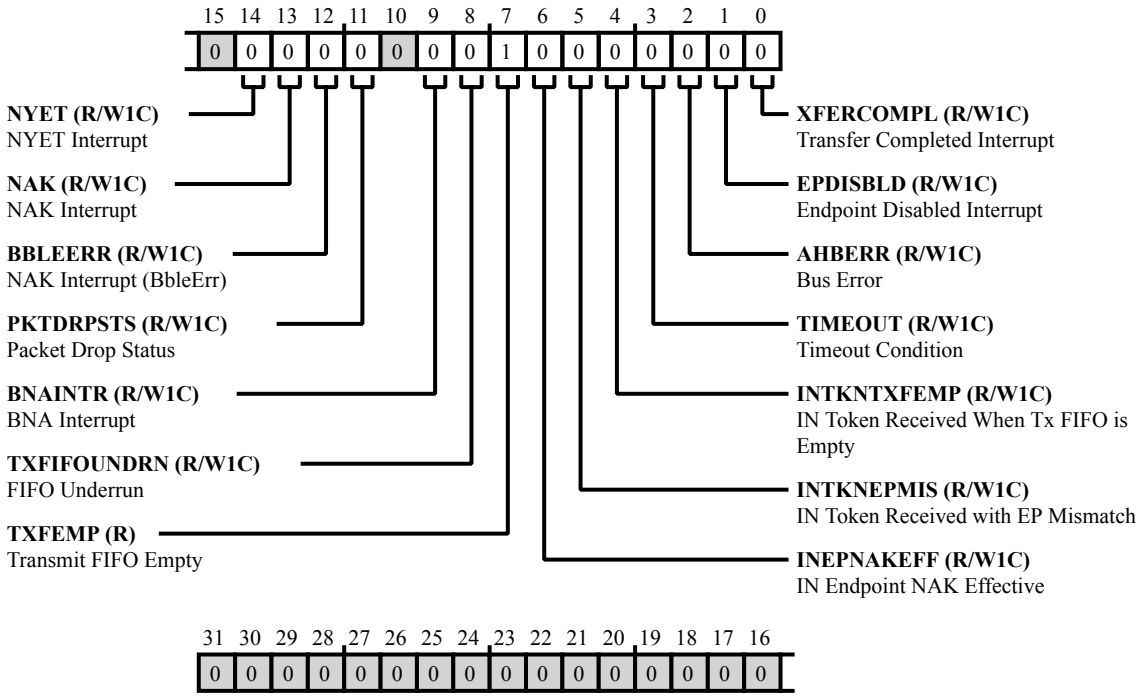

Figure 21-22: USBC_ISTAT_IEP[n]_D Register Diagram

Table 21-17: USBC_ISTAT_IEP[n]_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
14 (R/W1C)	NYET	NYET Interrupt. The core generates USBC_ISTAT_IEP[n]_D.NYET (NYETInterrupt) when a NYET response is transmitted for a non isochronous OUT endpoint.
13 (R/W1C)	NAK	NAK Interrupt. The core generates the USBC_ISTAT_IEP[n]_D.NAK (NAKInterrupt) when a NAK is transmitted or received by the device. In case of isochronous IN endpoints, the interrupt is generated when a zero length packet is transmitted due to unavailability of data in the Tx FIFO.
12 (R/W1C)	BBLEERR	NAK Interrupt (BbleErr). The core generates the USBC_ISTAT_IEP[n]_D.BBLEERR interrupt when babble is received for the endpoint.

Table 21-17: USBC_ISTAT_IEP[n]_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
11 (R/W1C)	PKTDRPSTS	Packet Drop Status. The `USBC_ISTAT_IEP[n]_D.PKTDRPSTS` bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. The `USBC_ISTAT_IEP[n]_D.PKTDRPSTS` bit is valid in non scatter/gather DMA mode when periodic transfer interrupt feature is selected.
9 (R/W1C)	BNAINTR	BNA Interrupt. The core generates the BNA (Buffer Not Available) interrupt when the descriptor accessed is not ready for the core to process, such as host busy or DMA done.
8 (R/W1C)	TXFIFOUNDRN	FIFO Underrun. The `USBC_ISTAT_IEP[n]_D.TXFIFOUNDRN` bit applies to IN endpoints only. The `USBC_ISTAT_IEP[n]_D.TXFIFOUNDRN` bit is valid only when thresholding is enabled. The core generates this interrupt when it detects a transmit FIFO underrun condition for this endpoint.
7 (R/NW)	TXFEMP	Transmit FIFO Empty. The `USBC_ISTAT_IEP[n]_D.TXFEMP` bit is valid only for IN endpoints. This interrupt is asserted when the Tx FIFO for this endpoint is either half or completely empty. The half or completely empty status is determined by the `USBC_AHB_CFG.NPTXFELVL` bit.
6 (R/W1C)	INEPNAKEFF	IN Endpoint NAK Effective. The `USBC_ISTAT_IEP[n]_D.INEPNAKEFF` bit applies to periodic IN endpoints only. The `USBC_ISTAT_IEP[n]_D.INEPNAKEFF` bit can be cleared when the application clears the IN endpoint NAK by writing to `USBC_CTL_IEP[n]_D.CNAK`. This interrupt indicates that the core has sampled the NAK bit. When set (either by the application or by the core), the interrupt indicates that the IN endpoint NAK bit set by the application has taken effect in the core. This interrupt does not guarantee that a NAK handshake is sent on the USB. A STALL bit takes priority over a NAK bit.
5 (R/W1C)	INTKNEPMIS	IN Token Received with EP Mismatch. The `USBC_ISTAT_IEP[n]_D.INTKNEPMIS` bit applies to non-periodic IN endpoints only. The `USBC_ISTAT_IEP[n]_D.INTKNEPMIS` bit indicates that the data in the top of the non-periodic Tx FIFO belongs to an endpoint other than the one for which the IN token was received. This interrupt is asserted on the endpoint for which the IN token was received.

Table 21-17: USBC_ISTAT_IEP[n]_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
4 (R/W1C)	INTKNTXFEMP	IN Token Received When Tx FIFO is Empty. The `USBC_ISTAT_IEP[n]_D.INTKNTXFEMP` bit applies to non-periodic IN endpoints only. The `USBC_ISTAT_IEP[n]_D.INTKNTXFEMP` bit indicates that an IN token was received when the associated Tx FIFO (periodic/non-periodic) was empty. This interrupt is asserted on the endpoint for which the IN token was received.
3 (R/W1C)	TIMEOUT	Timeout Condition. The `USBC_ISTAT_IEP[n]_D.TIMEOUT` bit indicates that the core has detected a timeout condition on the USB for the last IN token on this endpoint. In dedicated FIFO mode, the `USBC_ISTAT_IEP[n]_D.TIMEOUT` bit applies only to control IN endpoints. In scatter/gather DMA mode, the timeout interrupt is not asserted.
2 (R/W1C)	AHBERR	Bus Error. The `USBC_ISTAT_IEP[n]_D.AHBERR` bit applies to IN and OUT endpoints. The `USBC_ISTAT_IEP[n]_D.AHBERR` bit is set (=1) when there is a bus error during a bus read/write. The application can read the corresponding endpoint DMA address register to get the error address.
1 (R/W1C)	EPDISBLD	Endpoint Disabled Interrupt. The `USBC_ISTAT_IEP[n]_D.EPDISBLD` bit applies to IN and OUT endpoints. The `USBC_ISTAT_IEP[n]_D.EPDISBLD` bit indicates that the endpoint is disabled per the application's request.
0 (R/W1C)	XFERCOMPL	Transfer Completed Interrupt. The `USBC_ISTAT_IEP[n]_D.XFERCOMPL` bit applies to IN and OUT endpoints. When scatter/gather DMA mode is enabled: For IN endpoints, the `USBC_ISTAT_IEP[n]_D.XFERCOMPL` bit indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. For OUT endpoints, the `USBC_ISTAT_IEP[n]_D.XFERCOMPL` bit indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is set. When scatter/gather DMA mode is disabled, the `USBC_ISTAT_IEP[n]_D.XFERCOMPL` bit indicates that the programmed transfer is complete on the bus as well as on the USB, for this endpoint.

Device IN Endpoint Common Interrupt Mask Register

The USBC_IMASK_IEP_D register works with each of the Device IN Endpoint Interrupt (USBC_ISTAT_IEP[n]_D) registers for all endpoints to generate an interrupt per IN endpoint. The IN endpoint interrupt for a specific status in the USBC_ISTAT_IEP[n]_D register can be masked by writing to the corresponding bit in this register. Status bits are masked by default.

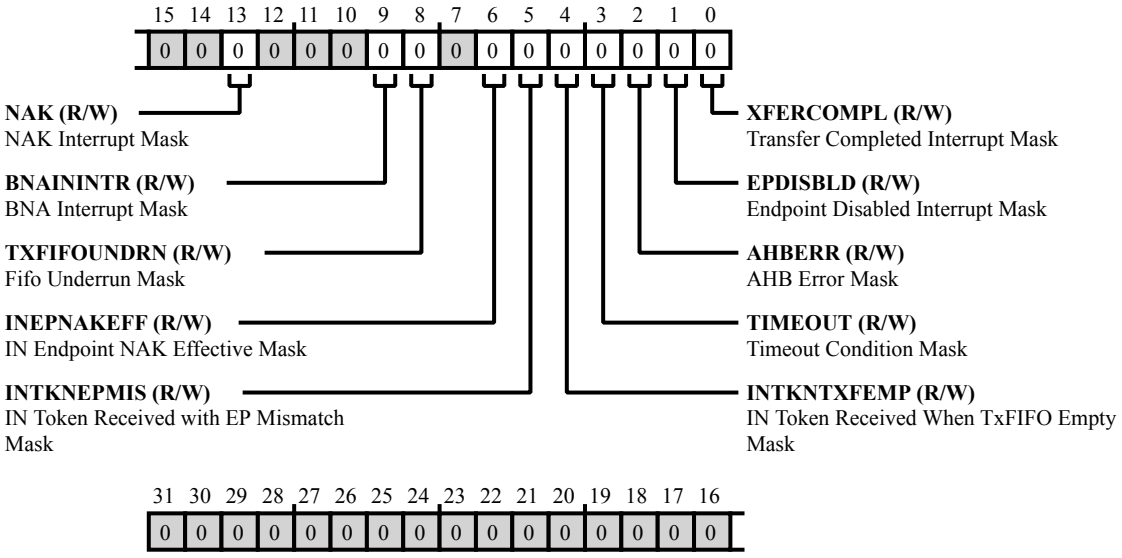

Figure 21-23: USBC_IMASK_IEP_D Register Diagram

Table 21-18: USBC_IMASK_IEP_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
13 (R/W)	NAK	NAK Interrupt Mask.
9 (R/W)	BNAININTR	BNA Interrupt Mask.
8 (R/W)	TXFIFOUNDRN	Fifo Underrun Mask.
6 (R/W)	INEPNAKEFF	IN Endpoint NAK Effective Mask.
5 (R/W)	INTKNEPMIS	IN Token Received with EP Mismatch Mask.
4 (R/W)	INTKNTXFEMP	IN Token Received When TxFIFO Empty Mask.

Table 21-18: USBC_IMASK_IEP_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
3 (R/W)	TIMEOUT	Timeout Condition Mask. Timeout Condition Mask (TimeOUTMsk) (Non-isochronous endpoints)
2 (R/W)	AHBERR	AHB Error Mask.
1 (R/W)	EPDISBLD	Endpoint Disabled Interrupt Mask.
0 (R/W)	XFERCOMPL	Transfer Completed Interrupt Mask.

Device Control IN Endpoint 0 Transfer Size Register

The application must modify the USBC_TSIZ_IEP0_D register before enabling endpoint 0. Once endpoint 0 is enabled using endpoint enable bit (USBC_CTL_IEP0_D.EPENA /USBC_CTL_OEP0_D.EPENA), the core modifies this register. The application can only read this register once the core has cleared the endpoint enable bit.

Nonzero endpoints use the registers for endpoints 1-15.

When scatter/gather DMA mode is enabled, this register must not be programmed by the application. If the application reads this register when scatter/gather DMA mode is enabled, the core returns all zeros.

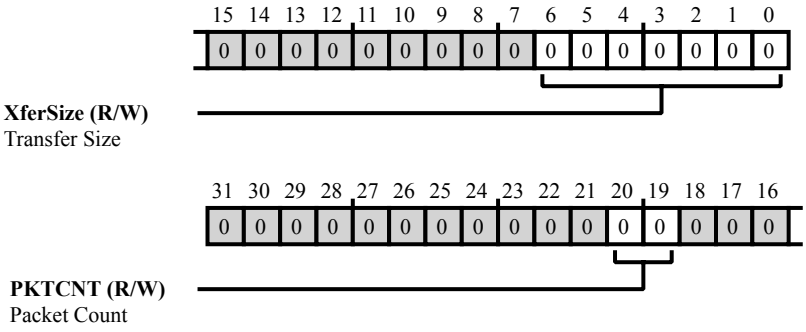

Figure 21-24: USBC_TSIZ_IEP0_D Register Diagram

Table 21-19: USBC_TSIZ_IEP0_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
20:19 (R/W)	PKTCNT	Packet Count. The USBC_TSIZ_IEP0_D.PKTCNT field indicates the total number of USB packets that constitute the transfer size amount of data for endpoint 0. For IN endpoints, the USBC_TSIZ_IEP0_D.PKTCNT field is decremented every time a packet (maximum size or short packet) is read from the TxFIFO. For OUT endpoints, the USBC_TSIZ_IEP0_D.PKTCNT field is decremented every time a packet (maximum size or short packet) is written to the RxFIFO.

Table 21-19: USBC_TSIZ_IEP0_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
6:0 (R/W)	XFERSIZE	Transfer Size. The `USBC_TSIZ_IEP0_D.XFERSIZE` field contains the transfer size in bytes for the current endpoint. The transfer size (XferSize) = Sum of buffer sizes across all descriptors in the list for the endpoint. In buffer DMA, the core only interrupts the application after it has exhausted the transfer size amount of data. The transfer size can be set to the maximum packet size of the endpoint, to be interrupted at the end of each packet. For IN endpoints, the core decrements the `USBC_TSIZ_IEP0_D.XFERSIZE` field every time a packet from the external memory is written to the TxFIFO. For OUT endpoints, the core decrements the `USBC_TSIZ_IEP0_D.XFERSIZE` field every time a packet is read from the RxFIFO and written to the external memory.

Device Control IN Endpoint n Transfer Size Register

The USBC_TSIZ_IEP[n]_D register indicates the Device IN Endpoint n transfer size.

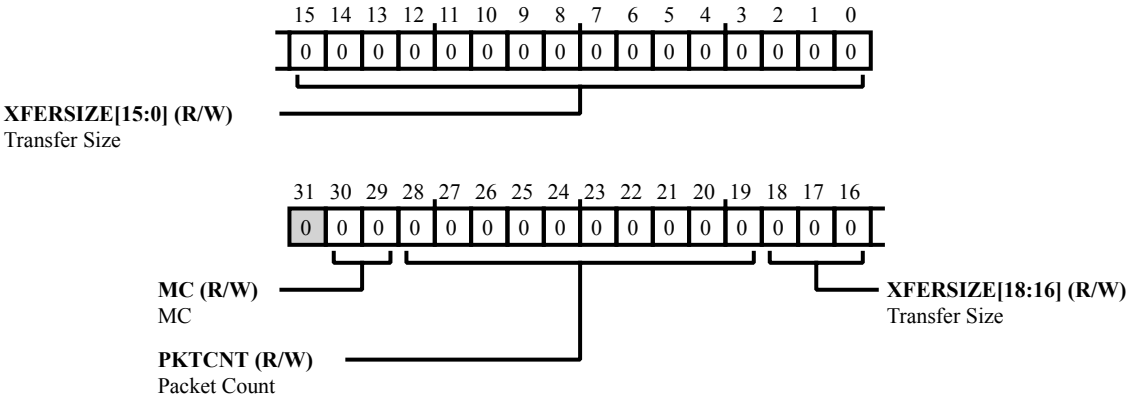

Figure 21-25: USBC_TSIZ_IEP[n]_D Register Diagram

Table 21-20: USBC_TSIZ_IEP[n]_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
30:29 (R/W)	MC	MC. For periodic IN endpoints, the USBC_TSIZ_IEP[n]_D.MC field indicates the number of packets that must be transmitted per microframe on the USB. The core uses this field to calculate the data PID for isochronous IN endpoints. For non-periodic IN endpoints, the USBC_TSIZ_IEP[n]_D.MC field is valid only in internal DMA mode. It specifies the number of packets the core must fetch for an IN endpoint before it switches to the next endpoint. The USBC_TSIZ_IEP[n]_D.MC field applies to IN endpoints only.	
		0	Reserved
		1	1 packet
		2	2 packets
		3	3 packets
28:19 (R/W)	PKTCNT	Packet Count. The USBC_TSIZ_IEP[n]_D.PKTCNT field indicates the total number of USB packets that constitute the transfer size amount of data for endpoint 0. The USBC_TSIZ_IEP[n]_D.PKTCNT field is decremented every time a packet (maximum size or short packet) is read from the Tx FIFO.	

Table 21-20: USBC_TSIZ_IEP[n]_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
18:0 (R/W)	XFERSIZE	Transfer Size. The `USBC_TSIZ_IEP[n]_D.XFERSIZE` field indicates the transfer size in bytes for endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be configured to the maximum packet size of the endpoint, to be interrupted at the end of each packet. The core decrements this field every time a packet from the external memory is written to the Tx FIFO.

Device IN Endpoint 1 Transmit FIFO Size Register

The USBC_TXFIFOSZ1_IEP_D register holds the size and memory start address of IN endpoint Tx FIFOs implemented in device mode. Each FIFO holds the data for one IN endpoint. The USBC_TXFIFOSZ1_IEP_D register is repeated for instantiated IN endpoint FIFOs 1 to 3.

For IN endpoint FIFO 0, use the USBC_TXFIFOSZ_PER_H register for programming the size and memory start address.

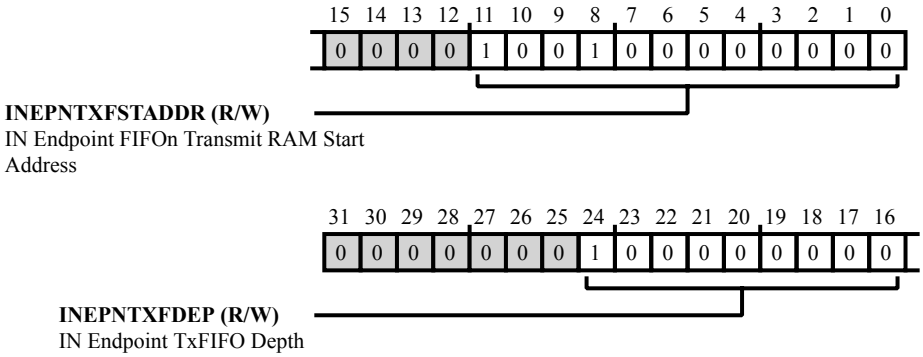

Figure 21-26: USBC_TXFIFOSZ1_IEP_D Register Diagram

Table 21-21: USBC_TXFIFOSZ1_IEP_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
24:16 (R/W)	INEPNTXFDEP	IN Endpoint TxFIFO Depth. The USBC_TXFIFOSZ1_IEP_D.INEPNTXFDEP field indicates the IN endpoint TxFIFO depth. The value is in terms of 32-bit words. Minimum value is 16 Maximum value is 32,768 Programmed values must not exceed the power-on value.
11:0 (R/W)	INEPNTXFSTADDR	IN Endpoint FIFOn Transmit RAM Start Address. The USBC_TXFIFOSZ1_IEP_D.INEPNTXFSTADDR field contains the memory start address for IN endpoint transmit FIFOn (0<n< = 3). The power-on reset value of the USBC_TXFIFOSZ1_IEP_D register is specified as the largest Rx data FIFO depth.

Device IN Endpoint 2 Transmit FIFO Size Register

The USBC_TXFIFOSZ2_IEP_D register is valid only in dedicated FIFO mode (OTG_EN_DED_TX_FIFO=1). It holds the size and memory start address of IN endpoint TxFIFOs implemented in device mode. Each FIFO holds the data for one IN endpoint. The USBC_TXFIFOSZ2_IEP_D register is repeated for instantiated IN endpoint FIFOs 1 to 15. For IN endpoint FIFO 0, use the USBC_TXFIFOSZ_NP register for programming the size and memory start address.

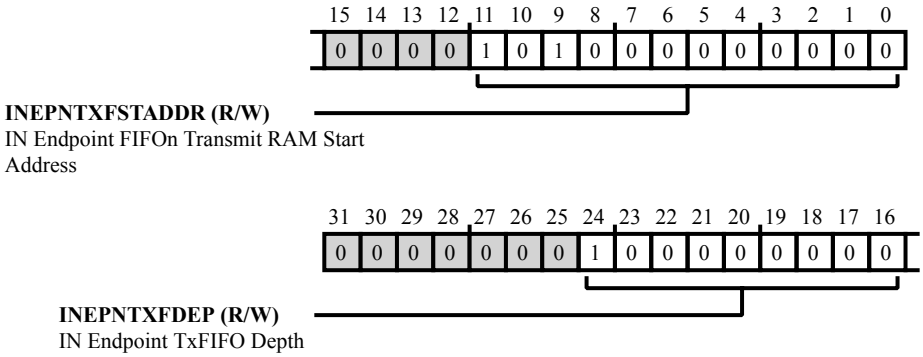

Figure 21-27: USBC_TXFIFOSZ2_IEP_D Register Diagram

Table 21-22: USBC_TXFIFOSZ2_IEP_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
24:16 (R/W)	INEPNTXFDEP	IN Endpoint TxFIFO Depth. The USBC_TXFIFOSZ2_IEP_D.INEPNTXFDEP field indicates the IN endpoint TXFIFO depth. The value is in terms of 32-bit words. Minimum value is 16 Maximum value is 32,768 The power-on reset value of the USBC_TXFIFOSZ2_IEP_D register is specified as the largest IN endpoint FIFO number depth Programmed values must not exceed the power-on value.

Table 21-22: USBC_TXFIFOSZ2_IEP_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
11:0 (R/W)	INEPNTXFSTADDR	IN Endpoint FIFOn Transmit RAM Start Address. This `USBC_TXFIFOSZ2_IEP_D.INEPNTXFSTADDR` field contains the memory start address for IN endpoint transmit FIFOn (0<n< = 15). The power-on reset value of the `USBC_TXFIFOSZ2_IEP_D` register is specified as the largest Rx data FIFO depth. The power-on reset value of the register is calculated according to the following formula: OTG_RX_DFIFO_DEPTH + SUM of OTG_TX_DINEP_DFIFO_DEPTH_'i' (where x = 0 to n 1) If at POR the calculated value (C) exceeds 65535, then the reset value becomes reset value(A) = (C 65536). For example: If the start address of IN endpoint FIFO 1 is OTG_RX_DFIFO_DEPTH + OTG_TX_DINEP_DFIFO_DEPTH_ 0 and the start address of IN endpoint FIFO 2 is OTG_RX_DFIFO_DEPTH + OTG_TX_DINEP_DFIFO_DEPTH_ 0 + OTG_TX_DINEP_DFIFO_DEPTH_ 1. Programmed values must not exceed the power-on value.

Device IN Endpoint 3 Transmit FIFO Size Register

The USBC_TXFIFOSZ3_IEP_D register is valid only in dedicated FIFO mode (OTG_EN_DED_TX_FIFO=1). It holds the size and memory start address of IN endpoint TxFIFOs implemented in device mode. Each FIFO holds the data for one IN endpoint. The USBC_TXFIFOSZ3_IEP_D register is repeated for instantiated IN endpoint FIFOs 1 to 15. For IN endpoint FIFO 0, use the USBC_TXFIFOSZ_NP register for programming the size and memory start address.

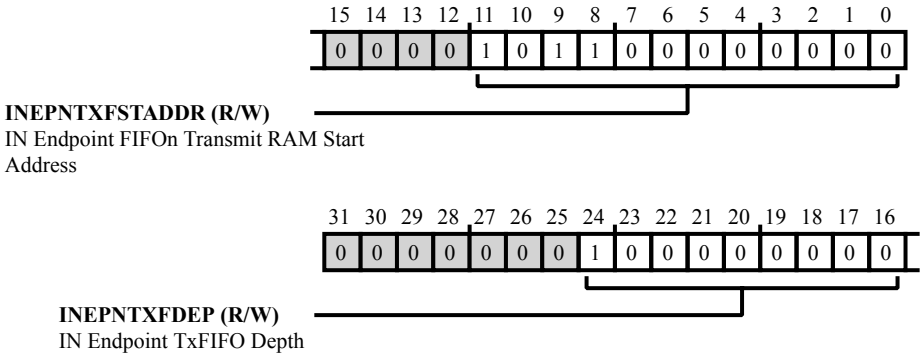

Figure 21-28: USBC_TXFIFOSZ3_IEP_D Register Diagram

Table 21-23: USBC_TXFIFOSZ3_IEP_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
24:16 (R/W)	INEPNTXFDEP	IN Endpoint TxFIFO Depth. The USBC_TXFIFOSZ3_IEP_D.INEPNTXFDEP field indicates the IN endpoint TXFIFO depth. The value is in terms of 32-bit words. Minimum value is 16 Maximum value is 32,768 The power-on reset value of the USBC_TXFIFOSZ3_IEP_D register is specified as the largest IN endpoint FIFO number depth. Programmed values must not exceed the power-on value.

Table 21-23: USBC_TXFIFOSZ3_IEP_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
11:0 (R/W)	INEPNTXFSTADDR	IN Endpoint FIFOn Transmit RAM Start Address. The `USBC_TXFIFOSZ3_IEP_D.INEPNTXFSTADDR` field contains the memory start address for IN endpoint transmit FIFOn (0<n< = 15). The power-on reset value of the `USBC_TXFIFOSZ3_IEP_D` register is specified as the largest Rx data FIFO depth. The power-on reset value of the register is calculated according to the following formula: OTG_RX_DFIFO_DEPTH + SUM of OTG_TX_DINEP_DFIFO_DEPTH_'i' (where x = 0 to n 1) If at POR the calculated value (C) exceeds 65535, then the reset value becomes reset value(A) = (C 65536). For example: If the start address of IN endpoint FIFO 1 is OTG_RX_DFIFO_DEPTH + OTG_TX_DINEP_DFIFO_DEPTH_ 0 and the start address of IN endpoint FIFO 2 is OTG_RX_DFIFO_DEPTH + OTG_TX_DINEP_DFIFO_DEPTH_ 0 + OTG_TX_DINEP_DFIFO_DEPTH_ 1. If Enable Dynamic FIFO Sizing is deselected in coreConsultant (OTG_DFIFO_DYNAMIC = 0), this field is read-only and read value is the power-on reset value. Programmed values must not exceed the power-on value.

Device OUT Endpoint 0 Control Register

In device mode, the USBC_CTL_OEP0_D register controls OUT endpoint 0.

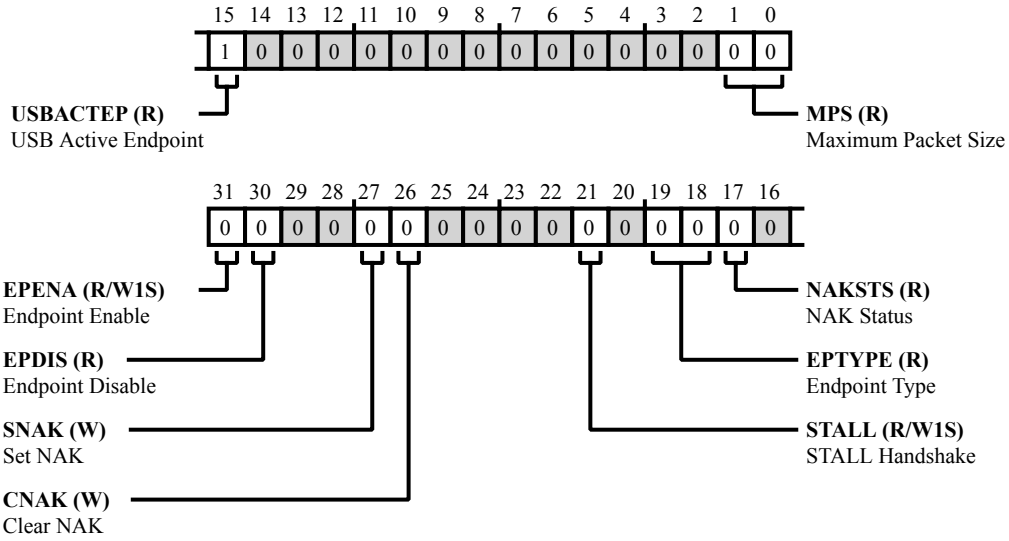

Figure 21-29: USBC_CTL_OEP0_D Register Diagram

Table 21-24: USBC_CTL_OEP0_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W1S)	EPENA	Endpoint Enable. When Scatter/Gather DMA mode is enabled, for OUT endpoints, the USBC_CTL_OEP0_D.EPENA bit indicates that the descriptor structure and data buffer to receive data is set up. When Scatter/Gather DMA mode is disabled (such as for buffer-pointer based DMA mode), the USBC_CTL_OEP0_D.EPENA bit indicates that the application has allocated the memory to start receiving data from the USB. The core clears the USBC_CTL_OEP0_D.EPENA bit before setting any of the following interrupts on this endpoint: SETUP Phase Done Endpoint Disabled Transfer Completed Note: In DMA mode, the USBC_CTL_OEP0_D.EPENA bit must be set for the core to transfer SETUP data packets into memory.
30 (R/NW)	EPDIS	Endpoint Disable. The application cannot disable control OUT endpoint 0.

Table 21-24: USBC_CTL_OEP0_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
27 (RX/W)	SNAK	Set NAK. A write to the USBC_CTL_OEP0_D.SNAK bit sets the NAK bit for the endpoint. Using the USBC_CTL_OEP0_D.SNAK bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also set bit on a Transfer Completed interrupt, or after a SETUP is received on the endpoint.	
26 (RX/W)	CNAK	Clear NAK. A write to the USBC_CTL_OEP0_D.CNAK bit clears the NAK bit for the endpoint.	
21 (R/W1S)	STALL	STALL Handshake. The application can only set the USBC_CTL_OEP0_D.STALL bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit or Global OUT NAK is Set along with the USBC_CTL_OEP0_D.STALL bit, the STALL bit takes priority. Irrespective of the configuration of the USBC_CTL_OEP0_D.STALL bit, the core always responds to SETUP data packets with an ACK handshake.	
19:18 (R/NW)	EPTYPE	Endpoint Type. The USBC_CTL_OEP0_D.EPTYPE field is hardcoded to 2'b00 for control.	
17 (R/NW)	NAKSTS	NAK Status. The USBC_CTL_OEP0_D.NAKSTS bit indicates whether the core is transmitting non-NAK handshakes based on the FIFO status or transmitting NAK handshakes on this endpoint. When either the application or the core sets the USBC_CTL_OEP0_D.NAKSTS bit, the core stops receiving data, even if there is space in the RxFIFO to accommodate the incoming packet. Irrespective of this bit's configuration, the core always responds to SETUP data packets with an ACK handshake.	
		0	Transmit non-NAK handshakes
		1	Transmit NAK handshakes
15 (R/NW)	USBACTEP	USB Active Endpoint. The USBC_CTL_OEP0_D.USBACTEP bit is always set to 1, indicating that a control endpoint 0 is always active in all configurations and interfaces.	
1:0 (R/NW)	MPS	Maximum Packet Size. The USBC_CTL_OEP0_D.MPS field indicates the maximum packet size for control OUT endpoint 0. It is the same size that is programmed in control IN Endpoint 0.	
		0	64 Bytes
		1	32 Bytes
		2	16 Bytes
		3	8 Bytes

Device OUT Endpoint n Control Register

In device mode, the `USBC_CTL_OEP[n]_D` register controls OUT endpoint n.

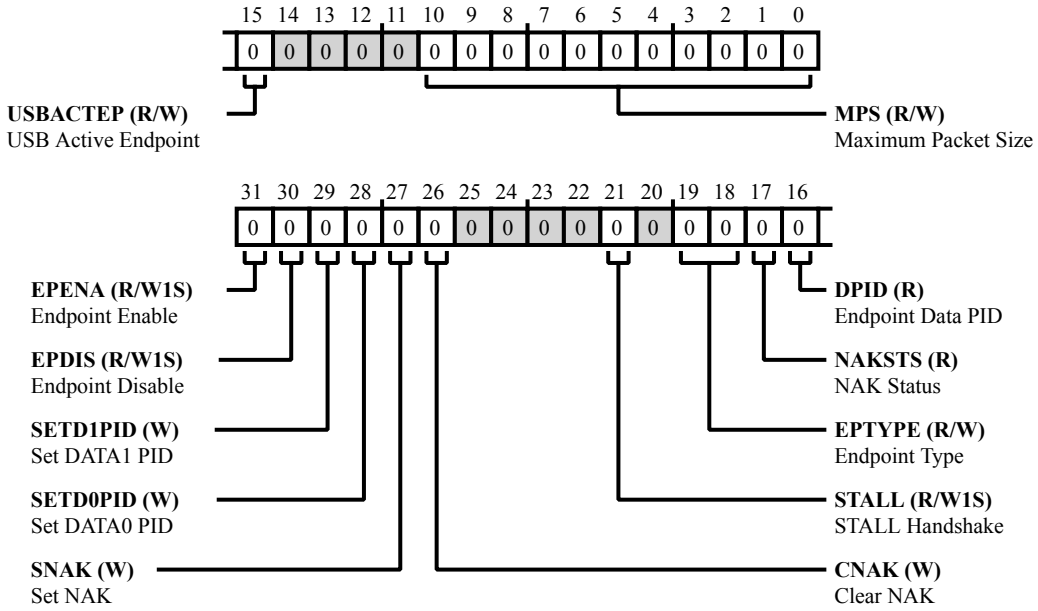

Figure 21-30: USBC_CTL_OEP[n]_D Register Diagram

Table 21-25: USBC_CTL_OEP[n]_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W1S)	EPENA	Endpoint Enable. When Scatter/Gather DMA mode is enabled: For IN endpoints, the USBC_CTL_OEP[n]_D.EPENA bit indicates that the descriptor structure and data buffer with data ready to transmit is configured. For OUT endpoints, the USBC_CTL_OEP[n]_D.EPENA bit indicates that the descriptor structure and data buffer to receive data is configured. When Scatter/Gather DMA mode is enabled such as for buffer-pointer based DMA mode: For IN endpoints, the USBC_CTL_OEP[n]_D.EPENA bit indicates that data is ready to be transmitted on the endpoint. For OUT endpoints, the USBC_CTL_OEP[n]_D.EPENA bit indicates that the application has allocated the memory to start receiving data from the USB. The core clears the USBC_CTL_OEP[n]_D.EPENA bit before setting any of the following interrupts on this endpoint: SETUP Phase Done Endpoint Disabled Transfer Completed Applies to IN and OUT endpoints. Note: For control endpoints in DMA mode, the USBC_CTL_OEP[n]_D.EPENA bit must be configured to be able to transfer SETUP data packets in memory.
30 (R/W1S)	EPDIS	Endpoint Disable. The application sets the USBC_CTL_OEP[n]_D.EPDIS bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears the USBC_CTL_OEP[n]_D.EPDIS bit before setting the Endpoint Disabled interrupt. The application must set the USBC_CTL_OEP[n]_D.EPDIS bit only if Endpoint Enable is already set for this endpoint. Applies to IN and OUT endpoints.
29 (RX/W)	SETD1PID	Set DATA1 PID. In non scatter-gather DMA mode, the bit sets the odd (micro)frame (SetOddFr). Writing to the bit sets the even and odd (micro)frame (EO_FrNum) field to odd (micro)frame. Applies to isochronous IN and OUT endpoints only.

Table 21-25: USBC_CTL_OEP[n]_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
28 (RX/W)	SETD0PID	Set DATA0 PID. A write to the USBC_CTL_OEP[n]_D.SETD0PID bit sets the endpoint data PID (DPID) field in this register to DATA0. The USBC_CTL_OEP[n]_D.SETD0PID bit applies to both scatter/gather DMA mode and non-scatter/gather DMA mode. In non-scatter/gather DMA mode: Set even (micro)frame (SetEvenFr). The SetEvenFr applies to isochronous IN and OUT endpoints only. A write to the USBC_CTL_OEP[n]_D.SETD0PID bit sets the even/odd (micro)frame (EO_FrNum) field to even (micro)frame. When scatter/gather DMA mode is enabled, the USBC_CTL_OEP[n]_D.SETD0PID bit is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. The USBC_CTL_OEP[n]_D.SETD0PID bit applies to interrupt/bulk IN and OUT endpoints only.
27 (RX/W)	SNAK	Set NAK. A write to the USBC_CTL_OEP[n]_D.SNAK bit sets the NAK bit for the endpoint. Using the USBC_CTL_OEP[n]_D.SNAK bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also set the USBC_CTL_OEP[n]_D.SNAK bit for an endpoint after a SETUP packet is received on that endpoint.
26 (RX/W)	CNAK	Clear NAK. A write to the USBC_CTL_OEP[n]_D.CNAK bit clears the NAK bit for the endpoint.
21 (R/W1S)	STALL	STALL Handshake. For non-control, non-isochronous IN and OUT endpoints: The application sets the USBC_CTL_OEP[n]_D.STALL bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear the USBC_CTL_OEP[n]_D.STALL bit, never the core. For control endpoints: The application can only set the USBC_CTL_OEP[n]_D.STALL bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's configuration, the core always responds to SETUP data packets with an ACK handshake.

Table 21-25: USBC_CTL_OEP[n]_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
19:18 (R/W)	EPTYPE	Endpoint Type. The `USBC_CTL_OEP[n]_D.EPTYPE` field indicates the transfer type supported by this logical endpoint.	
		0	Control
		1	Isochronous
		2	Bulk
		3	Interrupt
17 (R/NW)	NAKSTS	NAK Status. When the `USBC_CTL_OEP[n]_D.NAKSTS` bit is set, either by the application or core, the core stops receiving any data on an OUT endpoint, even if there is space in the Rx FIFO to accommodate the incoming packet. For non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the Tx FIFO. For isochronous IN endpoints: The core sends out a zero length data packet, even if there data is available in the TxFIFO. Irrespective of the bit configuration, the core always responds to SETUP data packets with an ACK handshake.	
		0	Transmit non NAK handshakes
		1	Transmit NAK handshakes

Table 21-25: USBC_CTL_OEP[n]_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
16 (R/NW)	DPID	Endpoint Data PID. The USBC_CTL_OEP[n]_D.DPID bit applies to interrupt/bulk IN and OUT endpoints only. The USBC_CTL_OEP[n]_D.DPID bit indicates the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID bits of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1 The USBC_CTL_OEP[n]_D.DPID bit applies to both scatter/gather DMA mode and non-scatter/gather DMA mode. Even/Odd (Micro)Frame (EO_FrNum) In non-scatter/gather DMA mode, the USBC_CTL_OEP[n]_D.DPID bit applies to isochronous IN and OUT endpoints only. The USBC_CTL_OEP[n]_D.DPID bit indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro)frame number in which it intends to transmit/ receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 0: Even (micro)frame 1: Odd (micro)frame When scatter/gather DMA mode is enabled, the USBC_CTL_OEP[n]_D.DPID bit is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure.
15 (R/W)	USBACTEP	USB Active Endpoint. The USBC_CTL_OEP[n]_D.USBACTEP bit indicates whether this endpoint is active in the current configuration and interface. The core clears the USBC_CTL_OEP[n]_D.USBACTEP bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit.
10:0 (R/W)	MPS	Maximum Packet Size. The USBC_CTL_OEP[n]_D.MPS field indicates the maximum packet size for the current logical endpoint. This value is in bytes.

Device OUT Endpoint 0 DMA Address Register

In device mode, the USBC_DMA_ADDR_OEP0_D register indicates the DWORD-aligned start address of the external memory for storing or fetching endpoint data. This register is incremented on every bus transaction.

When scatter/gather DMA mode is not enabled, the USBC_DMA_ADDR_OEP0_D register indicates the start address.

When scatter/gather DMA mode is enabled, the USBC_DMA_ADDR_OEP0_D register indicates the base pointer for the descriptor list.

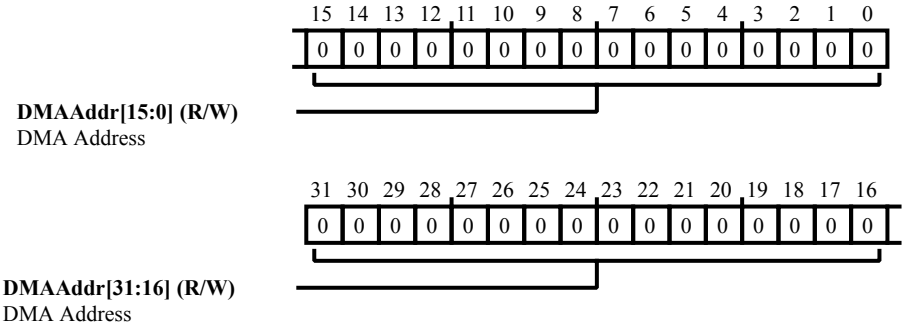

Figure 21-31: USBC_DMA_ADDR_OEP0_D Register Diagram

Table 21-26: USBC_DMA_ADDR_OEP0_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	DMAADDR	DMA Address. The USBC_DMA_ADDR_OEP0_D.DMAADDR field holds the start address of the external memory for storing or fetching endpoint data. Note: For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to- back, the SETUP data packet in the memory is overwritten.

Device OUT Endpoint 0 Buffer Address Register

In device mode, the USBC_DMA_BADDR_OEP0_D register indicates the buffer address for OUT endpoint 0. It is updated when the data transfer for the endpoint 0 is in progress.

The USBC_DMA_BADDR_OEP0_D register is available only in scatter/gather DMA mode and is otherwise reserved.

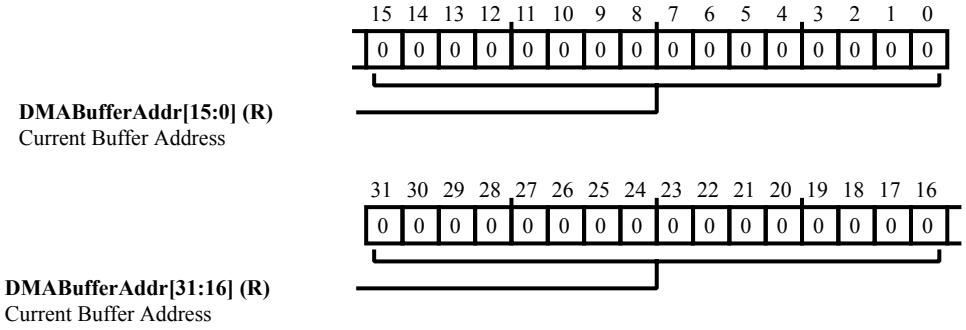

Figure 21-32: USBC_DMA_BADDR_OEP0_D Register Diagram

Table 21-27: USBC_DMA_BADDR_OEP0_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	DMABUFFERADDR	Current Buffer Address. The USBC_DMA_BADDR_OEP0_D.DMABUFFERADDR bit filed contains the current buffer address.

Device OUT Endpoint n Buffer Address Register

In device mode, the USBC_DMA_BADDR_OEP[n]_D register indicates the buffer address for OUT endpoint n. It is updated when the data transfer for the corresponding endpoint is in progress.

The USBC_DMA_BADDR_OEP[n]_D register is available only in scatter/gather DMA mode and is otherwise reserved.

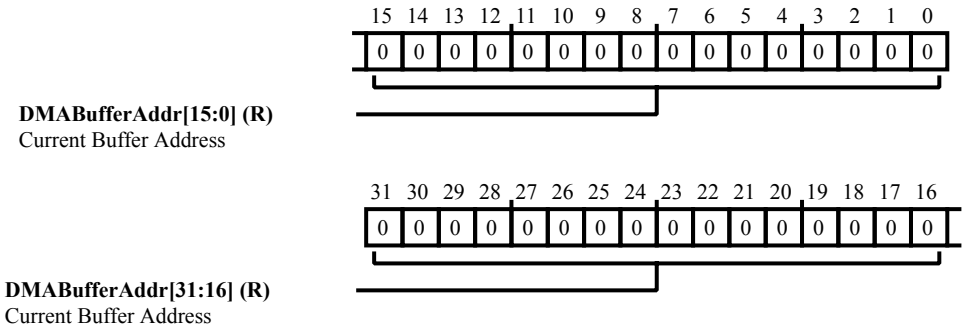

Figure 21-33: USBC_DMA_BADDR_OEP[n]_D Register Diagram

Table 21-28: USBC_DMA_BADDR_OEP[n]_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	DMABUFFERADDR	Current Buffer Address. The USBC_DMA_BADDR_OEP[n]_D.DMABUFFERADDR bit filed contains the current buffer address.

Device OUT Endpoint n DMA Address Register

The USBC_DMA_ADDR_OEP[n]_D register indicates the DWORD-aligned address. This register is incremented on every bus transaction.

When scatter/gather DMA mode is not enabled, the USBC_DMA_ADDR_OEP[n]_D register indicates the start address.

When scatter/gather DMA mode is enabled, the USBC_DMA_ADDR_OEP[n]_D register indicates the base pointer for the descriptor list.

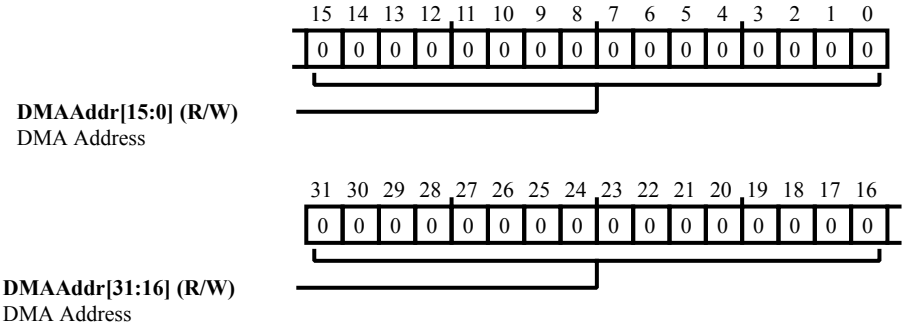

Figure 21-34: USBC_DMA_ADDR_OEP[n]_D Register Diagram

Table 21-29: USBC_DMA_ADDR_OEP[n]_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	DMAADDR	DMA Address. The USBC_DMA_ADDR_OEP[n]_D.DMAADDR field holds the start address of the external memory for storing or fetching endpoint data. Note: For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to- back, the SETUP data packet in the memory is overwritten.

Device OUT Endpoint 0 Interrupt Register

The USBC_ISTAT_OEP0_D register is the device OUT endpoint 0 interrupt register.

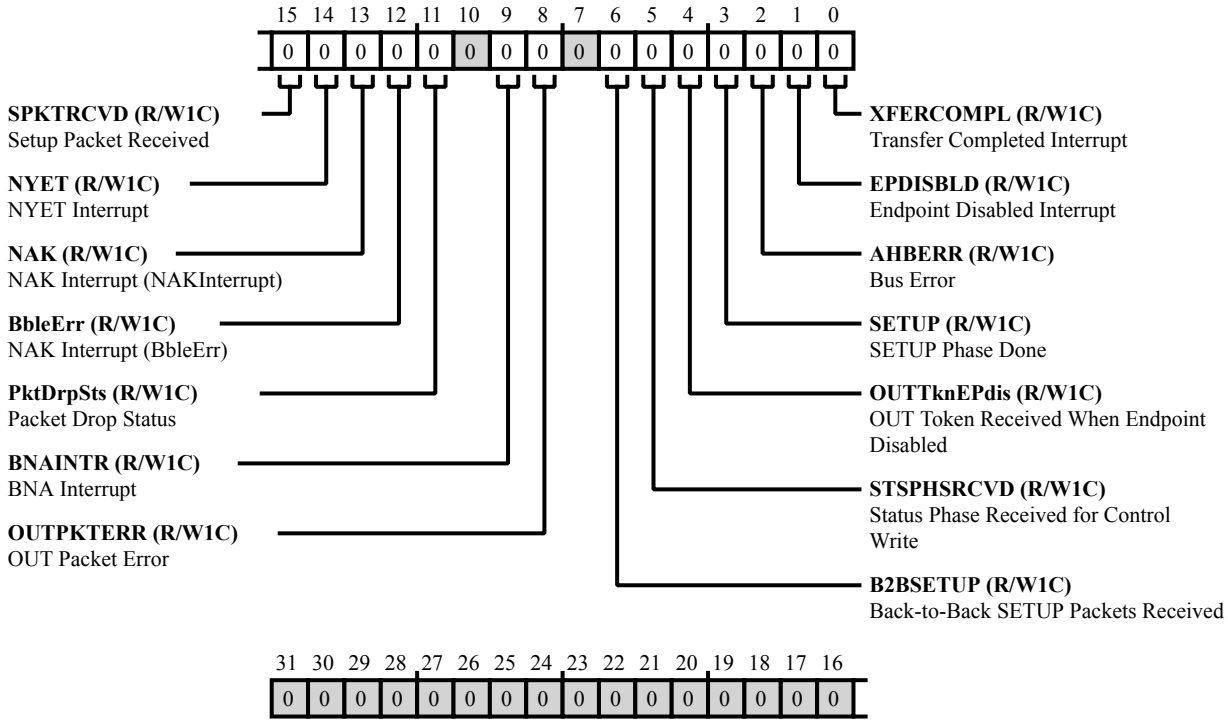

Figure 21-35: USBC_ISTAT_OEP0_D Register Diagram

Table 21-30: USBC_ISTAT_OEP0_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W1C)	SPKTRCVD	Setup Packet Received. The USBC_ISTAT_OEP0_D.SPKTRCVD bit applies to control OUT endpoints in only in the buffer DMA mode. Set by the controller, the USBC_ISTAT_OEP0_D.SPKTRCVD bit indicates that this buffer holds 8 bytes of setup data. There is only one SETUP packet per buffer. On receiving a SETUP packet, the controller closes the buffer and disables the corresponding endpoint. The application has to re-enable the endpoint to receive any OUT data for the control transfer and reprogram the buffer start address. Note: Because of the above behavior, the controller can receive any number of back to back setup packets and one buffer for every SETUP packet is used.	
		0	No SETUP packet received
		1	SETUP packet received

Table 21-30: USBC_ISTAT_OEP0_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
14 (R/W1C)	NYET	NYET Interrupt. The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint.
13 (R/W1C)	NAK	NAK Interrupt (NAKInterrupt). The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to unavailability of data in the Tx FIFO.
12 (R/W1C)	BBLEERR	NAK Interrupt (BbleErr). The core generates this interrupt when babble is received for the endpoint.
11 (R/W1C)	PKTDRPSTS	Packet Drop Status. The `USBC_ISTAT_OEP0_D.PKTDRPSTS` bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. The `USBC_ISTAT_OEP0_D.PKTDRPSTS` bit is valid in non scatter/gather DMA mode when periodic transfer interrupt feature is selected.
9 (R/W1C)	BNAINTR	BNA Interrupt. The `USBC_ISTAT_OEP0_D.BNAINTR` bit is valid only when scatter/gather DMA mode is enabled. The core generates the BNA (Buffer Not Available) interrupt when the descriptor accessed is not ready for the core to process, such as host busy or DMA done.
8 (R/W1C)	OUTPKTERR	OUT Packet Error. The `USBC_ISTAT_OEP0_D.OUTPKTERR` bit applies to OUT endpoints only. This interrupt is valid only when thresholding is enabled. This interrupt is asserted when the core detects an overflow or a CRC error for non-Isochronous OUT packet.
6 (R/W1C)	B2BSETUP	Back-to-Back SETUP Packets Received. The `USBC_ISTAT_OEP0_D.B2BSETUP` bit applies to control OUT endpoints only. The `USBC_ISTAT_OEP0_D.B2BSETUP` bit indicates that the core has received more than three back-to-back SETUP packets for this particular endpoint.

Table 21-30: USBC_ISTAT_OEP0_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
5 (R/W1C)	STSPHSRCVD	Status Phase Received for Control Write. This interrupt is valid only for control OUT endpoints and only in scatter/gather DMA mode. This interrupt is generated only after the core has transferred all the data that the host has sent during the data phase of a control write transfer, to the system memory buffer. The interrupt indicates to the application that the host has switched from data phase to the status phase of a control write transfer. The application can use this interrupt to ACK or STALL the status phase, after it has decoded the data phase. This is applicable only in case of scatter/gather DMA mode.
4 (R/W1C)	OUTTKNEPDIS	OUT Token Received When Endpoint Disabled. The `USBC_ISTAT_OEP0_D.OUTTKNEPDIS` bit applies only to control OUT endpoints. The `USBC_ISTAT_OEP0_D.OUTTKNEPDIS` bit indicates that an OUT token was received when the endpoint was not yet enabled. This interrupt is asserted on the endpoint for which the OUT token was received.
3 (R/W1C)	SETUP	SETUP Phase Done. The `USBC_ISTAT_OEP0_D.SETUP` bit applies to control OUT endpoints only. The `USBC_ISTAT_OEP0_D.SETUP` bit indicates that the SETUP phase for the control endpoint is complete and no more back-to-back SETUP packets were received for the current control transfer. On this interrupt, the application can decode the received SETUP data packet.
2 (R/W1C)	AHBERR	Bus Error. The `USBC_ISTAT_OEP0_D.AHBERR` bit applies to IN and OUT endpoints. The `USBC_ISTAT_OEP0_D.AHBERR` bit is generated only in internal DMA mode when there is a bus error during an bus read/write. The application can read the corresponding endpoint DMA address register to get the error address.
1 (R/W1C)	EPDISBLD	Endpoint Disabled Interrupt. The `USBC_ISTAT_OEP0_D.EPDISBLD` bit applies to IN and OUT endpoints. The `USBC_ISTAT_OEP0_D.EPDISBLD` bit indicates that the endpoint is disabled per the application's request.

Table 21-30: USBC_ISTAT_OEP0_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
0 (R/W1C)	XFERCOMPL	Transfer Completed Interrupt. The `USBC_ISTAT_OEP0_D.XFERCOMPL` bit applies to IN and OUT endpoints. When scatter/gather DMA mode is enabled: For IN endpoints, the `USBC_ISTAT_OEP0_D.XFERCOMPL` bit indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. For OUT endpoints, the `USBC_ISTAT_OEP0_D.XFERCOMPL` bit indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is set. Note: In DMA mode, this bit must be set for the core to transfer SETUP data packets into memory. When scatter/gather DMA mode is disabled, the bit indicates that the programmed transfer is complete on the bus as well as on the USB, for this endpoint.

Device OUT Endpoint n Interrupt Register

The `USBC_ISTAT_OEP[n]_D` register is the device OUT endpoint n interrupt register.

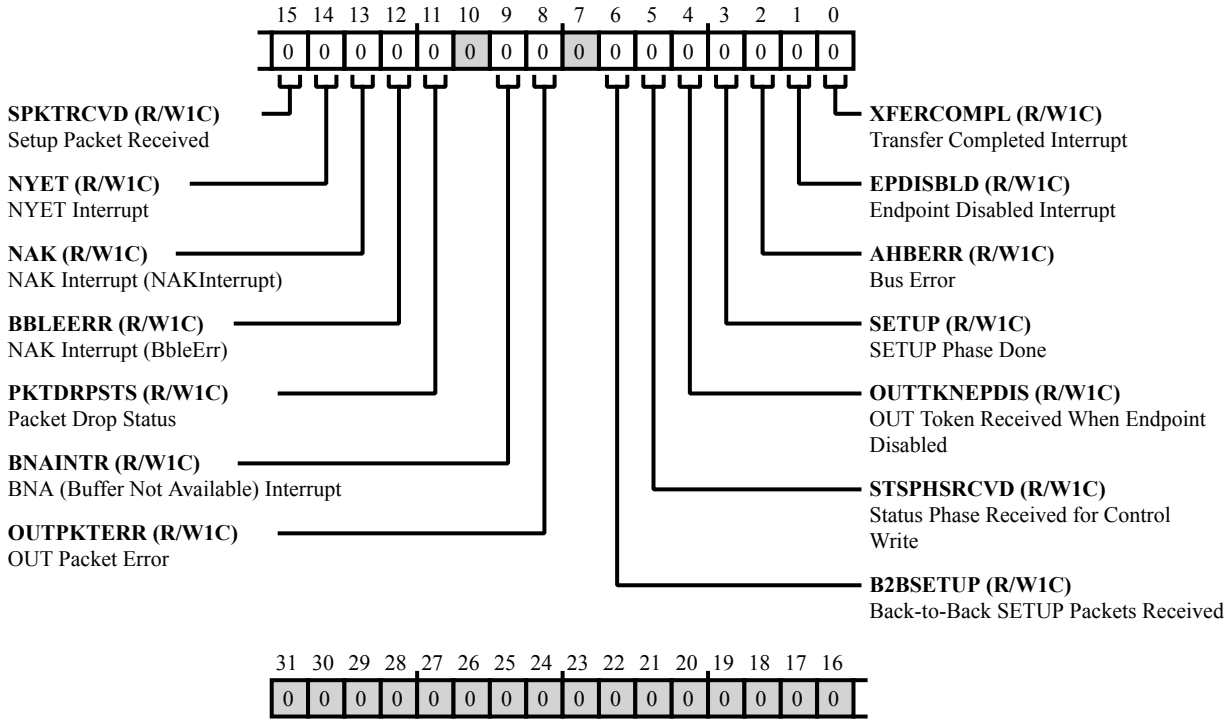

Figure 21-36: USBC_ISTAT_OEP[n]_D Register Diagram

Table 21-31: USBC_ISTAT_OEP[n]_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W1C)	SPKTRCVD	Setup Packet Received. The `USBC_ISTAT_OEP[n]_D.SPKTRCVD` bit applies to control OUT endpoints in only in the buffer DMA mode. Set by the controller, the `USBC_ISTAT_OEP[n]_D.SPKTRCVD` bit indicates whether the SETUP packet has been received. The buffer holds 8 bytes of SETUP data. There is only one SETUP packet per buffer. On receiving a SETUP packet, the controller closes the buffer and disables the corresponding endpoint. The application has to re-enable the endpoint to receive any OUT data for the control transfer and reprogram the buffer start address. Note: Because of the above behavior, the controller can receive any number of back-to-back SETUP packets and one buffer for every SETUP packet is used.	
		0	No SETUP packet received
		1	SETUP Packet Received

Table 21-31: USBC_ISTAT_OEP[n]_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
14 (R/W1C)	NYET	NYET Interrupt. The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint.
13 (R/W1C)	NAK	NAK Interrupt (NAKInterrupt). The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to unavailability of data in the Tx FIFO.
12 (R/W1C)	BBLEERR	NAK Interrupt (BbleErr). The core generates this interrupt when babble is received for the endpoint.
11 (R/W1C)	PKTDRPSTS	Packet Drop Status. The `USBC_ISTAT_OEP[n]_D.PKTDRPSTS` bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. The `USBC_ISTAT_OEP[n]_D.PKTDRPSTS` bit is valid in non scatter/gather DMA mode when periodic transfer interrupt feature is selected.
9 (R/W1C)	BNAINTR	BNA (Buffer Not Available) Interrupt. The `USBC_ISTAT_OEP[n]_D.BNAINTR` bit is valid only when scatter/gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the core to process, such as host busy or DMA done.
8 (R/W1C)	OUTPKTERR	OUT Packet Error. The `USBC_ISTAT_OEP[n]_D.OUTPKTERR` bit applies to OUT endpoints only. This interrupt is valid only when thresholding is enabled. This interrupt is asserted when the core detects an overflow or a CRC error for non-Isochronous OUT packet.
6 (R/W1C)	B2BSETUP	Back-to-Back SETUP Packets Received. The `USBC_ISTAT_OEP[n]_D.B2BSETUP` bit applies to control OUT endpoints only. The `USBC_ISTAT_OEP[n]_D.B2BSETUP` bit indicates that the core has received more than three back-to-back SETUP packets for this particular endpoint.

Table 21-31: USBC_ISTAT_OEP[n]_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
5 (R/W1C)	STSPHSRCVD	Status Phase Received for Control Write. The `USBC_ISTAT_OEP[n]_D.STSPHSRCVD` bit is valid only for control OUT endpoints and only in scatter/gather DMA mode. The `USBC_ISTAT_OEP[n]_D.STSPHSRCVD` bit indicates an interrupt that is generated after the core has transferred all the data that the host has sent during the data phase of a control write transfer, to the system memory buffer. The interrupt indicates to the application that the host has switched from data phase to the status phase of a control write transfer. The application can use this interrupt to ACK or STALL the status phase, after it has decoded the data phase. The `USBC_ISTAT_OEP[n]_D.STSPHSRCVD` bit is applicable only in case of scatter/gather DMA mode.
4 (R/W1C)	OUTTKNEPDIS	OUT Token Received When Endpoint Disabled. The `USBC_ISTAT_OEP[n]_D.OUTTKNEPDIS` bit applies only to control OUT endpoints. The `USBC_ISTAT_OEP[n]_D.OUTTKNEPDIS` bit indicates that an OUT token was received when the endpoint was not yet enabled. This interrupt is asserted on the endpoint for which the OUT token was received.
3 (R/W1C)	SETUP	SETUP Phase Done. The `USBC_ISTAT_OEP[n]_D.SETUP` bit applies to control OUT endpoints only. The `USBC_ISTAT_OEP[n]_D.SETUP` bit indicates that the SETUP phase for the control endpoint is complete and no more back-to-back SETUP packets were received for the current control transfer. On this interrupt, the application can decode the received SETUP data packet.
2 (R/W1C)	AHBERR	Bus Error. The `USBC_ISTAT_OEP[n]_D.AHBERR` bit applies to IN and OUT endpoints. The `USBC_ISTAT_OEP[n]_D.AHBERR` bit is generated when there is a bus error during an bus read/write. The application can read the corresponding endpoint DMA address register to get the error address.
1 (R/W1C)	EPDISBLD	Endpoint Disabled Interrupt. The `USBC_ISTAT_OEP[n]_D.EPDISBLD` bit applies to IN and OUT endpoints. The `USBC_ISTAT_OEP[n]_D.EPDISBLD` bit indicates that the endpoint is disabled per the application's request.

Table 21-31: USBC_ISTAT_OEP[n]_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
0 (R/W1C)	XFERCOMPL	Transfer Completed Interrupt. The `USBC_ISTAT_OEP[n]_D.XFERCOMPL` bit applies to IN and OUT endpoints. When scatter/gather DMA mode is enabled: For IN endpoints, the `USBC_ISTAT_OEP[n]_D.XFERCOMPL` bit indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. For OUT endpoints, the `USBC_ISTAT_OEP[n]_D.XFERCOMPL` bit indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is set. Note: In DMA mode, this bit must be set for the core to transfer SETUP data packets into memory. When scatter/gather DMA mode is disabled, the `USBC_ISTAT_OEP[n]_D.XFERCOMPL` bit indicates that the programmed transfer is complete on the bus as well as on the USB, for this endpoint.

Device OUT Endpoint Common Interrupt Mask Register

The USBC_IMASK_OEP_D register works with each of the device OUT endpoint interrupt (USBC_ISTAT_OEP[n]_D) registers for all endpoints to generate an interrupt per OUT endpoint. The OUT endpoint interrupt for a specific status in the USBC_ISTAT_OEP[n]_D register can be masked by writing into the corresponding bit in this register. Status bits are masked by default.

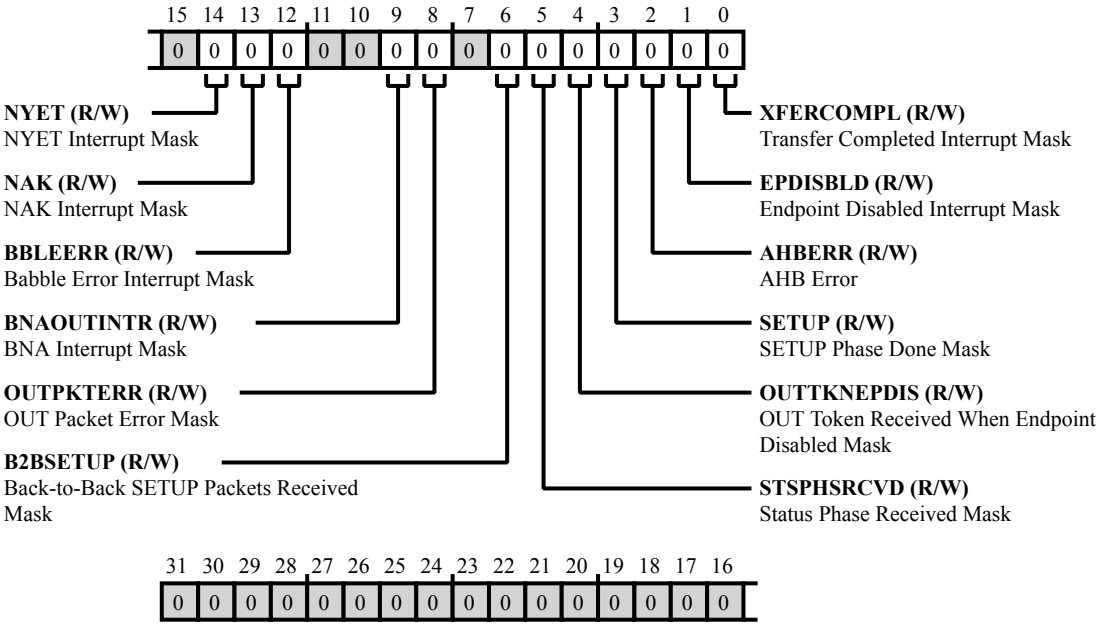

Figure 21-37: USBC_IMASK_OEP_D Register Diagram

Table 21-32: USBC_IMASK_OEP_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
14 (R/W)	NYET	NYET Interrupt Mask.
13 (R/W)	NAK	NAK Interrupt Mask.
12 (R/W)	BBLEERR	Babble Error Interrupt Mask.
9 (R/W)	BNAOUTINTR	BNA Interrupt Mask. BNA interrupt Mask (BnaOutIntrMsk)
8 (R/W)	OUTPKTERR	OUT Packet Error Mask.

Table 21-32: USBC_IMASK_OEP_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
6 (R/W)	B2BSETUP	Back-to-Back SETUP Packets Received Mask. The `USBC_IMASK_OEP_D.B2BSETUP` bit only applies to control OUT endpoints.
5 (R/W)	STSPHSRCVD	Status Phase Received Mask. The `USBC_IMASK_OEP_D.STSPHSRCVD` bit only applies to control OUT endpoints.
4 (R/W)	OUTTKNEPDIS	OUT Token Received When Endpoint Disabled Mask. The `USBC_IMASK_OEP_D.OUTTKNEPDIS` bit only applies to control OUT endpoints.
3 (R/W)	SETUP	SETUP Phase Done Mask. The `USBC_IMASK_OEP_D.SETUP` bit only applies to control endpoints.
2 (R/W)	AHBERR	AHB Error.
1 (R/W)	EPDISBLD	Endpoint Disabled Interrupt Mask.
0 (R/W)	XFERCOMPL	Transfer Completed Interrupt Mask.

Device OUT Endpoint 0 Transfer Size Register

The USBC_TSIZ_OEP0_D register holds the transfer size of OUT endpoint 0 implemented in device mode.

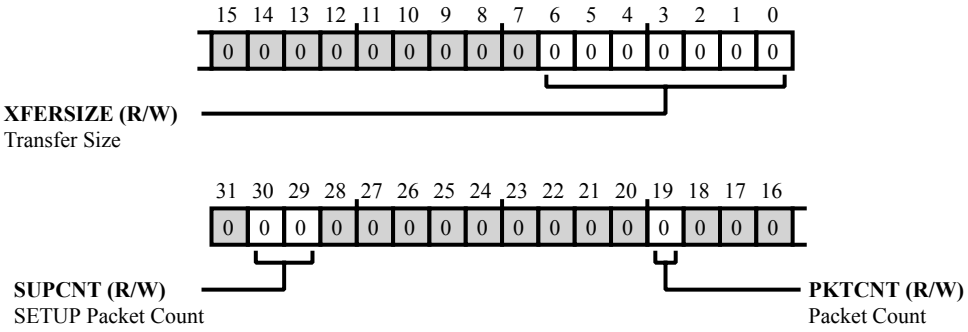

Figure 21-38: USBC_TSIZ_OEP0_D Register Diagram

Table 21-33: USBC_TSIZ_OEP0_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
30:29 (R/W)	SUPCNT	SETUP Packet Count. The USBC_TSIZ_OEP0_D.SUPCNT field specifies the number of back-to-back SETUP data packets the endpoint can receive.	
		0	Reserved
		1	1 packet
		2	2 packets
		3	3 packets
19 (R/W)	PKTCNT	Packet Count. The USBC_TSIZ_OEP0_D.PKTCNT field is decremented to zero after a packet is written into the Rx FIFO.	
6:0 (R/W)	XFERSIZE	Transfer Size. The USBC_TSIZ_OEP0_D.XFERSIZE field indicates the transfer size in bytes for endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be set to the maximum packet size of the endpoint, to be interrupted at the end of each packet. The core decrements the USBC_TSIZ_OEP0_D.XFERSIZE field every time a packet is read from the Rx FIFO and written to the external memory.	

Device OUT Endpoint n Transfer Size Register

The USBC_TSIZ_OEP[n]_D register holds the transfer size of OUT endpoint n implemented in device mode.

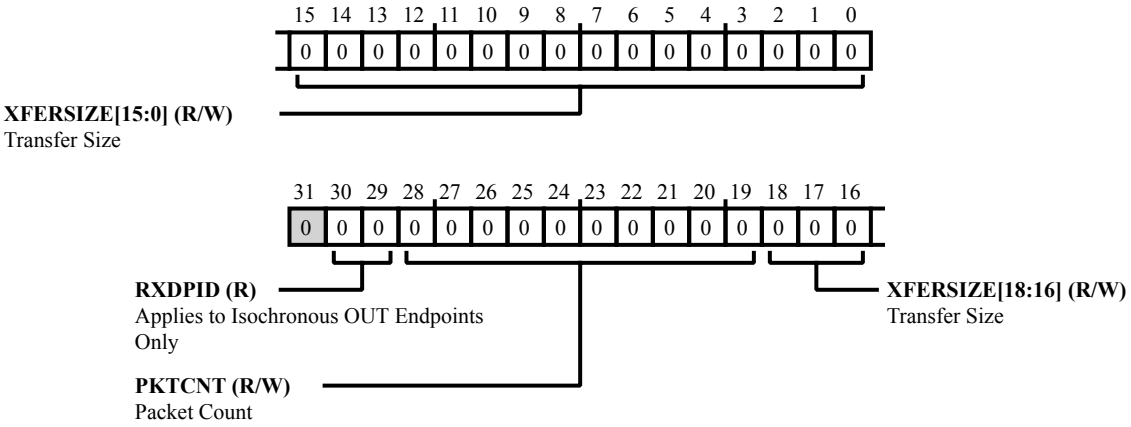

Figure 21-39: USBC_TSIZ_OEP[n]_D Register Diagram

Table 21-34: USBC_TSIZ_OEP[n]_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
30:29 (R/NW)	RXDPID	Applies to Isochronous OUT Endpoints Only. The USBC_TSIZ_OEP[n]_D.RXDPID field indicates the data PID received in the last packet for this endpoint.	
		0	DATA0
		1	DATA2
		2	DATA1
		3	MDATA
28:19 (R/W)	PKTCNT	Packet Count. The USBC_TSIZ_OEP[n]_D.PKTCNT field is decremented to zero after a packet is written into the Rx FIFO.	
18:0 (R/W)	XFERSIZE	Transfer Size. The USBC_TSIZ_OEP[n]_D.XFERSIZE field indicates the transfer size in bytes for endpoint n. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be set to the maximum packet size of the endpoint, to be interrupted at the end of each packet. The core decrements this field every time a packet is read from the RxFIFO and written to the external memory.	

Device Status Register

The USBC_STAT_D register indicates the status of the core with respect to USB-related events. It must be read on interrupts from the USBC_ISTAT_D register.

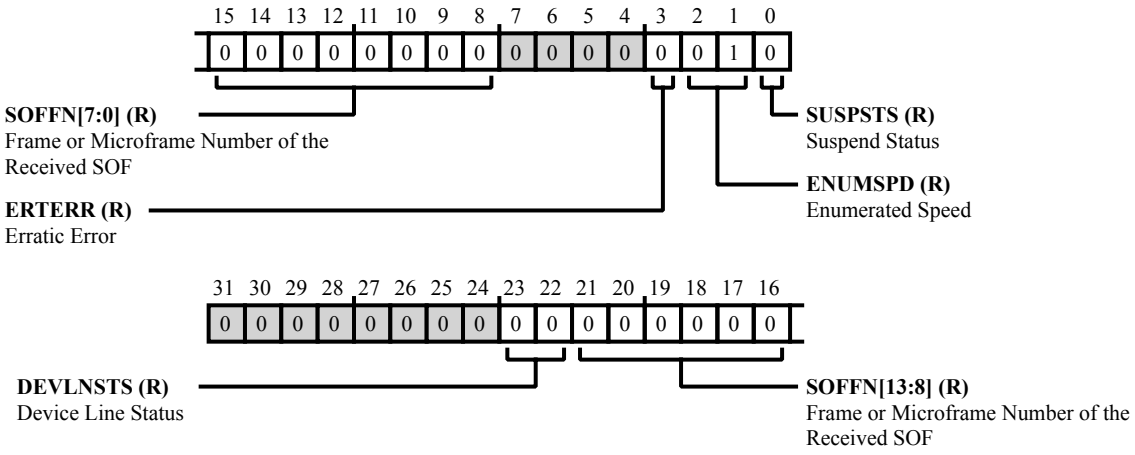

Figure 21-40: USBC_STAT_D Register Diagram

Table 21-35: USBC_STAT_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
23:22 (R/NW)	DEVLNSTS	Device Line Status. The USBC_STAT_D.DEVLNSTS field indicates the current logic level USB data lines.	
		0	Logic Level of D+
		1	Logic Level of D-
21:8 (R/NW)	SOFFN	Frame or Microframe Number of the Received SOF. When the core is operating at high speed, the USBC_STAT_D.SOFFN field contains a microframe number. When the core is operating at full or low speed, this field contains a frame number. Note: This register may return a non-zero value if read immediately after power-on reset. In case the register bit reads non-zero immediately after power-on reset, it does not indicate that SOF has been received from the host. The read value of this interrupt is valid only after a valid connection between host and device is established.	

Table 21-35: USBC_STAT_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/NW)	ERTERR	Erratic Error. The core sets the USBC_STAT_D.ERTERR bit to report any erratic errors (due to PHY error) seen on the ULPI. Due to erratic errors, the USBC_otg core goes into a SUSPEND state and an interrupt is generated to the application with the USBC_ISTAT.ERLYSUSP bit. If the early suspend is asserted due to an erratic error, the application can only perform a soft disconnect recovery.	
2:1 (R/NW)	ENUMSPD	Enumerated Speed. The USBC_STAT_D.ENUMSPD field indicates the speed at which the controller has come up after speed detection through a connect or reset sequence. Low speed is not supported for devices using a ULPI PHY.	
		0	High speed. PHY clock is running at 30 or 60 Mhz.
		1	Full speed. PHY clock is running at 30 or 60 Mhz.
		2	Low speed. PHY clock is running at 6 Mhz.
		3	Full speed. PHY clock is running at 48 Mhz.
0 (R/NW)	SUSPSTS	Suspend Status. In device mode, the USBC_STAT_D.SUSPSTS bit is set (=1) as long as a SUSPEND condition is detected on the USB. The core enters the SUSPEND state when there is no activity on the linestate signal for an extended period of time. The core comes out of the suspend under the following conditions : - If there is any activity on the linestate signal, or - If the application writes to the Remote Wakeup Signaling bit in the USBC_CTL_D register. When the core comes out of the suspend, the USBC_STAT_D.SUSPSTS bit is cleared (=0).	

Device Threshold Control Register

The USBC_THR_CTL_D register indicates the device threshold control information.

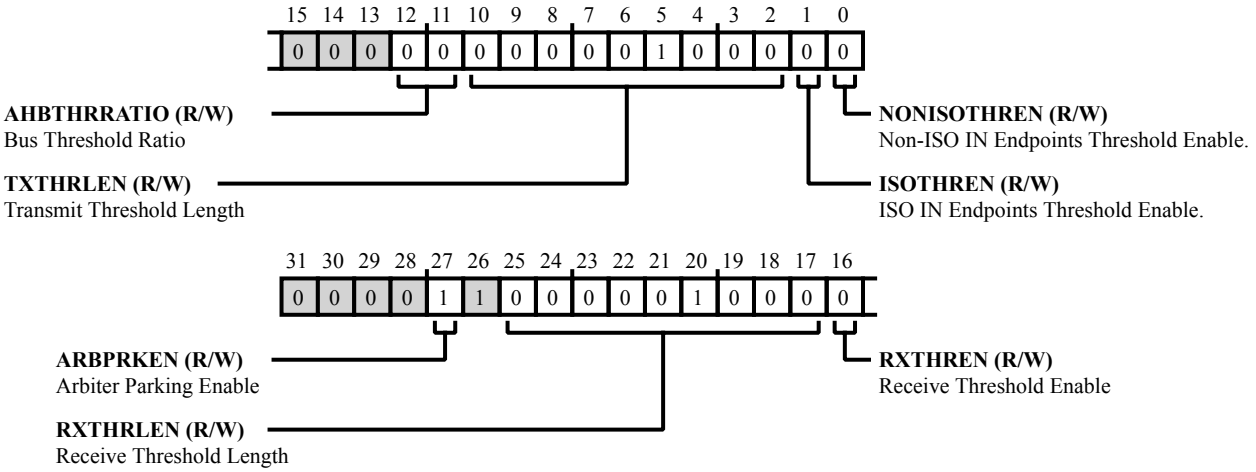

Figure 21-41: USBC_THR_CTL_D Register Diagram

Table 21-36: USBC_THR_CTL_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
27 (R/W)	ARBPRKEN	Arbiter Parking Enable. The USBC_THR_CTL_D.ARBPRKEN bit controls internal DMA arbiter parking for IN endpoints. If thresholding is enabled and the USBC_THR_CTL_D.ARBPRKEN bit is set (=1), the arbiter parks on the IN endpoint for which there is a token received on the USB. This avoids getting into underrun conditions. By default, arbiter parking is enabled.
25:17 (R/W)	RXTHRLEN	Receive Threshold Length. The USBC_THR_CTL_D.RXTHRLEN field specifies receive thresholding size in DWORDS. The USBC_THR_CTL_D.RXTHRLEN field also specifies the amount of data received on the USB before the core can start transmitting on the bus. The threshold length has to be at least eight DWORDS. The recommended value for ThrLen must be the same as USBC_AHB_CFG.HBSTLEN.
16 (R/W)	RXTHREN	Receive Threshold Enable. When the USBC_THR_CTL_D.RXTHREN bit is set, the core enables thresholding in the receive direction. Note: Do not enable the USBC_THR_CTL_D.RXTHREN bit, because it may cause issues in the RxFIFO, especially during error conditions such as RxError and Babble.

Table 21-36: USBC_THR_CTL_D Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
12:11 (R/W)	AHBTHRRATIO	Bus Threshold Ratio. The USBC_THR_CTL_D.AHBTHRRATIO field defines the ratio between the bus threshold and the MAC threshold for the transmit path only. The bus threshold always remains less than or equal to the USB threshold, because this does not increase overhead. Both the bus and the MAC threshold must be DWORD-aligned. The application must program USBC_THR_CTL_D.TXTHRLEN and the USBC_THR_CTL_D.AHBTHRRATIO bits to make the bus threshold value DWORD aligned. If the bus threshold value is not DWORD aligned, the core might not behave correctly. When programming the USBC_THR_CTL_D.TXTHRLEN and USBC_THR_CTL_D.AHBTHRRATIO, the application must ensure that the minimum bus threshold value does not go below 8 DWORDS to meet the USB turnaround time requirements.	
		0	MAC threshold
		1	MAC threshold/2
		2	MAC threshold/4
		3	MAC threshold/8
10:2 (R/W)	TXTHRLEN	Transmit Threshold Length. The USBC_THR_CTL_D.TXTHRLEN field specifies the transmit thresholding size in DWORDS. It also forms the MAC threshold and specifies the amount of data in bytes to be in the corresponding endpoint transmit FIFO, before the core can start transmit on the USB. The threshold length must be at least eight DWORDS when the value of USBC_THR_CTL_D.AHBTHRRATIO is zero. When the USBC_THR_CTL_D.AHBTHRRATIO bit field is non zero, the application must ensure that the bus threshold value does not go below the recommended eight DWORD. The USBC_THR_CTL_D.TXTHRLEN field controls both isochronous and non-isochronous IN endpoint thresholds. The recommended value for the USBC_THR_CTL_D.TXTHRLEN field is the same as the programmed bus burst length in the USBC_AHB_CFG.HBSTLEN field.	
1 (R/W)	ISOTHREN	ISO IN Endpoints Threshold Enable.. When the USBC_THR_CTL_D.ISOTHREN bit is set, the core enables thresholding for isochronous IN endpoints.	
0 (R/W)	NONISOTHREN	Non-ISO IN Endpoints Threshold Enable.. When the USBC_THR_CTL_D.NONISOTHREN bit is set, the core enables thresholding for non Isochronous IN endpoints.	

Device Control IN Endpoint Transmit FIFO Status Register

The USBC_TXFSTAT_IEP0_D register indicates the amount of free space available in the endpoint Tx FIFO.

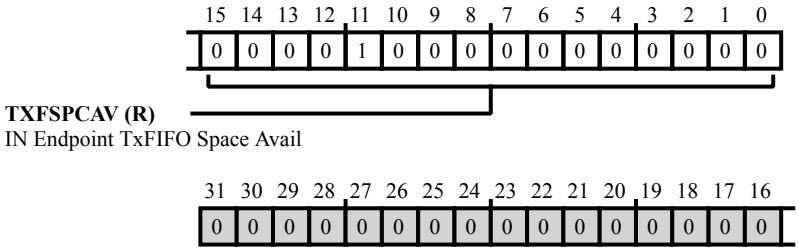

Figure 21-42: USBC_TXFSTAT_IEP0_D Register Diagram

Table 21-37: USBC_TXFSTAT_IEP0_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	TXFSPCAV	IN Endpoint TxFIFO Space Avail. The USBC_TXFSTAT_IEP0_D.TXFSPCAV field indicates the amount of free space available in the endpoint TxFIFO. Values are in terms of 32-bit words. - 16'h0: Endpoint TxFIFO is full - 16'h1: 1 word available - 16'h2: 2 words available - 16'hn: n words available (where 0 n 32,768) - 16'h8000: 32,768 words available - Others: Reserved

Device Control IN Endpoint Transmit FIFO Status Register

In device mode, the `USBC_TXFSTAT_IEP[n]_D` register indicates the status of the Tx FIFO in the endpoint.

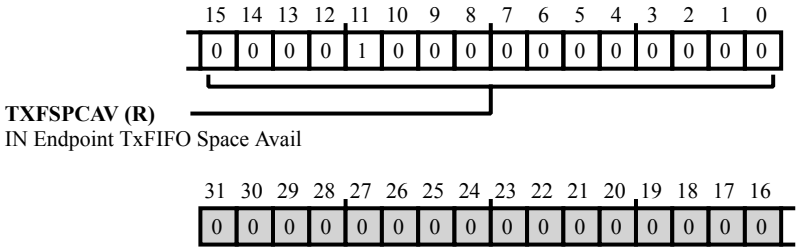

Figure 21-43: USBC_TXFSTAT_IEP[n]_D Register Diagram

Table 21-38: USBC_TXFSTAT_IEP[n]_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	TXFSPCAV	IN Endpoint TxFIFO Space Avail. The `USBC_TXFSTAT_IEP[n]_D.TXFSPCAV` field indicates the amount of free space available in the endpoint TxFIFO. Values are in terms of 32-bit words. - 16'h0: Endpoint TxFIFO is full - 16'h1: 1 word available - 16'h2: 2 words available - 16'hn: n words available (where 0 n 32,768) - 16'h8000: 32,768 words available - Others: Reserved

Device VBUS Discharge Time Register

The USBC_VBUSDIS_D register specifies the VBUS discharge time after VBUS pulsing during SRP.

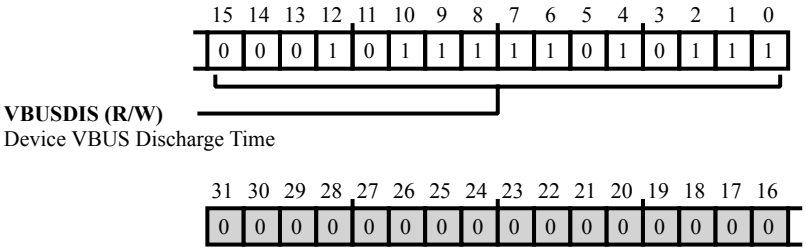

Figure 21-44: USBC_VBUSDIS_D Register Diagram

Table 21-39: USBC_VBUSDIS_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VBUSDIS	Device VBUS Discharge Time. The USBC_VBUSDIS_D.VBUSDIS bit indicates the VBUS discharge time after VBUS pulsing during SRP. This value equals (VBUS discharge time in PHY clocks) / 1,024. The value used depends whether the PHY is operating at 30 MHz (16-bit data width) or 60 MHz (8-bit data width). Depending on the VBUS load, this value can need adjustment.

Device VBUS Pulsing Time Register

The USBC_VBUSPULSE_D register indicates the pulsing time during SRP.

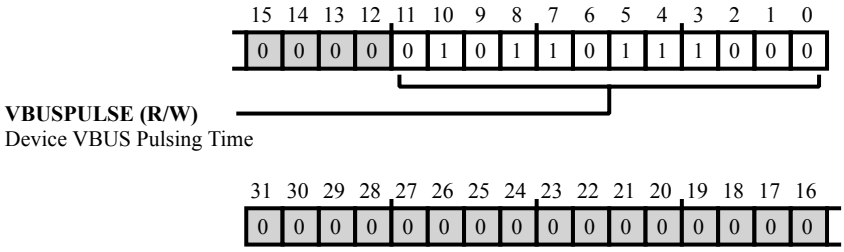

Figure 21-45: USBC_VBUSPULSE_D Register Diagram

Table 21-40: USBC_VBUSPULSE_D Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
11:0 (R/W)	VBUSPULSE	Device VBUS Pulsing Time. The USBC_VBUSPULSE_D.VBUSPULSE field specifies the VBUS pulsing time during SRP. This value equals (VBUS pulsing time in PHY clocks) / 1,024. The value used depends whether the PHY is operating at 30 MHz (16-bit data width) or 60 MHz (8-bit data width).

Bus Configuration Register

The USBC_AHB_CFG register can be used to configure the core after power-on or a change in mode. This register mainly contains bus system-related configuration parameters. Do not change this register after the initial programming. The application must program this register before starting any transactions on either the bus or the USB.

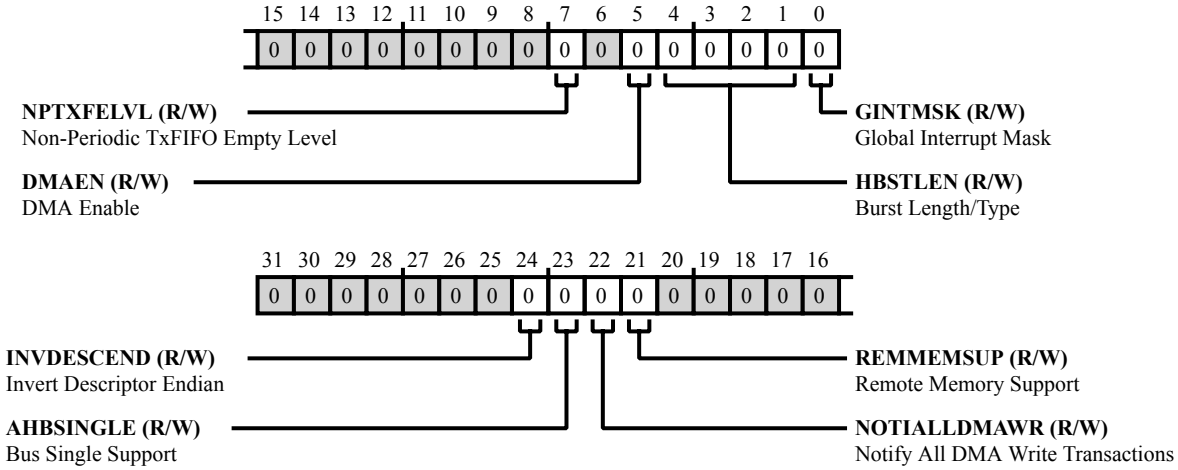

Figure 21-46: USBC_AHB_CFG Register Diagram

Table 21-41: USBC_AHB_CFG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
24 (R/W)	INVDESCEND	Invert Descriptor Endian. The USBC_AHB_CFG.INVDESCEND bit is applicable in host and device modes. The USBC_AHB_CFG.INVDESCEND bit indicates whether the byte order function (endian) of the bus requester is the same as the descriptor or is inverted.	
		0	Endian configuration is the same as the bus requester
		1	Endian configuration is the opposite of the bus requester. If the byte order function of the bus requester is big endian, the descriptor is little endian. If the byte order function of bus requester is little endian, the descriptor is big endian.

Table 21-41: USBC_AHB_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
23 (R/W)	AHBSINGLE	Bus Single Support. When the core is operating in DMA mode, the USBC_AHB_CFG.AHBSINGLE bit supports single transfers for the remaining data in a transfer. It determines whether the remaining data is sent in an INCR burst size or a single burst size. The USBC_AHB_CFG.AHBSINGLE bit is active in both host and device modes. Note: If this feature is enabled, the bus RETRY and SPLIT transfers still have INCR burst type. Enable this feature when the bus responder connected to the core does not support INCR burst (and when Split, and Retry transactions are not being used in the bus). 0 – INCR Burst Size 1 – Single Burst Size
22 (R/W)	NOTIALLDMAWR	Notify All DMA Write Transactions. The USBC_AHB_CFG.NOTIALLDMAWR bit is applicable in host and device modes. The USBC_AHB_CFG.NOTIALLDMAWR bit is programmed to enable the system DMA Done functionality for all the DMA write Transactions corresponding to the channel/endpoint. The USBC_AHB_CFG.NOTIALLDMAWR bit is valid only when USBC_AHB_CFG.REMMEMSUP = 1 and USBC_AHB_CFG.NOTIALLDMAWR = 1. The core asserts dma request for all the DMA write transactions on the bus interface. The core waits for system dma done signal for all the DMA write transactions in order to complete the transfer of a particular channel/endpoint. When USBC_AHB_CFG.NOTIALLDMAWR = 0, the core asserts dma request signal only for the last transaction of DMA write transfer corresponding to a particular channel/endpoint. Similarly, the core waits for system dma done signal only for that transaction of DMA write to complete the transfer of a particular channel/endpoint.
21 (R/W)	REMMEMSUP	Remote Memory Support. The USBC_AHB_CFG.REMMEMSUP bit is applicable in host and device modes. The USBC_AHB_CFG.REMMEMSUP bit is programmed to enable the functionality to wait for the system DMA Done signal for the DMA write transfers. When USBC_AHB_CFG.REMMEMSUP = 1, the dma request output signal is asserted when the DMA starts write transfer to the external memory. When the core is done with the transfers it asserts dma done signal to flag the completion of DMA writes from the controller. The core then waits for system dma done signal from the system to proceed further and complete the data transfer corresponding to a particular channel/endpoint. When USBC_AHB_CFG.REMMEMSUP = 0, the dma request and dma done signals are not asserted and the core proceeds with the assertion of the XferComp interrupt as soon as the DMA write transfer is done at the core boundary and it does not wait for the system dma done signal to complete the DATA transfers.

Table 21-41: USBC_AHB_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	NPTXFELVL	Non-Periodic TxFIFO Empty Level. The USBC_AHB_CFG.NPTXFELVL bit is applicable in host and device modes. In host mode and with shared FIFO and device mode: - 1'b0: the USBC_ISTAT.NPTXFEMP interrupt indicates that the non-periodic TxFIFO is half empty. - 1'b1: the USBC_ISTAT.NPTXFEMP interrupt indicates that the non-periodic TxFIFO is completely empty. In dedicated FIFO in device mode: - 1'b0: the USBC_ISTAT_IEP[n]_D.TXFEMP interrupt indicates that the IN endpoint TxFIFO is half empty. - 1'b1: the USBC_ISTAT_IEP[n]_D.TXFEMP interrupt indicates that the IN endpoint TxFIFO is completely empty.	
		0	TxFIFO half empty: device mode and host mode with shared FIFO USBC_ISTAT.NPTXFEMPinterrupt / device mode with dedicated FIFO USBC_ISTAT_IEP[n]_D.TXFEMP interrupt
		1	TxFIFO completely empty: device mode and host mode with shared FIFO USBC_ISTAT.NPTXFEMP interrupt / device mode with dedicated FIFO USBC_ISTAT_IEP[n]_D.TXFEMP interrupt
5 (R/W)	DMAEN	DMA Enable. The USBC_AHB_CFG.DMAEN bit is applicable in host and device modes. The USBC_AHB_CFG.DMAEN bit is always 0 when bus responder only mode has been selected. Reset: 1'b0	
4:1 (R/W)	HBSTLEN	Burst Length/Type. The USBC_AHB_CFG.HBSTLEN bit field indicates the burst length. It is applicable in host and device modes.	
		0	Single
		1	INCR
		2	Reserved
		3	INCR4
		4	Reserved
		5	INCR8
		6	Reserved
		7	INCR16

Table 21-41: USBC_AHB_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	GINTMSK	Global Interrupt Mask. The application uses the `USBC_AHB_CFG.GINTMSK` bit to mask or unmask the interrupt line assertion to itself. Irrespective of the configuration of the `USBC_AHB_CFG.GINTMSK` bit, the interrupt status registers are updated by the controller. The `USBC_AHB_CFG.GINTMSK` bit is applicable in host and device modes.	
		0	Mask
		1	Unmask

DFIFO Configuration Register

The USBC_DFIFO_CFG register represents the global DFIFO configuration.

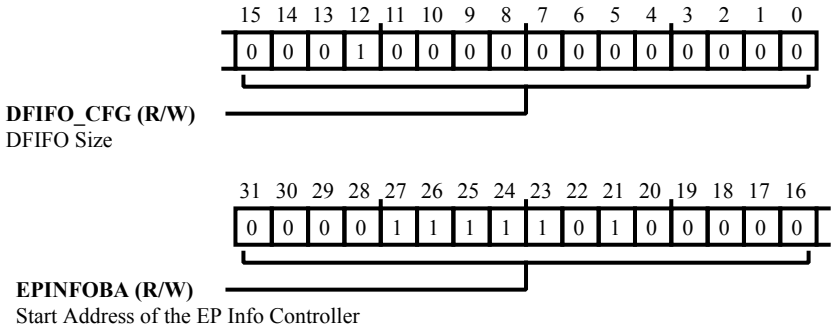

Figure 21-47: USBC_DFIFO_CFG Register Diagram

Table 21-42: USBC_DFIFO_CFG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/W)	EPINFOBA	Start Address of the EP Info Controller. The USBC_DFIFO_CFG.EPINFOBA field provides the start address of the EP info controller.
15:0 (R/W)	DFIFO_CFG	DFIFO Size. The USBC_DFIFO_CFG.DFIFO_CFG field is for dynamic programming of the DFIFO Size. This value takes effect only when the application programs a non zero value to this register. The value programmed must conform to the guidelines described in 'FIFO RAM Allocation'. The core does not have any corrective logic if the FIFO sizes are programmed incorrectly.

User Hardware Configuration 1 Register

The USBC_HWCFG1 register contains the logical endpoint direction(s).

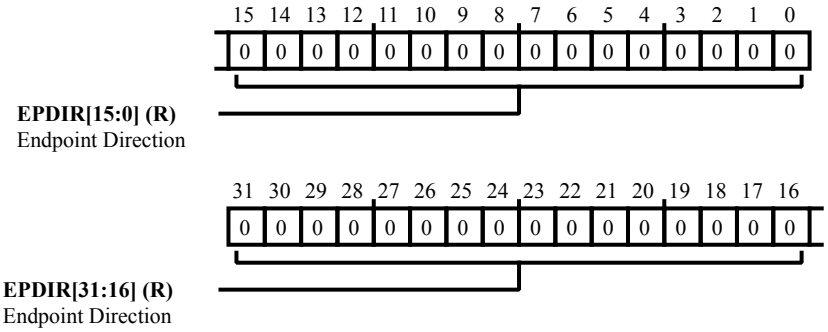

Figure 21-48: USBC_HWCFG1 Register Diagram

Table 21-43: USBC_HWCFG1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:0 (R/NW)	EPDIR	Endpoint Direction. The USBC_HWCFG1.EPDIR field uses two bits per endpoint to determine the endpoint direction. Endpoint - Bits [31:30]: Endpoint 15 direction - Bits [29:28]: Endpoint 14 direction ... - Bits [3:2]: Endpoint 1 direction - Bits[1:0]: Endpoint 0 direction (always BIDIR)	
		0	BIDIR (IN and OUT) endpoint
		1	IN endpoint
		2	OUT endpoint
		3	Reserved

User Hardware Configuration 2 Register

The USBC_HWCFG2 register contains configuration options.

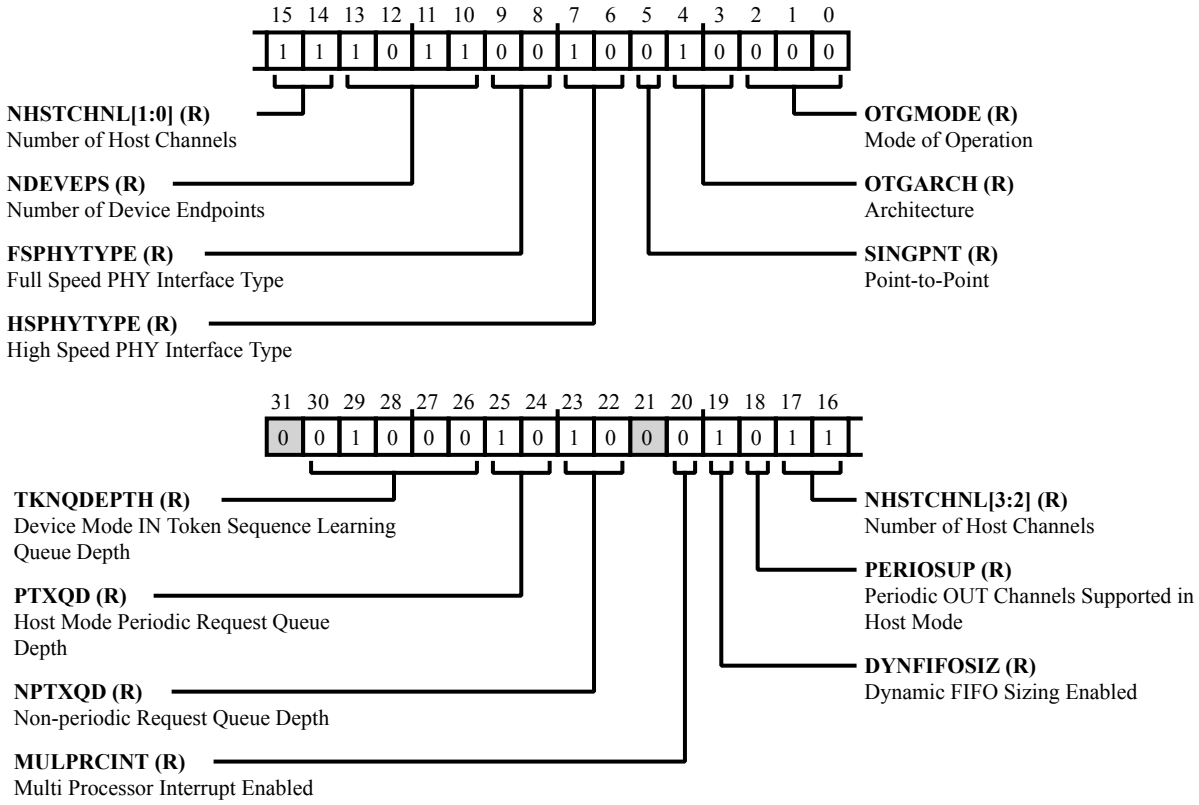

Figure 21-49: USBC_HWCFG2 Register Diagram

Table 21-44: USBC_HWCFG2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
30:26 (R/NW)	TKNQDEPTH	Device Mode IN Token Sequence Learning Queue Depth. The USBC_HWCFG2.TKNQDEPTH field indicates the device mode IN token sequence learning queue depth. The depth can range from 0 to 30.	
25:24 (R/NW)	PTXQD	Host Mode Periodic Request Queue Depth. The USBC_HWCFG2.PTXQD field indicates the host mode periodic request queue depth.	
		0	2
		1	4
		2	8
		3	16

Table 21-44: USBC_HWCFG2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
23:22 (R/NW)	NPTXQD	Non-periodic Request Queue Depth. The `USBC_HWCFG2.NPTXQD` field indicates the non-periodic request queue depth.	
		0	2
		1	4
		2	8
		3	Reserved
20 (R/NW)	MULPRCINT	Multi Processor Interrupt Enabled. The `USBC_HWCFG2.MULPRCINT` bit indicates if the multiprocessor interrupt is enabled.	
		0	No
		1	Yes
19 (R/NW)	DYNFIFOSIZ	Dynamic FIFO Sizing Enabled. The `USBC_HWCFG2.DYNFIFOSIZ` bit indicates if dynamic FIFO sizing is enabled.	
18 (R/NW)	PERIOSUP	Periodic OUT Channels Supported in Host Mode. The ${.::} field indicates if the periodic OUT channel is supported in host mode.	
		0	No
		1	Yes
17:14 (R/NW)	NHSTCHNL	Number of Host Channels. The `USBC_HWCFG2.NHSTCHNL` field indicates the number of host channels supported by the core in host mode. The range of this field is 0-15: 0 specifies 1 channel, 15 specifies 16 channels.	
13:10 (R/NW)	NDEVEPS	Number of Device Endpoints. The `USBC_HWCFG2.NDEVEPS` field indicates the number of device endpoints supported by the core in device mode. The range of this field is 0-15.	
9:8 (R/NW)	FSPHYTYPE	Full Speed PHY Interface Type. The `USBC_HWCFG2.FSPHYTYPE` field indicates the type of full speed PHY interface.	
		0	Full speed interface not supported
		1	Dedicated full speed interface
		2	FS pins shared with UTMI+ pins
		3	FS pins shared with ULPI pins

Table 21-44: USBC_HWCFG2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7:6 (R/NW)	HSPHYTYPE	High Speed PHY Interface Type. The `USBC_HWCFG2.HSPHYTYPE` field indicates the type of high speed PHY interface.	
		0	High speed interface is not supported
		1	UTMI+
		2	ULPI
		3	UTMI+ and ULPI
5 (R/NW)	SINGPNT	Point-to-Point. The `USBC_HWCFG2.SINGPNT` bit indicates whether the application is a single point application with hub and split support or a multipoint application with no hub and split support.	
		0	Multipoint Application
		1	Single Point Application
4:3 (R/NW)	OTGARCH	Architecture. The `USBC_HWCFG2.OTGARCH` field indicates the architecture.	
		0	Responder Only
		1	External DMA
		2	Internal DMA
		3	Reserved
2:0 (R/NW)	OTGMODE	Mode of Operation. The `USBC_HWCFG2.OTGMODE` field indicates the mode of operation.	
		0	HNP and SRP Capable OTG (Host and Device)
		1	SRP Capable OTG (Host and Device)
		2	Non-HNP and Non-SRP Capable OTG (Host and Device)
		3	SRP Capable Device
		4	Non-OTG Device
		5	SRP Capable Host
		6	Non-OTG Host
		7	Reserved

User Hardware Configuration 3 Register

The USBC_HWCFG3 register contains configuration options.

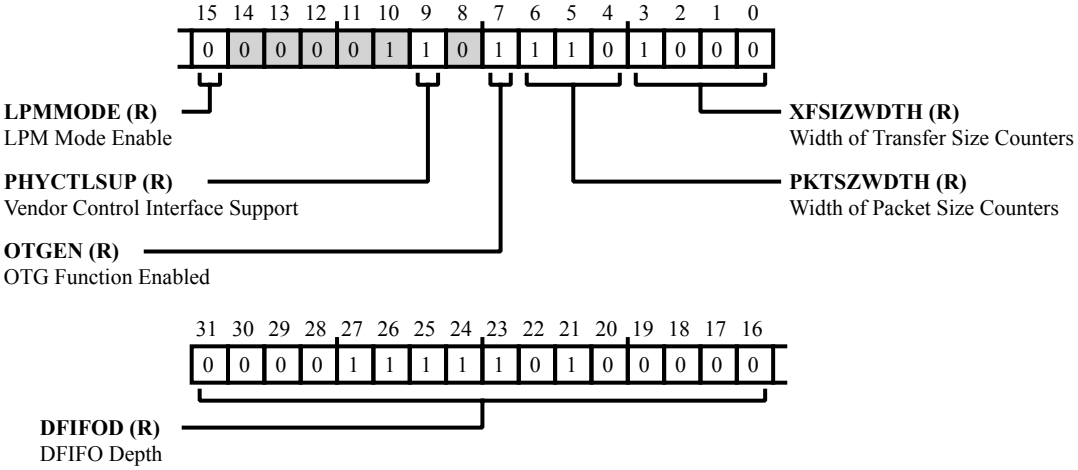

Figure 21-50: USBC_HWCFG3 Register Diagram

Table 21-45: USBC_HWCFG3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:16 (R/NW)	DFIFOD	DFIFO Depth. The USBC_HWCFG3.DFIFOD field indicates the DFIFO depth. This value is in terms of 32-bit words, with a minimum value is 32 and a maximum value is 32,768.	
15 (R/NW)	LPMMODE	LPM Mode Enable. The USBC_HWCFG3.LPMMODE bit enables the LPM mode of operation.	
9 (R/NW)	PHYCTLSUP	Vendor Control Interface Support. The USBC_HWCFG3.PHYCTLSUP bit indicates whether the vendor control interface is available on the core.	
		0	Not available
		1	Available
7 (R/NW)	OTGEN	OTG Function Enabled. The application uses the USBC_HWCFG3.OTGEN bit to indicate the OTG capabilities of the controller.	
		0	Not OTG capable
		1	OTG capable
6:4 (R/NW)	PKTSZWDTH	Width of Packet Size Counters. The USBC_HWCFG3.PKTSZWDTH field indicates the width of the transfer size counters.	

Table 21-45: USBC_HWCFG3 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		0	4 Bits
		1	5 Bits
		2	6 Bits
		3	7 Bits
		4	8 Bits
		5	9 Bits
		6	10 Bits
3:0 (R/NW)	XFSIZWDTH	Width of Transfer Size Counters. The `USBC_HWCFG3.XFSIZWDTH` field indicates the width of the transfer size counters.	
		0	11 Bits
		1	12 Bits
		2	13 Bits
		3	14 Bits
		4	15 Bits
		5	16 Bits
		6	17 Bits
		7	18 Bits
		8	19 Bits

User Hardware Configuration 4 Register

The USBC_HWCFG4 register contains configuration options.

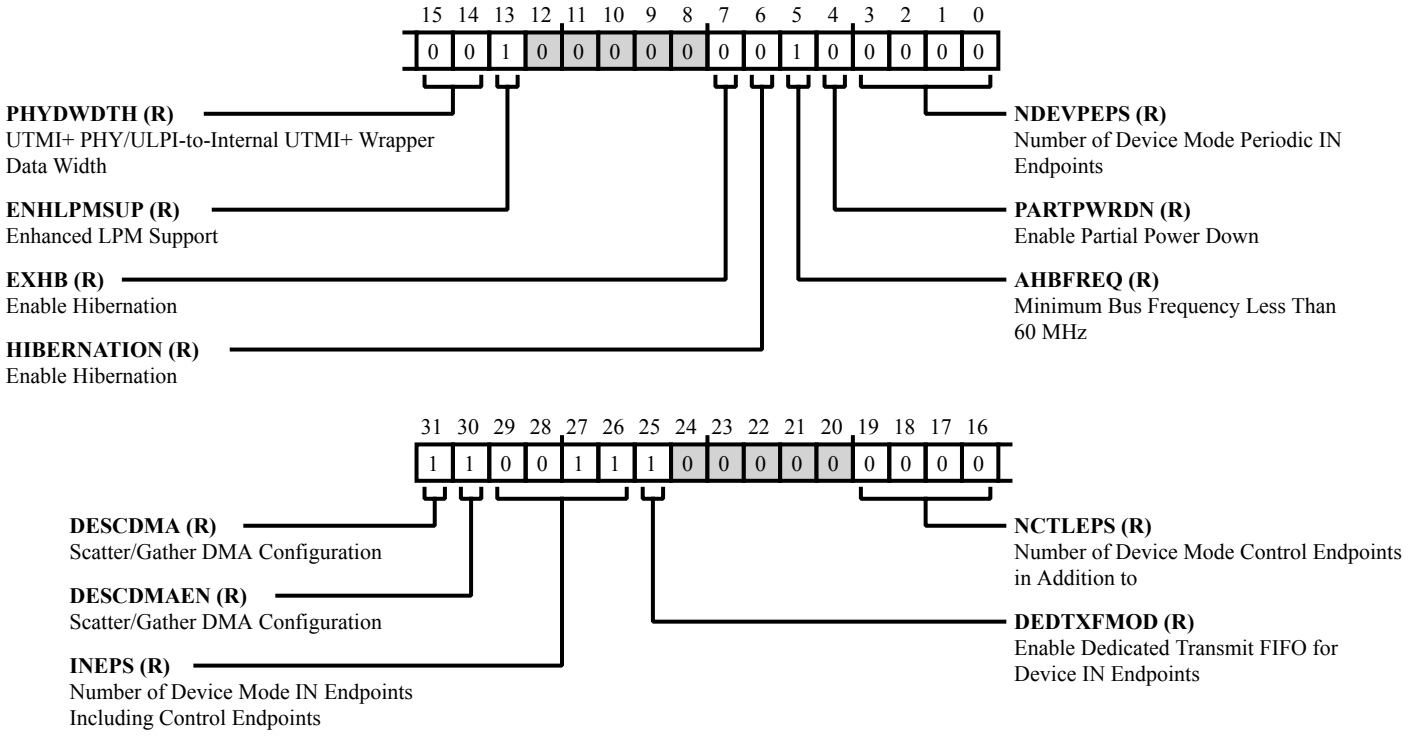

Figure 21-51: USBC_HWCFG4 Register Diagram

Table 21-46: USBC_HWCFG4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/NW)	DESCDMA	Scatter/Gather DMA Configuration. The USBC_HWCFG4.DESCDMA bit enables dynamic scatter/gather DMA configuration.	
		0	Disable
		1	Enable
30 (R/NW)	DESCDMAEN	Scatter/Gather DMA Configuration. The USBC_HWCFG4.DESCDMAEN bit enables scatter/gather DMA configuration.	
		0	Non scatter/gather DMA
		1	Scatter/gather DMA
29:26 (R/NW)	INEPS	Number of Device Mode IN Endpoints Including Control Endpoints. The USBC_HWCFG4.INEPS field indicates the number of device mode IN endpoints (including control endpoints).	

Table 21-46: USBC_HWCFG4 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		0	1 IN Endpoint
		1	2 IN Endpoints
		2	3 IN Endpoints
		3	4 IN Endpoints
		4	5 IN Endpoints
		5	6 IN Endpoints
		6	7 IN Endpoints
		7	8 IN Endpoints
		8	9 IN Endpoints
		9	10 IN Endpoints
		10	11 IN Endpoints
		11	12 IN Endpoints
		12	13 IN Endpoints
		13	14 IN Endpoints
		14	15 IN Endpoints
		15	16 IN Endpoints
25 (R/NW)	DEDTXFMOD	Enable Dedicated Transmit FIFO for Device IN Endpoints. The `USBC_HWCFG4.DEDTXFMOD` bit enables a dedicated transmit FIFO for device IN endpoints (DedFifoMode).	
		0	Disable
		1	Enable
19:16 (R/NW)	NCTLEPS	Number of Device Mode Control Endpoints in Addition to. Endpoint 0 (NCTLEPS) Range: 0-15	
15:14 (R/NW)	PHYDWDTH	UTMI+ PHY/ULPI-to-Internal UTMI+ Wrapper Data Width. When a ULPI PHY is used, an internal wrapper converts ULPI to UTMI+.	
		0	8 bits
		1	16 bits
		2	8/16 bits, software selectable
		3	Reserved

Table 21-46: USBC_HWCFG4 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
13 (R/NW)	ENHLPMSUP	Enhanced LPM Support. The `USBC_HWCFG4.ENHLPMSUP` bit indicates that the controller supports the following behavior: L1 entry behavior is based on FIFO status: - TX FIFO - Accept L1 request even if ISOC OUT TX FIFO is not empty. - Reject L1 request if non-periodic TX FIFO is not empty. - Ensure application can flush the TX FIFO while the controller is in L1. - RX FIFO - Accept L1 request even if RX FIFO (common to periodic and non-periodic) is not empty. - Accept L1 request but delay SLEEPM assertion until RX SINK buffer is empty. Prevent L1 entry if a control transfer is in progress on any control Endpoint. Ability to Flush TxFIFO even if PHY Clock is gated.	
7 (R/NW)	EXHB	Enable Hibernation. The `USBC_HWCFG4.EXHB` bit enables extended hibernation.	
		0	Disable
		1	Enable
6 (R/NW)	HIBERNATION	Enable Hibernation. The `USBC_HWCFG4.HIBERNATION` bit enables hibernation.	
		0	Disable
		1	Enable
5 (R/NW)	AHBFREQ	Minimum Bus Frequency Less Than 60 MHz. The `USBC_HWCFG4.AHBFREQ` bits indicates whether the minimum bus frequency is less than 60 MHz.	
		0	No
		1	Yes
4 (R/NW)	PARTPWRDN	Enable Partial Power Down. The `USBC_HWCFG4.PARTPWRDN` bit enables or disables partial power down.	
		0	Disable
		1	Enable
3:0 (R/NW)	NDEVPEPS	Number of Device Mode Periodic IN Endpoints. The `USBC_HWCFG4.NDEVPEPS` field indicates the number of periodic IN endpoints (0-15).	

Interrupt Mask Register

The USBC_IMSK register works with the Interrupt Register (USBC_ISTAT) to interrupt the application. When an interrupt bit is masked, the interrupt associated with that bit is not generated. However, the USBC_ISTAT register bit corresponding to that interrupt is still set.

Note: The fields of this register change depending on host or device mode.

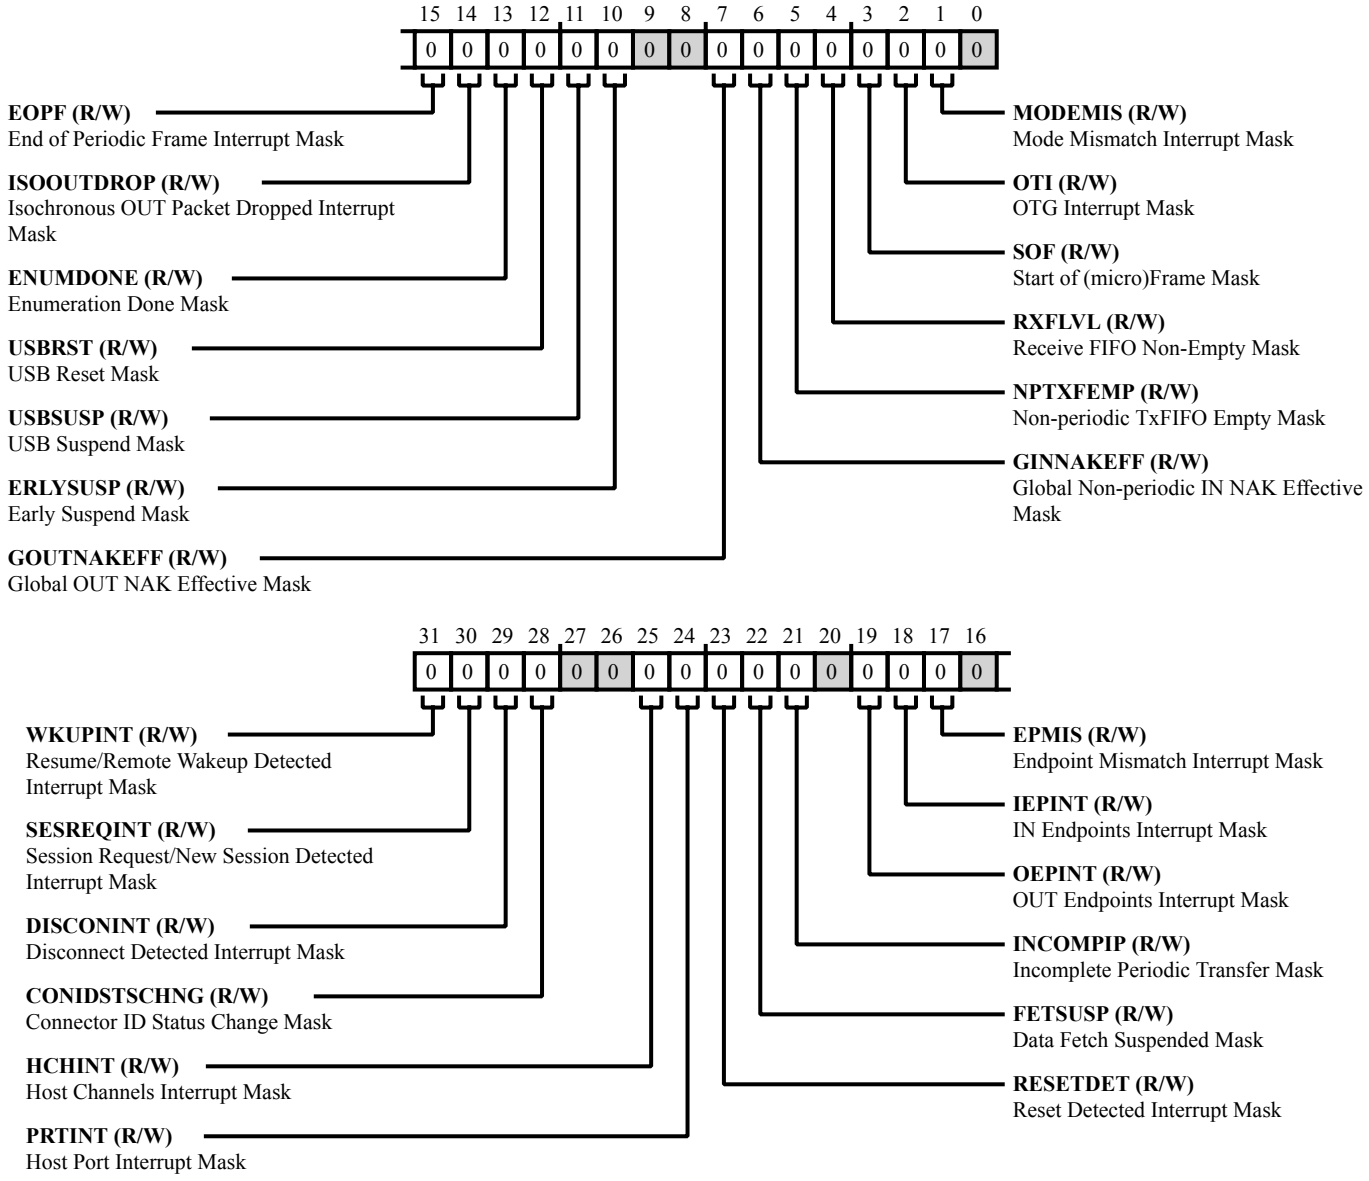

Figure 21-52: USBC_IMSK Register Diagram

Table 21-47: USBC_IMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	WKUPINT	Resume/Remote Wakeup Detected Interrupt Mask. Mode: Host and Device The WakeUp bit is used for LPM state wake up in a way similar to that of wake up in suspend state.
30 (R/W)	SESREQINT	Session Request/New Session Detected Interrupt Mask. Mode: Host and Device
29 (R/W)	DISCONINT	Disconnect Detected Interrupt Mask. Mode: Host and Device Disconnect Detected Interrupt Mask (DisconnIntMsk)
28 (R/W)	CONIDSTSCHNG	Connector ID Status Change Mask. Mode: Host and Device Connector ID Status Change Mask (ConIDStsChngMsk)
25 (R/W)	HCHINT	Host Channels Interrupt Mask. Mode: Host only
24 (R/W)	PRTINT	Host Port Interrupt Mask. Mode: Host only
23 (R/W)	RESETDET	Reset Detected Interrupt Mask. Mode: Device only
22 (R/W)	FETSUSP	Data Fetch Suspended Mask. Mode: Device only
21 (R/W)	INCOMPIP	Incomplete Periodic Transfer Mask. Mode: Host only Incomplete Isochronous OUT Transfer Interrupt Mask (incompISOOUTMsk) Mode: Device only
19 (R/W)	OEPINT	OUT Endpoints Interrupt Mask. Mode: Device only
18 (R/W)	IEPINT	IN Endpoints Interrupt Mask. Mode: Device only
17 (R/W)	EPMIS	Endpoint Mismatch Interrupt Mask. Mode: Device only
15 (R/W)	EOPF	End of Periodic Frame Interrupt Mask. Mode: Device only
14 (R/W)	ISOOUTDROP	Isochronous OUT Packet Dropped Interrupt Mask. Mode: Device only
13 (R/W)	ENUMDONE	Enumeration Done Mask. Mode: Device only

Table 21-47: USBC_IMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
12 (R/W)	USBRST	USB Reset Mask. Mode: Device only
11 (R/W)	USBSUSP	USB Suspend Mask. Mode: Device only
10 (R/W)	ERLYSUSP	Early Suspend Mask. Mode: Device only
7 (R/W)	GOUTNAKEFF	Global OUT NAK Effective Mask. Mode: Device only
6 (R/W)	GINNAKEFF	Global Non-periodic IN NAK Effective Mask. Mode: Device only,
5 (R/W)	NPTXFEMP	Non-periodic TxFIFO Empty Mask. Mode: Host and Device
4 (R/W)	RXFLVL	Receive FIFO Non-Empty Mask. Mode: Host and Device
3 (R/W)	SOF	Start of (micro)Frame Mask. Mode: Host and Device
2 (R/W)	OTI	OTG Interrupt Mask. Mode: Host and Device
1 (R/W)	MODEMIS	Mode Mismatch Interrupt Mask. Mode: Host and Device

Interrupt Status Register

The USBC_ISTAT register interrupts the application for system-level events in the current mode (device mode or host mode). Some of the bits in this register are valid only in host mode, while others are valid in device mode only. This register also indicates the current mode. To clear the interrupt status bits of type R_SS_WC, the application must write 1'b1 into the bit.

The FIFO status interrupts are read only; once software reads from or writes to the FIFO while servicing these interrupts, FIFO interrupt conditions are cleared automatically.

The application must clear the USBC_ISTAT register at initialization before unmasking the interrupt bit to avoid any interrupts generated prior to initialization.

Note: Read the reset value of USBC_ISTAT.CURMOD only after the following conditions:

If IDDIG_FILTER is disabled, read only after PHY clock is stable.

If IDDIG_FILTER is enabled, read only after the filter timer expires.

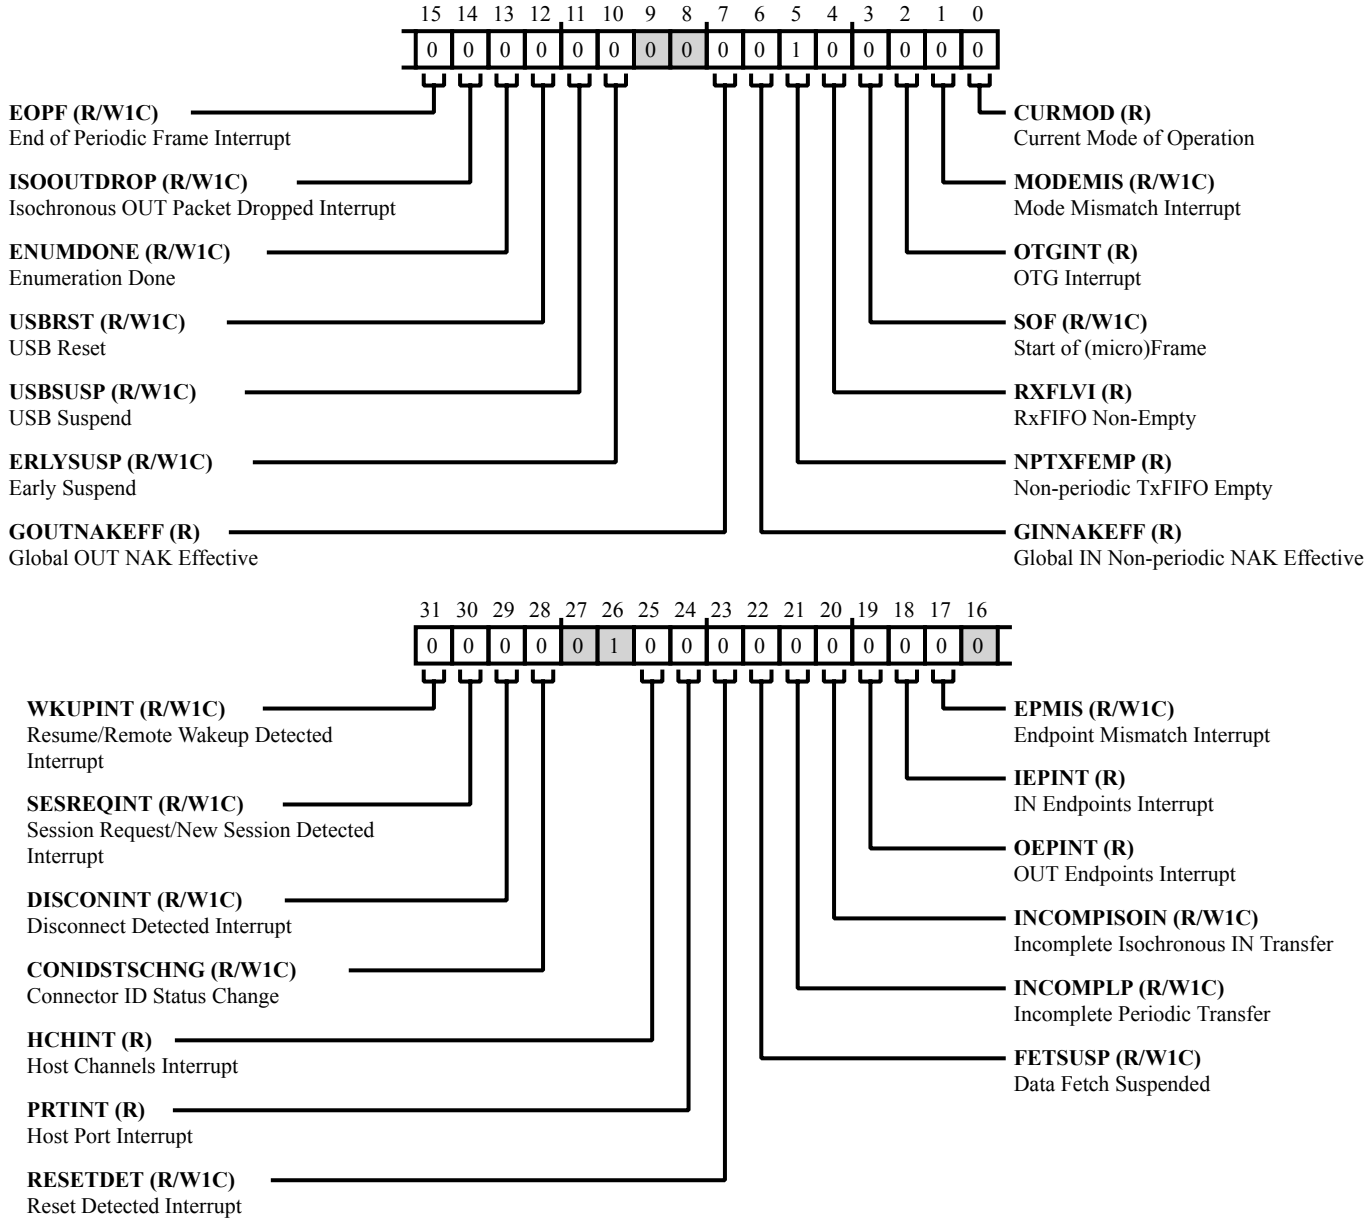

Figure 21-53: USBC_ISTAT Register Diagram

Table 21-48: USBC_ISTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W1C)	WKUPINT	Resume/Remote Wakeup Detected Interrupt. The USBC_ISTAT.WKUPINT bit is applicable in host and device mode. Wakeup interrupt during Suspend(L2) or LPM(L1) state. During Suspend(L2): In device mode, the USBC_ISTAT.WKUPINT bit is set only when a host-initiated resume is detected on the USB. In host mode, the USBC_ISTAT.WKUPINT bit is set only when a device-initiated remote wakeup is detected on USB. During LPM(L1): In device mode, the USBC_ISTAT.WKUPINT bit is set for either host-initiated resume or device-initiated remote wakeup on USB. In host mode, the USBC_ISTAT.WKUPINT bit is set for either host-initiated resume or device-initiated remote wakeup on USB.
30 (R/W1C)	SESREQINT	Session Request/New Session Detected Interrupt. The USBC_ISTAT.SESREQINT bit is applicable in host and device mode.
29 (R/W1C)	DISCONINT	Disconnect Detected Interrupt. The USBC_ISTAT.DISCONINT bit is applicable in host mode. Disconnect Detected Interrupt (DisconnInt) The USBC_ISTAT.DISCONINT bit is set (=1) when a device disconnect is detected.
28 (R/W1C)	CONIDSTSCHNG	Connector ID Status Change. The USBC_ISTAT.CONIDSTSCHNG bit is applicable in host and device mode. The core sets the USBC_ISTAT.CONIDSTSCHNG bit when there is a change in connector ID status.
25 (R/NW)	HCHINT	Host Channels Interrupt. The USBC_ISTAT.HCHINT bit is applicable in host mode. The core sets the USBC_ISTAT.HCHINT bit to indicate that an interrupt is pending on one of the channels of the core (in Host mode). The application must read the USBC_ISTAT_H register to determine the exact number of the channel on which the interrupt occurred, and Then read the corresponding USBC_ISTAT[n]_H register to determine the exact cause of the interrupt. The application must clear the appropriate status bit in the USBC_ISTAT[n]_H register to clear this bit.

Table 21-48: USBC_ISTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
24 (R/NW)	PRTINT	Host Port Interrupt. The USBC_ISTAT.PRTINT bit is applicable in host mode. The core sets the USBC_ISTAT.PRTINT bit to indicate a change in port status of one of the controller ports in host mode. The application must read the USBC_PORT_CTL_H register to determine the exact event that caused this interrupt. The application must clear the appropriate status bit in the Host Port Control and Status register to clear the USBC_ISTAT.PRTINT bit.
23 (R/W1C)	RESETDET	Reset Detected Interrupt. The USBC_ISTAT.RESETDET bit is applicable in device mode. In device mode, this interrupt is asserted when a reset is detected on the USB in partial power-down mode when the device is in Suspend. In host mode, this interrupt is not asserted.
22 (R/W1C)	FETSUSP	Data Fetch Suspended. The USBC_ISTAT.FETSUSP bit is applicable in device mode. This interrupt indicates that the core has stopped fetching data. For IN endpoints due to the unavailability of TxFIFO space or request queue space. This interrupt is used by the application for an endpoint mismatch algorithm. For example, after detecting an endpoint mismatch, the application: - Sets a global non-periodic IN NAK handshake - Disables IN endpoints - Flushes the FIFO - Determines the token sequence from the IN token sequence learning queue - Re-enables the endpoints - Clears the global non-periodic IN NAK handshake If the global non-periodic IN NAK is cleared, the core has not yet fetched data for the IN endpoint, and the IN token is received. The core generates an 'IN token received when FIFO empty' interrupt. The USBC_otg then sends the host a NAK response. To avoid this scenario, the application can check the USBC_ISTAT.FETSUSP interrupt, which ensures that the FIFO is full before clearing a global NAK handshake. Alternatively, the application can mask the IN token received when FIFO empty interrupt when clearing a global IN NAK handshake.

Table 21-48: USBC_ISTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
21 (R/W1C)	INCOMPLP	Incomplete Periodic Transfer. The USBC_ISTAT.INCOMPLP bit is applicable in host and device mode. In host mode, the core sets the USBC_ISTAT.INCOMPLP bit when there are incomplete periodic transactions still pending which are scheduled for the current microframe. Incomplete Isochronous OUT Transfer (incompISOOUT) In device mode, the core sets (=1) the USBC_ISTAT.INCOMPLP bit to indicate that there is at least one isochronous OUT endpoint on which the transfer is not completed in the current microframe. The USBC_ISTAT.INCOMPLP bit is set along with the USBC_ISTAT.EOPF bit.
20 (R/W1C)	INCOMPISOIN	Incomplete Isochronous IN Transfer. The USBC_ISTAT.INCOMPISOIN bit is applicable in device mode. The core sets this interrupt to indicate that there is at least one isochronous IN endpoint on which the transfer is not completed in the current microframe. This interrupt is asserted along with the End of Periodic Frame Interrupt (EOPF) bit in this register. Note: This interrupt is not asserted in scatter/gather DMA mode.
19 (R/NW)	OEPINT	OUT Endpoints Interrupt. The USBC_ISTAT.OEPINT bit is applicable in device mode. The controller sets the USBC_ISTAT.OEPINT bit to indicate that an interrupt is pending on one of the OUT endpoints of the core (in device mode). The application must read the USBC_ISTAT_D register to determine the exact number of the OUT endpoint on which the interrupt occurred, and then read the corresponding USBC_ISTAT_OEP[n]_D register to determine the exact cause of the interrupt. The application must clear the appropriate status bit in the corresponding USBC_ISTAT_OEP[n]_D register to clear the USBC_ISTAT.OEPINT bit.
18 (R/NW)	IEPINT	IN Endpoints Interrupt. The USBC_ISTAT.IEPINT bit is applicable in device mode. The core sets the USBC_ISTAT.IEPINT bit to indicate that an interrupt is pending on one of the IN endpoints of the core (in device mode). The application must read the USBC_ISTAT_D register to determine the exact number of the IN endpoint on the USBC_ISTAT_IEP[n]_D register to determine the exact cause of the interrupt. The application must clear the appropriate status bit in the corresponding USBC_ISTAT_IEP[n]_D register to clear the USBC_ISTAT.IEPINT bit.

Table 21-48: USBC_ISTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
17 (R/W1C)	EPMIS	Endpoint Mismatch Interrupt. The USBC_ISTAT.EPMIS bit is applicable in device mode. Note: This interrupt is valid only in shared FIFO operation. The USBC_ISTAT.EPMIS bit indicates that an IN token has been received for a non-periodic endpoint, but the data for another endpoint is present in the top of the non-periodic transmit FIFO and the IN endpoint mismatch count programmed by the application has expired.
15 (R/W1C)	EOPF	End of Periodic Frame Interrupt. The USBC_ISTAT.EOPF bit is applicable in device mode. The USBC_ISTAT.EOPF bit indicates that the period specified in the USBC_CFG_D.PERFRINT field has been reached in the current microframe.
14 (R/W1C)	ISOOUTDROP	Isochronous OUT Packet Dropped Interrupt. The USBC_ISTAT.ISOOUTDROP bit is applicable in device mode. The controller sets the USBC_ISTAT.ISOOUTDROP bit when it fails to write an isochronous OUT packet into the RxFIFO because the RxFIFO does not have enough space to accommodate a maximum packet size packet for the isochronous OUT endpoint.
13 (R/W1C)	ENUMDONE	Enumeration Done. The USBC_ISTAT.ENUMDONE bit is applicable in device mode. The core sets the USBC_ISTAT.ENUMDONE bit to indicate that speed enumeration is complete. The application must read the USBC_STAT_D register to obtain the enumerated speed.
12 (R/W1C)	USBRST	USB Reset. The USBC_ISTAT.USBRST bit is applicable in device mode. The controller sets the USBC_ISTAT.USBRST bit to indicate that a reset is detected on the USB.
11 (R/W1C)	USBSUSP	USB Suspend. The USBC_ISTAT.USBSUSP bit is applicable in device mode. The controller sets the USBC_ISTAT.USBSUSP bit to indicate that a suspend was detected on the USB. The controller enters the suspended state when there is no activity on the linestate signal for an extended period of time.
10 (R/W1C)	ERLYSUSP	Early Suspend. The USBC_ISTAT.ERLYSUSP bit is applicable in device mode. The controller sets the USBC_ISTAT.ERLYSUSP bit to indicate that an idle state has been detected on the USB for 3 ms.

Table 21-48: USBC_ISTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
7 (R/NW)	GOUTNAKEFF	Global OUT NAK Effective. The USBC_ISTAT.GOUTNAKEFF bit is applicable in device mode. The USBC_ISTAT.GOUTNAKEFF bit indicates that the USBC_CTL_D.SGOUTNAK bit, set by the application, has taken effect in the core. The USBC_ISTAT.GOUTNAKEFF bit can be cleared by writing to the USBC_CTL_D.CGOUTNAK bit.
6 (R/NW)	GINNAKEFF	Global IN Non-periodic NAK Effective. The USBC_ISTAT.GINNAKEFF bit is applicable in device mode. The USBC_ISTAT.GINNAKEFF bit indicates that the USBC_CTL_D.SGNPINNAK bit, set by the application, has taken effect in the core. That is, the core has sampled the Global IN NAK bit set by the application. The USBC_ISTAT.GINNAKEFF bit can be cleared by clearing the USBC_CTL_D.CGNPINNAK bit. This interrupt does not necessarily mean that a NAK handshake is sent out on the USB. The STALL bit takes precedence over the NAK bit.
5 (R/NW)	NPTXFEMP	Non-periodic TxFIFO Empty. The USBC_ISTAT.NPTXFEMP bit is applicable in host and device mode. The USBC_ISTAT.NPTXFEMP bit indicates that an interrupt is asserted when the non-periodic TxFIFO is either half or completely empty, and there is space for at least one Entry to be written to the non-periodic transmit request queue. The half or completely empty status is determined by the USBC_AHB_CFG.NPTXFELVL bit. In host mode, the application can use the USBC_ISTAT.NPTXFEMP bit In device mode, the application uses uses USBC_ISTAT_IEP[n]_D.TXFEMP.
4 (R/NW)	RXFLVI	RxFIFO Non-Empty. The USBC_ISTAT.RXFLVI bit is applicable in host and device mode. The USBC_ISTAT.RXFLVI bit indicates that there is at least one packet pending to be read from the RxFIFO.

Table 21-48: USBC_ISTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
3 (R/W1C)	SOF	Start of (micro)Frame. The USBC_ISTAT.SOF bit is applicable in host and device mode. In host mode, the core sets the USBC_ISTAT.SOF bit to indicate that an SOF (FS), micro-SOF (HS), or Keep-Alive (LS) is transmitted on the USB. The application must write a 1 to the USBC_ISTAT.SOF bit to clear the interrupt. In device mode, the controller sets the USBC_ISTAT.SOF bit to indicate that an SOF token has been received on the USB. The application can read the Device Status register to get the current (micro)Frame number. This interrupt is seen only when the core is operating at either HS or FS. The USBC_ISTAT.SOF bit can be set only by the core; the application must write 1 to clear it. Note: This register may return 1'b1 if read immediately after power-on reset. If the register bit reads 1'b1 immediately after power-on reset, it does not indicate that an SOF has been sent (in case of host mode) or SOF has been received (in case of device mode). The read value of this interrupt is valid only after a valid connection between host and device is established. If the bit is set after power on reset the application can clear the bit.
2 (R/NW)	OTGINT	OTG Interrupt. The USBC_ISTAT.OTGINT bit is applicable in host and device mode. The controller sets the USBC_ISTAT.OTGINT bit to indicate an OTG protocol event. The application must read the USBC_OTG_IRQ register to determine the exact event that caused this interrupt. The application must clear the appropriate status bit in the USBC_OTG_IRQ register to clear thE USBC_ISTAT.OTGINT bit.
1 (R/W1C)	MODEMIS	Mode Mismatch Interrupt. The USBC_ISTAT.MODEMIS bit is applicable in host and device mode. The core sets the USBC_ISTAT.MODEMIS bit when the application is trying to access: - A host mode register, when the controller is operating in device mode - A device mode register, when the controller is operating in host mode The register access is completed on the bus with an OKAY response, but is ignored by the controller internally and does not affect the operation of the controller. The USBC_ISTAT.MODEMIS bit can be set only by the core; the application should write 1 to clear it.

Table 21-48: USBC_ISTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/NW)	CURMOD	Current Mode of Operation. The `USBC_ISTAT.CURMOD` bit is applicable in host and device mode. Current Mode of Operation (CurMod) The `USBC_ISTAT.CURMOD` bit indicates the current mode. Note: The reset value of this register field can be read only after the PHY clock is stable.	
		0	Device mode
		1	Host mode

Non-periodic Transmit FIFO Size Register

The application can program the RAM size and the memory start address for the non-periodic TxFIFO.

Note: The fields of the USBC_TXFIFOSZ_NP register change depending on host or device mode.

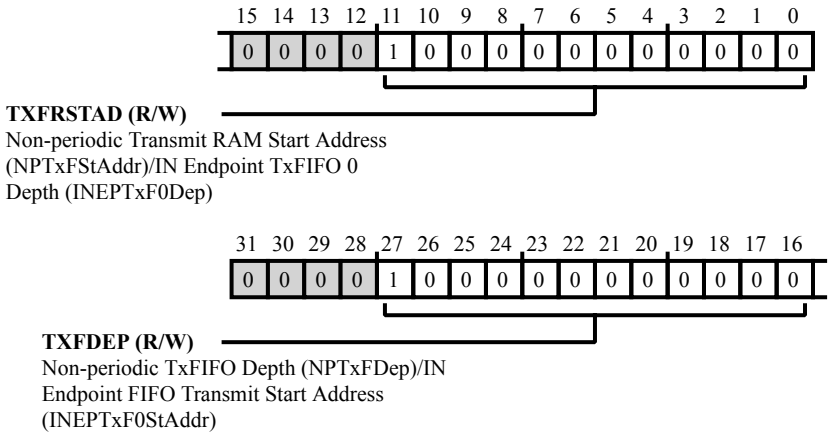

Figure 21-54: USBC_TXFIFOSZ_NP Register Diagram

Table 21-49: USBC_TXFIFOSZ_NP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
27:16 (R/W)	TXFDEP	Non-periodic TxFIFO Depth (NPTxFDep)/IN Endpoint FIFO Transmit Start Address (INEPTxF0StAddr). In host mode, this field contains the Non-periodic TxFIFO Depth (NPTxFDep). In device mode, this field contains the IN Endpoint FIFO Transmit Start Address (INEPTxF0StAddr). Programmed values must not exceed the power-on value. The power-on reset value of this field is 2048.
11:0 (R/W)	TXFRSTAD	Non-periodic Transmit RAM Start Address (NPTxFStAddr)/IN Endpoint TxFIFO 0 Depth (INEPTxF0Dep). In host mode, this field is Non-periodic Transmit RAM Start Address (NPTxFStAddr). In device mode, this field is IN Endpoint TxFIFO 0 Depth (INEPTxF0Dep). This value is in terms of 32-bit words. The minimum value is 16, the maximum value is 32,768, and the reset value is 256.

Non-periodic Transmit FIFO/Queue Status Register

In device mode, the USBC_TXFIFO_STAT_NP register is valid only in shared FIFO operation.

The read-only USBC_TXFIFO_STAT_NP register contains the free space information for the non-periodic TxFIFO and the non-periodic transmit request queue.

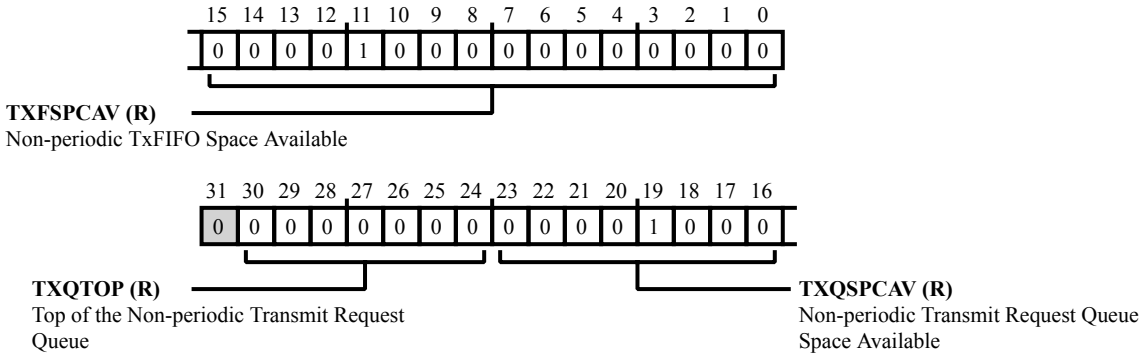

Figure 21-55: USBC_TXFIFO_STAT_NP Register Diagram

Table 21-50: USBC_TXFIFO_STAT_NP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
30:24 (R/NW)	TXQTOP	Top of the Non-periodic Transmit Request Queue. Entry in the Non-periodic Tx Request Queue that is currently being processed by the MAC. - Bits [30:27]: Channel/endpoint number - Bits [26:25]: - 2'b00: IN/OUT token -- 2'b01: Zero-length transmit packet (device IN/host OUT) -- 2'b10: PING/CSPLIT token -- 2'b11: Channel halt command - Bit [24]: Terminate (last Entry for selected channel/endpoint)	
23:16 (R/NW)	TXQSPCAV	Non-periodic Transmit Request Queue Space Available. The USBC_TXFIFO_STAT_NP.TXQSPCAV bit field indicates the amount of free space available in the non-periodic transmit request queue. This queue holds both IN and OUT requests in host mode. Device mode has only IN requests. Values are in terms of 32-bit words.	
		0	Queue Full
		1	1 Location Available
		2	2 Locations Available

Table 21-50: USBC_TXFIFO_STAT_NP Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		3	3 Locations Available
		4	4 Locations Available
		5	5 Locations Available
		6	6 Locations Available
		7	7 Locations Available
		8	8 Locations Available
15:0 (R/NW)	TXFSPCAV	Non-periodic TxFIFO Space Available. The `USBC_TXFIFO_STAT_NP.TXFSPCAV` bit field indicates the amount of free space available in the Non-periodic TxFIFO. Values are in terms of 32-bit words. 16'hn: n words available, where 0 <= n <= 32,768) reserved where n > 32,768, and full where n = 0.	
		0	TxFIFO Full

OTG Control and Status Register

The USBC_OTG_CTL register controls the behavior and reflects the status of the OTG function of the controller.

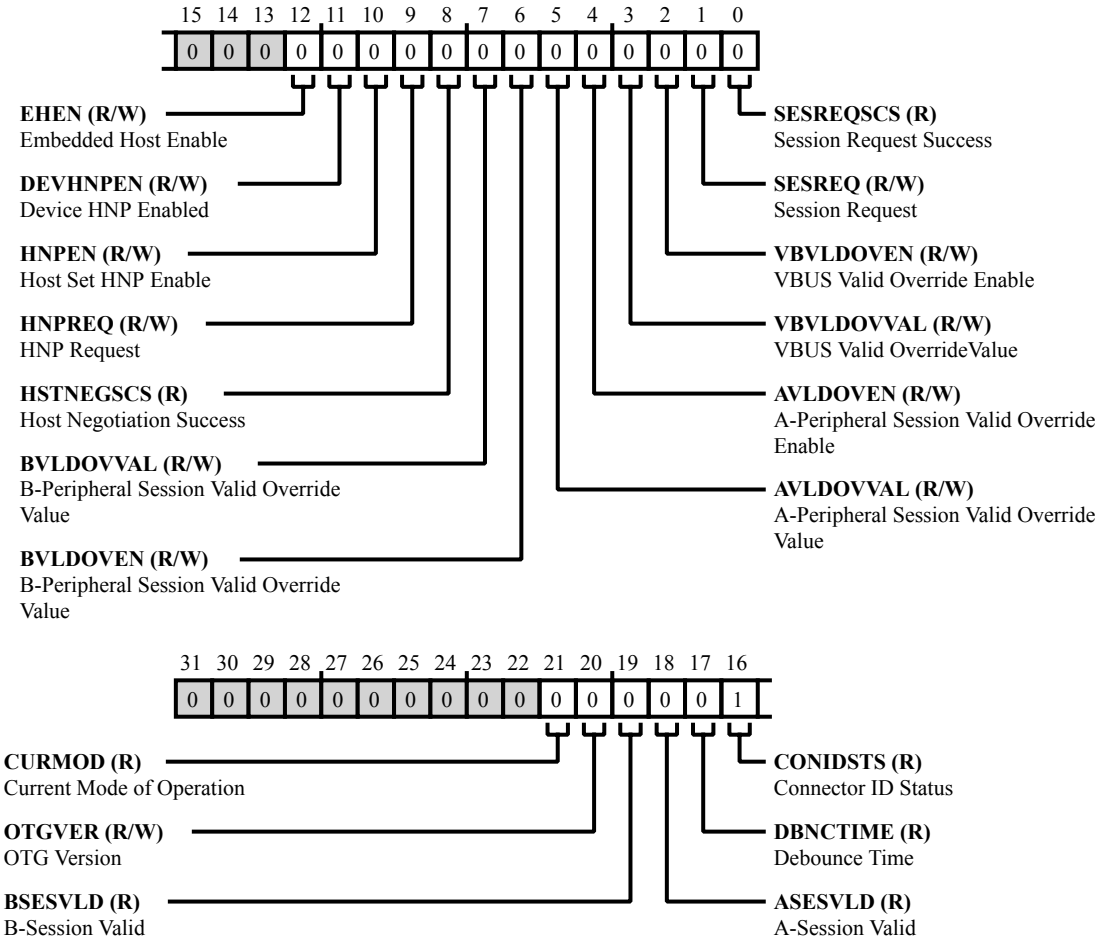

Figure 21-56: USBC_OTG_CTL Register Diagram

Table 21-51: USBC_OTG_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
21 (R/NW)	CURMOD	Current Mode of Operation. Current Mode of Operation (CurMod) Mode: Host and Device The USBC_OTG_CTL.CURMOD bit indicates the current mode. Reset:1'b0 Note: The reset value of this register field can be read only after the PHY clock is stable.	
		0	Host Mode
		1	Device Mode

Table 21-51: USBC_OTG_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
20 (R/W)	OTGVER	OTG Version. The USBC_OTG_CTL.OTGVER bit indicates the OTG revision.	
		0	OTG Version 1.3: Core supports data line pulsing and VBus pulsing for SRP
		1	OTG Version 2.0: Core supports only data line pulsing for SRP
19 (R/NW)	BSESVLD	B-Session Valid. Mode: Device only The USBC_OTG_CTL.BSESVLD bit indicates the device mode transceiver status. In OTG mode, the USBC_OTG_CTL.BSESVLD bit is used to determine if the device is connected or disconnected. Note:The reset value of the USBC_OTG_CTL.BSESVLD bit is 1'b0. - The reset value of this register field can be read only after the PHY clock is stable.	
		0	B-session is not valid
		1	B-session is valid
18 (R/NW)	ASESVLD	A-Session Valid. Mode: Host only The USBC_OTG_CTL.ASESVLD bit indicates the host mode transceiver status. Note:The reset value of the USBC_OTG_CTL.ASESVLD bit is 1'b0.	
		0	A-session is not valid
		1	A-session is valid
17 (R/NW)	DBNCTIME	Debounce Time. Mode: Host only The USBC_OTG_CTL.DBNCTIME bit indicates the debounce time of a detected connection.	
		0	Long debounce time, used for physical connections (100 ms + 2.5 micro-sec)
		1	Short debounce time, used for soft connections (2.5 micro-sec)

Table 21-51: USBC_OTG_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/NW)	CONIDSTS	Connector ID Status. Mode: Host and Device The `USBC_OTG_CTL.CONIDSTS` bit indicates the connector ID status on a connect event. Note: The reset value of this register field can be read only after the PHY clock is stable	
		0	The core is in A-Device mode
		1	The core is in B-Device mode
12 (R/W)	EHEN	Embedded Host Enable. Mode: SRP Capable Host The `USBC_OTG_CTL.EHEN` bit is used to select between OTG A device state machine and embedded host state machine.	
		0	OTG A Device state machine is selected
		1	Embedded Host State Machine is selected
11 (R/W)	DEVHNPEN	Device HNP Enabled. Mode: HNP Capable OTG Device The application sets the `USBC_OTG_CTL.DEVHNPEN` bit when it successfully receives a SetFeature.SetHNPEnable command from the connected USB host.	
		0	HNP Not Enabled
		1	HNP Enabled
10 (R/W)	HNPEN	Host Set HNP Enable. Mode: HNP Capable OTG Host The application sets the `USBC_OTG_CTL.HNPEN` bit when it has successfully enabled HNP (using the SetFeature.SetHNPEnable command) on the connected device.	
		0	Host Set HNP is not enabled
		1	Host Set HNP is enabled

Table 21-51: USBC_OTG_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W)	HNPREQ	HNP Request. Mode: HNP Capable OTG Device The application sets the USBC_OTG_CTL.HNPREQ bit to initiate an HNP request to the connected USB host. The application can clear the USBC_OTG_CTL.HNPREQ bit by writing a 0 when the Host Negotiation Success Status Change bit in the OTG Interrupt register (USBC_OTG_IRQ.HNEGSSTSCHG) is set. The controller clears the USBC_OTG_CTL.HNPREQ bit when the USBC_OTG_IRQ.HNEGSSTSCHG bit is cleared.	
		0	No HNP request
		1	HNP request
8 (R/NW)	HSTNEGSCS	Host Negotiation Success. Mode: HNP-capable Device The controller sets the USBC_OTG_CTL.HSTNEGSCS bit when host negotiation is successful. The controller clears the USBC_OTG_CTL.HNPREQ bit is set.	
		0	Host negotiation failure
		1	Host negotiation success
7 (R/W)	BVLDOVVAL	B-Peripheral Session Valid Override Value. Mode: Device only The USBC_OTG_CTL.BVLDOVVAL bit is used to set Override value for Bvalid signal when the USBC_OTG_CTL.BVLDOVEN bit is set.	
		0	Bvalid value is 0
		1	Bvalid value is 1
6 (R/W)	BVLDOVEN	B-Peripheral Session Valid Override Value. Mode: Device only The USBC_OTG_CTL.BVLDOVEN bit is used to enable/disable the software to override the Bvalid signal using the USBC_OTG_CTL.BVLDOVVAL bit.	
		0	Override is disabled and bvalid signal from the respective PHY selected is used internally by the force
		1	Internally Bvalid received from the PHY is overridden

Table 21-51: USBC_OTG_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (R/W)	AVLDOVVAL	A-Peripheral Session Valid Override Value. Mode: Host only The USBC_OTG_CTL.AVLDOVVAL bit is used to set override value for the Avalid signal when the USBC_OTG_CTL.AVLDOVEN bit is set.	
		0	Avalid value is 0
		1	Avalid value is 1
4 (R/W)	AVLDOVEN	A-Peripheral Session Valid Override Enable. Mode: Host only The USBC_OTG_CTL.AVLDOVEN bit is used to enable/disable the software to override the Avalid signal using the USBC_OTG_CTL.AVLDOVVAL bit.	
		0	Override is disabled and Avalid signal from the respective PHY selection is used internally by the core
		1	Internally Avalid received from the PHY is overridden
3 (R/W)	VBVLDOVVAL	VBUS Valid OverrideValue. Mode: Host only The USBC_OTG_CTL.VBVLDOVVAL bit is used to set override value for vbusvalid signal when the USBC_OTG_CTL.VBVLDOVEN is set.	
		0	vbusvalid value is 0
		1	vbusvalid value is 1
2 (R/W)	VBVLDOVEN	VBUS Valid Override Enable. Mode: Host only The USBC_OTG_CTL.VBVLDOVEN bit is used to enable/disable the software to override the Bvalid signal using the USBC_OTG_CTL.VBVLDOVVAL bit.	
		0	Override is disabled and bvalid signal from the respective PHY selected is used internally by the controller
		1	Internally Bvalid received from the PHY is overridden

Table 21-51: USBC_OTG_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W)	SESREQ	Session Request. Mode: Device only The application sets the USBC_OTG_CTL.SESREQ bit to initiate a session request on the USB. The application can clear the USBC_OTG_CTL.SESREQ bit by writing a 0 when the Host Negotiation Success Status Change bit in the OTG Interrupt register (USBC_OTG_IRQ.HNEGSSTSCHG) is set. The core clears the USBC_OTG_CTL.SESREQ bit when the USBC_OTG_IRQ.HNEGSSTSCHG bit is cleared. If you use the USB 1.1 Full-Speed Serial Transceiver interface to initiate the session request, the application must wait until the VBUS discharges to 0.2 V, after the B-Session Valid bit in this register (USBC_OTG_CTL.BSESVLD) is cleared. This discharge time varies between different PHYs and can be obtained from the PHY vendor.	
		0	No session request
		1	Session request
0 (R/NW)	SESREQSCS	Session Request Success. Mode: Device only The core sets the USBC_OTG_CTL.SESREQSCS bit when a session request initiation is successful.	
		0	Failure
		1	Success

OTG Interrupt Register

The application reads the USBC_OTG_IRQ register whenever there is an OTG interrupt and clears the bits in this register to clear the OTG interrupt.

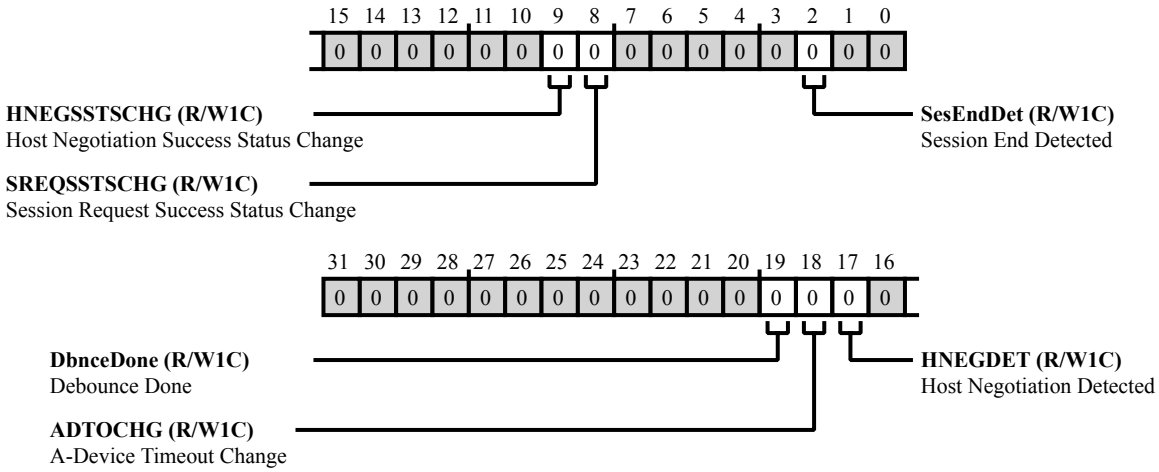

Figure 21-57: USBC_OTG_IRQ Register Diagram

Table 21-52: USBC_OTG_IRQ Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
19 (R/W1C)	DBNCEDONE	Debounce Done. Mode: Host only The core sets the USBC_OTG_IRQ.DBNCEDONE bit when the debounce is completed after the device connect. The application can start driving USB reset after seeing this interrupt. This bit is only valid when the HNP Capable (USBC_CFG.HNPCAP) or SRP Capable (${.:GUSBCFG:SRPCap) is set. This bit can be set only by the core and the application should write 1 to clear it.
18 (R/W1C)	ADTOCHG	A-Device Timeout Change. Mode: Host and Device The core sets the USBC_OTG_IRQ.ADTOCHG bit to indicate that the A-device has timed out while waiting for the B-device to connect. This bit can be set only by the core and the application should write 1 to clear it.
17 (R/W1C)	HNEGDET	Host Negotiation Detected. Mode:Host and Device The core sets the USBC_OTG_IRQ.HNEGDET bit when it detects a host negotiation request on the USB. This bit can be set only by the core and the application should write 1 to clear it.

Table 21-52: USBC_OTG_IRQ Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
9 (R/W1C)	HNEGSSTSCHG	Host Negotiation Success Status Change. Mode: Host and Device The core sets the `USBC_OTG_IRQ.HNEGSSTSCHG` bit on the success or failure of a USB host negotiation request. The application must read the Host Negotiation Success bit (`USBC_OTG_CTL.HSTNEGSCS`) to check for success or failure. This bit can be set only by the core and the application should write 1 to clear it.
8 (R/W1C)	SREQSSTSCHG	Session Request Success Status Change. Mode: Host and Device The core sets the `USBC_OTG_IRQ.SREQSSTSCHG` bit on the success or failure of a session request. The application must read the Session Request Success bit in the OTG Control and Status register (`USBC_OTG_CTL.SESREQSCS`) to check for success or failure. This bit can be set only by the core and the application should write 1 to clear it.
2 (R/W1C)	SESENDDET	Session End Detected. Mode: Host and Device This bit can be set only by the core and the application should write 1 to clear it.

PHY Interface Control Register

The application can use the USBC_PHYIF_CTL register to access PHY registers.

The application sets the USBC_PHYIF_CTL register for PHY register access. The application polls the VStatus Done bit in USBC_PHYIF_CTL register for the completion of the PHY register access.

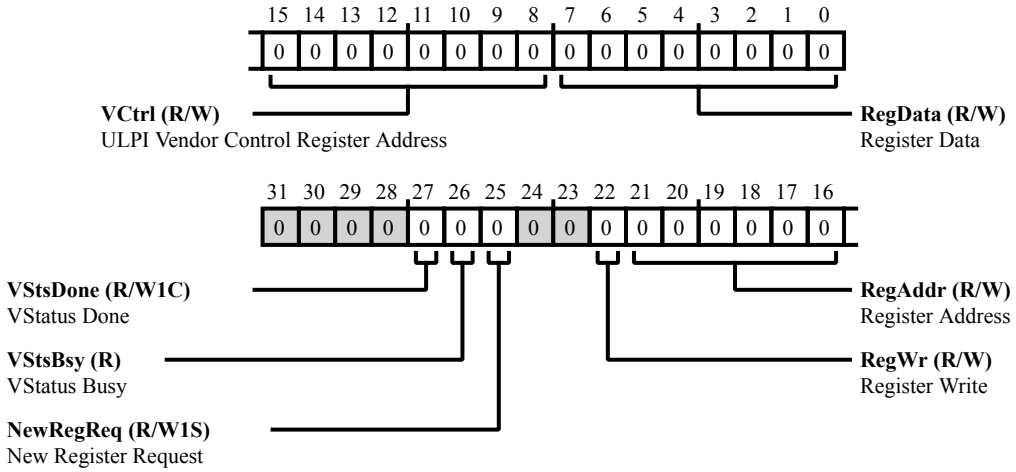

Figure 21-58: USBC_PHYIF_CTL Register Diagram

Table 21-53: USBC_PHYIF_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
27 (R/W1C)	VSTSDONE	VStatus Done. The core sets the USBC_PHYIF_CTL.VSTSDONE bit when the vendor control access is done. This bit is cleared by the core when the application sets the New Register Request bit (USBC_PHYIF_CTL.NEWREGREQ).
26 (R/NW)	VSTSBSY	VStatus Busy. The core sets the USBC_PHYIF_CTL.VSTSBSY bit when the vendor control access is in progress and clears this bit when done.
25 (R/W1S)	NEWREGREQ	New Register Request. The application sets the USBC_PHYIF_CTL.NEWREGREQ bit for a new vendor control access.
22 (R/W)	REGWR	Register Write. Set the USBC_PHYIF_CTL.REGWR bit for register writes and clear it for register reads.
21:16 (R/W)	REGADDR	Register Address. The 6-bit PHY register address for immediate PHY Register set access. Set the USBC_PHYIF_CTL.REGADDRfield to 0x2F for Extended PHY Register set access.

Table 21-53: USBC_PHYIF_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15:8 (R/W)	VCTRL	ULPI Vendor Control Register Address. The 4-bit register address a vendor defined 4-bit parallel output bus. Bits 11:8 of this field are placed on utmi_vcontrol[3:0]. ULPI Extended Register Address (ExtRegAddr) The 6-bit PHY extended register address.
7:0 (R/W)	REGDATA	Register Data. The `USBC_PHYIF_CTL.REGDATA` bit field contains the write data for register write. Read data for register read is valid when the `USBC_PHYIF_CTL.VSTSDONE` bit is set.

Reset Register

The USBC_RST_CTL register resets various hardware features inside the controller.

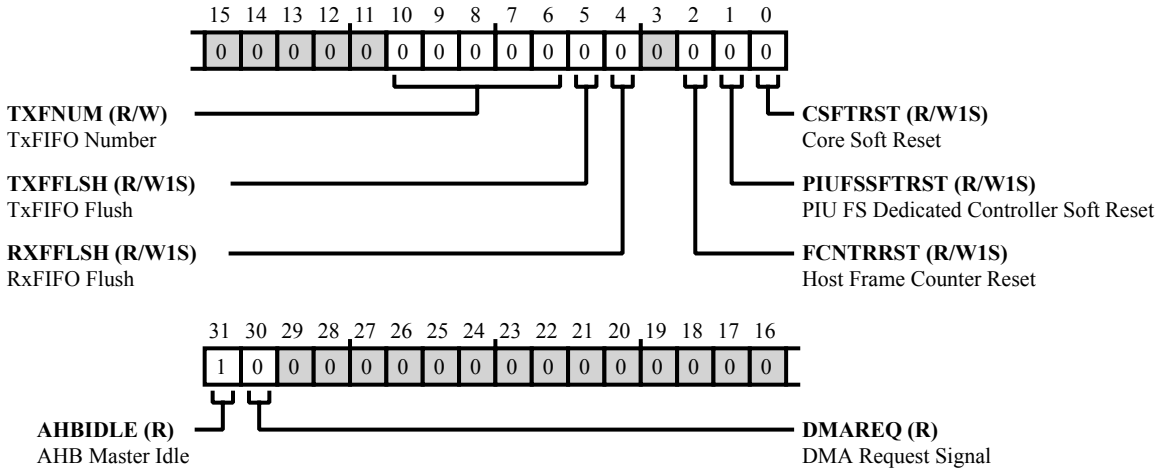

Figure 21-59: USBC_RST_CTL Register Diagram

Table 21-54: USBC_RST_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/NW)	AHBIDLE	AHB Master Idle. Mode: Host and Device The USBC_RST_CTL.AHBIDLE bit indicates that the bus master state machine is in the IDLE condition.	
30 (R/NW)	DMAREQ	DMA Request Signal. Mode: Host and Device The USBC_RST_CTL.DMAREQ bit indicates that the DMA request is in progress. Used for debug.	
10:6 (R/W)	TXFNUM	TxFIFO Number. Mode: Host and Device This is the FIFO number that must be flushed using the TxFIFO Flush bit. This field must not be changed until the core clears the TxFIFO Flush bit.	
		0	Non-periodic TxFIFO flush in host mode Non-periodic TxFIFO flush in device mode when in shared FIFO operation Tx FIFO 0 flush in device mode when in dedicated FIFO mode

Table 21-54: USBC_RST_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		1	Non-periodic TxFIFO flush in host mode Non-periodic TxFIFO 1 flush in device mode when in shared FIFO operation Tx FIFO 1 flush in device mode when in dedicated FIFO mode
		2	Non-periodic TxFIFO flush in host mode Non-periodic TxFIFO 2 flush in device mode when in shared FIFO operation Tx FIFO 2 flush in device mode when in dedicated FIFO mode
		3	Non-periodic TxFIFO flush in host mode Non-periodic TxFIFO 3 flush in device mode when in shared FIFO operation Tx FIFO 3 flush in device mode when in dedicated FIFO mode
		4	Non-periodic TxFIFO flush in host mode Non-periodic TxFIFO 4 flush in device mode when in shared FIFO operation Tx FIFO 4 flush in device mode when in dedicated FIFO mode
		5	Non-periodic TxFIFO flush in host mode Non-periodic TxFIFO 5 flush in device mode when in shared FIFO operation Tx FIFO 5 flush in device mode when in dedicated FIFO mode
		6	Non-periodic TxFIFO flush in host mode Non-periodic TxFIFO 6 flush in device mode when in shared FIFO operation Tx FIFO 6 flush in device mode when in dedicated FIFO mode
		7	Non-periodic TxFIFO flush in host mode Non-periodic TxFIFO 7 flush in device mode when in shared FIFO operation Tx FIFO 7 flush in device mode when in dedicated FIFO mode

Table 21-54: USBC_RST_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		8	Non-periodic TxFIFO flush in host mode Non-periodic TxFIFO 8 flush in device mode when in shared FIFO operation Tx FIFO 8 flush in device mode when in dedicated FIFO mode
		9	Non-periodic TxFIFO flush in host mode Non-periodic TxFIFO 9 flush in device mode when in shared FIFO operation Tx FIFO 9 flush in device mode when in dedicated FIFO mode
		10	Non-periodic TxFIFO flush in host mode Non-periodic TxFIFO 10 flush in device mode when in shared FIFO operation Tx FIFO 10 flush in device mode when in dedicated FIFO mode
		11	Non-periodic TxFIFO flush in host mode Non-periodic TxFIFO 11 flush in device mode when in shared FIFO operation Tx FIFO 11 flush in device mode when in dedicated FIFO mode
		12	Non-periodic TxFIFO flush in host mode Non-periodic TxFIFO 12 flush in device mode when in shared FIFO operation Tx FIFO 12 flush in device mode when in dedicated FIFO mode
		13	Non-periodic TxFIFO flush in host mode Non-periodic TxFIFO 13 flush in device mode when in shared FIFO operation Tx FIFO 13 flush in device mode when in dedicated FIFO mode
		14	Non-periodic TxFIFO flush in host mode Non-periodic TxFIFO 14 flush in device mode when in shared FIFO operation Tx FIFO 14 flush in device mode when in dedicated FIFO mode

Table 21-54: USBC_RST_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		15	Non-periodic TxFIFO flush in host mode Non-periodic TxFIFO 15 flush in device mode when in shared FIFO operation Tx FIFO 15 flush in device mode when in dedicated FIFO mode
		16	Flush all transmit FIFOs in device or host mode
5 (R/W1S)	TXFFLSH	TxFIFO Flush. Mode: Host and Device The USBC_RST_CTL.TXFFLSH bit selectively flushes a single or all transmit FIFOs, but cannot do so If the core is in the midst of a transaction. The application must write this bit only after checking that the core is neither writing to the TxFIFO nor reading from the TxFIFO. Verify using these registers: - Read the NAK Effective Interrupt to ensure the core is not reading from the FIFO. - Write the USBC_RST_CTL.AHBIDLE bit to ensure the core is not writing anything to the FIFO. Flushing is normally recommended when FIFOs are reconfigured. FIFO flushing is also recommended during device endpoint disable. The application must wait until the core clears this bit before performing any operations. This bit takes eight clocks to clear, using the slower of PHY or bus clock.	
4 (R/W1S)	RXFFLSH	RxFIFO Flush. Mode: Host and Device The application can flush the entire RxFIFO using the USBC_RST_CTL.RXFFLSH bit, but must first ensure that the core is not in the middle of a transaction. The application must only write to the USBC_RST_CTL.RXFFLSH bit after checking that the controller is neither reading from the RxFIFO nor writing to the RxFIFO. The application must wait until the USBC_RST_CTL.RXFFLSH bit is cleared before performing any other operations. This bit requires eight clocks (slowest of PHY or bus clock) to clear.	
2 (R/W1S)	FCNTRRST	Host Frame Counter Reset. Mode: Host only The application writes to the USBC_RST_CTL.FCNTRRST bit to reset the (micro)frame number counter inside the core. When the (micro)frame counter is reset, the subsequent SOF sent out by the core has a (micro)frame number of 0. When application writes 1 to the bit, it might not be able to read back the value as it will get cleared by the core in a few clock cycles.	

Table 21-54: USBC_RST_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
1 (R/W1S)	PIUFSSFTRST	PIU FS Dedicated Controller Soft Reset. Mode: Host and Device The `USBC_RST_CTL.PIUFSSFTRST` bit resets the PIU FS dedicated controller. All module state machines in FS dedicated controller of the PIU are reset to the IDLE state. The bit is used to reset the FS dedicated controller in PIU in case of any PHY errors like loss of activity or babble error resulting in the PHY remaining in RX state for more than one frame boundary. The `USBC_RST_CTL.PIUFSSFTRST` bit is a self clearing bit and core clears this bit after all the necessary logic is reset in the core.
0 (R/W1S)	CSFTRST	Core Soft Reset. Mode: Host and Device Resets the hclk and phy_clock domains as follows: - Clears the interrupts and all the CSR registers except the following register bits: `USBC_PWR_CTL.RSTPDWNMODULE`, `USBC_CFG.FRCDEVMOD`, `USBC_CFG.FRCHSTMOD`, `USBC_CFG.DDRSEL`, `USBC_CFG.PHYSEL`, `USBC_CFG.FSINTF`, `USBC_CFG.ULPI_UTMI_SEL`, `USBC_CFG.PHYIF`, `USBC_CFG.TXENDDLY`, `USBC_CFG.TSDLPULSE`, `USBC_CFG.CLKSUSM`, `USBC_CFG.AUTORES`, `USBC_CFG_H.PCLKSEL`, `USBC_CFG_D.SPD`, and `USBC_CTL_D.SFTDISCON`: - All module state machines: - All module state machines (except the bus completer unit) are reset to the IDLE state, and all the transmit FIFOs and the receive FIFO are flushed.: - Any transactions on the bus requester are terminated as soon as possible, after gracefully completing the last data phase of a bus transfer. Any transactions on the USB are terminated immediately.: The application can write to this bit any time it wants to reset the core. This is a self-clearing bit and the core clears this bit after all the necessary logic is reset in the core, which can take several clocks, depending on the current state of the core. Once this bit is cleared software must wait at least 3 PHY clocks before doing any access to the PHY domain (synchronization delay). Software must also must check that bit 31 of this register is 1 (bus requester is IDLE) before starting any operation. Typically software reset is used during software development and also when dynamically changing the PHY selection bits in the USB configuration registers listed above. When the PHY is changed, the corresponding clock for the PHY is selected and used in the PHY domain. Once a new clock is selected, the PHY domain has to be reset for proper operation.

Receive FIFO Size Register

The USBC_RXFIFOSZ register indicates the RAM size that must be allocated to the RxFIFO.

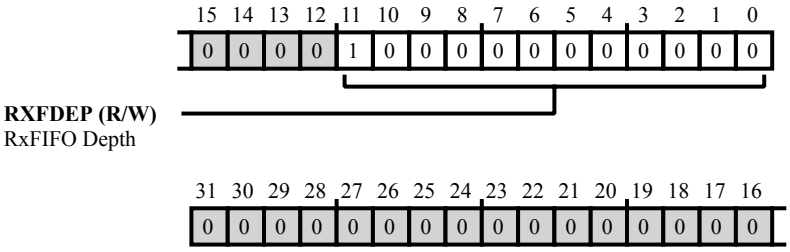

Figure 21-60: USBC_RXFIFOSZ Register Diagram

Table 21-55: USBC_RXFIFOSZ Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
11:0 (R/W)	RXFDEP	RxFIFO Depth. Mode: Host and Device The USBC_RXFIFOSZ.RXFDEP field indicates the RxFIFO depth. This value is in terms of 32-bit words. - Minimum value is 16 - Maximum value is 32,768 The power-on reset value of this register is specified as the largest Rx data FIFO depth The reset value is 2048.

Receive Status Read/Pop Register

A read to the USBC_RXDATA_STAT register returns the contents of the top of the receive FIFO and additionally pops the top data entry out of the RxFIFO.

The receive status contents must be interpreted differently in host and device modes. The core ignores the receive status pop/read when the receive FIFO is empty and returns a value of 32'h0000_0000. The application must only pop the receive status FIFO when the receive FIFO non-empty bit of the core interrupt register (USBC_ISTAT.RXFLVI) is asserted.

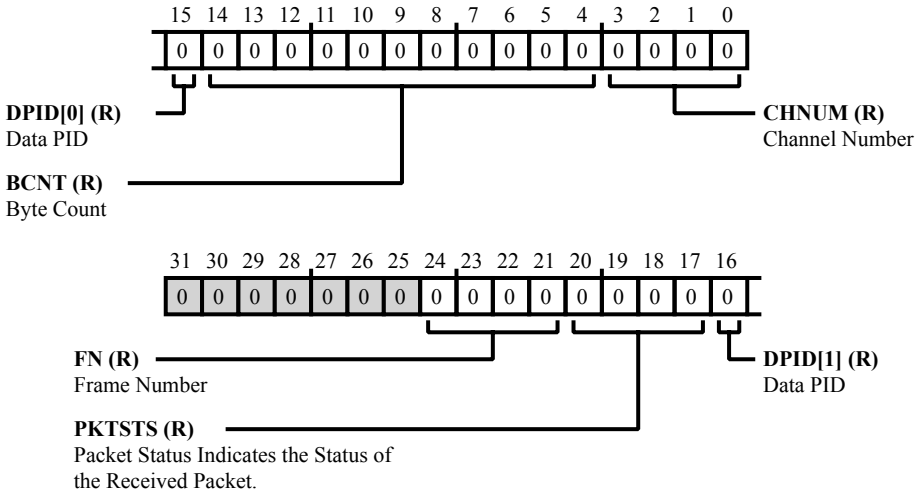

Figure 21-61: USBC_RXDATA_STAT Register Diagram

Table 21-56: USBC_RXDATA_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
24:21 (R/NW)	FN	Frame Number. Mode: Device only The USBC_RXDATA_STAT.FN bit field is the least significant 4 bits of the (micro)Frame number in which the packet is received on the USB. This field is supported only when isochronous OUT endpoints are supported.

Table 21-56: USBC_RXDATA_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
20:17 (R/NW)	PKTSTS	Packet Status Indicates the Status of the Received Packet.. In host mode, - 4'b0010: IN data packet received - 4'b0011: IN transfer completed (triggers an interrupt) - 4'b0101: Data toggle error (triggers an interrupt) - 4'b0111: Channel halted (triggers an interrupt) - Others: Reserved Reset:4'b0 In device mode, - 4'b0001: Global OUT NAK (triggers an interrupt) - 4'b0010: OUT data packet received - 4'b0011: OUT transfer completed (triggers an interrupt) - 4'b0100: SETUP transaction completed (triggers an interrupt) - 4'b0110: SETUP data packet received - Others: Reserved Reset:4'h0
16:15 (R/NW)	DPID	Data PID. In host mode, the `USBC_RXDATA_STAT.DPID` bit field indicates the data PID of the received packet. In device mode, the `USBC_RXDATA_STAT.DPID` bit field indicates the data PID of the received OUT data packet. Reset: 2'h0
		0 DATA0
		1 DATA1
		2 DATA2
		3 MDATA
14:4 (R/NW)	BCNT	Byte Count. In host mode, the `USBC_RXDATA_STAT.BCNT` bit indicates the byte count of the received IN data packet. In device mode, the `USBC_RXDATA_STAT.BCNT` bit indicates the byte count of the received data packet.

Table 21-56: USBC_RXDATA_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
3:0 (R/NW)	CHNUM	Channel Number. Mode: Host only The `USBC_RXDATA_STAT.CHNUM` bit indicates the channel number to which the current received packet belongs. Endpoint Number (EPNum) Mode: Device only The `USBC_RXDATA_STAT.CHNUM` bit indicates the endpoint number to which the current received packet belongs.

Receive Status Debug Read Register

A read to the USBC_RXDBG_STAT register returns the contents of the top of the receive FIFO.

The receive status contents must be interpreted differently in Host and device modes. The core ignores the receive status read when the receive FIFO is empty and returns a value of 32'h0000_0000.

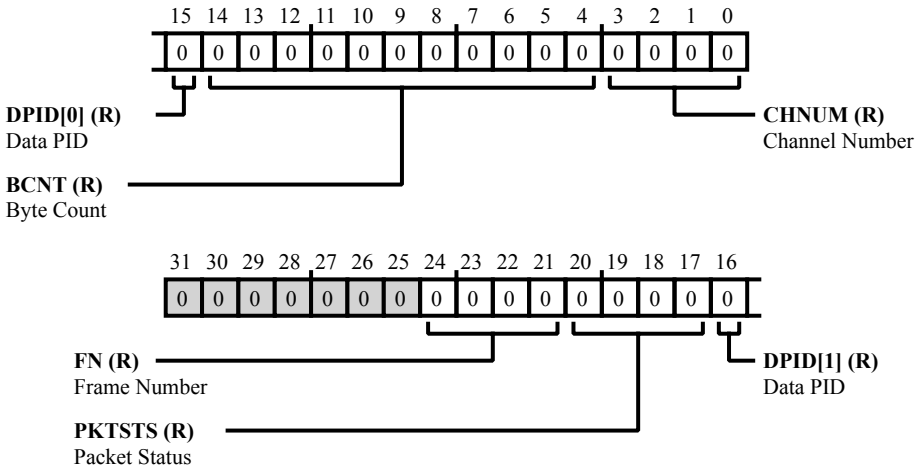

Figure 21-62: USBC_RXDBG_STAT Register Diagram

Table 21-57: USBC_RXDBG_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
24:21 (R/NW)	FN	Frame Number. Mode: Device only The USBC_RXDBG_STAT.FN field is the least significant 4 bits of the (micro)frame number in which the packet is received on the USB. This field is supported only when isochronous OUT endpoints are supported.

Table 21-57: USBC_RXDBG_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
20:17 (R/NW)	PKTSTS	Packet Status. In host mode, the `USBC_RXDBG_STAT.PKTSTS`field indicates the status of the received packet. - 4'b0010: IN data packet received - 4'b0011: IN transfer completed (triggers an interrupt) - 4'b0101: Data toggle error (triggers an interrupt) - 4'b0111: Channel halted (triggers an interrupt) - Others: Reserved Reset:4'b0 In device mode, - 4'b0001: Global OUT NAK (triggers an interrupt) - 4'b0010: OUT data packet received - 4'b0011: OUT transfer completed (triggers an interrupt) - 4'b0100: SETUP transaction completed (triggers an interrupt) - 4'b0110: SETUP data packet received - Others: Reserved Reset:4'h0	
16:15 (R/NW)	DPID	Data PID. In host mode, the `USBC_RXDBG_STAT.DPID` field indicates the data PID of the received packet. In device mode, the `USBC_RXDBG_STAT.DPID` field indicates the data PID of the received OUT data packet. Reset: 2'h0	
		0	DATA0
		1	DATA2
		2	DATA1
		3	MDATA
14:4 (R/NW)	BCNT	Byte Count. In host mode, the `USBC_RXDBG_STAT.BCNT` field indicates the byte count of the received IN data packet. In device mode, the `USBC_RXDBG_STAT.BCNT` field indicates the byte count of the received data packet.	

Table 21-57: USBC_RXDBG_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
3:0 (R/NW)	CHNUM	Channel Number. Mode: Host only The `USBC_RXDBG_STAT.CHNUM` field indicates the channel number to which the current received packet belongs. Endpoint Number (EPNum) Mode: Device only The `USBC_RXDBG_STAT.CHNUM` field indicates the endpoint number to which the current received packet belongs.

Module ID Register

The USBC_MODID register (read-only) contains the module ID.

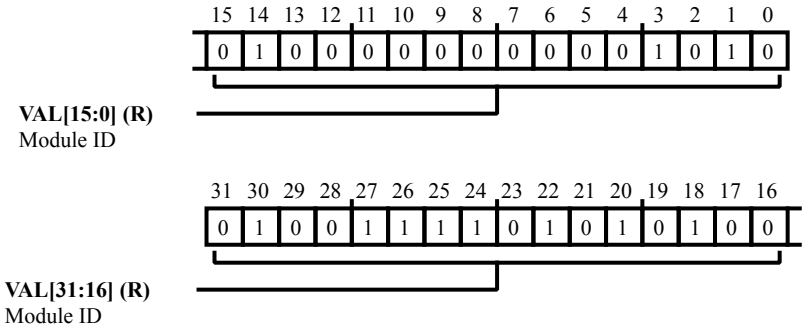

Figure 21-63: USBC_MODID Register Diagram

Table 21-58: USBC_MODID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VAL	Module ID. Module ID of the controller being used currently.

USB Configuration Register

The USBC_CFG register can be used to configure the core after power-on or a changing to host mode or device mode. It contains USB and USB-PHY related configuration parameters. The application must program this register before starting any transactions on either the bus or the USB. Do not make changes to this register after the initial programming.

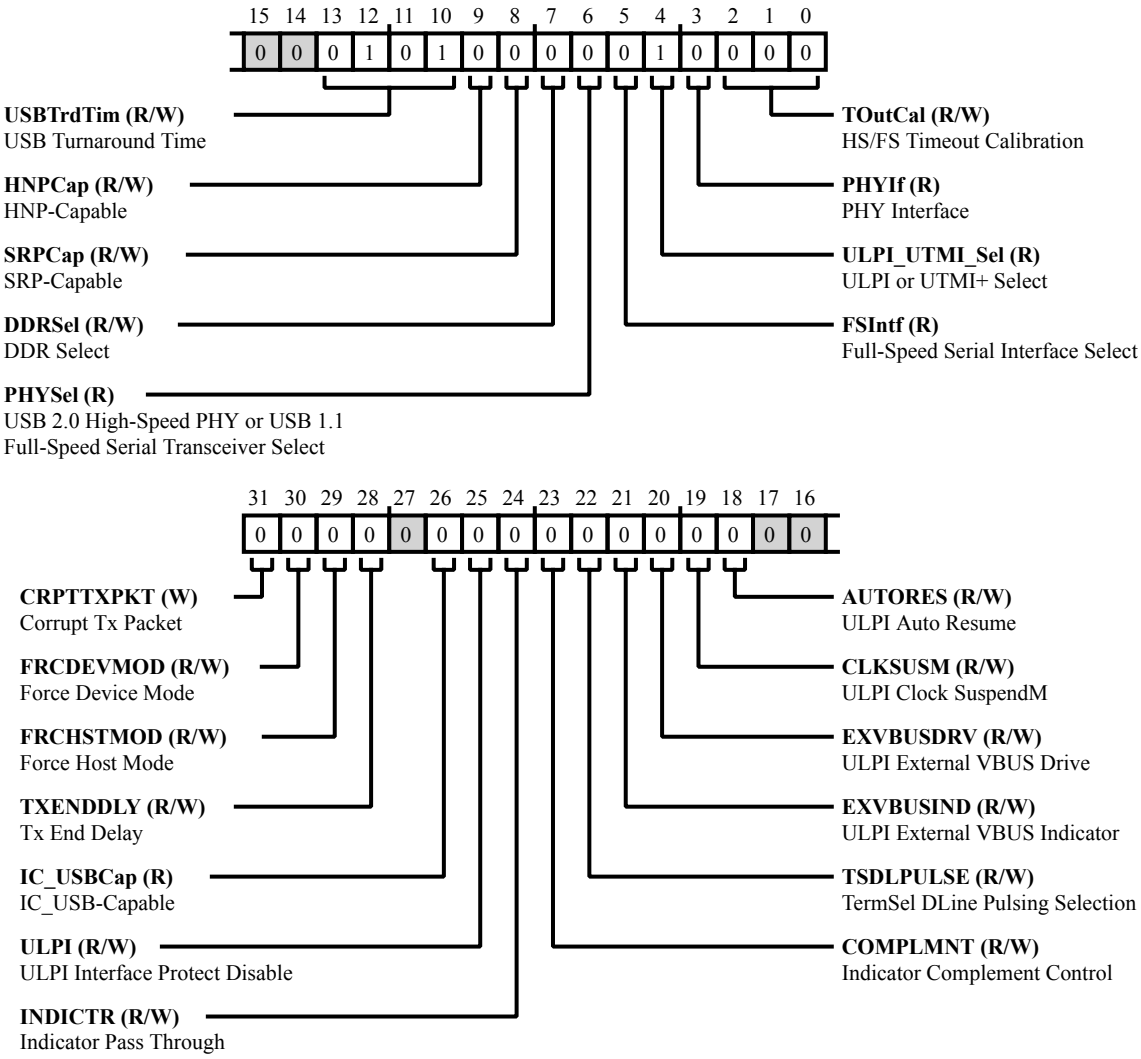

Figure 21-64: USBC_CFG Register Diagram

Table 21-59: USBC_CFG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (RX/W)	CRPTTXPKT	Corrupt Tx Packet. Mode: Host and device The `USBC_CFG.CRPTTXPKT` bit is for debug purposes only. Never set this bit to 1. The application should always write zero to this bit.	
30 (R/W)	FRCDEVMOD	Force Device Mode. Mode:Host and device Writing a 1 to the `USBC_CFG.FRCDEVMOD` bit forces the controller to device mode. After setting the force bit, the application must wait at least 25 ms before the change to take effect.	
		0	Normal Mode
		1	Force Device Mode
29 (R/W)	FRCHSTMOD	Force Host Mode. Mode: Host and device Writing a 1 to the `USBC_CFG.FRCHSTMOD` bit forces the core to host mode. After setting the force bit, the application must wait at least 25 ms before the change to take effect.	
		0	Normal Mode
		1	Force Host Mode
28 (R/W)	TXENDDLY	Tx End Delay. Mode: Device only Writing a one to the `USBC_CFG.TXENDDLY` bit enables the controller to follow the TxEndDelay timings as per UTMI+ specification 1.05 section 4.1.5 for opmode signal during remote wakeup.	
		0	Normal Mode
		1	Tx End Delay
26 (R/NW)	IC_USBCAP	IC_USB-Capable. Mode: Host and Device The application uses the `USBC_CFG.IC_USBCAP` bit to control the core's IC_USB capabilities.	
		0	IC_USB PHY Interface Not Selected
		1	IC_USB PHY Interface Selected

Table 21-59: USBC_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
25 (R/W)	ULPI	ULPI Interface Protect Disable. Mode: Host only Controls circuitry built into the PHY for protecting the ULPI interface when the link tri-states STP and data. Any pull-ups or pull-downs employed by this feature can be disabled.	
		0	Enable Interface Protect Circuit
		1	Disable Interface Protect Circuit
24 (R/W)	INDICTR	Indicator Pass Through. Mode: Host only Controls whether the complement output is qualified with the internal Vbus valid comparator before being used in the Vbus state in the RX CMD.	
		0	Complement Output Signal Qualified with Internal VbusValid Comparator
		1	Complement Output Signal Not Qualified with Internal VbusValid Comparator
23 (R/W)	COMPLMNT	Indicator Complement Control. Mode: Host only The `USBC_CFG.COMPLMNT` bit controls the PHY to invert the ExternalVbusIndicator input signal, generating the complement output.	
		0	Do Not Invert ExternalVbusIndicator Signal
		1	Invert ExternalVbusIndicator Signal
22 (R/W)	TSDLPULSE	TermSel DLine Pulsing Selection. Mode: Device only The `USBC_CFG.TSDLPULSE` bit selects utmi_termselect to drive data line pulse during SRP.	
		0	Data Line Pulsing Using utmi_txvalid (Default)
		1	Data Line Pulsing Using utmi_termsel
21 (R/W)	EXVBUSIND	ULPI External VBUS Indicator. Mode: Host only The `USBC_CFG.EXVBUSIND` bit indicates to the ULPI PHY to use an external VBUS overcurrent indicator.	
		0	Internal VBUS Valid Comparator
		1	External VBUS Valid Comparator

Table 21-59: USBC_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
20 (R/W)	EXVBUSDRV	ULPI External VBUS Drive. Mode: Host only The USBC_CFG.EXVBUSDRV bit selects between internal or external supply to drive 5V on VBUS, in ULPI PHY.	
		0	Internal Charge Pump (Default)
		1	External Supply
19 (R/W)	CLKSUSM	ULPI Clock SuspendM. Mode: Host and Device The USBC_CFG.CLKSUSM bit sets the ClockSuspendM bit in the interface control register on the PHY. This bit applies only in serial or carkit modes.	
		0	PHY powers down internal clock during suspend
		1	PHY does not power down internal clock
18 (R/W)	AUTORES	ULPI Auto Resume. Mode: Host and Device The USBC_CFG.AUTORES bit sets the AutoResume bit in the interface control register on the PHY.	
		0	PHY does not use AutoResume feature
		1	HY uses AutoResume feature
13:10 (R/W)	USBTRDTIM	USB Turnaround Time. Mode: Device only The USBC_CFG.USBTRDTIM bit field the turnaround time in PHY clocks. Specifies the response time for a MAC request to the Packet FIFO Controller (PFC) to fetch data from the DFIFO (SPRAM). This must be programmed as follows: - 4'h5: When the MAC interface is 16-bit UTMI - 4'h9: When the MAC interface is 8-bit UTMI Note: The previous values are calculated for the minimum bus frequency of 30 MHz. USB turnaround time is critical for certification where long cables and 5-Hubs are used. If the bus needs to run at less than 30 MHz and the USB turnaround time is not critical, these bits can be programmed to a larger value.	

Table 21-59: USBC_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W)	HNPCAP	HNP-Capable. Mode: Host and Device The `USBC_CFG.HNPCAP` bit is for configuring the controller HNP capabilities. If HNP functionality is disabled by the software, the OTG signals on the PHY domain must be tied to the appropriate values.	
		0	HNP Capability Disabled
		1	HNP Capability Enabled
8 (R/W)	SRPCAP	SRP-Capable. Mode: Host and Device The `USBC_CFG.SRPCAP` bit is for configuring the controller SRP capabilities. If the core operates as a non-SRP-capable B-device, it cannot request the connected A-device (host) to activate VBUS and start a session. If SRP functionality is disabled by the software, the OTG signals on the PHY domain must be tied to the appropriate values.	
		0	SRP Capability Disabled
		1	SRP Capability Enabled
7 (R/W)	DDRSEL	DDR Select. Mode: Host and Device The application uses the `USBC_CFG.DDRSEL` bit to select a single data rate (SDR) or double data rate (DDR) for the USBC interface.	
		0	Single Data Rate USBC Interface: 8-bit-wide data bus
		1	Double Data Rate USBC Interface: 4-bit-wide data bus
6 (R/NW)	PHYSEL	USB 2.0 High-Speed PHY or USB 1.1 Full-Speed Serial Transceiver Select. Mode: Host and Device The application uses the `USBC_CFG.PHYSEL` bit to select either a high-speed UTMI+ or ULPI PHY, or a full-speed transceiver. This bit is always 0, with read only access.	
		0	USB 2.0 high-speed UTMI+ or ULPI PHY
		1	USB 1.1 full-speed serial transceiver

Table 21-59: USBC_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (R/NW)	FSINTF	Full-Speed Serial Interface Select. Mode: Host and Device The application uses the `USBC_CFG.FSINTF` bit to select either a unidirectional or bidirectional USB 1.1 full-speed serial transceiver interface.	
		0	6-pin unidirectional full-speed serial interface
		1	3-pin bidirectional full-speed serial interface
4 (R/NW)	ULPI_UTMI_SEL	ULPI or UTMI+ Select. Mode: Host and Device The application uses the `USBC_CFG.ULPI_UTMI_SEL` bit to select either a UTMI + interface or ULPI Interface.	
		0	UTMI+ Interface
		1	ULPI Interface
3 (R/NW)	PHYIF	PHY Interface. Mode: Host and Device The application uses this bit to configure the core to support a ULPI PHY with an 8- or 16-bit interface.	
		0	8 bits
		1	16 bits

Table 21-59: USBC_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
2:0 (R/W)	TOUTCAL	HS/FS Timeout Calibration. Mode: Host and Device The number of PHY clocks that the application programs in this field is added to the high-speed/full-speed interpacket timeout duration in the core to account for any additional delays introduced by the PHY. This can be required, because the delay introduced by the PHY in generating the linestate condition can vary from one PHY to another. The USB standard timeout value for high-speed operation is 736 to 816 (inclusive) bit times. The USB standard timeout value for full-speed operation is 16 to 18 (inclusive) bit times. The application must program this field based on the speed of enumeration. The number of bit times added per PHY clock are as follows: High-speed operation: - One 30-MHz PHY clock = 16 bit times - One 60-MHz PHY clock = 8 bit times Full-speed operation: - One 30-MHz PHY clock = 0.4 bit times - One 60-MHz PHY clock = 0.2 bit times - One 48-MHz PHY clock = 0.25 bit times

Host All Channels Interrupt Register

When a significant event occurs on a channel, the `USBC_ISTAT_H` register interrupts the application using the `USBC_ISTAT.HCHINT` bit. There is one interrupt bit per channel, up to a maximum of 16 bits. Bits in this register are set and cleared when the application sets and clears bits in the corresponding host channel n interrupt register.

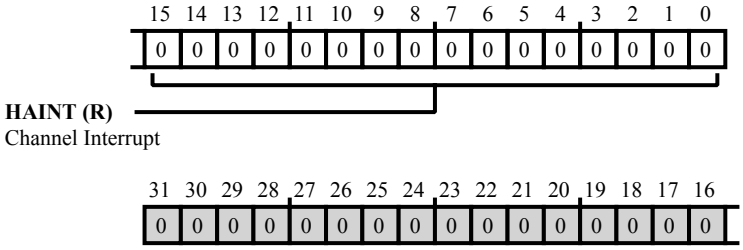

Figure 21-65: USBC_ISTAT_H Register Diagram

Table 21-60: USBC_ISTAT_H Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	HAINT	Channel Interrupt. Channel Interrupt for channel no.

Host All Channels Interrupt Mask Register

The USBC_IMSK_H register works with the Host All Channel Interrupt register to interrupt the application when an event occurs on a channel. There is one interrupt mask bit per channel, up to a maximum of 16 bits.

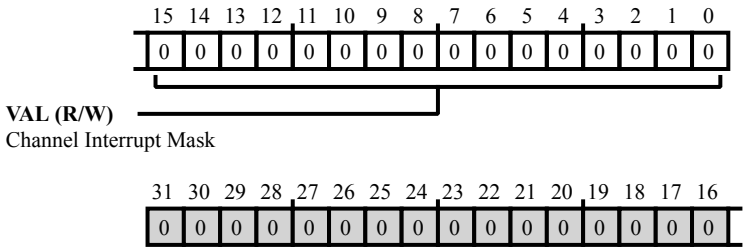

Figure 21-66: USBC_IMSK_H Register Diagram

Table 21-61: USBC_IMSK_H Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VAL	Channel Interrupt Mask. One bit per channel: Bit 0 for channel 0, bit 15 for channel 15

Host Channel n Characteristics Register

The USBC_CHAR[n]_H register indicates the characteristics of the host channel n.

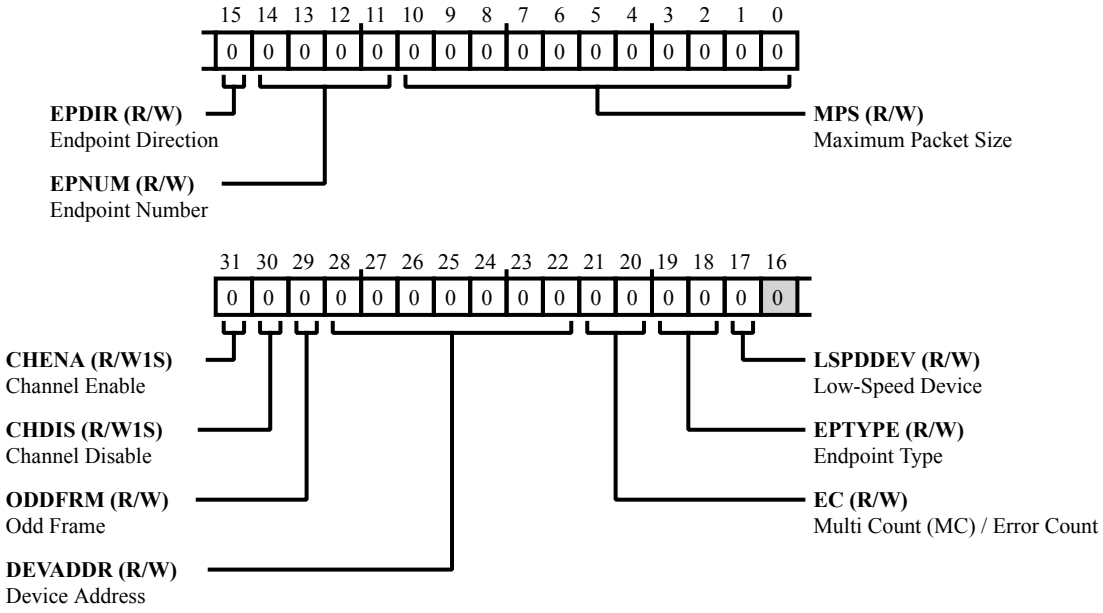

Figure 21-67: USBC_CHAR[n]_H Register Diagram

Table 21-62: USBC_CHAR[n]_H Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W1S)	CHENA	Channel Enable. When scatter/gather mode is enabled, the USBC_CHAR[n]_H.CHENA bit indicates that: - 1'b0: the descriptor structure is not yet ready. - 1'b1: the descriptor structure and data buffer with data is setup and this channel can access the descriptor. When scatter/gather mode is disabled, the USBC_CHAR[n]_H.CHENA bit set by the application and cleared by the OTG host. - 1'b0: Channel disabled - 1'b1: Channel enabled
30 (R/W1S)	CHDIS	Channel Disable. The application sets the USBC_CHAR[n]_H.CHDIS bit to stop transmitting/receiving data on a channel, even before the transfer for that channel is complete. The application must wait for the channel disabled interrupt before treating the channel as disabled.

Table 21-62: USBC_CHAR[n]_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
29 (R/W)	ODDFRM	Odd Frame. The USBC_CHAR[n]_H.ODDFRM bit is set (reset) by the application to indicate that the OTG host must perform a transfer in an odd (micro)frame. The USBC_CHAR[n]_H.ODDFRM bit is applicable for only periodic (isochronous and interrupt) transactions.	
		0	Even (micro)frame
		1	Odd (micro)frame
28:22 (R/W)	DEVADDR	Device Address. The USBC_CHAR[n]_H.DEVADDR field selects the specific device serving as the data source or sink.	
21:20 (R/W)	EC	Multi Count (MC) / Error Count. When the Split Enable bit of the Host Channel-n Split Control register (USBC_SPLT_CTL[n]_H.SPLTENA) is reset (=0), the USBC_CHAR[n]_H.EC field indicates to the host the number of transactions that must be executed per micro-frame for this periodic endpoint. For non periodic transfers, the USBC_CHAR[n]_H.EC field is used only in DMA mode and specifies the number packets to be fetched for this channel before the internal DMA engine changes arbitration. When the USBC_SPLT_CTL[n]_H.SPLTENA is set (=1), the USBC_CHAR[n]_H.EC field indicates the number of immediate retries to be performed for a periodic split transactions on transaction errors. The USBC_CHAR[n]_H.EC bit field must be set to at least 2'b01.	
		0	Reserved
		1	1
		2	2
		3	3
19:18 (R/W)	EPTYPE	Endpoint Type. The USBC_CHAR[n]_H.EPTYPE field indicates the transfer type selected.	
		0	Control
		1	Isochronous
		2	Bulk
		3	Interrupt
17 (R/W)	LSPDDEV	Low-Speed Device. The USBC_CHAR[n]_H.LSPDDEV bit is set by the application to indicate that this channel is communicating to a low-speed device.	

Table 21-62: USBC_CHAR[n]_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	EPDIR	Endpoint Direction. The `USBC_CHAR[n]_H.EPDIR` bit indicates whether the transaction is IN or OUT.	
		0	Out
		1	In
14:11 (R/W)	EPNUM	Endpoint Number. The `USBC_CHAR[n]_H.EPNUM` field indicates the endpoint number on the device serving as the data source or sink.	
10:0 (R/W)	MPS	Maximum Packet Size. The `USBC_CHAR[n]_H.MPS` field indicates the maximum packet size of the associated endpoint.	

Host Channel n DMA Buffer Address Register

The USBC_DMA_BADDR[n]_H register holds the current buffer address. It is present only for scatter/gather DMA. It is implemented in RAM instead of a flop-based implementation. The USBC_DMA_BADDR[n]_H register is updated during the data transfer for the corresponding end point.

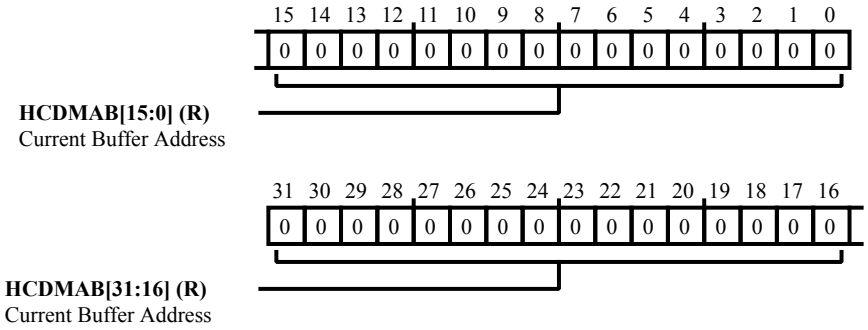

Figure 21-68: USBC_DMA_BADDR[n]_H Register Diagram

Table 21-63: USBC_DMA_BADDR[n]_H Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	HCDMAB	Current Buffer Address. The USBC_DMA_BADDR[n]_H.HCDMAB bit field indicates the current buffer address. The USBC_DMA_BADDR[n]_H register is present only in scatter/gather DMA mode. This field is reserved in other modes.

Host Channel n DMA Address Register

The USBC_DMA_ADDR[n]_H register is used by the OTG host in the internal DMA mode to maintain the current buffer pointer for IN/OUT transactions. The starting DMA address must be DWORD-aligned.This register is incremented on every bus transaction.

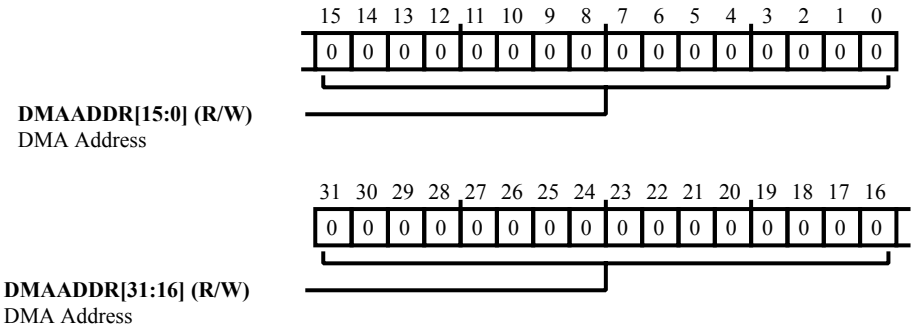

Figure 21-69: USBC_DMA_ADDR[n]_H Register Diagram

Table 21-64: USBC_DMA_ADDR[n]_H Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	DMAADDR	DMA Address. In buffer DMA mode: [31:0]: DMA Address (DMAAddr) The USBC_DMA_ADDR[n]_H.DMAADDR field holds the start address in the external memory from which the data for the endpoint must be fetched or to which it must be stored. For control endpoints, the USBC_DMA_ADDR[n]_H.DMAADDR field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every bus transaction. The application can give only a DWORD-aligned address. When scatter/gather DMA mode is not enabled, the application programs the start address value in the USBC_DMA_ADDR[n]_H.DMAADDR field. When scatter/gather DMA mode is enabled, the USBC_DMA_ADDR[n]_H.DMAADDR field indicates the base pointer for the descriptor list.

Host Configuration Register

The USBC_CFG_H register is the host configuration register.

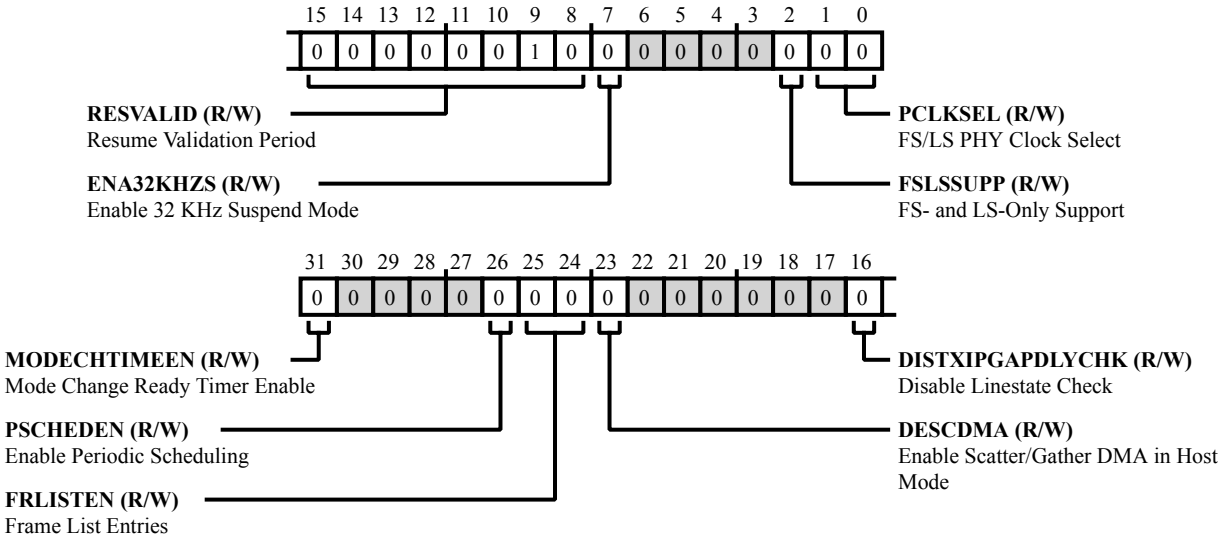

Figure 21-70: USBC_CFG_H Register Diagram

Table 21-65: USBC_CFG_H Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	MODECHTIMEEN	Mode Change Ready Timer Enable. The USBC_CFG_H.MODECHTIMEEN bit is used to enable/disable the host core to wait 200 PHY clock cycles at the end of resume to change the opmode signal to the PHY to 00 after suspend or LPM.	
		0	Host core waits for either 200 PHY clock cycles or a line state of SE0 at the end of resume, to the change the op-mode from 2'b10 to 2'b00
		1	Host core only waits for a line state of SE0 at the end of resume, to change the opmode from 2'b10 to 2'b0
26 (R/W)	PSCHEDEN	Enable Periodic Scheduling. The USBC_CFG_H.PSCHEDEN bit applies in host DMA mode only. The USBC_CFG_H.PSCHEDEN bit enables periodic scheduling within the core. Initially, the bit is reset. The core will not process any periodic channels. When the USBC_CFG_H.PSCHEDEN bit is set, the core will get ready to start scheduling periodic channels. When the USBC_CFG_H.PSCHEDEN bit is reset, the core will get ready to stop scheduling periodic channels.	

Table 21-65: USBC_CFG_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
25:24 (R/W)	FRLISTEN	Frame List Entries. The USBC_CFG_H.FRLISTEN field specifies the number of entries in the frame list. The USBC_CFG_H.FRLISTEN field is valid only in scatter/gather DMA mode.	
		0	8 Entries
		1	16 Entries
		2	32 Entries
		3	64 Entries
23 (R/W)	DESCDMA	Enable Scatter/Gather DMA in Host Mode. The application can set the USBC_CFG_H.DESCDMA bit during initialization to enable the scatter/gather DMA operation. Note: The USBC_CFG_H.DESCDMA bit must be modified only once after a reset. The following combinations are available for programming: - USBC_AHB_CFG.DMAEN = 0, USBC_CFG_H.DESCDMA = 0 => Slave mode - USBC_AHB_CFG.DMAEN = 0, USBC_CFG_H.DESCDMA = 1 => Invalid - USBC_AHB_CFG.DMAEN = 1, USBC_CFG_H.DESCDMA = 0 => Buffered DMA mode - USBC_AHB_CFG.DMAEN = 1, USBC_CFG_H.DESCDMA = 1 => Scatter/Gather DMA mode	
16 (R/W)	DISTXIPGAPDLYCHK	Disable Linestate Check. The USBC_CFG_H.DISTXIPGAPDLYCHK field applies only in HS mode of operation. When enabled, the controller implements counter based logic to detect the end of token transmission, otherwise controller monitors the linestate for end of token transmission, to start the token-to-token and token-to-data interpacket delay counter.	
15:8 (R/W)	RESVALID	Resume Validation Period. The USBC_CFG_H.RESVALID field is effective only when USBC_CFG_H.ENA32KHZS is set (=1). The USBC_CFG_H.RESVALID field controls the resume period when the core resumes from suspend. The core counts for USBC_CFG_H.RESVALID number of clock cycles to detect a valid resume when this is set.	
7 (R/W)	ENA32KHZS	Enable 32 KHz Suspend Mode. The USBC_CFG_H.ENA32KHZS bit can be set only in FS PHY interface is selected. Otherwise, this bit needs to be set to zero.	

Table 21-65: USBC_CFG_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W)	FSLSSUPP	FS- and LS-Only Support. The `USBC_CFG_H.FSLSSUPP` bit controls the core's enumeration speed. Using this bit, the application can make the core enumerate as a full speed host, even if the connected device supports high speed traffic. Do not make changes to this field after initial programming.	
		0	HS/FS/LS based on maximum speed suported by the connected device
		1	FS/LS only, even if the connected device can support high speed.
1:0 (R/W)	PCLKSEL	FS/LS PHY Clock Select. The `USBC_CFG_H.PCLKSEL` field selects the full speed and low speed PHY clock rates. When the core is in full-speed host mode: 0: PHY clock is running at 30/60 MHz 1: PHY clock is running at 48 MHz Others: Reserved When the core is in low speed host mode 00: PHY clock is running at 30/60 MHz. When the ULPI PHY low power mode is not selected, use 30/60 MHz. 01: PHY clock is running at 48 MHz. When the ULPI PHY low power mode is selected, use 48 MHz if the PHY supplies a 48 MHz clock during low speed mode. 10: PHY clock is running at 6 MHz. In USB 1.1 FS mode, use 6 MHz when the ULPI PHY low power mode is selected and the PHY supplies a 6 MHz clock during LS mode. If a 6 MHz clock is selected during LS mode, a soft reset is required. 11: Reserved Notes: When core in FS mode, the internal and external clocks have the same frequency. When core in LS mode, If `USBC_CFG_H.PCLKSEL` = 00: Internal and external clocks have the same frequency If `USBC_CFG_H.PCLKSEL` = 10: Internal clock is the divided by eight version of external 48 MHz clock	

Host Channel n Interrupt Mask Register

The USBC_IMSK[n]_H register reflects the mask for each channel status.

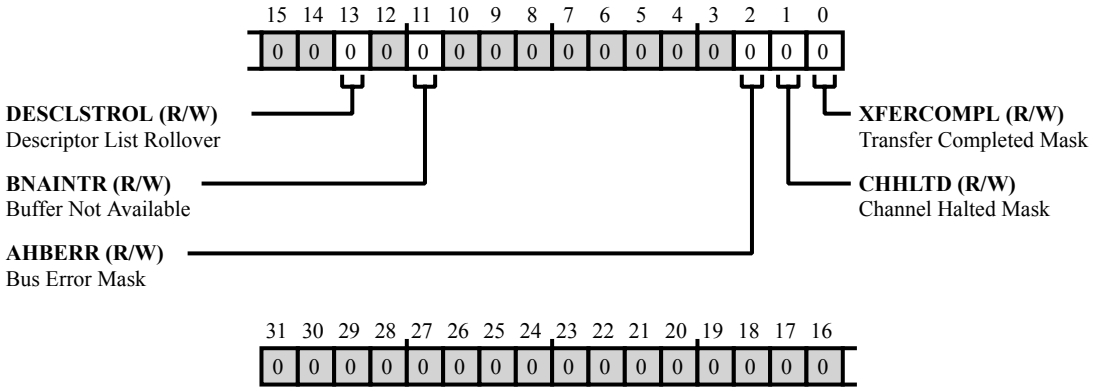

Figure 21-71: USBC_IMSK[n]_H Register Diagram

Table 21-66: USBC_IMSK[n]_H Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
13 (R/W)	DESCLSTROL	Descriptor List Rollover. This bit is valid only when Scatter/Gather DMA mode is enabled.
11 (R/W)	BNAINTR	Buffer Not Available. This bit indicates that the buffer is not available. It is valid only when scatter/gather DMA mode is enabled.
2 (R/W)	AHBERR	Bus Error Mask. In scatter/gather DMA mode for host, interrupts will not be generated due to the corresponding bits set in HCINTn.
1 (R/W)	CHHLTD	Channel Halted Mask.
0 (R/W)	XFERCOMPL	Transfer Completed Mask.

Host Channel n Interrupt Status Register

The USBC_ISTAT[n]_H register indicates the status of an endpoint with respect to USB and bus related events. The application must read this register when the USBC_ISTAT.HCHINT bit is set.

Before the application can read this register, it must first read the USBC_ISTAT_H register to get the exact channel number for the Host Channel n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the USBC_ISTAT_H and USBC_ISTAT registers.

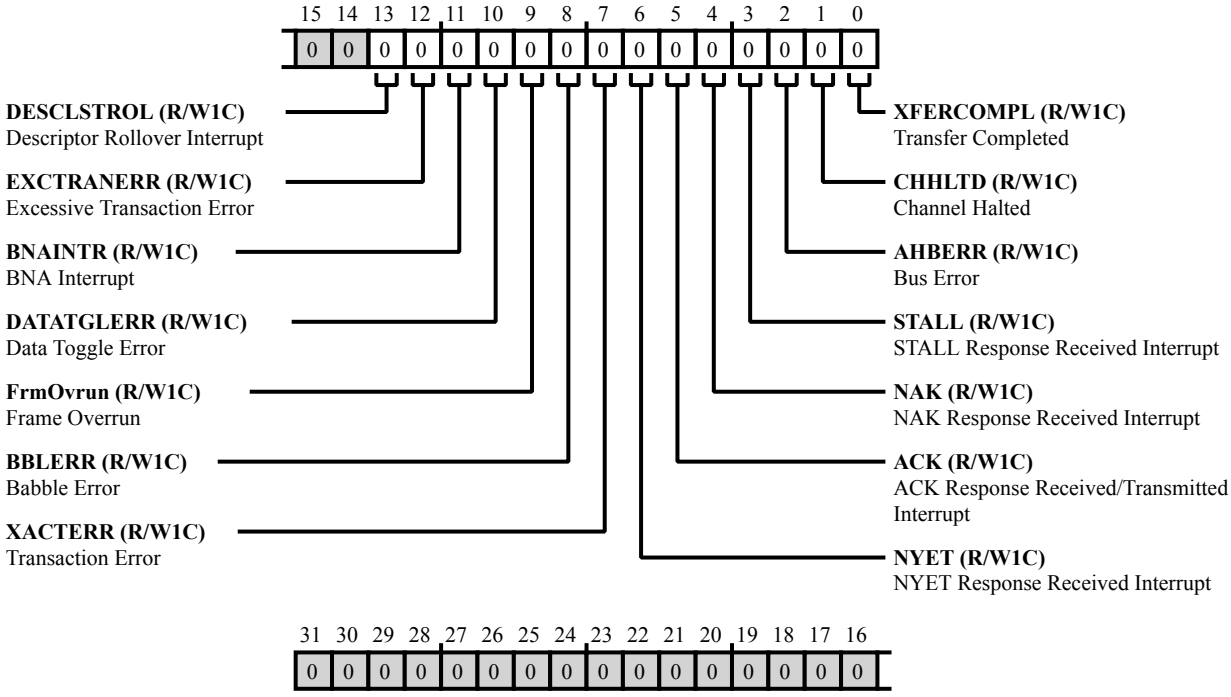

Figure 21-72: USBC_ISTAT[n]_H Register Diagram

Table 21-67: USBC_ISTAT[n]_H Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
13 (R/W1C)	DESCLSTROL	Descriptor Rollover Interrupt. The USBC_ISTAT[n]_H.DESCLSTROL bit is valid only when scatter/gather DMA mode is enabled. The core sets the USBC_ISTAT[n]_H.DESCLSTROL bit when the corresponding channel's descriptor list rolls over. For non scatter/gather DMA mode, the USBC_ISTAT[n]_H.DESCLSTROL bit is reserved.

Table 21-67: USBC_ISTAT[n]_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
12 (R/W1C)	EXCTRANERR	Excessive Transaction Error. The `USBC_ISTAT[n]_H.EXCTRANERR` bit is valid only when scatter/gather DMA mode is enabled. The core sets this bit when three consecutive transaction errors occurred on the USB bus. The `USBC_ISTAT[n]_H.EXCTRANERR` bit is not generated for isochronous channels. For non scatter/gather DMA mode, the `USBC_ISTAT[n]_H.EXCTRANERR` bit is reserved.
11 (R/W1C)	BNAINTR	BNA Interrupt. The `USBC_ISTAT[n]_H.BNAINTR` bit is valid only when scatter/gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process. BNA (Buffer Not Available) is not generated for isochronous channels. For non scatter/gather DMA mode, the `USBC_ISTAT[n]_H.BNAINTR` bit is reserved.
10 (R/W1C)	DATATGLERR	Data Toggle Error. The `USBC_ISTAT[n]_H.DATATGLERR` bit can be set only by the core and the application should write 1 to clear it. In scatter/gather DMA mode, the interrupt due to the `USBC_ISTAT[n]_H.DATATGLERR` bit is masked in the core.
9 (R/W1C)	FRMOVRUN	Frame Overrun. In scatter/gather DMA mode, the interrupt due to the `USBC_ISTAT[n]_H.FRMOVRUN` bit is masked in the core. The `USBC_ISTAT[n]_H.FRMOVRUN` bit bit can be set only by the core and the application should write 1 to clear it.
8 (R/W1C)	BBLERR	Babble Error. In scatter/gather DMA mode, the interrupt due to the `USBC_ISTAT[n]_H.BBLERR` bit is masked in the core. The `USBC_ISTAT[n]_H.BBLERR` bit can be set only by the core and the application should write 1 to clear it.
7 (R/W1C)	XACTERR	Transaction Error. The `USBC_ISTAT[n]_H.XACTERR` bit indicates one of the following errors occurred on the USB: CRC check failure, Timeout, Bit stuff error, or False EOP. In scatter/gather DMA mode, the interrupt due to the `USBC_ISTAT[n]_H.XACTERR` bit is masked in the core. The `USBC_ISTAT[n]_H.XACTERR` bit can be set only by the core and the application should write 1 to clear it.

Table 21-67: USBC_ISTAT[n]_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
6 (R/W1C)	NYET	NYET Response Received Interrupt. In scatter/gather DMA mode, the interrupt due to the `USBC_ISTAT[n]_H.NYET` bit is masked in the core. The `USBC_ISTAT[n]_H.NYET` bit can be set only by the core and the application should write 1 to clear it.
5 (R/W1C)	ACK	ACK Response Received/Transmitted Interrupt. In scatter/gather DMA mode, the interrupt due to the `USBC_ISTAT[n]_H.ACK` bit is masked in the core. The `USBC_ISTAT[n]_H.ACK` bit can be set only by the core and the application should write 1 to clear it.
4 (R/W1C)	NAK	NAK Response Received Interrupt. In scatter/gather DMA mode, the interrupt due to the `USBC_ISTAT[n]_H.NAK` bit is masked in the core. The `USBC_ISTAT[n]_H.NAK` bit can be set only by the core and the application should write 1 to clear it.
3 (R/W1C)	STALL	STALL Response Received Interrupt. In scatter/gather DMA mode, the interrupt due to the `USBC_ISTAT[n]_H.STALL` bit is masked in the core. The `USBC_ISTAT[n]_H.STALL` bit can be set only by the core and the application should write 1 to clear it.
2 (R/W1C)	AHBERR	Bus Error. The `USBC_ISTAT[n]_H.AHBERR` bit is generated only in internal DMA mode when there is a bus error during a bus read/write. The application can read the corresponding channel's DMA address register to get the error address.
1 (R/W1C)	CHHLTD	Channel Halted. In non scatter/gather DMA mode, the `USBC_ISTAT[n]_H.CHHLTD` bit indicates the transfer completed abnormally either because of any USB transaction error or in response to disable request by the application or because of a completed transfer. In scatter/gather DMA mode, the `USBC_ISTAT[n]_H.CHHLTD` bit indicates that transfer completed due to any of the following: EOL being set in descriptor Bus error Excessive transaction errors Babble Stall

Table 21-67: USBC_ISTAT[n]_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
0 (R/W1C)	XFERCOMPL	Transfer Completed. The `USBC_ISTAT[n]_H.XFERCOMPL` bit indicates that the transfer completed normally without any errors. The `USBC_ISTAT[n]_H.XFERCOMPL` bit can be set only by the core and the application should write 1 to clear it. For scatter/gather DMA mode, the `USBC_ISTAT[n]_H.XFERCOMPL` bit indicates that current descriptor processing completed with an IOC bit set in its descriptor. In non scatter/gather DMA mode, the `USBC_ISTAT[n]_H.XFERCOMPL` bit indicates that transfer completed normally without any errors.

Host Channel n Split Control Register

The USBC_SPLT_CTL[n]_H register controls split transactions for a channel.

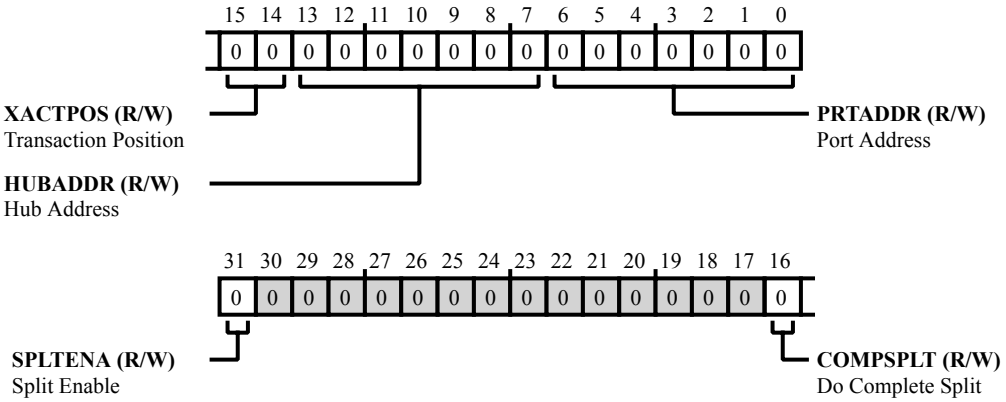

Figure 21-73: USBC_SPLT_CTL[n]_H Register Diagram

Table 21-68: USBC_SPLT_CTL[n]_H Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	SPLTENA	Split Enable. When set (=1), the USBC_SPLT_CTL[n]_H.SPLTENA bit enables the channel to perform split transactions.	
16 (R/W)	COMPSPLT	Do Complete Split. The USBC_SPLT_CTL[n]_H.COMPSPLT bit enables the request to the OTG host to perform a complete split transaction.	
15:14 (R/W)	XACTPOS	Transaction Position. The USBC_SPLT_CTL[n]_H.XACTPOS field is used to determine whether to send all, first, middle, or last payloads with each OUT transaction.	
		0	Mid. The middle payload of the transaction (which is larger than 188 bytes).
		1	End. The last payload of the transaction (which is larger than 188 bytes).
		2	Begin. The first data payload of the transaction (which is larger than 188 bytes).
		3	All. The entire data payload is the transaction (which is less than or equal to 188 bytes).
13:7 (R/W)	HUBADDR	Hub Address. The USBC_SPLT_CTL[n]_H.HUBADDR field holds the device address of the transaction translator's hub.	

Table 21-68: USBC_SPLT_CTL[n]_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
6:0 (R/W)	PRTADDR	Port Address. The `USBC_SPLT_CTL[n]_H.PRTADDR` field indicates the port number of the recipient transaction translator.

Host Channel n Transfer Size Register

The USBC_TSIZ[n]_H register represents the host channel n transfer size register.

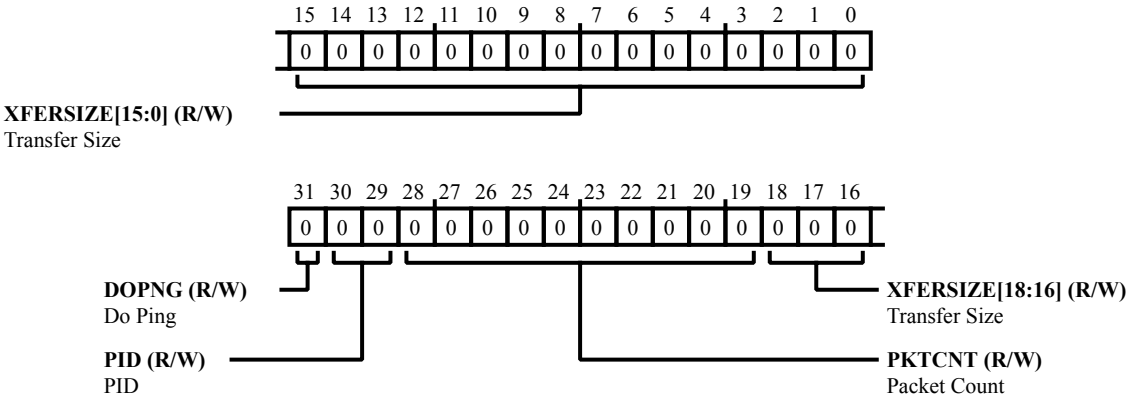

Figure 21-74: USBC_TSIZ[n]_H Register Diagram

Table 21-69: USBC_TSIZ[n]_H Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	DOPNG	Do Ping. The USBC_TSIZ[n]_H.DOPNG bit is used only for OUT transfers. Setting the USBC_TSIZ[n]_H.DOPNG bit (=1) directs the host to do PING protocol. Note: Do not set USBC_TSIZ[n]_H.DOPNG bit for IN transfers. If the USBC_TSIZ[n]_H.DOPNG bit is set for for IN transfers, it disables the channel.	
30:29 (R/W)	PID	PID. The USBC_TSIZ[n]_H.PID field indicates the type of PID to use for the initial transaction. The host maintains this field for the rest of the transfer.	
		0	DATA0
		1	DATA2
		2	DATA1
		3	MDATA (non-control) / SETUP (control)
28:19 (R/W)	PKTCNT	Packet Count. The USBC_TSIZ[n]_H.PKTCNT field indicates the expected number of packets to be transmitted (OUT) or received (IN). The host decrements this count on every successful transmission or reception of an OUT/IN packet. Once this count reaches zero, the application is interrupted to indicate normal completion.	

Table 21-69: USBC_TSIZ[n]_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
18:0 (R/W)	XFERSIZE	Transfer Size. For an OUT, the `USBC_TSIZ[n]_H.XFERSIZE` field is the number of data bytes the host sends during the transfer. For an IN, the `USBC_TSIZ[n]_H.XFERSIZE` field is the buffer size that the application has reserved for the transfer. The `USBC_TSIZ[n]_H.XFERSIZE` field must be programmed as an integer multiple of the maximum packet size for IN transactions (periodic and non-periodic). Scatter/Gather DMA Mode: [18:16]: Reserved [15:8]: NTD (Number of Transfer Descriptors) (Non Isochronous) This value is in terms of number of descriptors. Maximum number of descriptor that can be present in the list is 64. The values can be from 0 to 63. 0 1 descriptor 63 64 descriptors This field indicates the total number of descriptors present in that list. The core will wrap around after servicing NTD number of descriptors for that list. (Isochronous) This field indicates the number of descriptors present in that list microframe. The possible values for FS are 1-2, 3-4, 7-8, 15-16, 31-32, and 63-64 descriptors The possible values for HS are 7-8, 15-16, 31-32, 63-64, 127-128, and 255-256 descriptors [7:0]: SCHED_INFO (Schedule information) Every bit in this 8 bit register indicates scheduling for that microframe. Bit 0 indicates scheduling for 1st microframe and bit 7 indicates scheduling for 8th microframe in that frame. A value of 8b11111111 indicates that the corresponding interrupt channel is scheduled to issue a token every microframe in that frame. A value of 8b10101010 indicates that the corresponding interrupt channel is scheduled to issue a token every alternate microframe starting with second microframe. Note that this field is applicable only for periodic (Isochronous and Interrupt) channels.

Host Frame Interval Register

The USBC_FIR_H register indicates the frame interval. It also control the reloading of the USBC_FIR_H register during runtime.

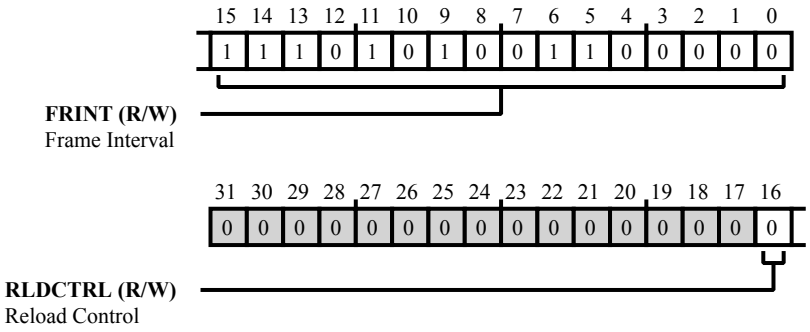

Figure 21-75: USBC_FIR_H Register Diagram

Table 21-70: USBC_FIR_H Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/W)	RLDCTRL	Reload Control. The USBC_FIR_H.RLDCTRL bit enables dynamic reloading of the USBC_FIR_H register during runtime. The USBC_FIR_H.RLDCTRL bit must be programmed during initial configuration and its value should not be changed during runtime.	
		0	Disable
		1	Enable
15:0 (R/W)	FRINT	Frame Interval. The USBC_FIR_H.FRINT field specifies the interval between two consecutive SPFs (FS) or micro-SOFs (HS) or keep-alive tokens (HS). The field contains the number of PHY clocks that constitute the required frame interval. The default value set in the USBC_FIR_H.FRINT field is for full-speed operation when the PHY clock frequency is 60 MHz. The application can write a value to this register only after the USBC_PORT_CTL_H.ENA bit is set (=1). If no value is programmed, the core calculates the value based on the PHY clock specified in the USBC_CFG_H.PCLKSEL field. Do not change the value of USBC_FIR_H.FRINT field after the initial configuration. 125 s * (PHY clock frequency for HS) 1 ms * (PHY clock frequency for FS/LS)	

Host Frame List Base Address Register

The USBC_FL_BADDR_H register holds the starting address of the frame list information. This register is used only for isochronous and interrupt channels.

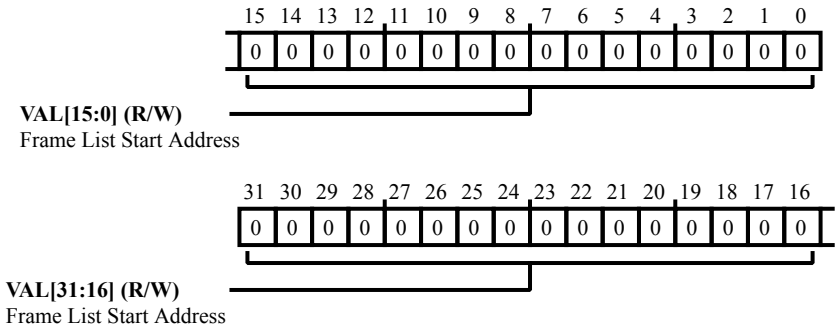

Figure 21-76: USBC_FL_BADDR_H Register Diagram

Table 21-71: USBC_FL_BADDR_H Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VAL	Frame List Start Address.

Host Frame Number/Frame Time Remaining Register

The USBC_FNUM_H register indicates the current frame number. It also indicates the time remaining (in terms of the number of PHY clocks) in the current (micro)frame.

Note: Read the reset value of this register only after the following conditions:

If IDDIG_FILTER is disabled, read only when the PHY clock is stable.

If IDDIG_FILTER is enabled, read only after the filter timer expires.

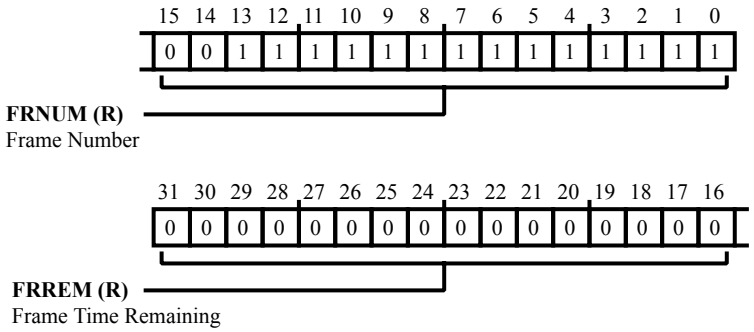

Figure 21-77: USBC_FNUM_H Register Diagram

Table 21-72: USBC_FNUM_H Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/NW)	FRREM	Frame Time Remaining. The USBC_FNUM_H.FRREM field indicates the amount of time remaining in the current microframe (HS) or frame (FS/LS), in terms of PHY clocks. This field decrements on each PHY clock. When it reaches zero, the USBC_FNUM_H.FRREM field is reloaded with the value in the frame interval register and a new SOF is transmitted on the USB.
15:0 (R/NW)	FRNUM	Frame Number. The USBC_FNUM_H.FRNUM field increments when a new SOF is transmitted on the USB. It is reset to 0 when it reaches 16'h3FFF.

Host Port Control and Status Register

The USBC_PORT_CTL_H register is available only in host mode. Currently, the OTG host supports only one port. A single register holds USB port-related information such as USB reset, enable, suspend, resume, connect status, and test mode for each port.

The R_SS_WC bits in this register can trigger an interrupt to the application through the USBC_ISTAT.PRTINT bit. On a port interrupt, the application must read this register and clear the bit that caused the interrupt. For the R_SS_WC bits, the application must write a 1 to the bit to clear the interrupt.

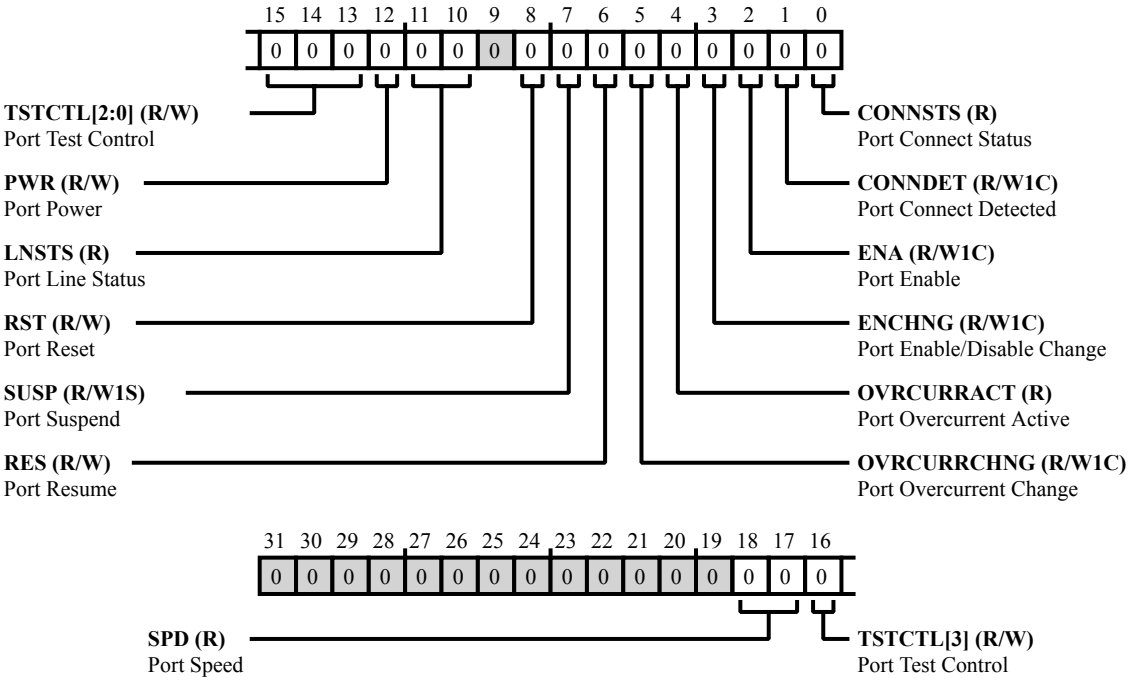

Figure 21-78: USBC_PORT_CTL_H Register Diagram

Table 21-73: USBC_PORT_CTL_H Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
18:17 (R/NW)	SPD	Port Speed. The USBC_PORT_CTL_H.SPD field indicates the speed of the device attached to this port.	
		0	High speed
		1	Full speed
		2	Low speed
		3	Reserved

Table 21-73: USBC_PORT_CTL_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
16:13 (R/W)	TSTCTL	Port Test Control. The application writes a nonzero value to the `USBC_PORT_CTL_H.TSTCTL` field to put the port into a test mode, and the corresponding pattern is signaled on the port. To move the USBC_otg controller to test mode, this field must be set. Complete the following steps to move the USBC_otg core to test mode: 1. Power on the core. 2. Load the USBC_otg driver. 3. Connect an HS device and enumerate to HS mode. 4. Access the `USBC_PORT_CTL_H` register to send test packets. 5. Remove the device and connect to fixture (OPT) port. The USBC_otg host core continues sending out test packets. 6. Test the eye diagram.	
		0	Test mode disabled
		1	Test_J mode
		2	Test_K mode
		3	Test_SEO_NAK mode
		4	Test_Packet mode
		5	Test_Force_Enable
		6	Reserved
		7	Reserved
		8	Reserved
		9	Reserved
		10	Reserved
		11	Reserved
		12	Reserved
		13	Reserved
		14	Reserved
		15	Reserved

Table 21-73: USBC_PORT_CTL_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W)	PWR	Port Power. The USBC_PORT_CTL_H.PWR bit controls power to the port (write 1 to set to 1 and write 0 to set to 0). The core can clear the USBC_PORT_CTL_H.PWR field bit on an overcurrent condition. Note: The USBC_PORT_CTL_H.PWR bit is interface independent. The application needs to program the USBC_PORT_CTL_H.PWR bit for all interfaces.	
		0	Power off
		1	Power on
11:10 (R/NW)	LNSTS	Port Line Status. The USBC_PORT_CTL_H.LNSTS field indicates the current logic level USB data lines Bit [10]: Logic level of D+ Bit [11]: Logic level of D-	
8 (R/W)	RST	Port Reset. When the application sets the USBC_PORT_CTL_H.RST bit, a reset sequence is started on this port. The application must time the reset period and clear the USBC_PORT_CTL_H.RST bit after the reset sequence is complete. The application must leave the USBC_PORT_CTL_H.RST bit set for at least a minimum duration mentioned below to start a reset on the port. The application can leave it set for another 10 ms in addition to the required minimum duration, before clearing the bit, even though there is no maximum limit set by the USB standard. The USBC_PORT_CTL_H.RST bit is cleared by the core even if there is no device connected to the host. High speed: 50 ms Full speed/low speed: 10 ms	
		0	Port not in reset
		1	Port in reset

Table 21-73: USBC_PORT_CTL_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W1S)	SUSP	Port Suspend. The application sets the USBC_PORT_CTL_H.SUSP bit to put this port in suspend mode. The core only stops sending SOFs when this is set. To stop the PHY clock, the application must set the port clock stop bit, which asserts the suspend input pin of the PHY. The USBC_PORT_CTL_H.SUSP bit indicates the current suspend status of the port. The USBC_PORT_CTL_H.SUSP bit is cleared by the core after a remote wakeup signal is detected or the application sets the port reset bit or port resume bit in this register or the (USBC_ISTAT.WKUPINT or USBC_ISTAT.DISCONINT bit. The USBC_PORT_CTL_H.SUSP bit is cleared by the core even if there is no device connected to the host.	
		0	Port not in suspend mode
		1	Port in suspend mode
6 (R/W)	RES	Port Resume. The application sets the USBC_PORT_CTL_H.RES bit to drive resume signaling on the port. The core continues to drive the resume signal until the application clears this bit. If the core detects a USB remote wakeup sequence, as indicated by the USBC_ISTAT.WKUPINT bit, the core starts driving resume signaling without application intervention and clears the USBC_PORT_CTL_H.RES bit when it detects a disconnect condition. When LPM is enabled, In L1 state the behavior of the USBC_PORT_CTL_H.RES bit is as follows: The application sets this bit to drive resume signaling on the port. The core continues to drive the resume signal. If the core detects a USB remote wakeup sequence, as indicated by the Port L1Resume/Remote L1Wakeup Detected Interrupt bit of the core Interrupt register the (USBC_ISTAT.L1WkUpInt), the core starts driving resume signaling without application intervention and clears the USBC_PORT_CTL_H.RES bit at the end of resume. This bit can be set by both core or application and also cleared by core or application. The USBC_PORT_CTL_H.RES bit is cleared by the core even if there is no device connected to the host.	
		0	No resume driven
		1	Resume driven
5 (R/W1C)	OVRCURRCHNG	Port Overcurrent Change. The core sets the USBC_PORT_CTL_H.OVRCURRCHNG bit when the status of the USBC_PORT_CTL_H.OVRCURRACT bit changes. The USBC_PORT_CTL_H.OVRCURRCHNG bit can be set only by the core and the application should write 1 to clear it.	

Table 21-73: USBC_PORT_CTL_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/NW)	OVRCURRACT	Port Overcurrent Active. The `USBC_PORT_CTL_H.OVRCURRACT` bit indicates the overcurrent condition of the port.	
		0	No overcurrent condition
		1	Overcurrent condition
3 (R/W1C)	ENCHNG	Port Enable/Disable Change. The core sets the `USBC_PORT_CTL_H.ENCHNG` bit when the status of the `USBC_PORT_CTL_H.ENA` bit changes. The `USBC_PORT_CTL_H.ENCHNG` bit can be set only by the core and the application should write 1 to clear it.	
2 (R/W1C)	ENA	Port Enable. The `USBC_PORT_CTL_H.ENA` bit enables the port. A port is enabled only by the core after a reset sequence, and is disabled by an overcurrent condition, a disconnect condition, or by the application clearing this bit. The application cannot set the `USBC_PORT_CTL_H.ENA` bit by a register write. It can only clear the `USBC_PORT_CTL_H.ENA` bit to disable the port by writing 1. This bit does not trigger any interrupt to the application.	
		0	Disable
		1	Enable
1 (R/W1C)	CONNDET	Port Connect Detected. The core sets the `USBC_PORT_CTL_H.CONNDET` bit when a device connection is detected to trigger an interrupt to the application using the `USBC_ISTAT.PRTINT` bit. The `USBC_PORT_CTL_H.CONNDET` bit can be set only by the core and the application should write 1 to clear it. The application must write a 1 to this bit to clear the interrupt.	
0 (R/NW)	CONNSTS	Port Connect Status. The `USBC_PORT_CTL_H.CONNSTS` bit indicates whether a device is connected to the port.	
		0	No device attached to port
		1	Device attached to port

Host Periodic Transmit FIFO Size Register

The USBC_TXFIFOSZ_PER_H register holds the size and the memory start address of the periodic TxFIFO.

Note: Read the reset value of this register only after the following conditions:

If IDDIG_FILTER is disabled, read only after PHY clock is stable.

If IDDIG_FILTER is enabled, read only after the filter timer expires.

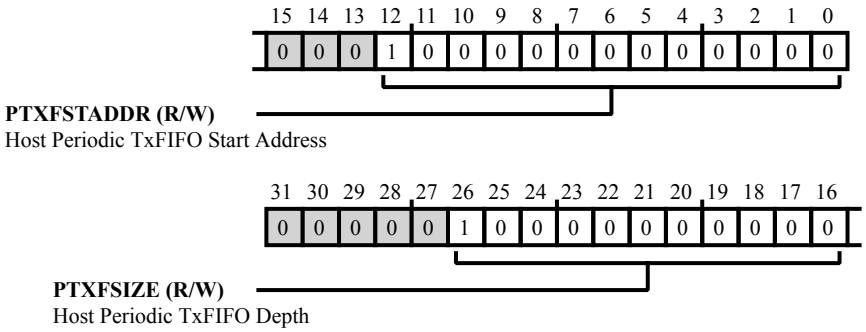

Figure 21-79: USBC_TXFIFOSZ_PER_H Register Diagram

Table 21-74: USBC_TXFIFOSZ_PER_H Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
26:16 (R/W)	PTXFSIZE	Host Periodic TxFIFO Depth. The USBC_TXFIFOSZ_PER_H.PTXFSIZE field indicates the host periodic TXFIFO depth. The value is in terms of 32-bit words. Minimum value is 16 Maximum value is 32,768 The power-on reset value is specified as the largest host mode periodic Tx Data FIFO depth. Programmed values must not exceed the power-on value.
12:0 (R/W)	PTXFSTADDR	Host Periodic TxFIFO Start Address.

Power and Clock Gating Control Register

The USBC_PWR_CTL register controls power down, sleep, and clock stopping features.

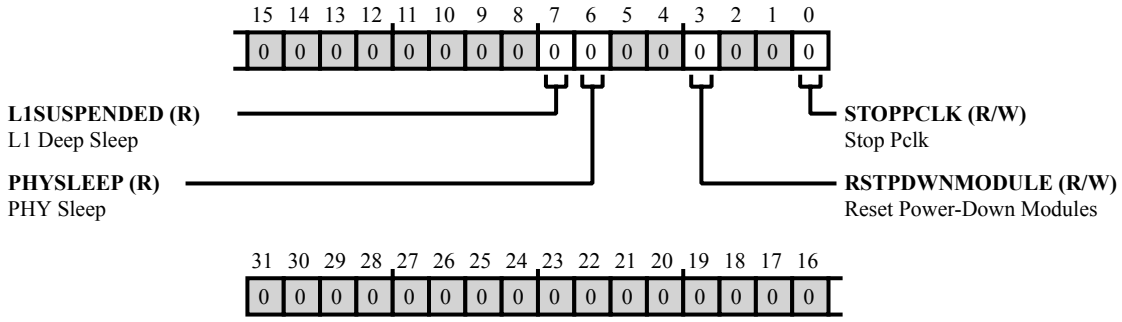

Figure 21-80: USBC_PWR_CTL Register Diagram

Table 21-75: USBC_PWR_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7 (R/NW)	L1SUSPENDED	L1 Deep Sleep. The USBC_PWR_CTL.L1SUSPENDED bit indicates that the PHY is in deep sleep when in L1 state.
6 (R/NW)	PHYSLEEP	PHY Sleep. The USBC_PWR_CTL.PHYSLEEP indicates that the PHY is in a sleep state.
3 (R/W)	RSTPDWNMODULE	Reset Power-Down Modules. The USBC_PWR_CTL.RSTPDWNMODULE bit is valid only in Partial Power-Down mode. - The application sets this bit when the power is turned off. - The application clears this bit after the power is turned on and the PHY clock is up. Note: The R/W of all core registers are possible only when this bit is set to 1b0.
0 (R/W)	STOPPCLK	Stop Pclk. The USBC_PWR_CTL.STOPPCLK bit stops the PHY clock (phy_clk), when set (=1) and the USB is suspended, the session is not valid, or the device is disconnected. The USBC_PWR_CTL.STOPPCLK bit, when clear (=0), the USB resumes or a new session starts.

22 Serial Peripheral Interface (SPI)

The serial peripheral interface is an industry-standard synchronous serial link that supports communication with multiple SPI-compatible devices. The baseline SPI peripheral is a synchronous, four-wire interface consisting of two data pins, one device select pin, and a gated clock pin. The two data pins allow full-duplex operation to other SPI-compatible devices. Two extra (optional) data pins are provided on specific SPIs to support quad SPI operation. Enhanced modes of operation such as flow control, fast mode, and dual-I/O mode (DIOM) are also supported. In addition, a direct memory access (DMA) mode allows for transferring several words with minimal CPU interaction.

With a range of configurable options, the SPI ports provide a glueless hardware interface with other SPI-compatible devices in controller mode, target mode, and multi-controller environments. The SPI peripheral includes programmable baud rates, clock phase, and clock polarity. The peripheral can operate in a multi-controller environment by interfacing with several other devices, acting as either a controller device or a target device. In a multi-controller environment, the SPI peripheral uses open-drain outputs to avoid data bus contention. The flow control features enable slow target devices to interface with fast controller devices by providing an SPI ready pin which flexibly controls the transfers.

NOTE: SPI peripherals on the processor operate in the SCLK0 domain. For more details on SCLK programming, refer the *Clock Generation Unit (CGU)* chapter.

SPI Features

The SPI module supports the following features:

- Full-duplex, synchronous serial interface
- 8, 16-bit and 32-bit word sizes
- Programmable baud rate, clock phase, and polarity
- Programmable interframe latency
- Flow control
- Support for Fast and DIOM modes
- SPI1 and SPI2 support quad mode. Memory-mapped mode is supported by SPI2 only.
- Independent receive and transmit DMA channels

- Burst transfer mode for non-DMA write accesses

SPI Functional Description

This section provides information on the function of the SPI module.

Shift register functionality

The SPI is a shift register that serially transmits and receives data bits to or from other SPI devices. During an SPI transfer, data is simultaneously transmitted (shifted out serially) and received (shifted in serially). A serial clock line synchronizes shifting and sampling of the information on the two serial data lines.

Controller/target functionality

During a data transfer, one SPI system acts as the link controller which controls the data flow. The other system acts as the target, which has data shifted into and out of it by the controller. Different devices can take turn being controllers, and one controller can simultaneously shift data into multiple targets (broadcast mode). However, only one target can drive its output to write data back to the controller at any given time. This rule must be enforced in the broadcast mode. Several targets can be selected to receive data from the controller in this mode. But, only one target can be enabled to send data back to the controller.

Enhanced operating modes

SPI supports enhanced modes of operation like fast mode, DIOM, and Quad-SPI, and optional flow control. In fast mode, received data is sampled on the transmit edge instead of the standard receive edge, thus enabling a full-cycle path for the received data. In DIOM, both MOSI and MISO are configured as input or output pins, and 2 bits are shifted in or out on each receive or transmit edge. In Quad-SPI mode, SPI_D3:0 are configured as input or output pins and 4 bits are shifted in or out on each receive or transmit edge. A slower target can use flow control to stall a faster controller device.

Single and multi-controller use

The SPI can be used in a single controller as well as multi-controller environment. The `SPI_MOSI`, `SPI_MISO`, and the `SPI_CLK` signals are all tied together in both configurations. SPI transmission and reception can be enabled simultaneously or individually, depending on `SPI_RXCTL` and `SPI_TXCTL` settings. In broadcast mode, several target can be enabled to receive, but only one target must be in transmit mode and driving the `SPI_MISO` line.

ADSP-SC59x SPI Register List

The Serial Peripheral Interface (SPI) provides a full-duplex, synchronous serial interface, which supports both master/slave modes and multi-master environments. The SPI's baud rate and clock phase/polarities are programmable, and it has integrated DMA channels for both transmit and receive data streams. A set of registers governs SPI operations. For more information on SPI functionality, see the SPI register descriptions.

Table 22-1: ADSP-SC59x SPI Register List

Name	Description
SPI_CLK	Clock Rate Register
SPI_CTL	Control Register
SPI_DLY	Delay Register
SPI_ILAT	Masked Interrupt Condition Register
SPI_ILAT_CLR	Masked Interrupt Clear Register
SPI_IMSK	Interrupt Mask Register
SPI_IMSK_CLR	Interrupt Mask Clear Register
SPI_IMSK_SET	Interrupt Mask Set Register
SPI_MMRDH	Memory Mapped Read Header
SPI_MMTOP	SPI Memory Top Address
SPI_RFIFO	Receive FIFO Data Register
SPI_RWC	Received Word Count Register
SPI_RWCR	Received Word Count Reload Register
SPI_RXCTL	Receive Control Register
SPI_SLVSEL	Slave Select Register
SPI_STAT	Status Register
SPI_TFIFO	Transmit FIFO Data Register
SPI_TWC	Transmitted Word Count Register
SPI_TWCR	Transmitted Word Count Reload Register
SPI_TXCTL	Transmit Control Register

SPI Block Diagram

The ***SPI Controller Block Diagram*** illustrates the blocks of the SPI module. The module is comprised of three primary parts:

- SPI core contains the receive and transmit FIFOs and their associated shift registers
- Control blocks contain the synchronizer and logic to control the data flow through the data pipelines
- Register block

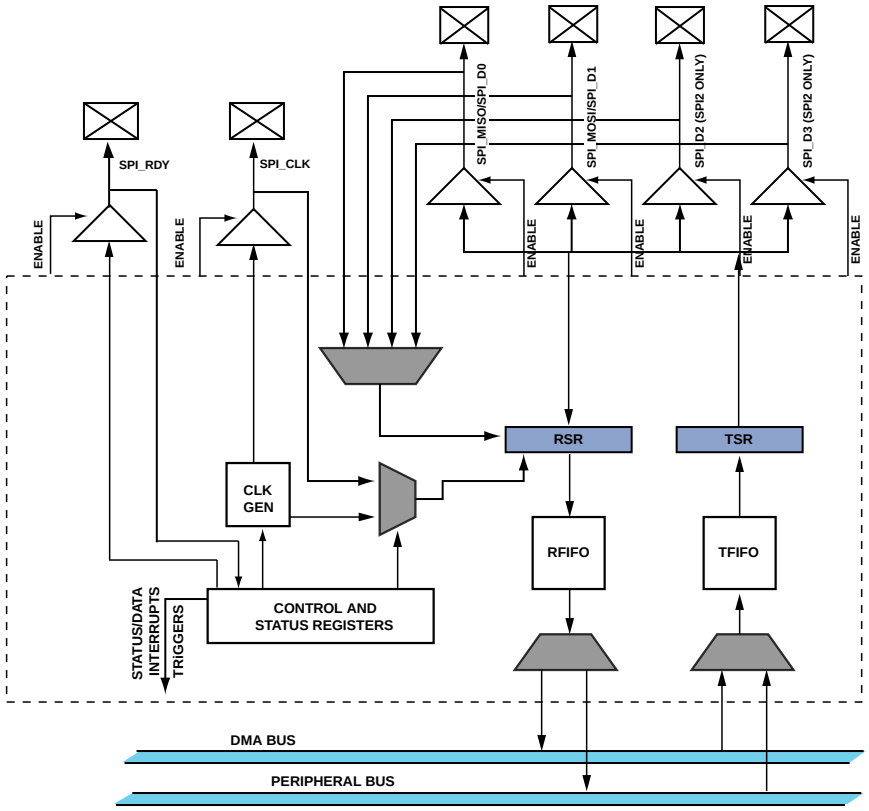

Figure 22-1: SPI Controller Block Diagram, Quad Mode

Transfer Protocol

The SPI module implements two channels that are independent of each other. The SPI module uses the SPI_RXCTL and SPI_TXCTL dedicated control registers to control these channels. Except in dual and quad modes, SPI can enable and use both channels simultaneously.

The SPI protocol supports four different combinations of serial clock phase and polarity. These combinations are selected through the SPI_CTL.CPOL and SPI_CTL.CPHA bits.

The ***SPI Transfer Protocol*** figures demonstrate the two basic transfer formats as defined by the CPHA bit. Two waveforms are shown for SPI_CLK; one for SPI_CTL.CPOL=0 and the other for SPI_CTL.CPOL=1. The diagrams can be interpreted as controller or target timing diagrams since the SPI_CLK, SPI_MISO, and SPI_MOSI pins are directly connected between the controller and the target. The SPI_MISO signal is the output from the target (target transmission), and the SPI_MOSI signal is the output from the controller (controller transmission). The controller generates the SPI_CLK signal. The SPI_SS signal is the target device select input to the target from the controller. The diagrams represent an 8-bit transfer (SPI_CTL.SIZE=0) with the MSB first (SPI_CTL.LSBF=0). Any combination of the SPI_CTL.SIZE and SPI_CTL.LSBF bits is permissible. For example, a 16-bit transfer with the LSB first is another possible configuration.

The clock polarity and the clock phase could be identical for the controller device and the target device involved in the communication link. The transfer format from the controller can be changed between transfers to adjust for various requirements of a target device.

The SPI module uses the SPI_CTL.ASSEL bit to determine when the SPI hardware or software control the SPI_SEL[n] line. When SPI_CTL.ASSEL=1, the target select line must be set to the polarity set in the SPI_CTL.SELST field between each serial transfer. The actual behavior of SPI_SEL[n] also depends on the parameters programmed into the SPI_DLY register. The SPI hardware logic automatically controls this functionality. When SPI_CTL.ASSEL=0, SPI_SEL[n] can either remain active between successive transfers or be inactive. The software must control this activity through manipulation of the SPI_SLVSEL register.

The ***SPI Transfer Protocol*** pair of figures illustrates the case when SPI_CTL.ASSEL = 1 and the SPI_SEL[n] line is inactive between frames. If ASSEL = 0, the SPI_SEL[n] line can remain active between frames; however, the first bit is only driven when an active transition of SPI_CLK occurs.

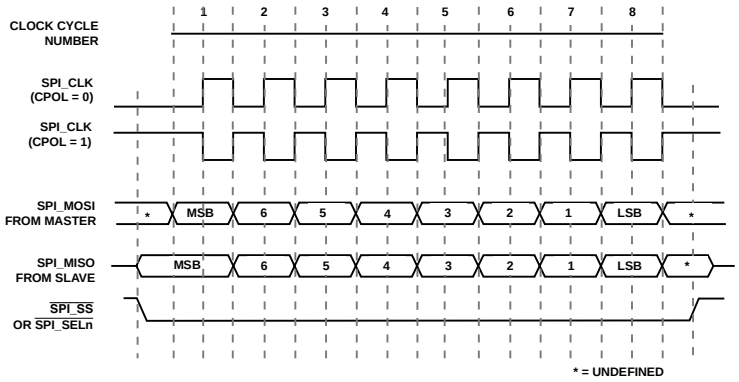

Figure 22-2: SPI Transfer Protocol for CPHA=0

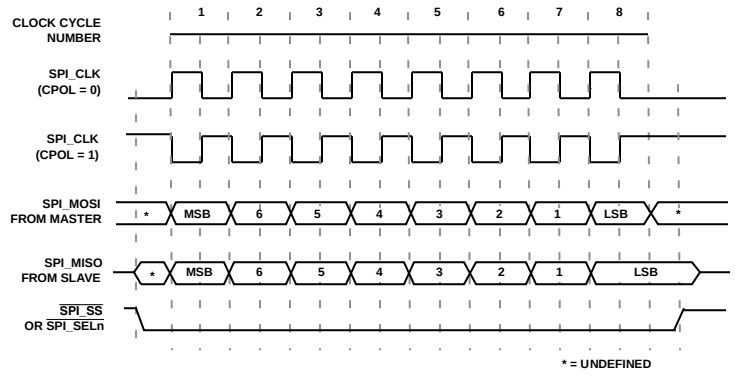

Figure 22-3: SPI Transfer Protocol for CPHA=1

Clock Considerations

The SPI_CLK signal is a gated clock that is only active during data transfers, for the time of the transferred word. In normal mode, the number of active edges is equal to the number of bits to be transmitted or received. In dual-I/O mode, it is half of the number of bits to be transmitted or received, and in quad-SPI mode it is one-fourth of the number. The clock rate can be derived using both even and odd dividers from CLKO6.

For controller devices, the SPI uses the SPI_CLK register value to determine the clock rate, whereas this value is ignored for target devices.

When the SPI controller is a controller, SPI_CLK is an output signal. Conversely, when the SPI controller is a target, SPI_CLK is an input signal. Peripheral devices ignore the SPI clock when the target select input is driven inactive. The SPI uses the SPI_CLK signal to shift out and shift in the data driven onto the SPI_MISO and SPI_MOSI lines. The data is always shifted out on one edge of the clock (the active edge) and sampled on the opposite edge of the clock (the sampling edge). Clock polarity and clock phase relative to data are programmable through the SPI_CTL register and define the transfer format.

Controlling Delay Between Frames

The ***SPI Timing with Lead and Lag Programming (Independent of SPI_CTL.CPHA Setting)*** figure illustrates SPI timing using the SPI_DLY.LEADX and SPI_DLY.LAGX programming. The SPI uses the SPI_DLY.LAGX bits to control the timing between the chip select (SPI_SS) signal assertion and the first SPI_CLK edge. The SPI uses the SPI_DLY.LEADX bits to control the timing between the last SPI_CLK edge and deassertion of the SPI_SS signal. The lead and lag timing can be extended by a 1 SPI_CLK duration to ease timing restrictions on the target device.

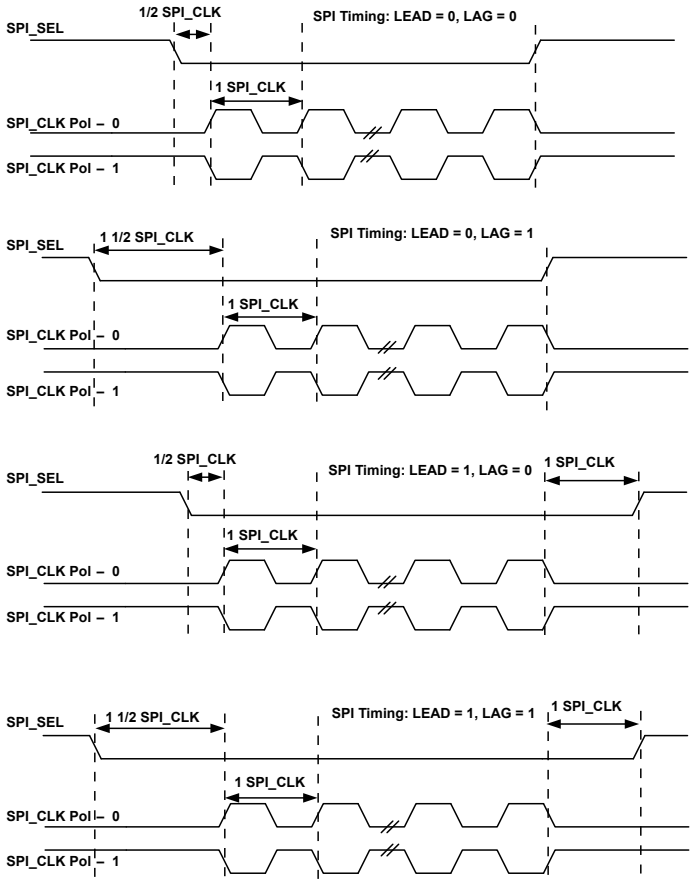

Figure 22-4: SPI Timing with Lead and Lag Programming (Independent of SPI_CTL.CPHA Setting)

The ***SPI Timing with SPI_DLY.STOP Programming (Independent of SPI_CTL.CPHA Setting)*** figure illustrates SPI timing with STOP programming. The SPI module uses this timing to insert multiples of `SPI_CLK` period delays between transfers. The `SPI_SS` line is deasserted for the duration specified in the `SPI_DLY.STOP` bit field, assuming the `SPI_CTL.SELST` bit is configured for deassertion between transfers.

If the `SPI_DLY.STOP` bit =0, the controller operates in a *continuous mode*. This mode causes an immediate start of the second word after the last bit is transferred from the first word. During this mode of operation, the chip select line is continuously asserted.

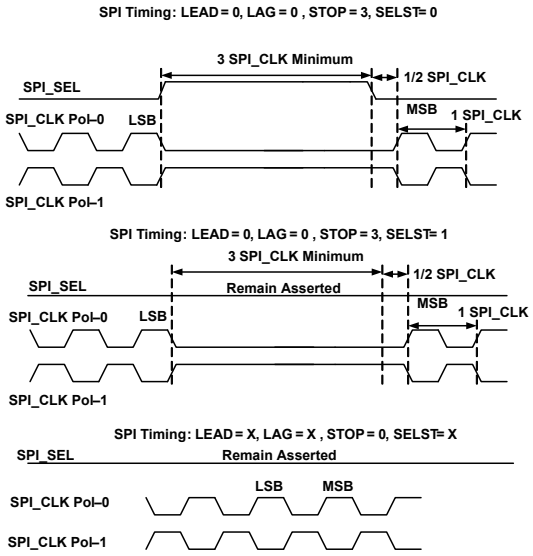

Figure 22-5: SPI Timing with SPI_DLY.STOP Programming (Independent of SPI_CTL.CPHA Setting)

When the SPI_DLY.STOP bit =0 and initial conditions for a transfer are not met, the interface pauses before the next transfer. During this pause, the SPI uses the SPI_CTL.SELST bit to determine the state of the chip select pin. The SPI uses the SPI_DLY.LEADX and SPI_DLY.LAGX bits to determine the timing between SPI_CLK edges and the chip select line.

Flow Control

In controller mode, the target device must drive the SPI_RDY pin. The pin acts as an input signal. The target can deassert the SPI_RDY pin to stop the controller from initiating any new transfer. If SPI_RDY is deasserted in the middle of a transfer, the current transfer continues, and the next transfer will not start unless the target asserts the SPI_RDY signal. Whenever the target deasserts SPI_RDY and stalls the controller, the SPI controller goes into a waiting state, and the SPI_STAT.FCS bit is set. When the target asserts SPI_RDY, the SPI controller resumes operation, and the SPI_STAT.FCS bit is cleared.

In target mode, the SPI_RDY pin acts as an output signal. Flow control can be configured on either the TX channel or the RX channel. The SPI uses the SPI_CTL.FCCH bit to control this configuration. If flow control is configured on the TX channel, as the SPI_TFIFO status nears the empty condition, the SPI_RDY pin is deasserted. If flow control is configured on the RX channel, as the SPI_RFIFO status nears the full condition, the SPI_RDY pin is deasserted. The SPI uses the SPI_CTL.FCWM bits to control the FIFO status at which SPI_RDY deassertion takes place. Flow control in target mode is purely based on the FIFO status and does not depend on the word counters.

The ***SPI Flow Control Timing in Controller Mode*** figure illustrates this timing.

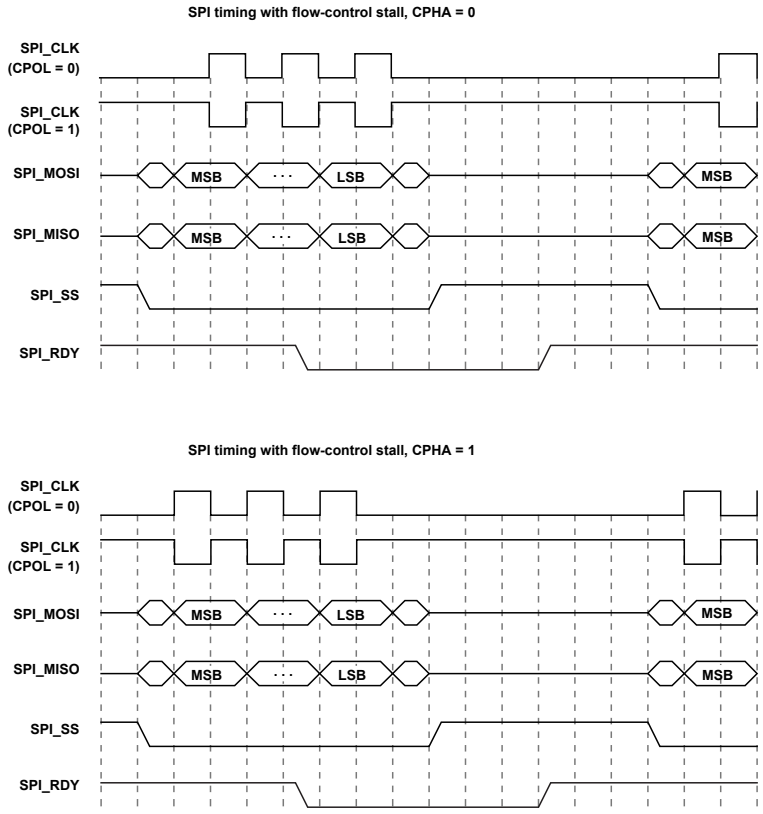

Figure 22-6: SPI Flow Control Timing in Controller Mode.

Target Select Operation

If the SPI is in target mode, $\overline{\texttt{SPI_SS}}$ acts as the target select input. When SPI is enabled as a controller, $\overline{\texttt{SPI_SS}}$ can serve as an error detection input for the SPI in a multi-controller environment. The `SPI_CTL.PSSE` bit enables this feature. When `SPI_CTL.PSSE`=1, the $\overline{\texttt{SPI_SS}}$ input is the controller mode error input. Otherwise, $\overline{\texttt{SPI_SS}}$ is ignored.

The $\overline{\texttt{SPI_SS}}$ signal is an active-low signal. The controller asserts the signal during the transfer. The signal can be deasserted or remain asserted between transfers. When $\overline{\texttt{SPI_SS}}$ is deasserted, `SPI_CLK` and inputs are ignored, and outputs are three-stated.

The target select bits (`SPI_SLVSEL.SSEL1` – `SPI_SLVSEL.SSEL7`) are used in a multiple-target SPI environment. For example, if there are eight SPI devices in the system including a processor controller, the controller processor can support the SPI mode transactions across the other seven devices. This configuration requires only one controller processor in this multi-target environment.

For example, assume that the SPI of the processor is the controller. The `SPI_SLVSEL.SSEL1` – `SPI_SLVSEL.SSEL7` bits on the processor can be connected to the target select pin of each target device. In this configuration, the target select bits can be used in three ways. In cases 1 and 2, the processor is the controller and the seven microcontrollers or targets with SPI interfaces are targets. The processor can do one of the following:

1. Transmit to all seven SPI devices at the same time in a broadcast mode. Here, all target select bits are set.

2. Receive and transmit from one SPI device by enabling only one target SPI device at a time.
3. If all the targets are also processors, then the requester can receive data from only one processor at a time. (The functionality is enabled by clearing the SPI_CTL.EMISO bit in the six other slave processors.) The requestor can transmit broadcast data to all seven at the same time. This MISO enabling feature is available in some other microcontrollers. Therefore, it is possible to use the MISO enabling feature with any other SPI device that includes this functionality.

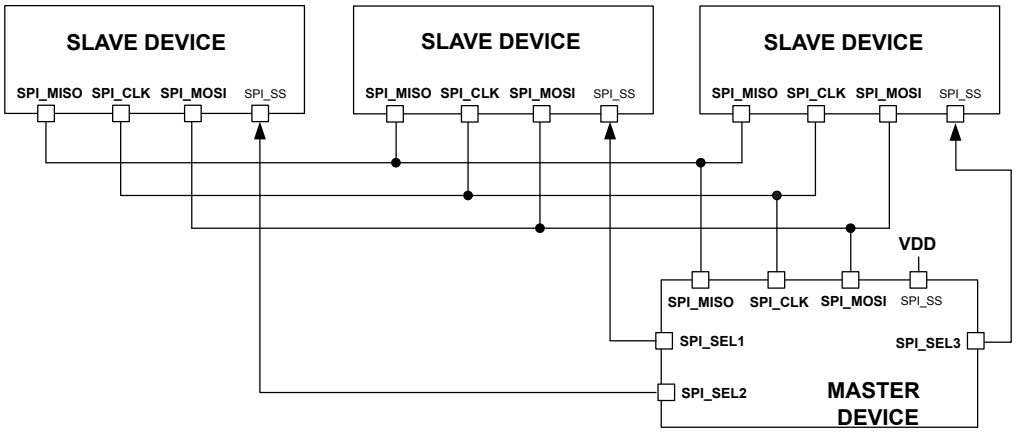

Figure 22-7: Single-Controller, Multiple-Target Configuration

Beginning and Ending a Non-DMA SPI Transfer

The start and finish of a non-DMA SPI transfer depend on the following settings.

1. Whether the device is configured as a controller or a target.
2. The state of the SPI_CTL.ASSEL bit, which selects between hardware and software control over SPI_SLVSEL.

When SPI_CTL.CPHA=0, the enabled target select outputs are driven active. However, the SPI_CLK signal remains inactive for the first half of the first cycle of SPI_CLK. For a target with SPI_CTL.CPHA=0, the transfer starts as soon as the SPI_SS input goes low.

When SPI_CTL.CPHA=1, a transfer starts with the first active edge of SPI_CLK for both target and controller devices. For a controller device, a transfer is complete after it sends the last data and simultaneously receives the last data bit. A transfer for a target device ends after the last sampling edge of SPI_CLK. If SPI_CTL.ASSEL=1, the hardware maintains responsibility for toggling SPI_SS between frames. If SPI_CTL.ASSEL=0, software controls the SPI_SS line and can keep it active between frames.

The SPI_STAT.RFE bit defines when the receive buffer can be read, indicating that SPI_RFIFO is not empty. The SPI_STAT.TFF bit defines when the transmit buffer can be written, indicating that the SPI_TFIFO is not full. The end of a single word transfer occurs when the SPI_STAT.RFE bit is cleared. The status indicates that a new word has been received and written into the receive FIFO. The SPI_STAT.RFE bit remains cleared when the receive FIFO has valid data.

To maintain software compatibility with other SPI devices, the SPI_STAT.SPIF bit is also available for polling. This bit can have a slightly different behavior from other commercially available devices.

In controller mode with the SPI_CTL.ASSEL bit cleared, software manually asserts the required target select signal before starting the transaction. After all data transfers, software typically releases the target select line.

When the receive or transmit word counters are enabled in the SPI_TXCTL or SPI_RXCTL registers, the SPI generates a finish interrupt at the end of the transfer. It signals the end of all transfers related to that transaction.

Transmit Operation in Non-DMA Mode

The transmit operation in non-DMA mode is enabled through the SPI_TXCTL.TEN bit. It can be enabled independently from the receive operation, and the transmit channel can become the initiating channel based on the SPI_TXCTL.TTI bit setting.

Transmit underrun is not possible in this mode, as no new transfer initiates unless the transmit FIFO is empty (in the case that SPI_TXCTL.TTI =1). A receive overflow is detected when data from a new frame transfer replaces older data in a full receive FIFO. This event can occur if SPI_TXCTL.TTI =1 and the receive channel is enabled in a non-initiating capacity.

An SPI transmit interrupt request is signaled once the transmit channel has been enabled and the transmit FIFO is not full. The SPI uses the SPI_TXCTL.TDR bit setting to control the frequency of the interrupt request.

Receive Operation in Non-DMA Mode

The receive operation in non-DMA mode is enabled through the SPI_RXCTL.REN bit. It can be enabled independently from the transmit operation, and the receive channel can become the initiating channel based on the SPI_RXCTL.RTI bit setting.

Receive overflow is not possible in this mode, as no new transfer initiates when the receive FIFO is full (in the case of SPI_RXCTL.RTI =1). A transmit underrun can occur (SPI_TXCTL.TDU bit) when no valid data is in the SPI_TFIFO register when a transfer is initiated. This event can occur if SPI_RXCTL.RTI =1 and the transmit channel is enabled in a non-initiating capacity.

An SPI receive interrupt request is signaled once the receive channel has been enabled and there is data waiting to be read. The SPI uses the SPI_RXCTL.RDR bit setting to control the frequency of the interrupt request.

Dual I/O Mode

In Dual I/O mode, the SPI_MISO and SPI_MOSI pins are configured to operate in the same direction which doubles bandwidth. The SPI uses the SPI_CTL.SOSI bit to determine the order of bits on the pins. When set, the processor sends the first bit on the SPI_MOSI pin and the second bit on the SPI_MISO pin. If the SPI_CTL.SOSI bit is cleared, the order is reversed. Since dual I/O mode uses both pins to transmit or receive data, only one channel can be enabled, either transmit or receive. Flow control through the SPI_RDY pin is supported. Interrupt request generation is unaffected by dual I/O mode. However, the interrupt service interval is reduced because the individual transfer latency is halved.

Changing to quad SPI mode must be done when the SPI is in a quiescent state.

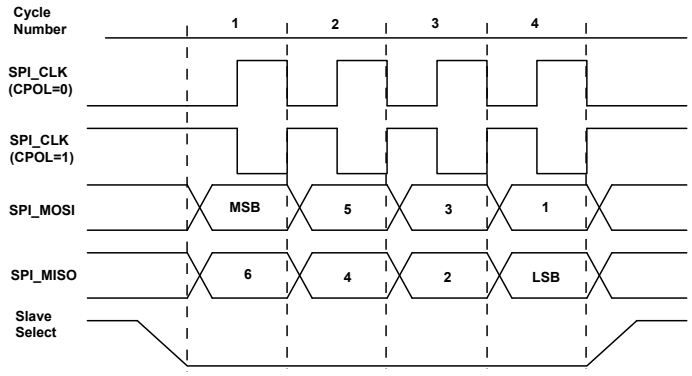

Figure 22-8: Dual I/O Mode Transfer Protocol for CPHA=0, SOSI=1, 8-Bit Transfer, LSBF=0.

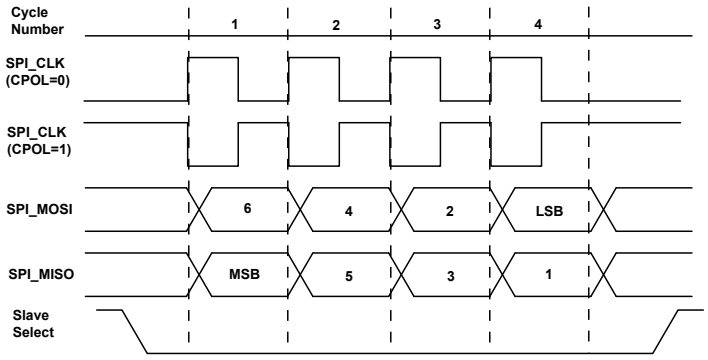

Figure 22-9: Dual I/O Mode Transfer Protocol for CPHA=1, SOSI=0, 8-Bit Transfer, LSBF=0.

Quad I/O Mode (SPI1/SPI2)

In quad SPI mode, the SPI_MISO and SPI_MOSI pins, in tandem with the SPI_D2 and SPI_D3 pins, are configured to operate in the same direction. The SPI uses the SPI_CTL.SOSI bit to determine the order of bits on the pins. When set, the processor sends:

- The first bit on the SPI_MOSI pin
- The second bit on the SPI_MISO pin
- The third bit on the SPI_D2 pin
- The fourth bit on the SPI_D3 pin

If the SPI_CTL.SOSI bit is cleared, the order is reversed. Since quad SPI mode uses all four pins to transmit or receive data, only one channel can be enabled as either transmit or receive. Flow control through the SPI_RDY pin is supported. Interrupt generation is unaffected by quad SPI mode.

Changing to quad SPI mode must be done when the SPI is in a quiescent state.

While using dual or quad I/O mode for communicating with flash devices, program the SPI_CTL.CPHA and the SPI_CTL.CPOL bits =1. This programming avoids bus contention during read operations, because the flash device starts driving out the bits immediately after dummy cycles in read header.

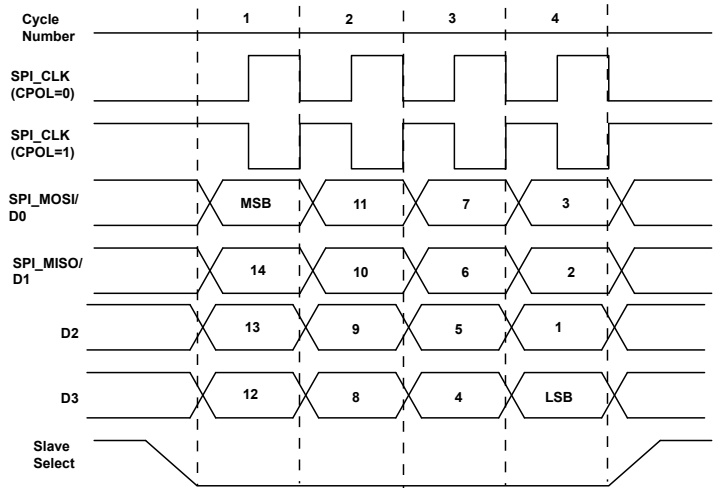

Figure 22-10: Quad Mode Timing for CPHA=0, SOSI=1, 16-Bit Transfer, LSBF=0.

NOTE: The SPI does support quad SPI 8-bit transfer in target continuous mode of operation with an CLKO6:SPI_CLK ratio of less than 1:2. A minimum of 2 CLKO6 cycles is required between transfers in 8-bit quad SPI target mode with an CLKO6:SPI_CLK ratio of less than 1:2.

Fast Mode

Fast mode is like the normal mode of operation when transmitting. When receiving, data is sampled at the next transmit edge allowing a full cycle of timing in the receive direction. This mode is valid in controller mode operation only. When the SPI operates in fast mode, the target drives the data for one full cycle.

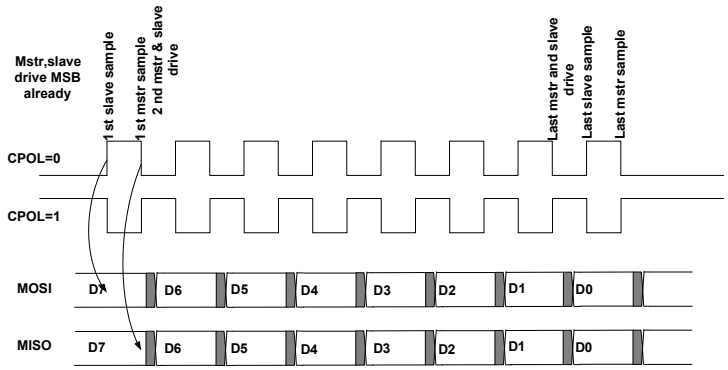

Figure 22-11: SPI Transfer Protocol in Fast Mode for SPI_CTL.CPHA = 0

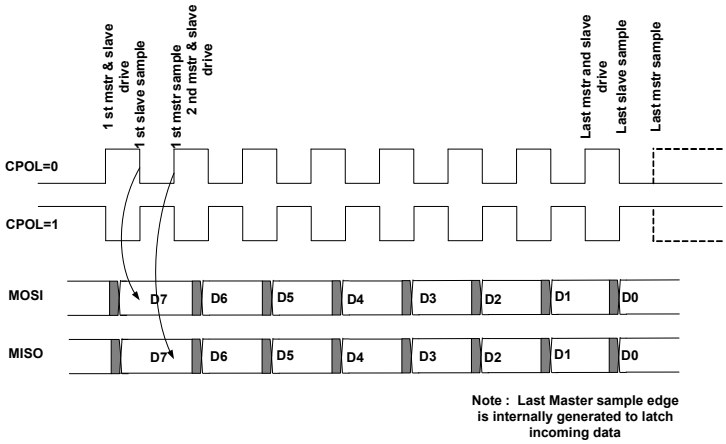

Figure 22-12: SPI Transfer Protocol in Fast Mode for SPI_CTL.CPHA = 1

Memory-Mapped Mode (SPI2)

The SPI supports direct memory-mapped read accesses from a SPI memory device, enabled by setting the `SPI_CTL.MMSE` bit. This mode allows for direct execution of instructions from a SPI memory device without the need for a low-level software driver, as hardware handles all overhead tasks (for example, transmission of the read header, pin turnaround timing, and receive data sizing). The SPI features configurable options in the memory-mapped read header register (`SPI_MMRDH`) to provide compatibility with a wide range of SPI memory devices.

In non-memory-mapped mode, the software is responsible for providing the command and required dummy words for the read response, whereas this is all handled by hardware when the SPI is in memory-mapped mode. The memory of the SPI device is accessible directly through reads of the processor address space. The read accesses can be code or data accesses in core mode or when using memory DMA (MDMA). These accesses allow code to execute directly from SPI memory devices (true eXecute-In-Place operations), and the contents can be cached to improve performance. It is not necessary to access the SPI data buffer registers nor poll status bits; however, the hardware does not support peripheral DMA accesses nor write operations to the SPI memory space.

The ***Types of Operations*** table is a comparison of the permitted operations in the non-memory-mapped and memory-mapped modes supported by the SPI controller.

Table 22-6: Types of Operations

SPI Operation	Non-Memory-Mapped Mode	Memory-Mapped Mode
Core data write	Yes	No
Core data read	Yes	Yes
Code fetch: Execute-In-Place (XIP)	No	Yes
Read/Write accesses using SPI peripheral DMA	Yes	No
Read/Write accesses by other peripheral DMA channels	No	No
MDMA read*	No	Yes

Table 22-6: Types of Operations (Continued)

SPI Operation	Non-Memory-Mapped Mode	Memory-Mapped Mode
MDMA write	No	No

Memory-Mapped Description of Operation

Memory-mapped mode is enabled by setting the SPI_CTL.MMSE bit. When enabled, the SPI (if ready) accepts the read requests through a dedicated on-chip target interface. The memory subsystem controller drives this dedicated interface through the SCB fabric.

In a typical scenario, the memory subsystem controller issues read requests to the fabric, and the fabric routes these requests to the target port of the SPI peripheral. The controller describes the read access using a number of parameters such as starting address, transfer size, and burst type. The SPI responds to this read access request when it is ready for a new transfer. It loads the opcode, a specified number of address bytes, and an optional mode byte into the transmit FIFO. The SPI memory state machine begins when both the transmit and receive channels of the SPI are enabled with:

- the transmit transfer initiation bit is set (SPI_TXCTL.TTI=1), *and*
- the receive initiation bit is cleared (SPI_RXCTL.RTI=0)

The SPI memory read sequence starts with the assertion of $\overline{\text{SPI_SEL1}}$. If the SPI memory state machine is in the reset state, it looks for a command. The SPI hardware then sends the specific 8-bit read command (which can be optionally skipped), followed by the SPI memory read address. After this, a dummy period is inserted, in which a mode byte is optionally sent, and the pins are held or three-stated during the dummy clocking period.

NOTE: This read header is transmitted over the SPI standard protocol pins (SPI_CLK, SPI_MOSI, SPI_MISO, $\overline{\text{SPI_SEL1}}$) or over the extended SPI protocol pins (SPI_CLK, SPI_MOSI, SPI_MISO, SPI_D2, SPI_D3, $\overline{\text{SPI_SEL1}}$), based on the SPI_MMRDH.CMDPINS, SPI_MMRDH.ADRPINS, and SPI_CTL.MIOM bit settings. SPI memory devices usually support communication in MSB-first mode. In dual mode, the SPI typically uses SPI_MISO as IO1 and SPI_MOSI as IO0. In quad mode, the SPI typically uses SPI_D3 pin as IO3, SPI_D2 as IO2, SPI_MISO as IO1, and SPI_MOSI as IO0.

When all I/O data pins are three-stated, the SPI continues clocking the SPI memory device, which drives out the data bits at the addressed location, until all bytes are received. The SPI hardware reads the data as configured by the SPI_CTL.MIOM bit setting. Upon reception of the last byte, the SPI typically deasserts $\overline{\text{SPI_SEL1}}$ to prepare for the next requested read header.

Application code must ensure that the opcode sent is consistent with multiple I/O programming and that the parameters specified in the memory-mapped read header register are consistent with flash read access timing.

The ***SPI Memory-Mapped Register Operations Flow*** diagram shows how the fields of the SPI_MMRDH register determine the read header while initiating transfers in memory-mapped mode.

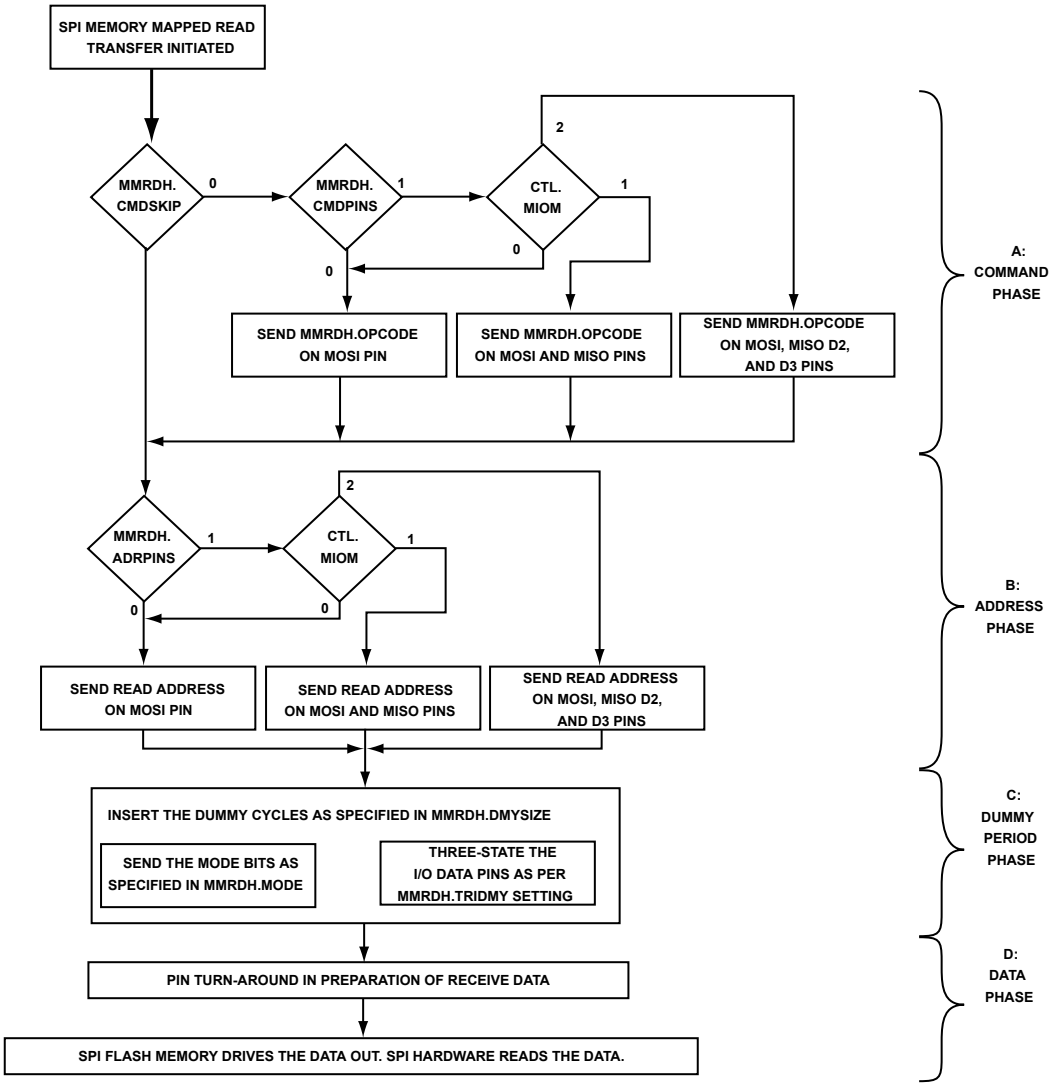

Figure 22-13: SPI Memory-Mapped Register Operations Flow

Memory-Mapped Architectural Concepts

In memory-mapped mode, the SPI accepts read requests through a dedicated on-chip slave interface. The SPI (when ready) accepts these requests and begins the process of assembling the read header based on access attributes described in both the SPI_MMRDH register and the internal bus request. After the read header transmission completes, a pin turnaround period is timed, and the receiver is enabled. The SPI continues clocking the SPI memory device until all bytes are received.

The SPI memory-mapped hardware accommodates various memory devices with different read timing. The capabilities include extra mode bits, flexible dummy period timing, and three-state control, as configured in the SPI_MMRDH register.

The ***Memory-Mapped Protocol*** figure shows the protocol for the SPI controller in memory-mapped mode.

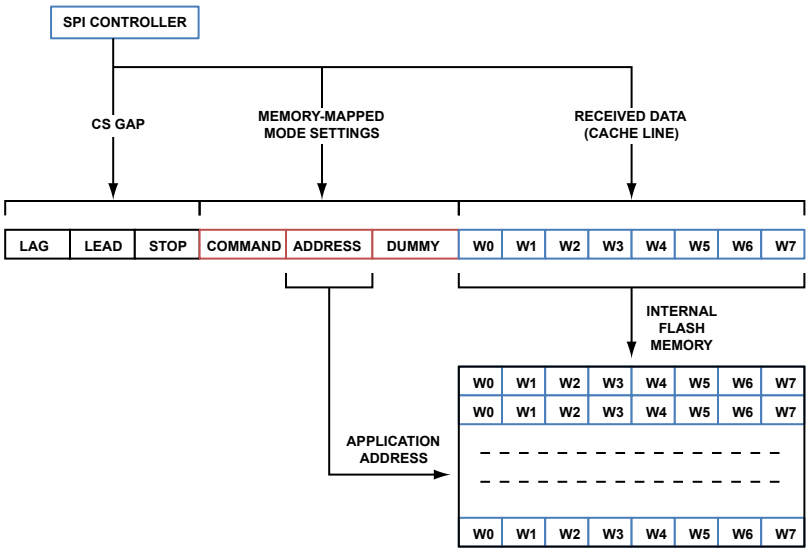

Figure 22-14: Memory-Mapped Protocol

As shown in the figure, the COMMAND field (`SPI_MMRDH.OPCODE`) is transmitted upon assertion of the `SPI_SEL[n]` signal. The SPI memory interprets this 8-bit value as a read command. Any 8-bit read opcode whose timing is compliant with the processor SPI and features provided by memory-mapped hardware is allowed, the most common being:

- Standard Read (0x03)
- Fast Read (0x0B)
- Fast Read Dual Output (0x3B)
- Fast Read Dual I/O (0x6B)
- Fast Read Quad Output (0xBB)
- Fast Read Quad I/O (0xEB)

NOTE: The SPI hardware does not validate the content of the `SPI_MMRDH.OPCODE` field prior to transmitting.

DMYSIZE (Number of Dummy Bytes)

When operating at a high clock frequency in multi-IO modes, most flash devices require some dummy clocks after the address bits. These dummy clock cycles allow the internal circuits of the device extra time for setting up the initial address. These bits specify the number of bytes separating address transmission and read data return.

The number of dummy cycles required varies per manufacturer, the read command used, and the SPI access time. The SPI hardware allows dummy cycles to be programmed in bytes in the `SPI_MMRDH.DMYSIZE` field, the value of which is a function of the number of pins used to transmit the address (`SPI_MMRDH.ADRPINS`), as shown in the ***Pins Used to Transmit the Address (ADRPINS)*** table.

Table 22-7: Pins Used to Transmit the Address (ADRPINS)

	Dummy clock cycles		
SPI_MMRDH.DMYSIZE	(**SPI_MMRDH.ADRPINS**=0, **SPI_CTL.MIOM**=x) Dummy bytes elapse over 1-pin	(**SPI_MMRDH.ADRPINS**=1, **SPI_CTL.MIOM**=1) Dummy bytes elapse over 2-pins	(**SPI_MMRDH.ADRPINS**=1, MIOM=2) Dummy bytes elapse over 4-pins
000	0	0	0
001	8	4	2
010	16	8	4
011	24	12	6
100	32	16	8
101	40	20	10
110	48	24	12
111	56	28	14

This dummy clocking period allows the mode bits to be sent, the pins to be three-stated, and the pins to be turned around in preparation for the receive data.

Memory-Mapped Read Accesses

The SPI hardware supports the most used read operations.

- Two standard SPI reads (read and read fast), which use the unidirectional `SPI_MOSI` and `SPI_MISO` pins in addition to `SPI_SEL[n]` and `SPI_CLK`
- Four extended SPI multiple I/O reads: dual output, quad output, dual I/O, and quad I/O reads

The ***SPI Read Operations*** table and ***SPI Flash Fast Read Sequence*** figures summarize the types of read operations. Program each read operation in a way that is compatible with the description given in the SPI flash data sheet.

Table 22-8: SPI Read Operations

Operation	Read Command (Opcode)	CMDPIN	ADRPIN	DMYSIZE	Three-state	Multiple I/O Mode	Data Pins
Read	0x03	1	1	Zero	No	No	1
Fast Read	0x0B	1	1	Non-Zero	Yes	No	1
Dual Output Read	0x3B	1	1	Non-Zero	Yes	Yes(IO0-1)	2
Quad Output Read	0x6B	1	1	Non-Zero	Yes	Yes(IO0-3)	4
Dual I/O Read	0xBB	1, 2	2	Non-Zero	Yes	Yes (IO0-1)	2
Quad I/O Read	0xEB	1, 4	4	Non-Zero	Yes	Yes (IO0-3)	4

Some memory devices also support word quad I/O read (0xE7) and octal quad I/O read (0xE3) operations. These operations require fewer dummy cycles than normal quad I/O read operations.

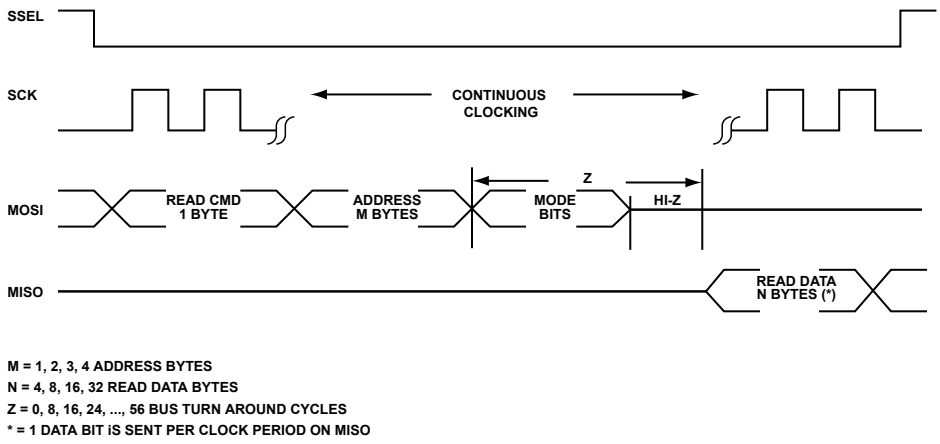

Figure 22-15: SPI Flash Fast Read Sequence

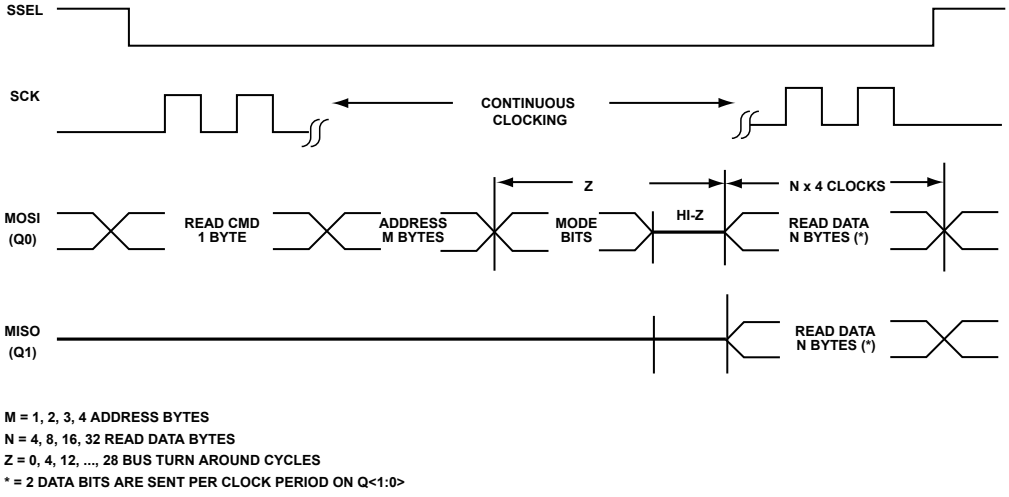

Figure 22-16: SPI Flash Fast Read (Dual Output) Sequence

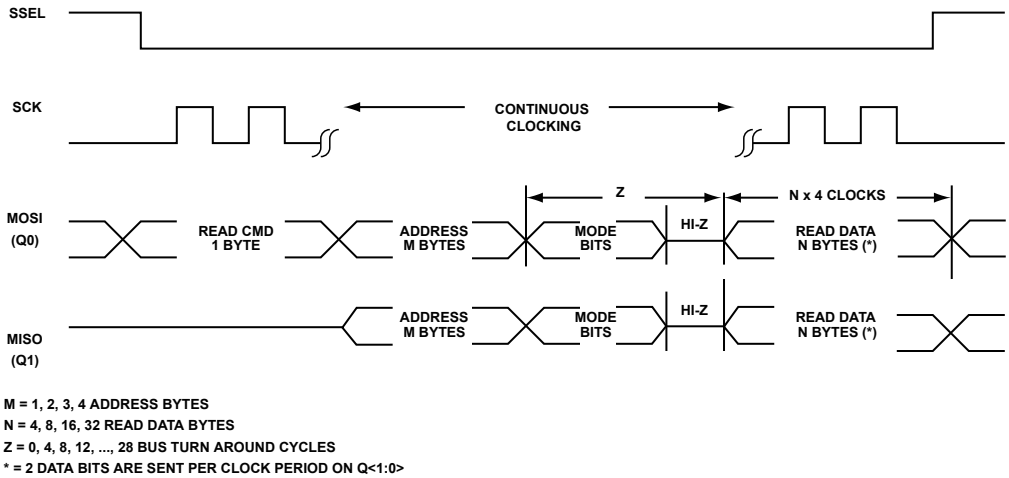

Figure 22-17: SPI Flash Fast Read (Dual I/O) Sequence

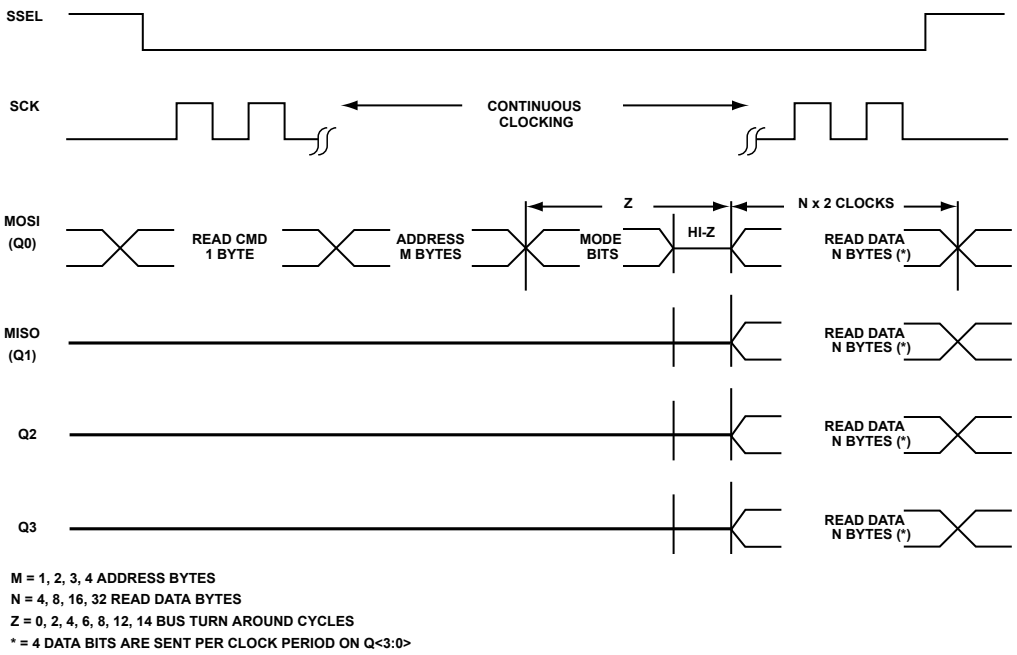

Figure 22-18: SPI Flash Quad Output Read Sequence

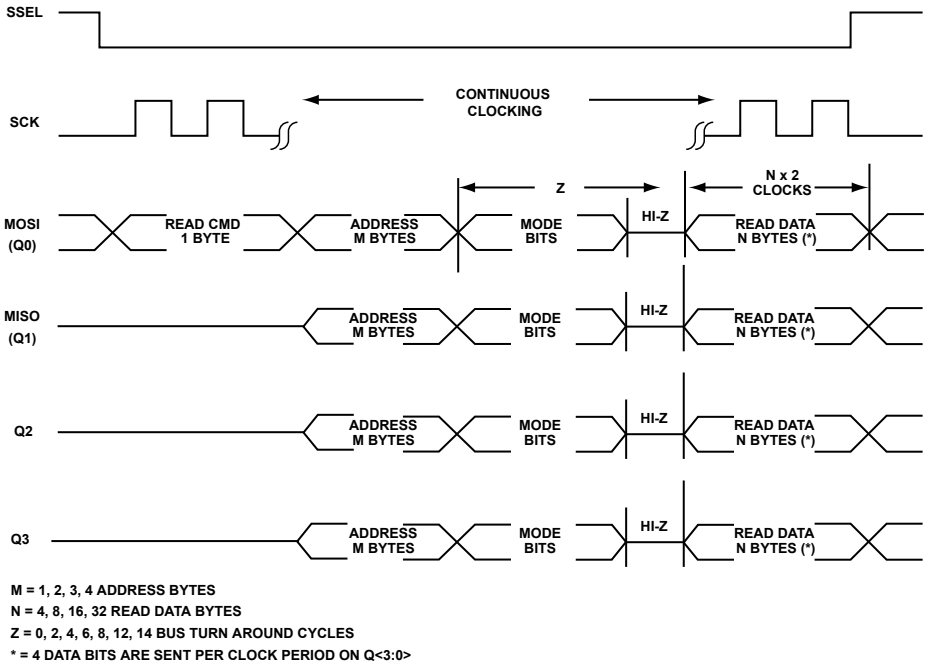

Figure 22-19: SPI Flash Quad I/O Read Sequence

SPI memory-mapped reads can be made cacheable in the core's internal memory by properly configuring the region as cacheable memory without bypass (see the related core's cache configuration documentation for details). In the figures, the number of read data bytes (N) is based on the following:

- For an instruction fetch by core (when in XIP mode); the number of instruction bytes to be fetched depends on the cache line size of the cache.

- For a data fetch by the core (data read), the number of data bytes to be fetched depends on the cache line size of the cache.

Although the minimum size of a memory-mapped data read transfer is 4 bytes, applications can fetch a single byte or a 2-byte data. (For example, it can fetch an unsigned char or short access in C code). In this case, only the required bytes are provided to the core and the other bytes are cached.

The on-chip memory subsystem controller provides a starting address for the burst and the SPI hardware issues this address as part of the read header. The address provided is N-byte aligned. For example, to read the 30th byte from SPI memory, then the typical address to provide is:

- 28 (0x0000_001C) for a 32-bit cache line
- 24 (0x0000_0018) for a 64-bit cache line
- 16 (0x0000_0010) for a 128-bit cache line
- 0 (0x0000_0000) for a 256-bit cache line

The read data is returned to the memory subsystem in the order provided by the SPI memory. There can be considerable delay for the expected data provided to the controller.

To minimize this delay, the wrap feature can be used where the memory subsystem provides the address of the critical word.

- For MDMA reads, the number of read data bytes (N) is always equal to 4 bytes. The MDMA read does not depend on the cache setting. For MDMA reads, limit the `DMA_CFG.MSIZE` field to one, two or four bytes. The address provided by the memory subsystem controller to the SPI hardware is always 4-bytealigned.

Memory-Mapped High-Performance Features

In addition to automating the SPI memory read accesses, the memory-mapped hardware also provides some features to improve SPI memory fetches and increase the system performance. The following sections describe these features.

Merged Read Accesses

It is common for the memory subsystem to fetch two or more cache lines from consecutive addresses (the address sequencing is linear without any jumps). To take advantage of this situation, the SPI memory-mapped hardware provides a feature called merging. Enable merging by setting the `SPI_MMRDH.MERGE` bit.

When enabled, the hardware compares the address of an incoming read request to the address of a request the SPI memory is actively servicing. It can decide to merge two accesses when the address for the second access is incremental. For example, if the first address of a 32-byte cache line fetch is 0x0000_0000 and the second fetch is to address 0x0000_0020, then these two accesses can be merged. Merging increases efficiency and overall fetch bandwidth by eliminating the read header for those accesses which only require continuation of the SPI clock.

Wrap Around Accesses

Many SPI flash memory devices support wrapping which is used to enhance critical word fetching of cache lines. In this mode, the SPI device automatically wraps the read address to the base of a cache line once the end of the cache line is reached.

Wrap around accesses are enabled by setting the SPI_MMRDH.WRAP bit.

Some flash devices require programs to send a ***Set Wrap*** command to place the device in wrap mode. Other flash devices provide a configuration register which must be programmed to set the flash in wrap mode. Since the SPI memory-mapped hardware does not support any write operations to flash, perform this step in non-memory-mapped mode (SPI_CTL.MMSE=0) by accessing the SPI registers.

Data access is limited to 8-byte, 16-byte, or 32-byte sections of flash page in wrap mode. The Arm core uses the Wrap 4 access (64-bit data) for L1 cache. The Arm core uses Wrap 4 and Wrap 8 accesses (64-bit data) for L2 cache. The cores use the Wrap 8 accesses for unaligned accesses. During the read request to the SPI memory-mapped hardware, the memory subsystem controller of the processor provides the address of a critical word instead of the line base. The read-data starts at the address specified in the instruction. Once it reaches the end boundary of the 8, 16, or 32-byte section, the output automatically wraps around to the beginning boundary to the line base address. The data fetch continues. It is not necessary to deassert the SPI SPI_SEL[n] signal or resend the read header to wrap to the cache line base when servicing misaligned cache fill requests.

The ***Byte Sequence in Wrap Modes*** table shows byte sequences in various wrap modes.

Table 22-9: Byte Sequence in Wrap Modes

Starting Address	8-Byte Wrap (cache_line = 8 byte)
0	0-1-2- . . . -6-7
1	1-2- 3-. . . -7-0
7	7-0-1- . . . -5-6
15	15-8-9- . . . -13-14
31	31-24-25-. . . .-29-30

The burst with wrap feature allows applications to fetch a critical address quickly. Applications then fill the cache afterwards within a fixed length (8/16/32-byte) of data without issuing multiple read commands. Certain applications can benefit from this feature to improve cache fill efficiency and overall performance of system code execution.

NOTE: Do not use the merge and wrap feature together. Using wrap bursts can unintentionally disable merging (merging cannot occur for unaligned wrapping bursts). A wrap burst can start fetching data words in the middle of the cache line and cannot be merged with the next access.

Execute-In-Place (XIP, SPI2 only)

Execute-In-Place, known as XIP, permits software code to execute directly from an SPI flash device rather than downloading the code and executing it out of RAM. XIP, also known as Command Skip mode, is a general term and can be applied to fetching data as well.

There is a difference between XIP mode and standard mode. In XIP mode, after the SPI memory device is selected (CS# =LOW), the memory device does not decode the first input byte as command code. Instead, it expects the read header to directly start with address bytes. In standard mode, the memory decodes the first input byte it receives as a command code.

The XIP mode dramatically reduces random access time for applications that require fast code execution without shadowing the memory content on a RAM. The SPI memory-mapped hardware provides a control bit, SPI_MMRDH.CMDSKIP to skip the command from read header.

Some SPI memory devices require configuration of their control register to enable the XIP mode of operation, using the non-memory-mapped mode of the processor SPI. Typically, during the dummy cycle period, the mode bits are used to confirm the XIP operation and the SPI_MMRDH.MODE field must be set appropriately. A dummy memory-mapped access may be needed before setting the SPI_MMRDH.CMDSKIP bit to set the SPI memory device in Command Skip mode.

For more details about how to configure SPI memories into XIP mode, refer to the device data sheet.

NOTE: When configuring the flash to XIP mode from the SHARC+ core, ensure that the routine that configures flash to XIP is not routed through the L2CC. This is accomplished by first configuring the flash to XIP mode, then enabling the L2CC from the core.

Memory-Mapped Mode Error Status Bits

The SPI memory-mapped hardware provides bits in the SPI_STAT register to report errors. It provides these bits for notification only and their state has no effect on SPI operations. The status register bits are sticky. A W1C (write-1-to-clear) operation clears the bits.

- Memory-Mapped Write Error (SPI_STAT.MMWE). This bit is set (=1) if an attempt is made to write to address space that is reserved for memory-mapped SPI memory. The SPI memory-mapped hardware does not support automated write access to SPI memory space.
- Memory-Mapped Read Error (SPI_STAT.MMRE). This bit is set (=1) if an attempt is made to read address space reserved for memory-mapped SPI memory while memory mapping is disabled (SPI_CTL.MMSE =0).
- Memory-Mapped Access Error (SPI_STAT.MMAE). This bit is set (=1) if an attempt is made to access either the TX or RX FIFO while memory-mapped access of SPI memory is enabled. In this case, attempts to communicate with the SPI device using legacy methods are blocked and receive fabric reports an error. Legacy methods include any direct access made to the TX and RX FIFOs, whether by DMA or processor MMR.
- Memory-Mapped Write Error Mask (SPI_CTL.MMWEM) bit specifies whether an error response is returned to the fabric on write attempts to address space that is reserved for memory-mapped SPI memory reads. Regardless of whether a write error response is masked using this bit, the memory-mapped write error (SPI_STAT.MMWE) sticky notification bit is still set.

  NOTE: Unlike other bits in the SPI_STAT register, these memory-mapped mode error bits do not have associated bits in the SPI interrupt mask (SPI_IMSK) and SPI interrupt condition (SPI_ILAT) registers.

The memory-mapped top register (SPI_MMTOP) is used to specify the upper limit of the SPI memory address. The memory-mapped accesses to SPI memory addresses equal to or above this range are considered illegal. The accesses are blocked, and a bus error response is generated.

This register is useful to block the invalid SPI memory address accesses. Some SPI memory vendors do not clearly specify (guarantee) that overrange address bits are ignored (address spaces can be wrapped).

Memory-Mapped Programming Guidelines

Setting the SPI_CTL.MMSE bit enables SPI memory-mapped mode. When enabled, the SPI interface is forced to be consistent with SPI memory requirements regardless the settings of certain control bits. The following tables specify typical settings for configuring the SPI in memory-mapped mode:

Table 22-10: SPI Control (SPI_CTL) Register

Bits	Typical values to set	Description	Comments
SPI_CTL.MSTR	1	Controller mode enable	
SPI_CTL.PSSE	0	Protected target select enable	
SPI_CTL.ODM	0	Open-drain mode enable	
SPI_CTL.CPHASPI_CTL.CPOL	0–0 or 1–1	SPI mode of communication	Flash dependent, usually SPI flash supports mode-0 (CPHA=CPOL=0) and mode-3 (CPHA=CPOL=1)
SPI_CTL.ASSEL	1	Hardware target select pin control	
SPI_CTL.SELST	1	Target select asserted between transfers	
SPI_CTL.EMISO	1	MISO pin enable	
SPI_CTL.SIZE	2	32-bit transfer size	
SPI_CTL.LSBF	0	MSB bit first mode	Flash dependent, usually SPI flash communicates in MSB bit first mode
SPI_CTL.FCEN SPI_CTL.FCCH SPI_CTL.FCPL SPI_CTL.FCWM	0	Hardware flow control related bits	
SPI_CTL.FMODE	1	Fast mode enable	Typically set to 1 for full cycle timing, 0 only works at low speed
SPI_CTL.SOSI	0	Treat SPI_MOSI pin as IO0 pin.	

Table 22-11: SPI Receive Control Register

Bits	Typical values to set	Description
SPI_RXCTL.REN	1	Receive channel enable
SPI_RXCTL.RTI	0	Receive transfer initiation disable
SPI_RXCTL.RWCEN	0	Receive word counter disable

Table 22-11: SPI Receive Control Register (Continued)

Bits	Typical values to set	Description
SPI_RXCTL.RDR	0	Receive data request disable
SPI_RXCTL.RDO	0	Discard incoming data if RFIFO is full
SPI_RXCTL.RRWM	0	Receive FIFO regular watermark
SPI_RXCTL.RUWM	0	Receive FIFO urgent watermark disable

Table 22-12: SPI Transmit Control Register

Bits	Typical values to set	Description
SPI_TXCTL.TEN	1	Transmit channel enable
SPI_TXCTL.TTI	1	Transmit transfer initiation disable
SPI_TXCTL.TWCEN	0	Transmit word counter disable
SPI_TXCTL.TDR	0	Transmit data request disable
SPI_TXCTL.TDU	0	Send last word when TFIFO is empty
SPI_TXCTL.TRWM	0	Transmit FIFO regular watermark
SPI_TXCTL.TUWM	0	Transmit FIFO urgent watermark disable

Table 22-13: SPI DLY Control Register

Bits	Typical Values to Set	Description	Comments See Flash data sheet for CS (for example, SSEL) Timing Specs
SPI_DLY.LAGX	1	Extended lag timing	
SPI_DLY.LEADX	1	Extended lead timing	
SPI_DLY.STOP	3	Stop bit between the transfers	Can be set to 1 at lower SPI clock frequencies.

The multiple I/O mode (SPI_CTL.MIOM) bits are partially ignored:

- The command (opcode) is transmitted using either just one or the number of pins specified by the SPI_CTL.MIOM bits, depending on SPI_MMRDH.CMDPINS bit setting.
- The address is then transmitted using either just one or the number of pins specified by the SPI_CTL.MIOM bits, depending on SPI_MMRDH.ADRPINS bit setting.
- The data is always read with the number of pins specified by the SPI_CTL.MIOM bits.

NOTE: Set the SPI module enable bits SPI_CTL.EN last after configuring all registers.

Use the following programming guidelines for memory-mapped mode:

- The SPI memory-mapped hardware does not check the flash status before initiating the access. It assumes that SPI memory is always able to respond to a read access. Before enabling memory-mapped mode (for example, setting the SPI_CTL.MMSE bit) ensure that SPI flash is ready for a read access. When using non-memory-mapped mode, a write-complete status can be examined prior to enabling the SPI in memory-mapped mode. (See the write in progress bit in the SPI flash memory status register.) Also, immediately after initial power-up, SPI memory devices can be inaccessible for a vendor-specified period.
- When SPI is enabled in memory-mapped mode, attempts to communicate with the SPI device using legacy methods are blocked. Legacy methods include any direct access made to the transmit or receive FIFOs, whether initiated by DMA or by a processor MMR access.
- To use some of the features offered by SPI memory devices, programs can first configure the SPI memory device by setting its control word or sending some commands. Because SPI memory-mapped hardware does not allow any type of SPI write operations, configure the SPI in non-memory-mapped mode prior to enabling memory-mapped mode.
- The memory-mapped hardware does not interpret the opcode. It does not check the validity of the timing that is specified in the SPI_MMRDH register for a particular opcode. Programs must set the fields of the SPI_MMRDH register to be consistent with the read-type selected.
- When the core requests the data or code fetch, the memory-mapped transfer depends on cache settings. The cache configuration register in the SPI memory device must be appropriately configured before enabling memory-mapped mode. Some of the high performance modes like merge, wrap, and transfer size depend on cache parameters.
- SPI memory-mapped MDMA reads do not support wrapping. For MDMA reads, limit the DMA_CFG.MSIZE field to 1 byte, 2 bytes or 4 bytes.
- There is not always tool support to change the SPI memory-mapped hardware setting or cache settings on-the-fly. Changing these settings can optimize the performance of code that accesses SPI memory in memory-mapped mode. It is expected that the SPI memory, SPI peripheral, and cache are programmed to one specific set of control settings for the whole application. Profiling or benchmarking of the actual application can be done to find the setting that works best.

SPI Interrupt Signals

The SPI controller supports three types of interrupt request signals that correspond to data, status, and error conditions.

Data Interrupts

The SPI target supports two data interrupt channels – receive and transmit. These interrupt signals are multiplexed into the DMA request lines. Since the target interfaces with separate read and write interfaces with DMA, the read and write data interrupts are independent. When the DMA channels are not used, the interrupts are routed directly to the system event controller. The interrupts occupy the same vector locations as the corresponding DMA channels.

Each of the data interrupt requests can be individually controlled. Program the SPI_RXCTL.RDR and SPI_TXCTL.TDR bit fields for receive and transmit, respectively. When receive is enabled, the RX interrupt request is issued whenever there is data available in the receive datapath for reading. (The event occurs according to the SPI_RXCTL.RDR bit setting.) When transmit is enabled, the TX interrupt request is issued whenever the transmit datapath can be written. (The event occurs according to the SPI_TXCTL.TDR setting.) DMA data interrupts are compatible with second-generation DMA to incorporate urgent data requests and transfer finish interrupt requests apart from the usual data request interrupts. Transmit interrupt requests operate independently from the word counter-value in the SPI_TWC register.

Status Interrupts

The SPI controller supports several status interrupt requests to indicate different conditions of the receiver and transmitter. All status interrupt requests can be masked. Status interrupt requests are signaled directly through a single SPI status IRQ line. The line cannot be combined with the SPI error IRQ line for some processors. The ***SPI Status Interrupts*** table describes the status interrupt requests that are available for the SPI controller.

Table 22-14: SPI Status Interrupts

SPI_STAT Bit	Description
SPI_STAT.RUWM	Receive FIFO urgent watermark interrupt request. Issued when the level of the RFIFO breaches the watermark set in the SPI_RXCTL.RUWM field. It is cleared when the level of the RFIFO reaches the watermark set in the SPI_RXCTL.RRWM field. If the RX channel is configured in DMA mode, SPI_RXCTL.RUWM is multiplexed with the data request.
SPI_STAT.TUWM	Transmit FIFO urgent watermark interrupt request. Issued when the level of the TFIFO breaches the watermark set using the SPI_TXCTL.TUWM bit. It is cleared when the level of the TFIFO reaches the watermark set in the SPI_TXCTL.TRWM field. If the TX channel is configured in DMA mode, SPI_STAT.TUWM is multiplexed with the data request.
SPI_STAT.TS	Transmit start interrupt request. Issued when the start of a transmit burst is detected by loading of the SPI_TWC register with the contents of the SPI_TWCR register.
SPI_STAT.RS	Receive start interrupt request. Issued when the start of a receive burst is detected by the loading of SPI_RWC with the contents of SPI_RWCR.
SPI_STAT.TF	Transmit finish interrupt request. Issued when a transmit burst completes (SPI_TWC decrements to zero).
SPI_STAT.RF	Receive finish interrupt request. Issued when a receive burst completes (SPI_RWC decrements to zero).

Error Conditions

The SPI controller supports interrupt requests upon several different error conditions. All interrupt requests are maskable. The individual error indications combine into a single SPI error IRQ signal, which can be multiplexed on some processors with the aggregated SPI status IRQ signal. The ***SPI Error Interrupts*** table details the possible error indications.

Error conditions arise depending on which of the channels (transmit or receive) are enabled. If a channel is disabled, all errors related to it are ignored. When both channels are enabled, errors from both channels are enabled.

Table 22-15: SPI Error Interrupts

Bit	Description
SPI_STAT.MF	Mode fault. Signaled when another device also tries to be a controller in a multi-controller system and drives the SPI_SS input low. This error is signaled in controller mode operation.
SPI_STAT.TUR	Transmission error. Signaled when an underflow condition occurs on the transmit channel. This event occurs when a new transfer starts but SPI_TFIFO is empty. This error does not occur in controller transmit initiating mode since SPI_TFIFO *Not Empty* is one of the conditions for transfer initiation.
SPI_STAT.ROR	Reception error. Signaled when an overflow condition occurs on the receive channel. This event occurs when a new data word is received, but the SPI_RFIFO is full. This error condition does not occur in controller receive initiating mode since SPI_RFIFO *Not Full* is one of the conditions for transfer initiation.
SPI_STAT.TC	Transmit collision error. Signaled when loading data to the transmit shift register happens near the first transmitting edge of SPI_CLK. In target mode of operation, the SPI controller is unaware of when the next transfer starts. Loading of data to the transmit shift register can happen just after the transmitting edge. This event results in the setup time not being met for the first bit transmitted. The transmitted data is corrupt. In SPI_CTL.CPHA 1 mode, the first SPI_CLK edge is taken as the first transmitting edge. If SPI_CTL.CPHA =0, then the last SPI_CLK edge of the last transmission (SPI_CTL.SELST =1) or target select deassertion (SPI_CTL.SELST =0) is taken as the first transmitting edge. This error is signaled only in the target mode of operation. In controller mode of operation, loading of data happens before the first transmitting edge of SPI_CLK.

SPI Programming Concepts

The following sections provide general programming guidelines and procedures.

Programming Guidelines

It is acceptable to program SPI_RXCTL and SPI_TXCTL registers after programming the SPI_CTL register. However, program the initiating mode register and its counter-register, if enabled, after the non-initiating mode register. For example, if transmit is the initiating mode and receive is the non-initiating mode, then program the SPI_RXCTL and SPI_RWC registers before the SPI_TXCTL and SPI_TWC registers. If enabling both transmit and receive in initiating mode, enable the SPI_CTL register after programming both the SPI_RXCTL and SPI_TXCTL registers.

These programming guidelines prevent SPI from starting a transfer when SPI registers are not fully programmed. Other ways of programming are also allowed when the initiating conditions prevent the start of communication until after programming of SPI registers is complete.

Avoid data corruption when changing the SPI module configuration. Do not change the configuration during a data transfer. Additionally, change the clock polarity only when no target is selected. However, an exception to this rule exists. When an SPI communication link consists of a single controller and target, SPI_CTL.ASSEL = 0. The target select input of the slave is permanently tied low. In this case, the target is always selected. Avoid data corruption by enabling the target only after both the controller and target devices are configured.

The module supports 8, 16-bit and 32-bit word sizes. To ensure correct operation, configure both the controller and target with the same word size.

Controller Operation in Non-DMA Modes

This section describes the operation of the SPI as a controller in non-DMA mode.

1. Write to the SPI_SLVSEL register, setting one or more of the SPI select enable bits. This operation ensures that the desired targets are properly deselected while the controller is configured.
2. The SPI_RXCTL.RTI and SPI_TXCTL.TTI bits determine the SPI initiating mode. The initiating mode defines the primary transfer channel, and also the initiating condition for the transfer.
3. Write to the SPI_CLK, SPI_CTL, SPI_RXCTL, and SPI_TXCTL registers. This operation enables the device as a controller and configures the SPI system. It specifies the transfer modes and channels, appropriate word length, transfer format, baud rate, and other control information.

   ADDITIONAL INFORMATION: If SPI_RXCTL.RTI is enabled and SPI_TXCTL.TTI is not, write to the SPI_RXCTL register after writing into SPI_CTL, SPI_TXCTL, and SPI_TFIFO registers to prevent a transmit underrun for the first transfer.
4. If SPI_CTL.ASSEL=0, activate the desired targets by clearing one or more of the SPI_SLVSEL flag bits. Otherwise, the SPI hardware performs target activation.
5. The SPI controller then generates the programmed clock pulses on SPI_CLK and simultaneously shifts data out of SPI_MOSI while shifting data in from SPI_MISO. Before a shift, the shift register is loaded with the contents of the SPI_TFIFO register. At the end of the transfer, the contents of the shift register are loaded into SPI_RFIFO.
6. Whenever the initiating conditions are satisfied, the SPI continues to send and receive words. If the transmit buffer remains empty or the receive buffer remains full, the device operates according to the states of the SPI_TXCTL.TDU and SPI_RXCTL.RDO bits.
7. It is possible to program a secondary channel in addition to the initiating channel. This feature allows usage of available channel resources for receives or transmits simultaneously with the initiating channel.

Target Operation in Non-DMA Modes

When a device is enabled as a target in a non-DMA mode, a transition of the $\overline{\text{SPI_SS}}$ select signal to the active state (low) triggers the start of a transfer. Or the first active edge of SPI_CLK triggers the start, depending on the state of SPI_CTL.CPHA bit. The interface operates in the following manner.

1. The core writes to the SPI_CTL, SPI_RXCTL, and SPI_TXCTL registers. The operation defines the mode of the serial link to be the same as the mode setup in the SPI controller.
2. To prepare for the data transfer, the core writes data to be transmitted into SPI_TFIFO.
3. Once the $\overline{\text{SPI_SS}}$ falling edge is detected, the target starts sending data on active SPI_CLK edges and sampling data on inactive SPI_CLK edges.
4. Reception or transmission continues until $\overline{\text{SPI_SS}}$ is released or until the target has received the proper number of clock cycles.

5. The target device continues to receive or transmit with each new falling edge transition on SPI_SS or active SPI_CLK edge. If the transmit buffer remains empty or the receive buffer remains full, the device operates according to the states of the SPI_TXCTL.TDU and SPI_RXCTL.RDO bits.

Configuring DMA Controller Mode

The SPI interface supports a write DMA channel and a read DMA channel. It can use these functions individually or in a lock-step manner in duplex mode (SPI_TXCTL.TTI= SPI_RXCTL.RTI=1).

1. Write to the appropriate DMA registers to enable the SPI DMA channel and to configure the necessary work units, access direction, word count, and so on.
2. Write to the SPI_SLVSEL register, setting one or more of the SPI flag select bits.
3. Write to the SPI_CLK and SPI_CTL registers, enabling the device as a controller and configuring the SPI system by specifying the appropriate word length, transfer format, baud rate, and so forth.
4. Write to SPI_RXCTL to configure SPI controller receive mode, or write to SPI_TXCTL to configure SPI controller transmit mode.
5. Finally, write to the SPI_RXCTL.REN bit to enable the receive channel, or write to SPI_TXCTL.TEN to enable the transmit channel.
6. When the SPI_RXCTL.RTI bit is enabled, a receive transfer is initiated upon enabling SPI_CTL.EN bit. If the receive word counter is enabled (SPI_RXCTL.RWCEN), then the SPI_RWC register must be non-zero for a transfer to initiate.

   ADDITIONAL INFORMATION: If enabling both receive and transmit DMA channels, but not enabling SPI_TXCTL.TTI, write to the SPI_RXCTL register after writing the SPI_CTL and SPI_TXCTL registers. In this way, a transmit underrun can be prevented for the first transfer. Subsequent transfers are initiated as the SPI reads data from the receive shift register and writes to the SPI receive FIFO. The SPI then requests a write from DMA to memory. Upon a DMA grant, the DMA engine reads a word from the SPI receive FIFO and writes to memory. New requests continue to be initiated as long as the receive FIFO does not fill up, when SPI_RWC does not become zero while SPI_RXCTL.RWCEN=1.
7. When SPI_TXCTL.TTI is enabled, the SPI controller requests DMA reads from memory when there is space for more data in the transmit pipe. Upon a DMA grant, the DMA engine reads a word from memory and writes to the transmit FIFO. As long as transmit data is available in the FIFO, and the SPI_TWC register is non-zero when SPI_TXCTL.TWCEN=1, the SPI continues to initiate transfers until disabled.
8. When both the SPI_TXCTL.TTI and SPI_RXCTL.RTI bits are enabled, the SPI controller requests a DMA read from memory. However, there must be space for more data in the transmit pipe and the number of words written into the SPI must be less than SPI_TWC if SPI_TXCTL.TWCEN=1. Upon a DMA grant, the DMA engine reads a word from memory and writes to the transmit FIFO.

   ADDITIONAL INFORMATION: As the SPI writes data from the transmit FIFO into the transmit shift register, it initiates a transfer on the SPI link. Data received from the transfer is moved from the SPI receive shift register to the receive FIFO. The SPI controller requests a write from DMA to memory. Upon a DMA grant,

the DMA engine reads a word from the receive FIFO and writes to memory. Transfer continues to be initiated when both receives and transmits can accommodate new data.

9. When the receive pipe fills up due to unavailability of DMA grants, the transmit pipe stalls until the pipe is drained. If the transmit pipe fills up, the SPI stops requesting for DMA writes. IWhen the value in SPI_RWC expires, further write-requests to DMA stop. However, data already written into the transmit FIFO is sent, and read requests to DMA continue until the receive data is read from the receive FIFO.
10. The SPI then generates the programmed clock pulses on SPI_CLK and simultaneously shifts data out of SPI_MOSI while shifting data in from SPI_MISO. For receive transfers, the value in the shift register is loaded into the SPI_RFIFO register at the end of the transfer. For transmit transfers, the value in the SPI_TFIFO register is loaded into the shift register at the start of the transfer.

Configuring DMA Target Mode Operation

This mode occurs when the SPI is enabled as a target and the DMA engine is configured to transmit or receive data. A transition of the SPI_SS signal to the active-low state triggers the start of a transfer. Or, the first active edge of SPI_CLK triggers the start of a transfer, depending on the state of the SPI_CTL.CPHA bit. The following steps illustrate the SPI receive or transmit DMA sequence in an SPI target (in response to a controller command). The SPI supports a receive DMA channel and a transmit DMA channel.

1. Write to the appropriate DMA registers to enable the SPI DMA channel and configure the necessary work units, access direction, word count, and so on.
2. Write to the SPI_CTL, SPI_RXCTL, and SPI_TXCTL registers to define the mode of the serial link to be the same as the mode configured in the SPI controller.
3. When the receive channel is enabled (SPI_RXCTL.REN is asserted), the following actions occur:
    a. Once the target select input is active, the target starts receiving and transmitting data on active SPI_CLK edges.
    b. The value in the shift register is loaded into the SPI_RFIFO register at the end of the transfer.
    c. Once SPI_RFIFO has valid data, it requests a write from DMA to memory.
    d. Upon a DMA grant, the DMA engine reads a word from the receive FIFO and writes to memory.
    e. When there is data in the receive FIFO, the SPI target continues to request a DMA write to memory. The DMA engine continues to read a word from the FIFO and writes to memory. The SPI target continues receiving words on active SPI_CLK edges when the SPI_SS input is active.
    f. When the data collected in the receive pipe breaches the set level, and the DMA engine cannot keep up with the receive rate, the target can deassert the SPI_RDY signal. This signaling throttles the controller. The receive pipe level is set according to the SPI_CTL.FCWM field. The signal is deasserted as the DMA drains the receive FIFO. Alternatively, the SPI can use the SPI_RXCTL.RDO bit to decide when the incoming data is discarded or overwritten into the receive FIFO (when SPI_CTL.FCEN is inactive).
4. When the transmit channel is enabled (SPI_TXCTL.TEN is asserted), the following actions occur:

a. The SPI requests a DMA read from memory.

b. Upon a DMA grant, the DMA engine reads a word from memory and writes to the transmit FIFO.

c. The SPI then reads DMA data from the transmit FIFO and writes to the transmit shift register, awaiting the start of the next transfer.

d. Once the target select input is active, the target starts receiving and transmitting data on active SPI_CLK edges.

e. When there is room in the transmit FIFO, the SPI target continues to request a DMA read from memory. The DMA engine continues to read a word from memory and write to the transmit FIFO. The SPI target continues transmitting words on active SPI_CLK edges as long as the SPI_SS input is active.

f. When the number of outstanding data entries in the transmit pipe breaches the level set and the DMA cannot keep up with the transmit rate, the target deasserts the SPI_RDY signal. This signaling throttles the controller. The transmit pipe level is set according to the SPI_CTL.FCWM field. The signal is deasserted as the DMA fills the transmit FIFO. Alternately, the SPI_TXCTL.TDU bit decides the state of the transmit data (when SPI_CTL.FCEN is deasserted).

5. When both receive and transmit channels are enabled, the following actions occur after the actions for each channel. Transfers continue when both receive and transmit channels can accommodate new data.

a. When the receive pipe fills up due to the unavailability of DMA grant, the SPI interface stalls the controller by asserting the SPI_RDY pin. This signal is deasserted as the DMA drains the receive FIFO. Alternately, the SPI uses the SPI_RXCTL.RDO bit to decide when the incoming data is discarded or overwritten in the receive FIFO (when SPI_CTL.FCEN is deasserted).

b. When the transmit pipe fills up, the SPI stops requesting DMA writes until the pipe clears.

c. When there is an underflow problem in the transmit pipe, the target stalls the controller by deasserting SPI_RDY while the DMA fills the transmit FIFO. Alternately, the SPI uses the SPI_TXCTL.TDU bit to decide the state of the transmit data (when SPI_CTL.FCEN is deasserted).

ADSP-SC59x SPI Register Descriptions

Serial Peripheral Interface (SPI) contains the following registers.

Table 22-16: ADSP-SC59x SPI Register List

Name	Description
SPI_CLK	Clock Rate Register
SPI_CTL	Control Register
SPI_DLY	Delay Register
SPI_ILAT	Masked Interrupt Condition Register
SPI_ILAT_CLR	Masked Interrupt Clear Register

Table 22-16: ADSP-SC59x SPI Register List (Continued)

Name	Description
SPI_IMSK	Interrupt Mask Register
SPI_IMSK_CLR	Interrupt Mask Clear Register
SPI_IMSK_SET	Interrupt Mask Set Register
SPI_MMRDH	Memory Mapped Read Header
SPI_MMTOP	SPI Memory Top Address
SPI_RFIFO	Receive FIFO Data Register
SPI_RWC	Received Word Count Register
SPI_RWCR	Received Word Count Reload Register
SPI_RXCTL	Receive Control Register
SPI_SLVSEL	Slave Select Register
SPI_STAT	Status Register
SPI_TFIFO	Transmit FIFO Data Register
SPI_TWC	Transmitted Word Count Register
SPI_TWCR	Transmitted Word Count Reload Register
SPI_TXCTL	Transmit Control Register

Clock Rate Register

The SPI_CLK register selects the baud rate for SPI data transfers, relating this rate to the SPI serial clock (SPI clock) and the system clock (CLKO6).

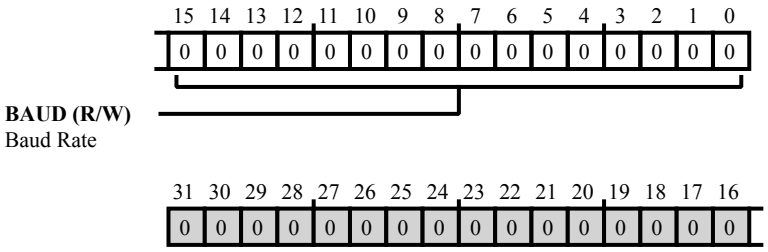

Figure 22-20: SPI_CLK Register Diagram

Table 22-17: SPI_CLK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	BAUD	Baud Rate. The SPI_CLK.BAUD bits set the SPI baud rate according to the formula: BAUD = (CLKO6 / SPI Clock) - 1

Control Register

The SPI_CTL register enables the SPI and configures settings for operating modes, communication protocols, and buffer operations.

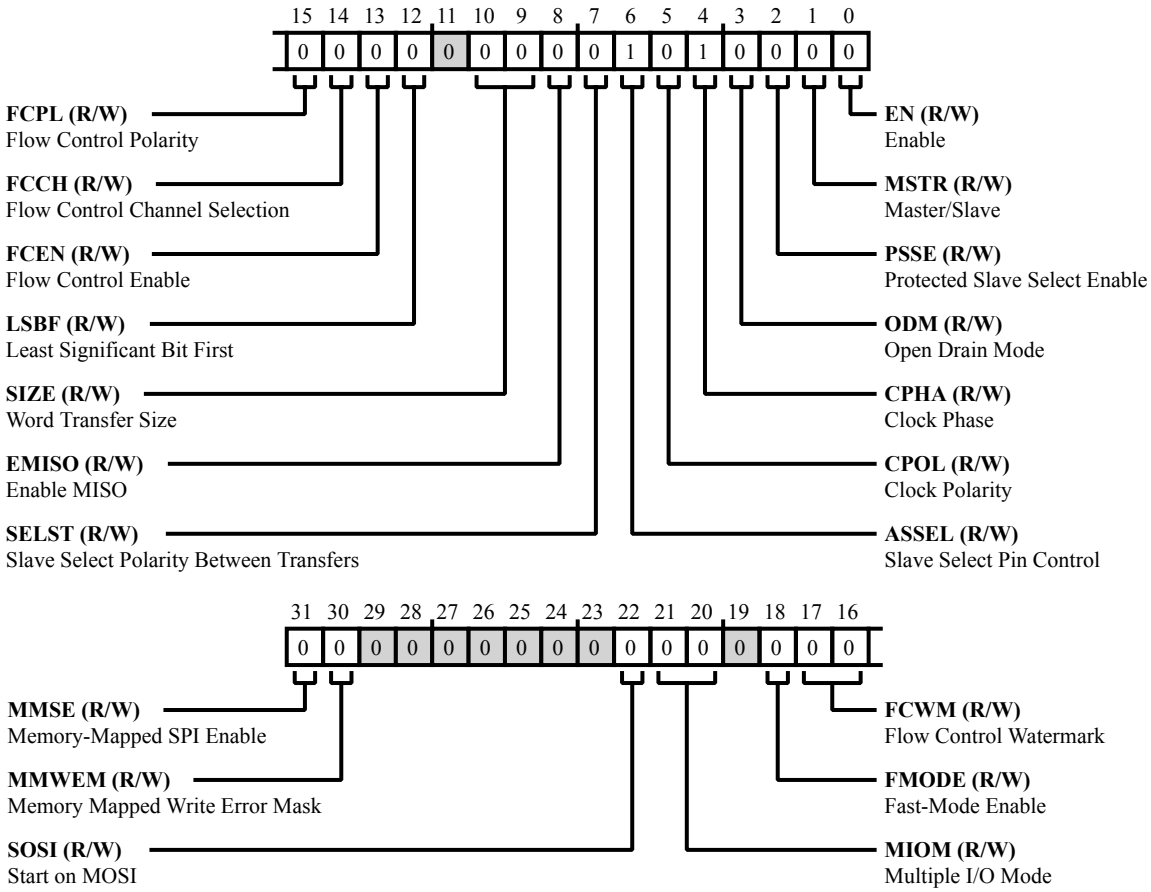

Figure 22-21: SPI_CTL Register Diagram

Table 22-18: SPI_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	MMSE	Memory-Mapped SPI Enable. When the SPI_CTL.MMSE bit is asserted, communication to an SPI memory device is automated such that the memory it contains is accessible directly through the read of processor address space assigned to it. (As far as the SPI peripheral is concerned, this includes all read accesses received by the SPI peripherals system crossbar slave port.) Note that when memory-mapped access of SPI memory is enabled, attempts to communicate with the SPI device using legacy methods are blocked and receive fabric error responses are generated. Legacy methods include any direct access made to the Tx and Rx FIFOs, whether initiated by DMA or processor MMR access.	
		0	Hardware automated access of memory-mapped SPI memory disabled.
		1	Hardware-automated access of memory-mapped SPI memory enabled.
30 (R/W)	MMWEM	Memory Mapped Write Error Mask. The SPI_CTL.MMWEM bit specifies whether an error response is returned to the fabric upon write attempts to address space reserved for memory-mapped reads of SPI memory.	
		0	Write error response returned upon write attempts to memory-mapped SPI memory
		1	Write error response masked (not returned) upon write attempts to memory-mapped SPI memory
22 (R/W)	SOSI	Start on MOSI. The SPI_CTL.SOSI bit is valid only when SPI_CTL.MIOM is enabled for either DIOM or QIOM, and this bit selects the starting pin and the bit placement on pins for these modes. In DIOM, by default, (SPI_CTL.SOSI =0) SPI sends the first bit on the SPI_MISO pin and the second bit on the SPI_MOSI pin. In QIOM, by default, the SPI sends the first bit on the SPI_D3 pin, the second bit on the SPI_D2 pin, the third bit on the SPI_MISO pin and the fourth bit on the SPI_MOSI pin. This order can be reversed by setting the SPI_CTL.SOSI bit. When this bit is set, the SPI sends the first bit on the SPI_MOSI pin. The first bit referred to here depends on the SPI_CTL.LSBF bit setting (MSB bit or LSB bit).	
		0	Start on MISO (DIOM) or start on SPI_D3
		1	Start on MOSI

Table 22-18: SPI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
21:20 (R/W)	MIOM	Multiple I/O Mode. The SPI_CTL.MIOM bits enable SPI operation in dual I/O mode (DIOM) or quad I/O mode (QIOM). These bits can only be changed when the SPI is disabled (SPI_CTL.EN =0).	
		0	No MIOM (disabled)
		1	DIOM operation
		2	QIOM operation
		3	Reserved
18 (R/W)	FMODE	Fast-Mode Enable. The SPI_CTL.FMODE bit enables fast mode operation for SPI receive transfers. SPI transmit operations in fast mode are the same as normal mode.	
		0	Disable
		1	Enable
17:16 (R/W)	FCWM	Flow Control Watermark. The SPI_CTL.FCWM bits select the watermark level of the transmit channel (SPI_TFIFO buffer) or receive channel (SPI_RFIFO buffer) that triggers flow control operation. These bits are applicable only when the SPI is a slave (SPI_CTL.MSTR = 0) and flow control is enabled (SPI_CTL.FCEN =1). When the watermark condition is met, the SPI slave deasserts the SPI_RDY pin.	
		0	TFIFO empty or RFIFO full
		1	TFIFO 75% or more empty, or RFIFO 75% or more full
		2	TFIFO 50% or more empty, or RFIFO 50% or more full
		3	Reserved
15 (R/W)	FCPL	Flow Control Polarity. The SPI_CTL.FCPL bit selects flow control polarity for the SPI_RDY pin when flow control is enabled. When the SPI_RDY pin is active, the SPI is indicating it is ready for data transfer.	
		0	Active-low RDY
		1	Active-high RDY

Table 22-18: SPI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
14 (R/W)	FCCH	Flow Control Channel Selection. The SPI_CTL.FCCH bit selects whether the SPI applies flow control to the transmit channel (SPI_TFIFO buffer) or receive channel (SPI_RFIFO buffer). This bit is applicable only when the SPI is a slave and flow control is enabled.	
		0	Flow control on RX buffer
		1	Flow control on TX buffer
13 (R/W)	FCEN	Flow Control Enable. The SPI_CTL.FCEN bit enables SPI flow control operation, which permits slow slave devices to interface with fast master devices. This bit controls the operation of the SPI_RDY pin. Note that options for flow control operation are available using the SPI_CTL.FCCH, SPI_CTL.FCPL, and SPI_CTL.FCWM bits.	
		0	Disable
		1	Enable
12 (R/W)	LSBF	Least Significant Bit First. The SPI_CTL.LSBF bit selects whether the SPI transmits/receives data as LSB first (little endian) or MSB first (big endian). This bit can only be changed when the SPI is disabled.	
		0	MSB sent/received first (big endian)
		1	LSB sent/received first (little endian)
10:9 (R/W)	SIZE	Word Transfer Size. The SPI_CTL.SIZE bits select the SPI transfer word size as 8, 16 or 32 bits. To ensure correct operation, both the master and slave must be configured with the same word size. This bit can only be changed when the SPI is disabled (SPI_CTL.EN =0).	
		0	8-bit word
		1	16-bit word
		2	32-bit word
		3	Reserved
8 (R/W)	EMISO	Enable MISO. The SPI_CTL.EMISO bit enables master-in-slave-out (MISO) mode. This SPI mode is applicable only when the SPI is a slave.	
		0	Disable
		1	Enable

Table 22-18: SPI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	SELST	Slave Select Polarity Between Transfers. The SPI_CTL.SELST bit selects the state (polarity) for the $\overline{\text{SPI_SEL[n]}}$ pin between SPI transfers when the SPI is a master and hardware slave select assertion is enabled (SPI_CTL.ASSEL =1). In slave mode, this bit affects the detection of both transmit collision (SPI_STAT.TC and underrun (SPI_STAT.TUR) errors.	
		0	Deassert slave select (high)
		1	Assert slave select (low)
6 (R/W)	ASSEL	Slave Select Pin Control. The SPI_CTL.ASSEL bit selects whether the SPI hardware sets the $\overline{\text{SPI_SEL[n]}}$ pin output value (ignoring the slave select SPI_SLVSEL.SSEL1 - SPI_SLVSEL.SSEL7 bits) or whether software control of the slave select bits set the $\overline{\text{SPI_SEL[n]}}$ pin output value. This feature is applicable only when the SPI is a master. When hardware control is enabled, the $\overline{\text{SPI_SEL[n]}}$ pin output is asserted during the transfers, and the pin polarity between transfers is selected by the SPI_CTL.SELST bit. When software control is enabled, the $\overline{\text{SPI_SEL[n]}}$ pin output value is set through software control of the slave select bits, and as such, the pin may either remain asserted (low) or be deasserted between transfers.	
		0	Software slave select control
		1	Hardware slave select control
5 (R/W)	CPOL	Clock Polarity. The SPI_CTL.CPOL bit selects whether the SPI uses an active-low or active-high signal for the SPI clock (SPI_CLK). This bit works with the SPI_CTL.CPHA bit to select combinations of clock phase and polarity for the SPI_CLK pin. This bit can only be changed when the SPI is disabled.	
		0	Active-high SPI CLK
		1	Active-low SPI CLK
4 (R/W)	CPHA	Clock Phase. The SPI_CTL.CPHA bit selects whether the SPI starts toggling the signal for the SPI clock (SPI_CLK) from the start of the first data bit or from the middle of the first data bit. The SPI_CTL.CPHA bit works with the SPI_CTL.CPOL bit to select combinations of clock phase and polarity for the SPI_CLK pin. This bit can only be changed when the SPI is disabled.	
		0	SPI CLK toggles from middle
		1	SPI CLK toggles from start

Table 22-18: SPI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	ODM	Open Drain Mode. The SPI_CTL.ODM bit configures the data output pins (SPI_MOSI and SPI_MISO) to behave as open drain outputs, which prevents contention and possible damage to pin drivers in multi-master or multi-slave SPI systems. When SPI_CTL.ODM is enabled and the SPI is a master, the SPI three-states the SPI_MOSI pin when the data driven out on MOSI is a logic-high. The SPI does not three-state the SPI_MOSI pin when the driven data is a logic-low. When SPI_CTL.ODM is enabled and the SPI is a slave, the SPI three-states the SPI_MISO pin when the data driven out on SPI_MISO is a logic-high. Note that an external pull-up resistor is required on both the SPI_MOSI and SPI_MISO pins when SPI_CTL.ODM is enabled.	
		0	Disable
		1	Enable
2 (R/W)	PSSE	Protected Slave Select Enable. The SPI_CTL.PSSE bit enables the $\overline{\text{SPI_SS}}$ pin to provide error detection input in a multi-master environment when the SPI is in master mode. If some other device in the system asserts the $\overline{\text{SPI_SS}}$ pin while SPI is enabled as master (and SPI_CTL.PSSE is enabled), this condition causes a mode fault error.	
		0	Disable
		1	Enable
1 (R/W)	MSTR	Master/Slave. The SPI_CTL.MSTR bit toggles the SPI between master mode and slave mode. This bit can only be changed when the SPI is disabled.	
		0	Slave
		1	Master
0 (R/W)	EN	Enable. The SPI_CTL.EN bit enables SPI operation.	
		0	Disable SPI module
		1	Enable

Delay Register

The SPI_DLY register selects a transfer delay and the lead/lag timing between slave select signals and SPI clock edge assertion/deassertion.

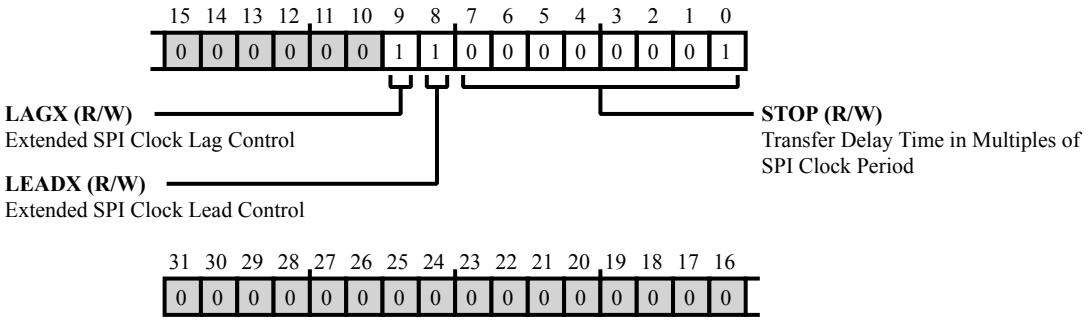

Figure 22-22: SPI_DLY Register Diagram

Table 22-19: SPI_DLY Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W)	LAGX	Extended SPI Clock Lag Control. The SPI_DLY.LAGX bit enables insertion of a 1-SPI_CLK cycle lag (extend lag) in the timing between the slave select (SPI_SEL[n]) assertion and first SPI clock edge.	
		0	Disable
		1	Enable
8 (R/W)	LEADX	Extended SPI Clock Lead Control. The SPI_DLY.LEADX bit enables insertion of a 1-SPI_CLK cycle lead (extend lead) in the timing between the slave select (SPI_SEL[n]) deassertion and last SPI clock edge.	
		0	Disable
		1	Enable
7:0 (R/W)	STOP	Transfer Delay Time in Multiples of SPI Clock Period. The SPI_DLY.STOP bits select a delay (number of stop bits in multiples of SPI clock duration) at the end of each SPI transfer. The default delay is the minimum value required to comply with the SPI protocol (1-bit duration). The SPI_DLY.STOP bits can be programmed with smaller delay values, resulting in continuous operation (for example, stop bits =0).	

Masked Interrupt Condition Register

The SPI_ILAT register latches interrupts, queuing the interrupt requests for service. When a condition is indicated by a bit in the SPI_STAT register and the corresponding interrupt request is unmasked in SPI_IMSK, the SPI latches the interrupt request bit in SPI_ILAT.

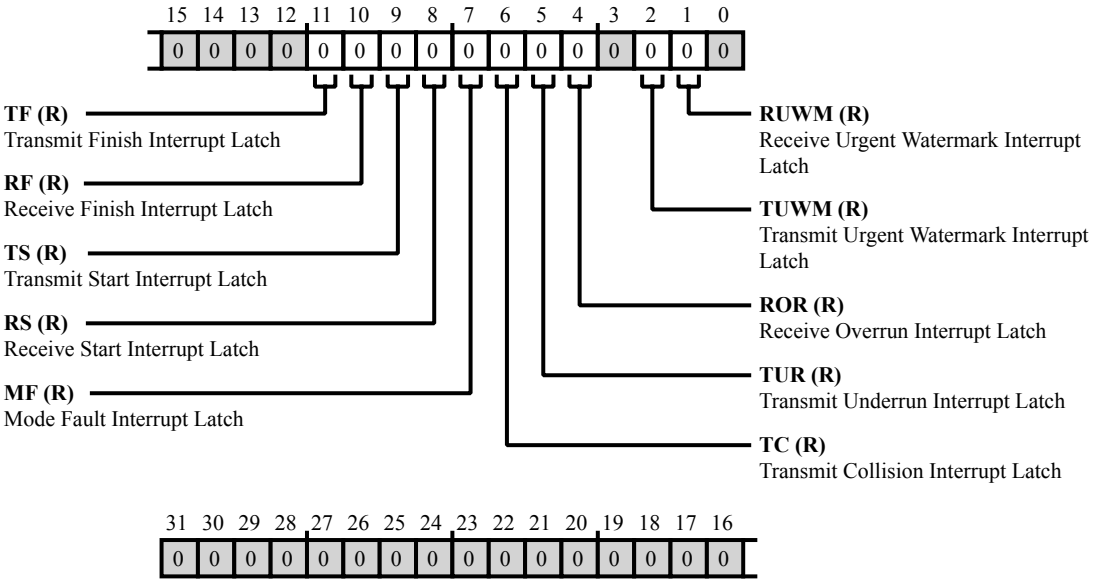

Figure 22-23: SPI_ILAT Register Diagram

Table 22-20: SPI_ILAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/NW)	TF	Transmit Finish Interrupt Latch.	
		0	No interrupt request
		1	Latched interrupt request
10 (R/NW)	RF	Receive Finish Interrupt Latch.	
		0	No interrupt request
		1	Latched interrupt request
9 (R/NW)	TS	Transmit Start Interrupt Latch.	
		0	No interrupt request
		1	Latched interrupt request
8 (R/NW)	RS	Receive Start Interrupt Latch.	
		0	No interrupt request
		1	Latched interrupt request

Table 22-20: SPI_ILAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/NW)	MF	Mode Fault Interrupt Latch.	
		0	No interrupt request
		1	Latched interrupt request
6 (R/NW)	TC	Transmit Collision Interrupt Latch.	
		0	No interrupt request
		1	Latched interrupt request
5 (R/NW)	TUR	Transmit Underrun Interrupt Latch.	
		0	No interrupt request
		1	Latched interrupt request
4 (R/NW)	ROR	Receive Overrun Interrupt Latch.	
		0	No interrupt request
		1	Latched interrupt request
2 (R/NW)	TUWM	Transmit Urgent Watermark Interrupt Latch.	
		0	No interrupt request
		1	Latched interrupt request
1 (R/NW)	RUWM	Receive Urgent Watermark Interrupt Latch.	
		0	No interrupt request
		1	Latched interrupt request

Masked Interrupt Clear Register

The SPI_ILAT_CLR register permits clearing individual mask bits in the SPI_ILAT register without affecting other bits in the register. Use write-1-to-clear on a bit in the SPI_ILAT_CLR register to clear the corresponding bit in the SPI_ILAT register.

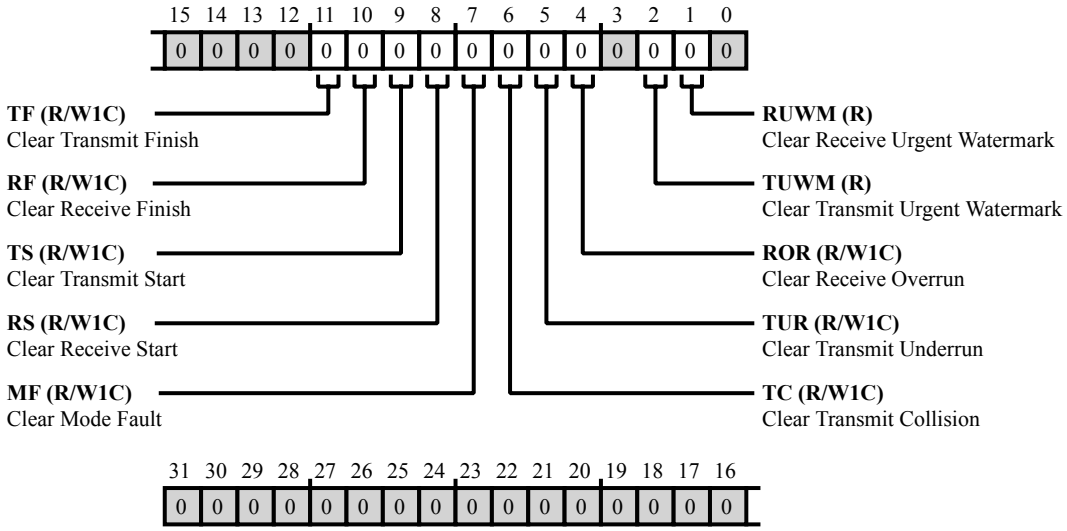

Figure 22-24: SPI_ILAT_CLR Register Diagram

Table 22-21: SPI_ILAT_CLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W1C)	TF	Clear Transmit Finish. The SPI_ILAT_CLR.TF bit clears the corresponding mask bit in the SPI_ILAT register.	
		0	No effect
		1	Clear mask bit
10 (R/W1C)	RF	Clear Receive Finish. The SPI_ILAT_CLR.RF bit clears the corresponding mask bit in the SPI_ILAT register.	
		0	No effect
		1	Clear mask bit
9 (R/W1C)	TS	Clear Transmit Start. The SPI_ILAT_CLR.TS bit clears the corresponding mask bit in the SPI_ILAT register.	
		0	No effect
		1	Clear mask bit

Table 22-21: SPI_ILAT_CLR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W1C)	RS	Clear Receive Start. The SPI_ILAT_CLR.RS bit clears the corresponding mask bit in the SPI_ILAT register.	
		0	No effect
		1	Clear mask bit
7 (R/W1C)	MF	Clear Mode Fault. The SPI_ILAT_CLR.MF bit clears the corresponding mask bit in the SPI_ILAT register.	
		0	No effect
		1	Clear mask bit
6 (R/W1C)	TC	Clear Transmit Collision. The SPI_ILAT_CLR.TC bit clears the corresponding mask bit in the SPI_ILAT register.	
		0	No effect
		1	Clear mask bit
5 (R/W1C)	TUR	Clear Transmit Underrun. The SPI_ILAT_CLR.TUR bit clears the corresponding mask bit in the SPI_ILAT register.	
		0	No effect
		1	Clear mask bit
4 (R/W1C)	ROR	Clear Receive Overrun. The SPI_ILAT_CLR.ROR bit clears the corresponding mask bit in the SPI_ILAT register.	
		0	No effect
		1	Clear mask bit
2 (R/NW)	TUWM	Clear Transmit Urgent Watermark. The SPI_ILAT_CLR.TUWM bit clears the corresponding mask bit in the SPI_ILAT register.	
		0	No effect
		1	Clear mask bit

Table 22-21: SPI_ILAT_CLR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/NW)	RUWM	Clear Receive Urgent Watermark. The `SPI_ILAT_CLR.RUWM` bit clears the corresponding mask bit in the `SPI_ILAT` register.	
		0	No effect
		1	Clear mask bit

Interrupt Mask Register

The SPI_IMSK register unmasks (enables) or masks (disables) SPI interrupt requests. When a condition is indicated by a bit in the SPI_STAT register and the corresponding interrupt request is unmasked in SPI_IMSK, the SPI latches the interrupt request bit in the SPI_ILAT register, queuing the interrupt request for service.

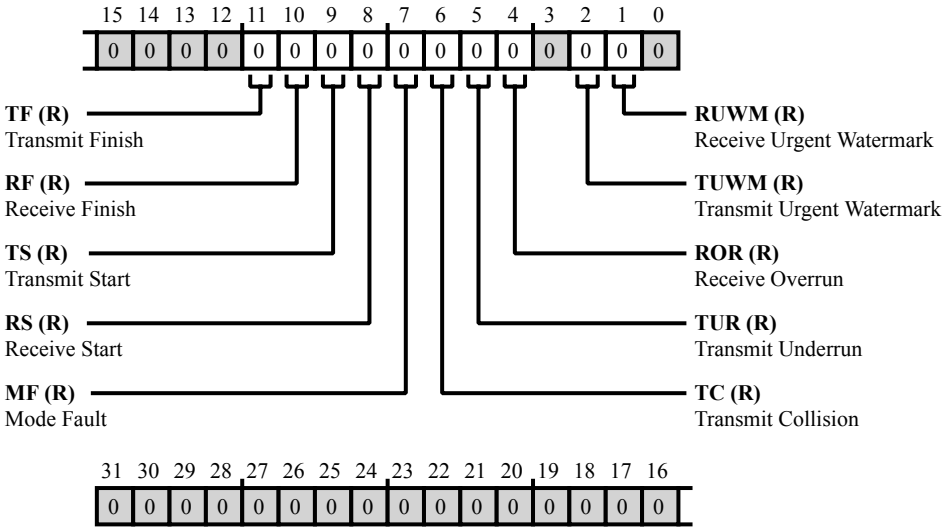

Figure 22-25: SPI_IMSK Register Diagram

Table 22-22: SPI_IMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/NW)	TF	Transmit Finish. The SPI_IMSK.TF bit unmasks (enables) or masks (disables) the TF interrupt.	
		0	Disable (mask) interrupt request
		1	Enable (unmask) interrupt request
10 (R/NW)	RF	Receive Finish. The SPI_IMSK.RF bit unmasks (enables) or masks (disables) the RF interrupt.	
		0	Disable (mask) interrupt request
		1	Enable (unmask) interrupt request
9 (R/NW)	TS	Transmit Start. The SPI_IMSK.TS bit unmasks (enables) or masks (disables) the TS interrupt.	
		0	Disable (mask) interrupt request
		1	Enable (unmask) interrupt request

Table 22-22: SPI_IMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/NW)	RS	Receive Start. The SPI_IMSK.RS bit unmasks (enables) or masks (disables) the RS interrupt.	
		0	Disable (mask) interrupt request
		1	Enable (unmask) interrupt request
7 (R/NW)	MF	Mode Fault. The SPI_IMSK.MF bit unmasks (enables) or masks (disables) the MF interrupt.	
		0	Disable (mask) interrupt request
		1	Enable (unmask) interrupt request
6 (R/NW)	TC	Transmit Collision. The SPI_IMSK.TC bit unmasks (enables) or masks (disables) the TC interrupt.	
		0	Disable (mask) interrupt request
		1	Enable (unmask) interrupt request
5 (R/NW)	TUR	Transmit Underrun. The SPI_IMSK.TUR bit unmasks (enables) or masks (disables) the TUR interrupt.	
		0	Disable (mask) interrupt request
		1	Enable (unmask) interrupt request
4 (R/NW)	ROR	Receive Overrun. The SPI_IMSK.ROR bit unmasks (enables) or masks (disables) the ROR interrupt.	
		0	Disable (mask) interrupt request
		1	Enable (unmask) interrupt request
2 (R/NW)	TUWM	Transmit Urgent Watermark. The SPI_IMSK.TUWM bit unmasks (enables) or masks (disables) the TUWM interrupt.	
		0	Disable (mask) interrupt request
		1	Enable (unmask) interrupt request
1 (R/NW)	RUWM	Receive Urgent Watermark. The SPI_IMSK.RUWM bit unmasks (enables) or masks (disables) the RUWM interrupt.	
		0	Disable (mask) interrupt request
		1	Enable (unmask) interrupt request

Interrupt Mask Clear Register

The SPI_IMSK_CLR register permits clearing individual mask bits in the SPI_IMSK register without affecting other bits in the register. Use write-1-to-clear on a bit in the SPI_IMSK_CLR register to clear the corresponding bit in the SPI_IMSK register.

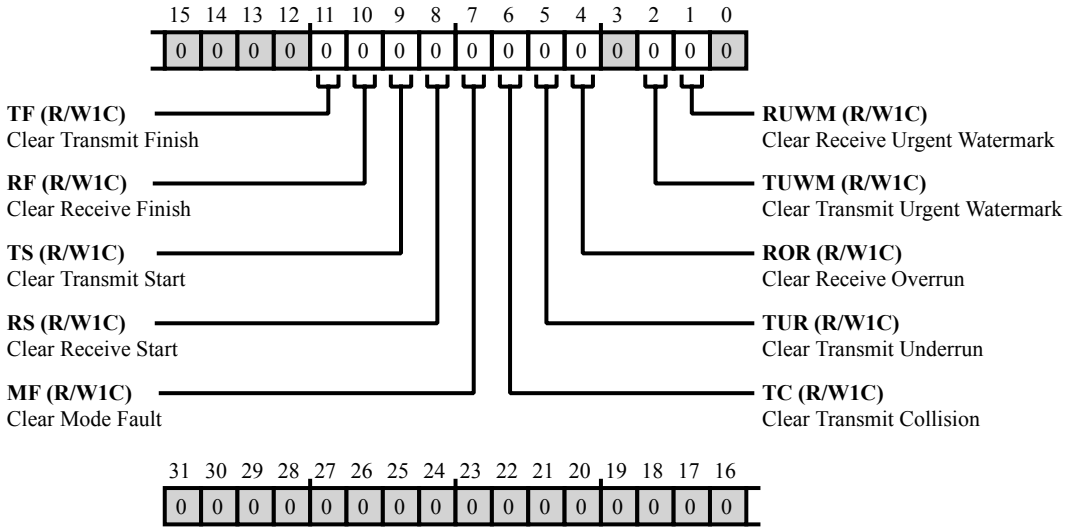

Figure 22-26: SPI_IMSK_CLR Register Diagram

Table 22-23: SPI_IMSK_CLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W1C)	TF	Clear Transmit Finish. The SPI_IMSK_CLR.TF bit clears the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Clear mask bit
10 (R/W1C)	RF	Clear Receive Finish. The SPI_IMSK_CLR.RF bit clears the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Clear mask bit
9 (R/W1C)	TS	Clear Transmit Start. The SPI_IMSK_CLR.TS bit clears the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Clear mask bit

Table 22-23: SPI_IMSK_CLR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W1C)	RS	Clear Receive Start. The SPI_IMSK_CLR.RS bit clears the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Clear mask bit
7 (R/W1C)	MF	Clear Mode Fault. The SPI_IMSK_CLR.MF bit clears the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Clear mask bit
6 (R/W1C)	TC	Clear Transmit Collision. The SPI_IMSK_CLR.TC bit clears the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Clear mask bit
5 (R/W1C)	TUR	Clear Transmit Underrun. The SPI_IMSK_CLR.TUR bit clears the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Clear mask bit
4 (R/W1C)	ROR	Clear Receive Overrun. The SPI_IMSK_CLR.ROR bit clears the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Clear mask bit
2 (R/W1C)	TUWM	Clear Transmit Urgent Watermark. The SPI_IMSK_CLR.TUWM bit clears the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Clear mask bit

Table 22-23: SPI_IMSK_CLR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W1C)	RUWM	Clear Receive Urgent Watermark. The `SPI_IMSK_CLR.RUWM` bit clears the corresponding mask bit in the `SPI_IMSK` register.	
		0	No effect
		1	Clear mask bit

Interrupt Mask Set Register

The SPI_IMSK_SET register permits setting individual mask bits in the SPI_IMSK register without affecting other bits in the register. Use write-1-to-set on a bit in the SPI_IMSK_SET register to set the corresponding bit in the SPI_IMSK register.

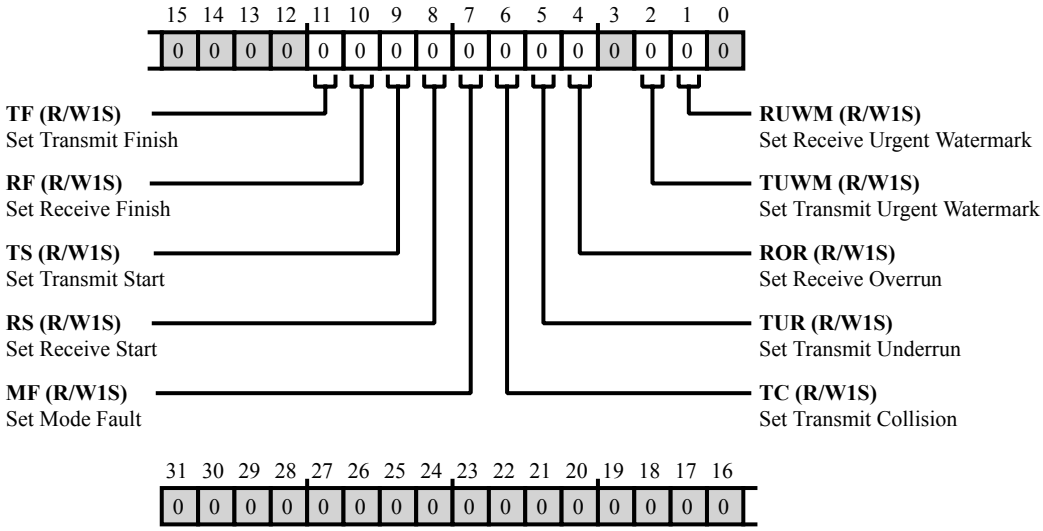

Figure 22-27: SPI_IMSK_SET Register Diagram

Table 22-24: SPI_IMSK_SET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W1S)	TF	Set Transmit Finish. The SPI_IMSK_SET.TF bit sets the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Set mask bit
10 (R/W1S)	RF	Set Receive Finish. The SPI_IMSK_SET.RF bit sets the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Set mask bit
9 (R/W1S)	TS	Set Transmit Start. The SPI_IMSK_SET.TS bit sets the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Set mask bit

Table 22-24: SPI_IMSK_SET Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W1S)	RS	Set Receive Start. The SPI_IMSK_SET.RS bit sets the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Set mask bit
7 (R/W1S)	MF	Set Mode Fault. The SPI_IMSK_SET.MF bit sets the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Set mask bit
6 (R/W1S)	TC	Set Transmit Collision. The SPI_IMSK_SET.TC bit sets the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Set mask bit
5 (R/W1S)	TUR	Set Transmit Underrun. The SPI_IMSK_SET.TUR bit sets the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Set mask bit
4 (R/W1S)	ROR	Set Receive Overrun. The SPI_IMSK_SET.ROR bit sets the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Set mask bit
2 (R/W1S)	TUWM	Set Transmit Urgent Watermark. The SPI_IMSK_SET.TUWM bit sets the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Set mask bit

Table 22-24: SPI_IMSK_SET Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W1S)	RUWM	Set Receive Urgent Watermark. The `SPI_IMSK_SET.RUWM` bit sets the corresponding mask bit in the `SPI_IMSK` register.	
		0	No effect
		1	Set mask bit

Memory Mapped Read Header

The SPI_MMRDH register enables the use of memory-mapped mode. This mode allows direct memory-mapped read accesses of an SPI memory device and is primarily used to directly execute instructions from an SPI FLASH memory without using a low-level software driver. All overhead tasks such as transmission of the read header, pin turnaround timing and receive data sizing are handled in hardware.

The memory-mapped access mode is enabled by setting the SPI_CTL.MMSE bit. The features within the SPI_MMRDH register include a command skip mode, variable length byte addressing, and independent multi-pin support for command transmission, address transmission and data reception. In addition, the command opcode and mode bytes are fully programmable.

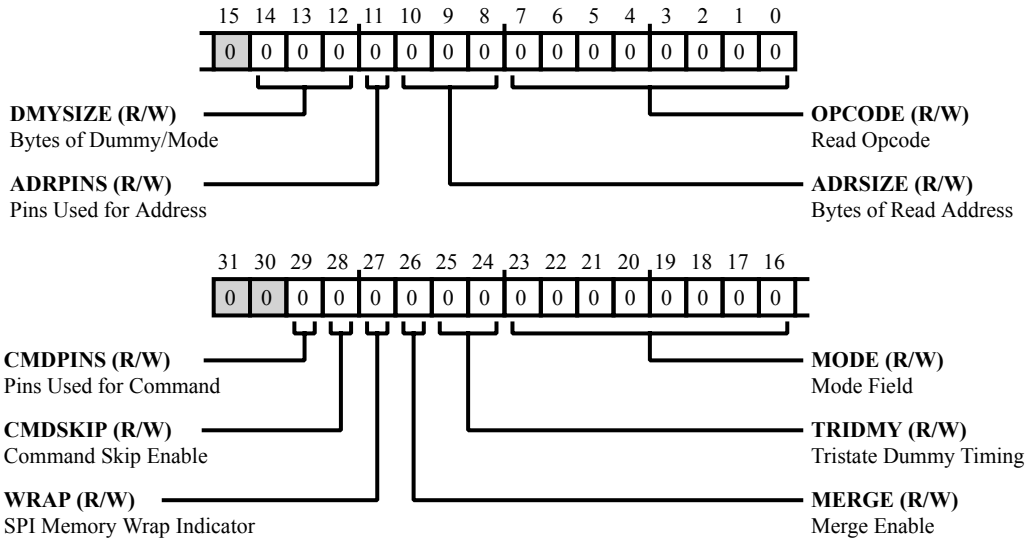

Figure 22-28: SPI_MMRDH Register Diagram

Table 22-25: SPI_MMRDH Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
29 (R/W)	CMDPINS	Pins Used for Command. The SPI_MMRDH.CMDPINS bit specifies the number of pins to be used for command transmission. This bit must be set consistent with the expectations established by the read opcode. Hardware does not interpret SPI_MMRDH.OPCODE, but rather relies on this bit to specify behavior. When cleared, it overrides the SPI_CTL.MIOM bits. When set, it uses bits specified by the SPI_CTL.MIOM bit setting.	
		0	Use only one pin: MOSI (overrides SPI_CTL.MIOM bits)
		1	Use pins specified by SPI_CTL.MIOM bits

Table 22-25: SPI_MMRDH Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
28 (R/W)	CMDSKIP	Command Skip Enable. The SPI_MMRDH.CMDSKIP bit enables command skip mode where the address is sent first and the OPCODE field is not sent (SPI_MMRDH.CMDSKIP bit =1). This mode is useful for supporting XIP (Execute-In-Place) operation where only the address is sent and the same read command is assumed. The SPI flash device must be primed with an initial read command, before the SPI_MMRDH.CMDSKIP bit is set.	
		0	OPCODE field is sent first followed by address
		1	OPCODE field is not sent; address is sent first
27 (R/W)	WRAP	SPI Memory Wrap Indicator. The SPI_MMRDH.WRAP bit must be set by software if software places a connected SPI memory device into a 8-byte, 16-byte or 32-byte wrap mode based on the ILINE and DLINE field setting of the cache configuration register address wrap mode. Software achieves this by transmitting a vendor specified command to the SPI memory device while the SPI_CTL.MMSE bit =0. If the SPI_MMRDH.WRAP bit =1, the SPI does not need to deassert the SPI slave select signal and resend the read header in order to wrap to the cache line base when servicing misaligned cache fill requests. Although this improves cache fill efficiency, it requires that the SPI deassert the SPI slave select pin and resend the read header whenever a DMA burst requests crosses 32 byte alignments. Setting this bit improves cache throughput but decreases DMA throughput.	
		0	SPI Memory auto increments address purely sequentially
		1	SPI Memory auto increments address but wraps within 32 Byte lines
26 (R/W)	MERGE	Merge Enable. When the SPI_MMRDH.MERGE bit is set, SPI hardware combines the two successive transfers. This increases the throughput rate when accessing a large number of sequential memory locations. For more information refer to the Merged Read Accesses section.	

Table 22-25: SPI_MMRDH Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
25:24 (R/W)	TRIDMY	Tristate Dummy Timing. The SPI_MMRDH.TRIDMY bits specify whether and when output pins are three-stated during the interval of time specified by the SPI_MMRDH.DMYSIZE bits. Output pins potentially three-stated include all pins which were used to transmit the address	
		0	Tristate outputs immediately
		1	Tristate outputs after 4 bits of dummy/mode are transmitted
		2	Tristate outputs after 8 bits of dummy/mode are transmitted
		3	Never tristate outputs (previously specified output state is held)
23:16 (R/W)	MODE	Mode Field. These bits specify up to a leading byte to be transmitted during the interval of time specified by the SPI_MMRDH.DMYSIZE bit field. This first byte, or a portion of it, is interpreted as mode bits when certain opcodes are used in conjunction with certain SPI memory devices. Mode bits are sent using the same number of pins which were used to transmit the address. Once sent, output pins will be held in their final resultant state until the conclusion of all dummy byte periods, unless three-stating the outputs is specified first by the SPI_MMRDH.TRIDMY bits.	
14:12 (R/W)	DMYSIZE	Bytes of Dummy/Mode. The SPI_MMRDH.DMYSIZE bit field specifies the number of bytes separating address transmission and read data return. Dummy bytes elapse assuming dummy bits are transmitted using the same number of pins which were used to transmit address.	
		0	0 Bytes
		1	1 Bytes
		2	2 Bytes
		3	3 Bytes
		4	4 Bytes
		5	5 Bytes
		6	6 Bytes
		7	7 Bytes

Table 22-25: SPI_MMRDH Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W)	ADRPINS	Pins Used for Address. The SPI_MMRDH.ADRPINS bit specifies the number of pins to be used for address transmission. This bit must be set consistent with expectations established by read opcode. Hardware does not interpret the SPI_MMRDH.OPCODE, but rather relies on this bit to specify behavior.	
		0	Use only one pin: MOSI (overrides SPI_CTL.MIOM bits)
		1	Use pins specified by SPI_CTL.MIOM bits
10:8 (R/W)	ADRSIZE	Bytes of Read Address. The SPI_MMRDH.ADRSIZE bit field defines the number of bytes used to specify the read address. The read address is sent immediately following the transmission of opcode. Unlike opcode bits, address bits may be sent using either one or multiple pins. The number of pins is selected using the SPI_MMRDH.ADRPINS bit. The address sent to a connected SPI memory device is an echo of the read address received by the SPI peripheral slave port. The least significant bytes of address are sent when the entire address is not sent.	
		0	1 Byte
		1	1 Byte
		2	2 Bytes
		3	3 Bytes
		4	4 Bytes
7:0 (R/W)	OPCODE	Read Opcode. The SPI_MMRDH.OPCODE bit field specifies the initial bits transmitted in response to a read request of SPI memory. Although any opcode may be sent, values 0x03, 0x0B, 0x3B, 0x6B, 0xBB, and 0xEB are likely to be the most commonly used. SPI_MMRDH.OPCODE is sent by the SPI without interpretation; the states of these bits have no effect beyond specifying what is initially shifted across the SPI interface.	

SPI Memory Top Address

The SPI_MMTOP register specifies the top populated address of a connected SPI memory device.

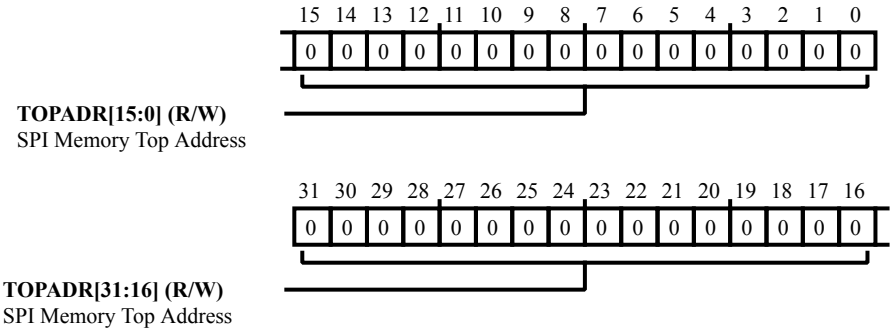

Figure 22-29: SPI_MMTOP Register Diagram

Table 22-26: SPI_MMTOP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	TOPADR	SPI Memory Top Address. The SPI_MMTOP.TOPADR bit field specifies the top populated address of a connected SPI memory device. Attempts to access SPI memory are not blocked if this address is exceeded and an error is generated as part of the read response.

Receive FIFO Data Register

The SPI_RFIFO register has an interface to the receive shift register in the SPI and has an interface to the processor's data buses. The top level of the buffer is visible to programs as the 32-bit SPI_RFIFO register, but the size (number of word locations) of the receive FIFO is actually flexible with transfer word size. The size of the receive FIFO is 8 if the word size is 8-bit, or the size is 4 if the word size is 16-bit, or the size is 2 if the word size is 32-bit.

Both masters and slaves may stop or stall receive transfers based on FIFO status. When the receive FIFO is full, the SPI master stops initiating new transfers on the SPI if SPI_RXCTL.RTI is enabled. A slave may stall the SPI interface when the content of the FIFO crosses the selected watermark. If data reception continues after SPI_RFIFO is full, the data in the receive FIFO is invalid. The SPI indicates this condition with receive overrun (SPI_STAT.ROR) error. This condition is possible when SPI_RXCTL.RTI =0 and SPI_RXCTL.REN =1 for a master, or for a slave that does not exercise flow control.

Note that the receive FIFO is reset (cleared) when the SPI is disabled after being enabled.

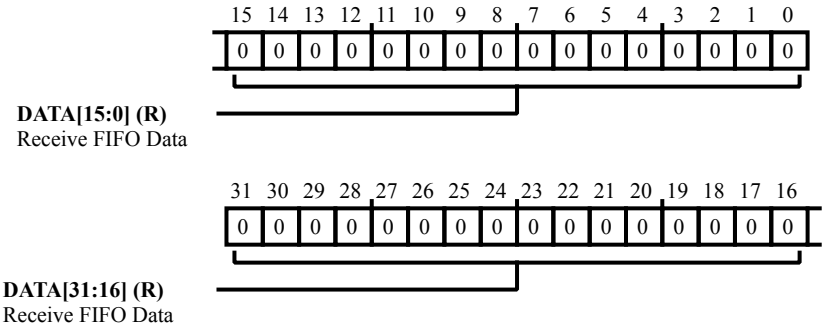

Figure 22-30: SPI_RFIFO Register Diagram

Table 22-27: SPI_RFIFO Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	DATA	Receive FIFO Data. The SPI_RFIFO.DATA bit field contains the FIFO receive data.

Received Word Count Register

The SPI_RWC register holds a count of the number of words remaining to be received by the SPI. To start the decrement of the word count in SPI_RWC, enable the receive word counter (SPI_RXCTL.RWCEN =1). The SPI uses the word count to control the duration of transfers and to signal the completion of a burst of transfers with the receive finish interrupt (SPI_ILAT.RF). In DMA mode, the SPI uses the SPI_RWC register to ensure that the number of frames received during a DMA transfer is equal to the number of words programmed in the DMA channel controller. The values programmed into the SPI_RWC registers should match the word count in the DMA configuration. The SPI_RWC register maintains the number of frames to be received in a transfer. The SPI_RWC should only be changed when the counter is disabled.

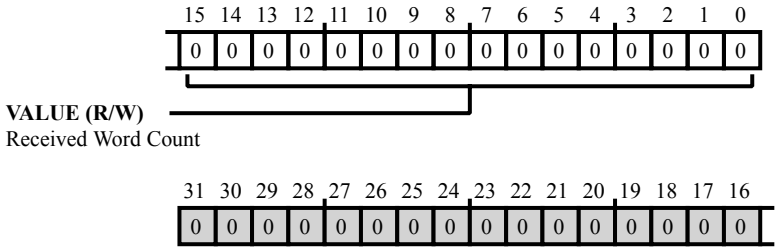

Figure 22-31: SPI_RWC Register Diagram

Table 22-28: SPI_RWC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Received Word Count. The SPI_RWC.VALUE bits hold the receive transfer word count.

Received Word Count Reload Register

The SPI_RWCR register holds the receive word count value that the SPI loads into the SPI_RWC register when the transfer count decrements to zero. To prevent the SPI from reloading the counter, use zero for the reload count value. The SPI_RWCR register should only be changed when the counter is disabled.

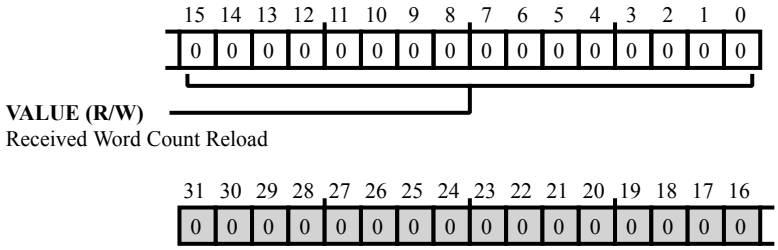

Figure 22-32: SPI_RWCR Register Diagram

Table 22-29: SPI_RWCR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Received Word Count Reload. The SPI_RWCR.VALUE bits hold the receive transfer word count reload value.

Receive Control Register

The SPI_RXCTL register enables the SPI receive channel, initiates receive transfers, and configures SPI_RFIFO buffer watermark settings.

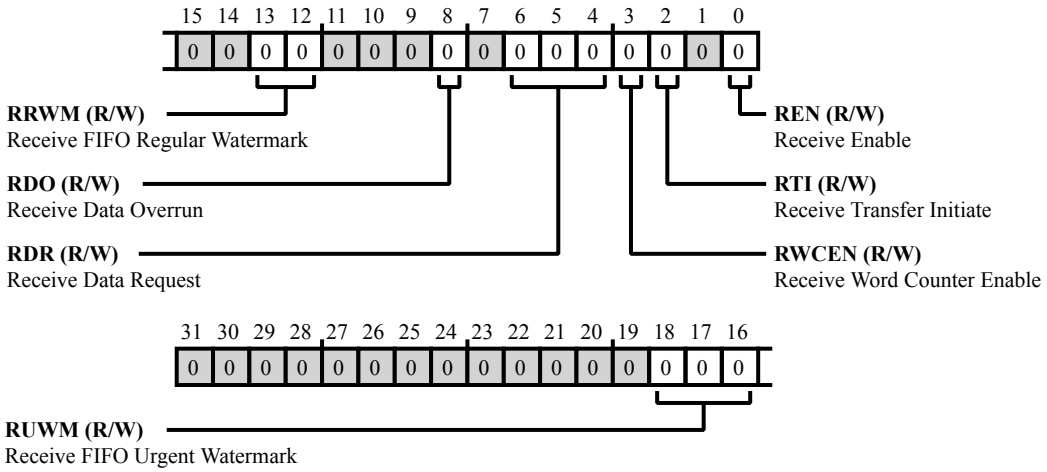

Figure 22-33: SPI_RXCTL Register Diagram

Table 22-30: SPI_RXCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
18:16 (R/W)	RUWM	Receive FIFO Urgent Watermark. The SPI_RXCTL.RUWM bits select the receive FIFO (SPI_RFIFO) watermark level for urgent data bus requests. The SPI also uses this watermark level for generation of the SPI_ILAT.RUWM interrupt. When an urgent SPI_RFIFO watermark is enabled with SPI_RXCTL.RUWM, the SPI_RXCTL.RRWM selection is used as the deassertion condition for any SPI_ILAT.RUWM interrupts that are latched.	
		0	Disabled
		1	25% full RFIFO
		2	50% full RFIFO
		3	75% full RFIFO
		4	Full RFIFO
		5	Reserved
		6	Reserved
		7	Reserved

Table 22-30: SPI_RXCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
13:12 (R/W)	RRWM	Receive FIFO Regular Watermark. The SPI_RXCTL.RRWM bits select the receive FIFO (SPI_RFIFO) watermark level for regular data bus requests. When an urgent SPI_RFIFO watermark is enabled with SPI_RXCTL.RUWM, the SPI_RXCTL.RRWM selection is used as the deassertion condition for any SPI_ILAT.RUWM interrupts that are latched.	
		0	Empty RFIFO
		1	RFIFO less than 25% full
		2	RFIFO less than 50% full
		3	RFIFO less than 75% full
8 (R/W)	RDO	Receive Data Overrun. The SPI_RXCTL.RDO bit selects handling for receive data requests when the receive buffer (SPI_RFIFO) is full. If enabled and SPI_RFIFO is full, the SPI overwrites old data in the buffer with incoming data. If disabled and SPI_RFIFO is full, the SPI keeps old data in the buffer and discards incoming data.	
		0	Discard incoming data if SPI_RFIFO is full
		1	Overwrite old data if SPI_RFIFO is full
6:4 (R/W)	RDR	Receive Data Request. The SPI_RXCTL.RDR bits select receive FIFO (SPI_RFIFO) watermark conditions that direct the SPI to generate a receive data request.	
		0	Disabled
		1	Not empty RFIFO
		2	25% full RFIFO
		3	50% full RFIFO
		4	75% full RFIFO
		5	Full RFIFO
		6	Reserved
		7	Reserved
3 (R/W)	RWCEN	Receive Word Counter Enable. The SPI_RXCTL.RWCEN bit enables the decrement of the SPI_RWC register when the count is not zero and SPI_RXCTL.RTI is enabled. Enabling SPI_RXCTL.RWCEN prevents receive overrun errors from occurring. The SPI_RXCTL.RWCEN bit is valid only when the SPI is a master.	
		0	Disable
		1	Enable

Table 22-30: SPI_RXCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W)	RTI	Receive Transfer Initiate. The SPI_RXCTL.RTI bit enables initiation of receive transfers if the receive FIFO (SPI_RFIFO) is not full. The bit also enables this initiation if SPI_RWC is not zero when SPI_RXCTL.RWCEN is enabled. Enabling SPI_RXCTL.RTI prevents receive overrun errors from occurring. The SPI_RXCTL.RTI bit is valid only when the SPI is a master.	
		0	Disable
		1	Enable
0 (R/W)	REN	Receive Enable. The SPI_RXCTL.REN bit enables SPI receive channel operation.	
		0	Disable
		1	Enable

Slave Select Register

The SPI_SLVSEL register enables the SPI_SEL[n] pins for output and indicates the state (high or low) of these pins when enabled.

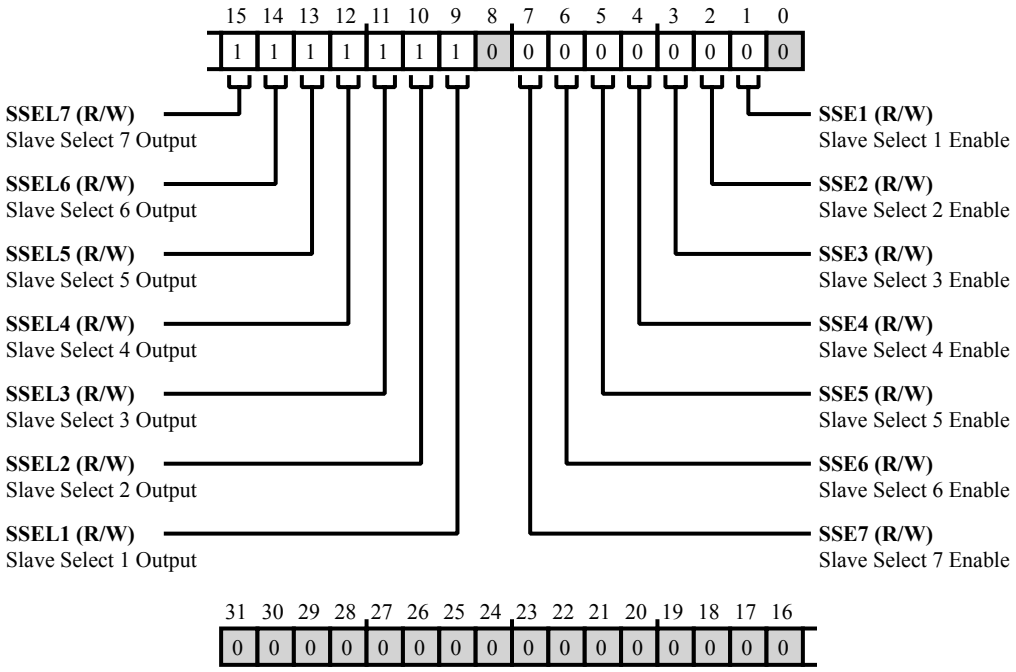

Figure 22-34: SPI_SLVSEL Register Diagram

Table 22-31: SPI_SLVSEL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	SSEL7	Slave Select 7 Output. The SPI_SLVSEL.SSEL7 bit state indicates the value driven on the related SPI_SEL[n] pin.	
		0	Low
		1	High
14 (R/W)	SSEL6	Slave Select 6 Output. The SPI_SLVSEL.SSEL6 bit state indicates the value driven on the related SPI_SEL[n] pin.

		0	Low
		1	High
12 (R/W)	SSEL4	Slave Select 4 Output. The SPI_SLVSEL.SSEL4 bit state indicates the value driven on the related SPI_SEL[n] pin.	
		0	Low
		1	High
11 (R/W)	SSEL3	Slave Select 3 Output. The SPI_SLVSEL.SSEL3 bit state indicates the value driven on the related SPI_SEL[n] pin.	
		0	Low
		1	High
10 (R/W)	SSEL2	Slave Select 2 Output. The SPI_SLVSEL.SSEL2 bit state indicates the value driven on the related SPI_SEL[n] pin.	
		0	Low
		1	High
9 (R/W)	SSEL1	Slave Select 1 Output. The SPI_SLVSEL.SSEL1 bit state indicates the value driven on the related SPI_SEL[n] pin.	
		0	Low
		1	High
7 (R/W)	SSE7	Slave Select 7 Enable. The SPI_SLVSEL.SSE7 bit enables the related SPI_SEL[n] pin for output. If disabled, the SPI three-states the related SPI_SEL[n] pin.	
		0	Disable
		1	Enable

Table 22-31: SPI_SLVSEL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6 (R/W)	SSE6	Slave Select 6 Enable. The SPI_SLVSEL.SSE6 bit enables the related $\overline{\texttt{SPI_SEL[n]}}$ pin for output. See the SPI_SLVSEL.SSE7 bit description for more information.	
		0	Disable
		1	Enable
5 (R/W)	SSE5	Slave Select 5 Enable. The SPI_SLVSEL.SSE5 bit enables the related $\overline{\texttt{SPI_SEL[n]}}$ pin for output. See the SPI_SLVSEL.SSE7 bit description for more information.	
		0	Disable
		1	Enable
4 (R/W)	SSE4	Slave Select 4 Enable. The SPI_SLVSEL.SSE4 bit enables the related $\overline{\texttt{SPI_SEL[n]}}$ pin for output. See the SPI_SLVSEL.SSE7 bit description for more information.	
		0	Disable
		1	Enable
3 (R/W)	SSE3	Slave Select 3 Enable. The SPI_SLVSEL.SSE3 bit enables the related $\overline{\texttt{SPI_SEL[n]}}$ pin for output. See the SPI_SLVSEL.SSE7 bit description for more information.	
		0	Disable
		1	Enable
2 (R/W)	SSE2	Slave Select 2 Enable. The SPI_SLVSEL.SSE2 bit enables the related $\overline{\texttt{SPI_SEL[n]}}$ pin for output. See the SPI_SLVSEL.SSE7 bit description for more information.	
		0	Disable
		1	Enable
1 (R/W)	SSE1	Slave Select 1 Enable. The SPI_SLVSEL.SSE1 bit enables the related $\overline{\texttt{SPI_SEL[n]}}$ pin for output. See the SPI_SLVSEL.SSE7 bit description for more information.	
		0	Disable
		1	Enable

Status Register

The SPI_STAT register indicates SPI status including FIFO status, error conditions, and interrupt conditions. When an interrupt condition from this register is unmasked (enabled) by the corresponding bit in the SPI_IMSK register, the interrupt request is latched into the corresponding bit in the SPI_ILAT register.

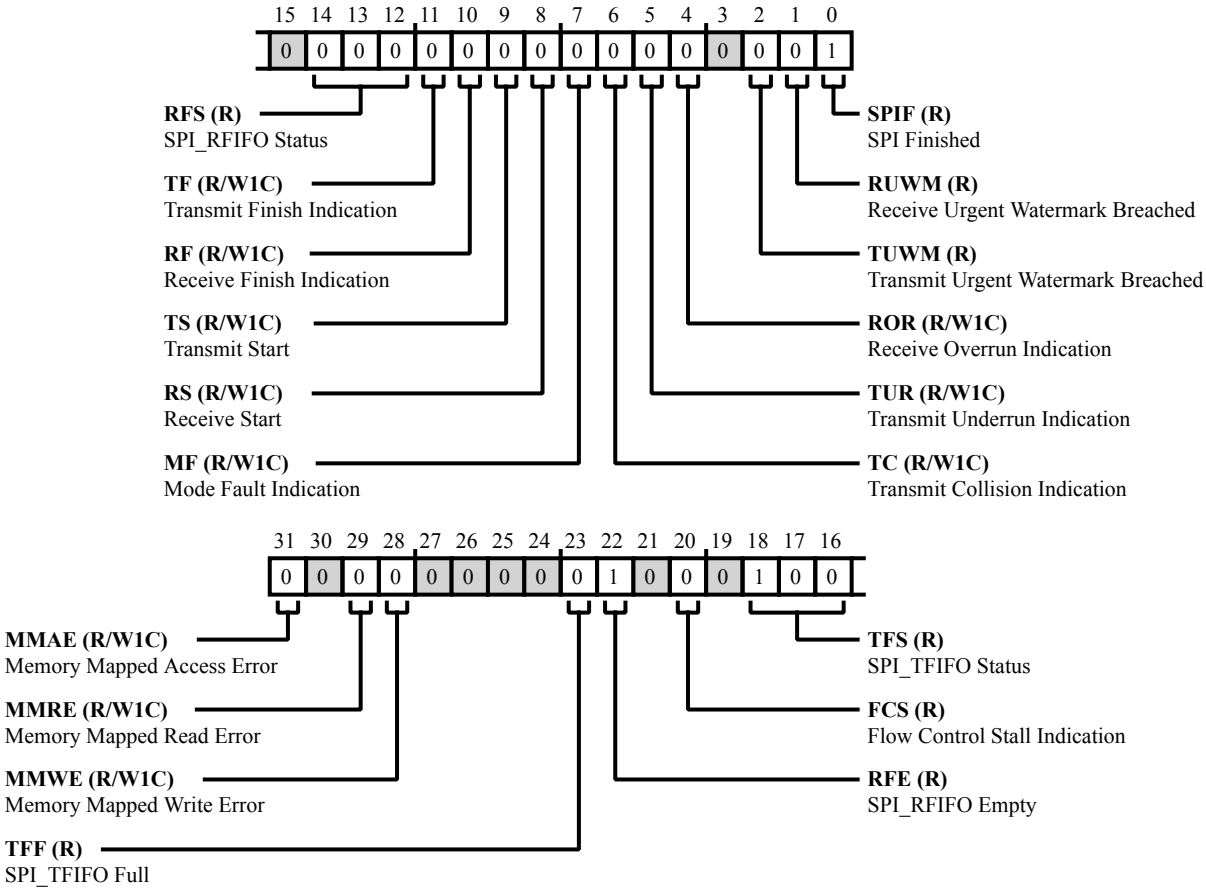

Figure 22-35: SPI_STAT Register Diagram

Table 22-32: SPI_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W1C)	MMAE	Memory Mapped Access Error. The SPI_STAT.MMAE bit =1 if an attempt is made to access either the Tx or Rx FIFO while memory-mapped access of SPI memory is enabled (see the SPI_CTL.MMSE bit). The SPI_STAT.MMAE bit =0 when a 1 is written to it. The SPI_STAT.MMAE bit is provided for software notification only. Its state has no further effect.

Table 22-32: SPI_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
29 (R/W1C)	MMRE	Memory Mapped Read Error. The SPI_STAT.MMRE bit =1 if an attempt is made to read address space reserved for memory-mapped SPI memory while memory mapping is disabled (see the SPI_CTL.MMSE bit). The SPI_STAT.MMRE bit =0 when a 1 is written to it. This bit is provided for software notification only. Its state has no further effect.	
28 (R/W1C)	MMWE	Memory Mapped Write Error. The SPI_STAT.MMWE bit =1 if an attempt is made to write address space reserved for memory-mapped SPI memory. The SPI_STAT.MMWE bit =0 when a 1 is written to it. This bit is provided for software notification only. Its state has no further effect.	
23 (R/NW)	TFF	SPI_TFIFO Full. The SPI_STAT.TFF bit indicates whether the SPI_TFIFO is full or not full.	
		0	Not full Tx FIFO
		1	Full Tx FIFO
22 (R/NW)	RFE	SPI_RFIFO Empty. The SPI_STAT.RFE bit indicates whether the SPI_RFIFO is empty or not empty.	
		0	Rx FIFO not empty
		1	Rx FIFO empty
20 (R/NW)	FCS	Flow Control Stall Indication. The SPI_STAT.FCS bit indicates whether a slave has deasserted the SPI_RDY pin to stall the SPI master while the slave is unable to service the SPI masters request. This bit is valid only when the SPI is a master (SPI_CTL.MSTR =1) and flow control is enabled (SPI_CTL.FCEN =1).	
		0	No Stall (RDY pin asserted)
		1	Stall (RDY pin deasserted)
18:16 (R/NW)	TFS	SPI_TFIFO Status. The SPI_STAT.TFS bits indicate the status of the SPI_TFIFO. The SPI uses this status when evaluating transmit watermark conditions.	
		0	Full TFIFO
		1	25% empty TFIFO
		2	50% empty TFIFO
		3	75% empty TFIFO
		4	Empty TFIFO

Table 22-32: SPI_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
14:12 (R/NW)	RFS	SPI_RFIFO Status. The SPI_STAT.RFS bits indicate the status of the SPI_RFIFO. The SPI uses this status when evaluating receive watermark conditions.	
		0	Empty RFIFO
		1	25% full RFIFO
		2	50% full RFIFO
		3	75% full RFIFO
		4	Full RFIFO
11 (R/W1C)	TF	Transmit Finish Indication. The SPI_STAT.TF bit indicates that the SPI has detected the finish of a transmit burst transfer (the SPI_TWC count decrements to zero). This condition can only occur when SPI_TXCTL.TTI and SPI_TXCTL.TWCEN are enabled.	
		0	No status
		1	Transmit finish detected
10 (R/W1C)	RF	Receive Finish Indication. The SPI_STAT.RF bit indicates that the SPI has detected the finish of a receive burst transfer (the SPI_RWC count decrements to zero). This condition can only occur when SPI_RXCTL.RTI and SPI_RXCTL.RWCEN are enabled.	
		0	No status
		1	Receive finish detected
9 (R/W1C)	TS	Transmit Start. The SPI_STAT.TS bit indicates that the SPI has detected the start of a transmit burst transfer. A transmit bursts starts with the load of SPI_TWC from the SPI_TWCR. This condition can only occur when SPI_TXCTL.TTI and SPI_TXCTL.TWCEN are enabled.	
		0	No status
		1	Transmit start detected
8 (R/W1C)	RS	Receive Start. The SPI_STAT.RS bit indicates that the SPI has detected the start of a receive burst transfer. A receive bursts starts with the load of SPI_RWC from the SPI_RWCR. This condition can only occur when SPI_RXCTL.RTI and SPI_RXCTL.RWCEN are enabled.	
		0	No status
		1	Receive start detected

Table 22-32: SPI_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W1C)	MF	Mode Fault Indication. The SPI_STAT.MF bit, when SPI is a master and SPI_CTL.PSSE is enabled, indicates that multiple masters have asserted slave select inputs.	
		0	No status
		1	Mode fault occurred
6 (R/W1C)	TC	Transmit Collision Indication. The SPI_STAT.TC bit, when SPI is a slave, indicates that the load of data into the shift register has occurred too close to the first transmitting edge of the SPI clock.	
		0	No status
		1	Transmit collision occurred
5 (R/W1C)	TUR	Transmit Underrun Indication. The SPI_STAT.TUR bit, when the transmit FIFO (SPI_TFIFO) is empty, indicates that the last word in the transmit FIFO has been re-sent as transmit data. Alternately, it indicates that zero has been sent as transmit data.	
		0	No status
		1	Transmit underrun occurred
4 (R/W1C)	ROR	Receive Overrun Indication. The SPI_STAT.ROR bit, when the receive FIFO (SPI_RFIFO) is full, indicates that a word in the receive FIFO has been overwritten with incoming receive data. Alternately, it indicates that incoming receive data has been discarded.	
		0	No status
		1	Receive overrun occurred
2 (R/NW)	TUWM	Transmit Urgent Watermark Breached. The SPI_STAT.TUWM bit indicates that the transmit urgent watermark (SPI_TXCTL.TUWM) has been reached. This condition is cleared when the transmit FIFO fills enough to reach the transmit regular watermark (SPI_TXCTL.TRWM).	
		0	Tx regular watermark reached
		1	Tx urgent watermark breached
1 (R/NW)	RUWM	Receive Urgent Watermark Breached. The SPI_STAT.RUWM bit indicates that the receive urgent watermark (SPI_RXCTL.RUWM) has been reached. This condition is cleared when the receive FIFO empties enough to reach the receive regular watermark (SPI_RXCTL.RRWM).	
		0	Rx regular watermark reached
		1	Rx urgent watermark breached

Table 22-32: SPI_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/NW)	SPIF	SPI Finished. The `SPI_STAT.SPIF` bit indicates that a single word transfer is complete.	
		0	No status
		1	Completed single word transfer

Transmit FIFO Data Register

The SPI_TFIFO register has an interface to the transmit shift register in the SPI and has an interface to the processor's data buses. The top level of the buffer is visible to programs as the 32-bit SPI_TFIFO register, but the size (number of word locations) of the transmit FIFO is actually flexible with transfer word size. The size of the transmit FIFO is 8 if the word size is 8-bit, or the size is 4 if the word size is 16-bit, or the size is 2 if the word size is 32-bit.

Both masters and slaves may stop or stall transmit transfers based on FIFO status. When the transmit FIFO is empty, the SPI master stops initiating new transfers on the SPI if SPI_TXCTL.TTI is enabled. A slave may stall the SPI interface when the content of the FIFO crosses the selected watermark. If data transmit requests continue after SPI_TFIFO is empty, the data sent from the transmit FIFO is invalid, and the SPI indicates this condition with transmit underrun (SPI_STAT.TUR). This condition is possible when SPI_TXCTL.TTI =0 and SPI_TXCTL.TEN =1 for a master, or for a slave that does not exercise flow control.

Note that the transmit FIFO is reset (cleared) when the SPI is disabled after being enabled.

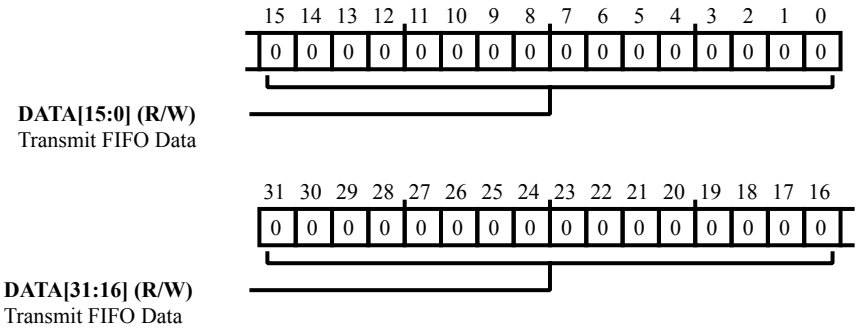

Figure 22-36: SPI_TFIFO Register Diagram

Table 22-33: SPI_TFIFO Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	DATA	Transmit FIFO Data. The SPI_TFIFO.DATA bit field contains the FIFO transmit data.

Transmitted Word Count Register

The SPI_TWC register holds a count of the number of words remaining to be transmitted by the SPI. To start the decrement of the word count in SPI_TWC, enable the transmit word counter (SPI_TXCTL.TWCEN =1). The SPI uses the word count to control the duration of transfers and to signal the completion of a burst of transfers with the transmit finish interrupt request. In DMA mode, the SPI uses the SPI_TWC to ensure that the number of frames transmitted during a DMA transfer is equal to the number of words programmed in the DMA channel controller. The values programmed into the SPI_TWC registers should match the word count in the DMA configuration. The SPI_TWC maintains the number of frames to be transmitted in a transfer. The SPI_TWC should only be changed when the counter is disabled.

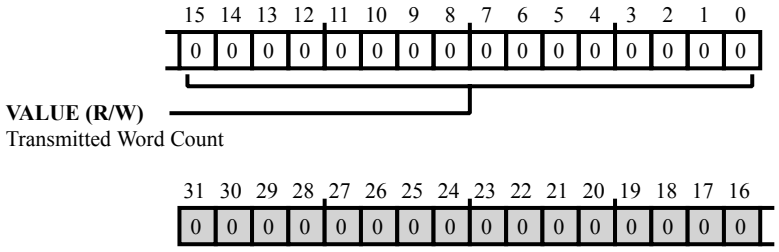

Figure 22-37: SPI_TWC Register Diagram

Table 22-34: SPI_TWC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Transmitted Word Count. The SPI_TWC.VALUE bits hold the transmit transfer word count.

Transmitted Word Count Reload Register

The SPI_TWCR register holds the transmit word count value that the SPI loads into the SPI_TWC register when the transfer count decrements to zero. To prevent the SPI from reloading the counter, use zero for the reload count value. The SPI_TWCR should only be changed when the counter is disabled.

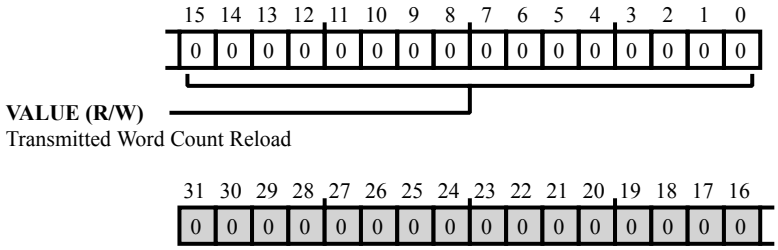

Figure 22-38: SPI_TWCR Register Diagram

Table 22-35: SPI_TWCR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Transmitted Word Count Reload. The SPI_TWCR.VALUE bits hold the transmit transfer word count reload value.

Transmit Control Register

The SPI_TXCTL register enables the SPI transmit channel, initiates transmit transfers, and configures SPI_TFIFO buffer watermark settings.

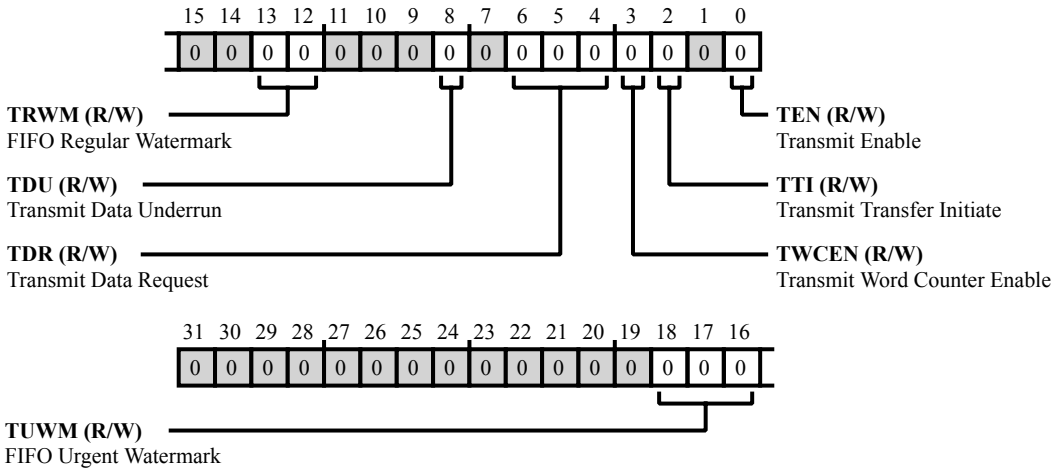

Figure 22-39: SPI_TXCTL Register Diagram

Table 22-36: SPI_TXCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
18:16 (R/W)	TUWM	FIFO Urgent Watermark. The SPI_TXCTL.TUWM bits select the transmit FIFO (SPI_TFIFO) watermark level for urgent data bus requests. The SPI also uses this watermark level for generation of the SPI_ILAT.TUWM interrupt request. When an urgent SPI_TFIFO watermark is enabled with SPI_TXCTL.TUWM, the SPI_TXCTL.TRWM selection is used as the deassertion condition for any SPI_ILAT.TUWM interrupt requests that are latched.	
		0	Disabled
		1	25% empty TFIFO
		2	50% empty TFIFO
		3	75% empty TFIFO
		4	Empty TFIFO

Table 22-36: SPI_TXCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
13:12 (R/W)	TRWM	FIFO Regular Watermark. The SPI_TXCTL.TRWM bits select the transmit FIFO (SPI_TFIFO) watermark level for regular data bus requests. When an urgent SPI_TFIFO watermark is enabled with SPI_TXCTL.TUWM, the SPI_TXCTL.TRWM selection is used as the deassertion condition for any SPI_ILAT.TUWM interrupt requests that are latched.	
		0	Full TFIFO
		1	TFIFO less than 25% empty
		2	TFIFO less than 50% empty
		3	TFIFO less than 75% empty
8 (R/W)	TDU	Transmit Data Underrun. The SPI_TXCTL.TDU bit selects handling for transmit data requests when the transmit buffer (SPI_TFIFO) is empty. If enabled and SPI_TFIFO is empty, the SPI transmits zero as data. If disabled and SPI_TFIFO is empty, the SPI transmits the last word in the buffer as data.	
		0	Send last word when SPI_TFIFO is empty
		1	Send zeros when SPI_TFIFO is empty
6:4 (R/W)	TDR	Transmit Data Request. The SPI_TXCTL.TDR bits select transmit FIFO (SPI_TFIFO) watermark conditions that direct the SPI to generate a transmit status interrupt request.	
		0	Disabled
		1	Not full TFIFO
		2	25% empty TFIFO
		3	50% empty TFIFO
		4	75% empty TFIFO
		5	Empty TFIFO
3 (R/W)	TWCEN	Transmit Word Counter Enable. The SPI_TXCTL.TWCEN bit enables the decrement of the transmit word count (SPI_TWC) register when the count is not zero and SPI_TXCTL.TTI is enabled. Enabling SPI_TXCTL.TWCEN prevents transmit underrun errors from occurring. The SPI_TXCTL.TWCEN bit is valid only when the SPI is a master.	
		0	Disable
		1	Enable

Table 22-36: SPI_TXCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W)	TTI	Transmit Transfer Initiate. The SPI_TXCTL.TTI bit enables initiation of transmit transfers if the transmit FIFO (SPI_TFIFO) is not empty. The bit also enables this initiation if SPI_TWC is not zero when SPI_TXCTL.TWCEN is enabled. Enabling SPI_TXCTL.TTI prevents transmit underrun errors from occurring. The SPI_TXCTL.TTI bit is valid only when the SPI is a master.	
		0	Disable
		1	Enable
0 (R/W)	TEN	Transmit Enable. The SPI_TXCTL.TEN bit enables SPI transmit channel operation.	
		0	Disable
		1	Enable

23 Octal Serial Peripheral Interface (OSPI)

The Octal Serial Peripheral Interface (OSPI) controller provides access to serial flash devices. It is designed to access flash devices with its modes enabling efficient communication, with minimum overhead on software. Standard SPI is supported along with high performance dual, quad, and octal SPI modes where data can be transferred on up to 8 data pins. Along with normal mode of operation in single transfer (STR) mode, the OSPI controller supports dual transfer rate (DTR) mode, where data, address, and commands are transferred on both edges of the serial clock. With direct access mode support, any read/write to the OSPI memory space triggers a read/write to flash memory.

Direct read accesses using core and DMA are possible, with the latter minimizing software overhead. The OSPI controller also provides Software Triggered Instruction Generation (STIG) mode, which can be used to erase the data on flash devices and access volatile and nonvolatile configuration registers, legacy flash status register, and other status/protection registers.

The OSPI provides a glueless hardware interface with SPI flash devices. The OSPI peripheral includes programmable baud rates, clock phase, clock polarity, separate dummy cycles for read and write accesses, data sampling control, programmable page size/block size, and so on. With this independent control of how many lines to use for command, address, and data allows to virtually interface any flash device with the processor through OSPI controller.

The OSPI also provides support for DQS when sampling data to improve read data capture and PHY mode support to enable high-speed data transfers.

OSPI Features

The OSPI controller supports the following features:

- Full-duplex, synchronous, serial interface
- Memory mapped direct mode operation for performing flash data transfers
- STIG mode operation to issue flash commands
- Automatic flash status polling support for flash program through direct access mode
- XIP (Execute in Place) support
- Support for single, dual, quad, or octal modes of operation
- Support for DDR mode and DTR protocol (including Octal DDR protocol)

- Up to 16-bit data transfer in each SPI clock cycle
- Programmable baud rate, clock phase, and polarity
- Programmable interrupt generation
- Programmable chip select control timing
- Programmable dummy cycles for read and write operations
- Tune data capture mechanism to improve high speed operation
- Programmable write protected regions to block system writes
- Support for DQS to sample the data to improve read data capturing
- PHY mode support to allow the high speed data transfers

OSPI Functional Description

ADSP-SC59x OSPI Register List

The OSPI is an Octal SPI controller. It contains the following registers.

Table 23-1: ADSP-SC59x OSPI Register List

Name	Description
OSPI_CTL	Octal SPI Control Register
OSPI_DLY	Device Delay Register
OSPI_DRICTL	Device Read Instruction Control Register
OSPI_DWICTL	Device Write Instruction Control Register
OSPI_DSCTL	Device Size Control Register
OSPI_DLLOB_LWR	DLL Observable Register (Lower)
OSPI_DLLOB_UP	DLL Observable Register (Upper)
OSPI_FCA	Flash Command Address Register
OSPI_FCCTL	Flash Command Control Register
OSPI_FCMCTL	Flash Command Control Memory Register
OSPI_FCRD_LWR	Flash Command Read Data Register (Lower)
OSPI_FCRD_UP	Flash Command Read Data Register (Upper)
OSPI_FCWD_LWR	Flash Command Write Data Register (Lower)
OSPI_FCWD_UP	Flash Command Write Data Register (Upper)
OSPI_IMSK	Interrupt Mask Register
OSPI_ISTAT	Interrupt Status Register

Table 23-1: ADSP-SC59x OSPI Register List (Continued)

Name	Description
OSPI_WRPROT_LWR	Lower Write Protection Register
OSPI_MBCTL	Mode Bit Control Register
OSPI_MODID	Module ID Register
OSPI_POLLEXP	Polling Expiration Register
OSPI_OE_LWR	Opcode Extension Register (Lower)
OSPI_OE_UP	Opcode Extension Register (Upper)
OSPI_PHYCTL	PHY Control Register
OSPI_PHYMCTL	PHY DLL Master Control Register
OSPI_POLSTAT	Polling Flash Status Register
OSPI_RDC	Read Data Capture Register
OSPI_REMAPADDR	Remap Address Register
OSPI_WRPROT_UP	Upper Write Protection Register
OSPI_WRPROT_CTL	Write Protection Control Register
OSPI_WCCTL	Write Completion Control Register

ADSP-SC59x OSPI Interrupt List

Table 23-2: ADSP-SC59x OSPI Interrupt List

Interrupt ID	Name	Description	Sensitivity	DMA Channel
137	OSPI0_INT	OSPI0 Error	Level	

OSPI Block Diagram

The OSPI module is comprised of:

- Low level SPI protocol controller
- Internal transmit/receive FIFOs
- DAC
- STIG controller
- Register interface

The ***OSPI Controller Block Diagram*** shows the OSPI controller functional blocks.

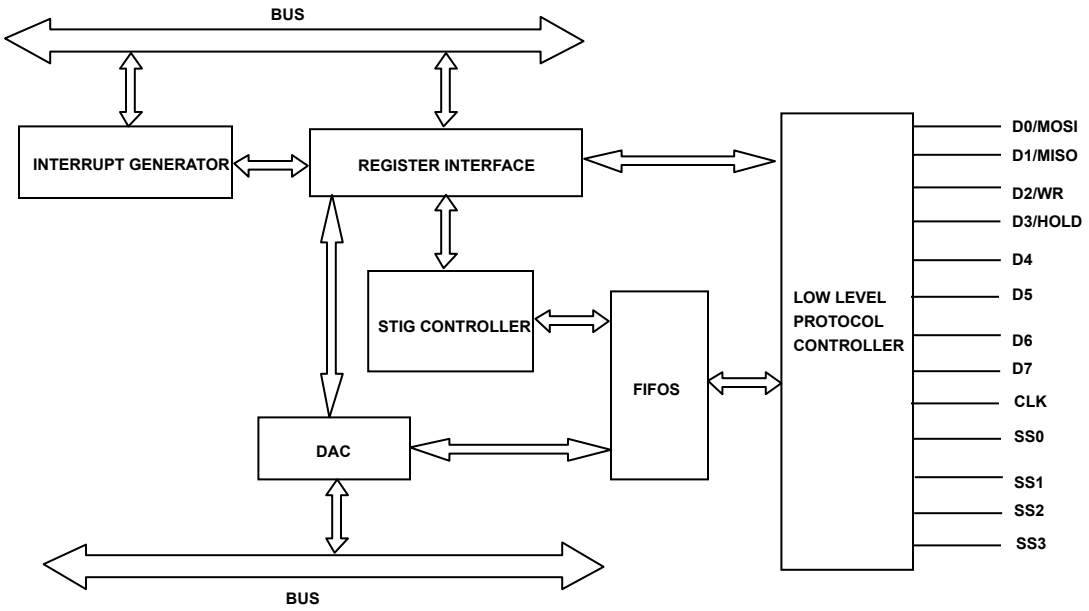

Figure 23-1: OSPI Controller Block Diagram

Architectural Concepts

There are two clock sources for the OSPI controller and one generated clock for clocking external flash device.

The SYSCLK is the main system clock used to transfer data over the AHB bus between the controller (core/DMA) and the OSPI controller. The SCLK0_0 clock is used to access the OSPI controller registers to perform basic configuration of the controller and interrupt handling. The OSPI_REFCLK, is used to serialize the data and drive the OSPI interface. The external clock driven on the OSPI_CLK pin, which is synchronous to the reference clock, is derived from the OSPI_REFCLK and divided using internal baud rate dividers. Using the OSPI_REFCLK clock, allows the core to decouple the frequency of the SPI flash device from system clocks, thereby providing a flexible clocking solution.

The OSPI controller supports two independent controllers (to support different types of flash accesses):

- Direct Access Controller (DAC)
- Software Triggered Instruction Generator (STIG)

The high-level architecture of the OSPI controller is divided into two blocks. The first is the high-level OSPI controller that interfaces with the rest of the SoC. It also queues flash transactions based on data from AHB and APB bus interfaces. The second module is the low-level SPI Protocol Controller. It is used for serializing data from high-level OSPI controller and translating them into the SPI transfer protocol where there are two data paths. The first path preserves backward compatibility with the previous SoCs. This path bypasses the PHY module. Use this path when there is no strict requirement for high performance (clock divider is greater or equal 4).

The second data path is through the PHY Module and is for dividers lower than 4. The configuration is set by software. The controller waits for a valid direct access from the AHB bus (which runs off SYSCLK) or for a software triggered read from the APB bus. When such an event occurs, the corresponding internal controller is selected

(DAC or STIG). The flash command generator block arbitrates between accesses and forwards control into the low-level SPI module. This block works on the reference clock. Transmit data is synchronized internally to the TX FIFO and then serialized to the SPI interface. When the direction of transfer changes and the device returns data to the controller, data is read into the RX FIFO and then synchronized to the internal clocks. The SPI control logic selects the source of the data path (with or without PHY) based on the register configuration. The reference clock and the associated delayed variants are relevant for this transfer type when the PHY mode is enabled.

Direct Access Controller (DAC)

Direct access refers to the operation where AHB bus accesses targeted to the OSPI memory mapped space of processor directly triggers a read/write on flash memory. It is memory mapped and used to access and directly execute the code from external flash memory. When DAC is enabled through the `OSPI_CTL.DACEN` field, any incoming AHB access is serviced by the DAC. Direct accesses can be launched by accessing the OSPI memory address space using core or via one of the MDMA channels. In memory mapped mode, communication to a flash device is automated. The flash memory is accessible directly through reads/write of the processor address space. This access allows code to execute directly from flash devices (true XIP operations). The content can be cached for good performance.

When servicing AHB reads, the DAC sends an additional access downstream apart from the one issued by the AHB in single AHB burst. This is invisible from the system interface. It is a predicted read and ensures that the SPI core operates with maximum bandwidth. The AHB burst not defined by the AMBA specification. It is defined as follows:

- The first access of the AHB burst is defined by:

  An AHB access that is non-sequential (based on address comparison).

  An AHB access that is non-sequential or sequential when the downstream modules are idle.
- The last access of the AHB burst is defined by an AHB access that is sequential and precedes a new burst.
- Size of the AHB burst is the number of AHB accesses (first access to last access).
- The number of DAC requests per AHB burst is equal to the size of the AHB burst + 1.

When AHB clock is slower than the SPI data rate, the sequential read transfer may be interrupted on the SPI side and continues after the AHB clock accepts the last data. The limiting value gets narrower as the SPI clock divider and AHB access size decrease and the number of data IOs (single, dual, quad, or octal) increase. If the system cannot meet the SPI data rate, use higher SPI clock divider. This decreases the SPI data rate but prevents OSPI accesses to external flash to break in between and pass the *Opcode-Address-Dummy* sequence each time. This increases the overall performance by keeping the data transfer continuous.

The controller is designed to work at high data rates. This predicted read results in redundant data during mixed AHB accesses on slow system data rate. Mixed accesses implies that direct AHB sequence of single non-sequential access following few sequential accesses. The predicted read cannot be dropped because of SPI transfer interruption. It is sent as a separate SPI transaction which creates redundant data on the interface for one access. To avoid this issue, drop this data by system or introduce wait states on AHB before issuing a non-sequential direct AHB access.

For bus writes, the DAC triggers a sequence of write commands that mimic the way reads are processed, though the number of DAC write requests are equal to the number of bus write requests received. The bus controller ensures

that flash bursts do not break the flash page boundary. When a page boundary is detected, only the number of byte accesses up to that boundary are forwarded. A sequential direct write request that crosses a page boundary must be detected as non-sequential, causing the controller to force the flash device to enter a self-timed page program cycle. The controller supports splitting the writes crossing the page boundaries only for word-aligned addresses.

The external bus controller supplying data for writes must guarantee write data for a particular page that can be provided to the controller in a timely fashion to avoid downstream starvation. If there is a large delay in the system issuing a sequential write, flash write cycle may be prematurely initiated, reducing the device lifetime.

Flash erase operations, which may be required before a page write, are triggered by software using the STIG. Once a page program cycle has been started, the OSPI controller automatically polls for write cycle to complete before allowing any bus accesses to complete. This is achieved by holding the subsequent AHB direct accesses in wait state.

For memory mapped accesses using the DAC, the flash memory is accessible using the address space 0x60000000 – 0x7FFFFFFF, as indicated in the processor datasheet. Since both SPI2 and OSPI controllers can accesses this space in memory mapped mode, there are control bits in the SCB5_SPI2_OSPI_REMAP register to control which controller is able to access this flash memory mapped space. Either OSPI or SPI2 can exclusively access whole of the flash memory space or there is an option to divide this space between OSPI and SPI2.

When the SCB5_SPI2_OSPI_REMAP register = 0x0, the entire flash memory mapped space is only accessible by the SPI2 controller. Do not try to access this space with the OSPI controller.

When the SCB5_SPI2_OSPI_REMAP register = 0x1, the entire flash memory mapped space is only accessible by the OSPI controller. Do not try to access this space with the SPI2 controller.

When the SCB5_SPI2_OSPI_REMAP register = 0x2, the flash memory mapped space is divided between the OSPI and SPI2 controllers. The flash memory mapped space (0x60000000 - 0x602FFFFF) is only accessible by SPI2 and the flash memory mapped space (0x60300000 - 0x7FFFFFFF) is only accessible by OSPI. This option is only valid for the ADSP-SC59x/2159x HPC package.

Software Triggered Instruction Generator (STIG)

DAC is primarily used to transfer data. To access the volatile and nonvolatile configuration registers, the legacy Flash SPI Status register, other status/protection registers and perform erase operations, a separate software controller is required.

The STIG is controlled using the OSPI_FCCTL register by setting up the command to issue to the flash device. This is a generic controller used to perform instructions that the flash device supports from the extended SPI protocol. The STIG controller command is sent to the flash device and written to the software in the OSPI_FCCTL.OPCODE field. This is different from the OSPI_DRICTL.OPCODERD and OSPI_DWICTL.OPCODEWR fields, as these fields do not impact the STIG operation.

Configuring instructions that are not compliant with the flash specifications can cause unpredicted behavior of the controller. Bit 0 is used to trigger the command, bit 1 used by software to poll the status of the command execution. For reads, when the command has been serviced (bit 1 toggles from 1 to 0), up to 8 bytes of read data is placed in the OSPI_FCRD_LWR and OSPI_FCRD_UP registers. For writes, data must be placed in the OSPI_FCWD_LWR and OSPI_FCWD_UP registers. The STIG completion request can be also checked by the corresponding interrupt.

The interrupt indicates that the controller is ready to accept a new STIG request. The STIG completion request is not equivalent to completion on the SPI side. For example, if STIG is configured to the data command only on transmit, data is taken from the corresponding STIG register fields and put into TX FIFO. As all write bytes are known, another STIG can be queued before completing serialization of the current one.

There are few commands that require more data to read than 8 bytes (for example, READ ID command). Additional STIG memory bank is implemented to accommodate this data, if required. The STIG memory bank is controlled by the OSPI_FCMCTL register. If enabled, the number of bytes to read in the STIG is extended to 16 bytes, as defined in the OSPI_FCMCTL.RDSZ field. There are few commands (excluding read arrays that are not intended to be handled in STIG mode, but in Direct Access Mode) that return more than 8 bytes to the controller.

If the number of read bytes in the STIG, as defined in the OSPI_FCMCTL.RDSZ field, exceeds the memory bank depth, the remaining data overwrites the STIG memory bank locations starting from its first address. When memory bank is enabled, the OSPI_FCRD_LWR and OSPI_FCRD_UP registers keep the last 8 bytes read from the flash device by the STIG. For example, to get a single byte from the last eight bytes of a long continuous read SPI data chain, there is no need to access the STIG memory bank as data can be obtained from the OSPI_FCRD_LWR and OSPI_FCRD_UP registers. To access more data, STIG memory bank data request must be triggered. It is controlled by the OSPI_FCMCTL register and works analogously to trigger the STIG. Bit 0 (OSPI_FCMCTL.TRIGREQ) is used to trigger the command. Bit 1 (OSPI_FCMCTL.BNKREQ) used by software to poll the status of the command execution. When bit 1 toggles from 1 to 0, the data byte (OSPI_FCMCTL.BNKDATA) from the corresponding address (OSPI_FCMCTL.BNKADDR) is valid. The address must be set before triggering the STIG memory bank access. Each consecutive STIG access overwrites the previous one so that the data in the bank fits into byte index fetched by the last STIG access configured to use the memory bank (first incoming byte equals first address of the memory bank, second one equals the second address and so on).

Servicing STIG Request

The OSPI controller determines the number of bytes in the OSPI_FCCTL register to be sent to the flash device, when there is a STIG request. The OSPI_FCCTL.OPCODE field indicates the instruction to be sent and is always pushed first. If there is an address to send, the address (size is also programmed in the same register) is sent next. The address is stored in the OSPI_FCA register. If there are dummy cycles (size of which is also programmed in the OSPI_FCCTL register), they are sent next.

For write data (size of which is also programmed in the OSPI_FCCTL register), up to 8 bytes can be sent (as stored in the OSPI_FCWD_LWR and OSPI_FCWD_UP registers). When read data is collected from the flash device, the OSPI controller stores it in the OSPI_FCRD_LWR and OSPI_FCRD_UP registers.

Arbitration Between DAC and STIG Access

When multiple controllers are simultaneously active, a simple, fixed priority arbitration scheme is used to arbitrate between each interface and to access the external flash.

The fixed priority is defined as follows, highest priority first:

1. Direct Access Write
2. STIG Access

3. Direct Access Read

When one controller is servicing the request, the other controller is back pressured while waiting to be serviced.

Auto Polling for DAC Write Access

For DAC write accesses, which initiate flash program operation, the OSPI controller provides an option to automatically poll the flash status for program completion. When a flash write operation is triggered through DAC, the OSPI controller sends the write data up to page size defined in the OSPI_DSCTL.PGSZ field. Once a page boundary is reached, the DAC stops sending data to the flash device as the flash device enters the program mode. Once the device is in program mode, the OSPI controller can automatically send the flash status read commands to check the state of the flash.

The OSPI_WCCTL register defines the setting to poll the flash device correctly. By default, it is configured to poll bit 0 of the Device STATUS register (using opcode 0x05), which is common across all devices to indicate Write in Progress (WIP). However, in some devices (such as Micron devices, where size is > 512 MB), it is required that the controller polls a different bit of a different device register. This means the controller must issue a different command during this polling phase. For example, in Micron N25Q devices, it is bit 7 of the FLAG STATUS register (opcode 0x70) instead of bit 0 of the STATUS register that must be polled. For this reason, the OSPI_WCCTL register has been provided for software to determine the bit and the opcode to use to poll for write completion, and also the number of successive valid polls that should take place.

To ensure that the bandwidth of the device is not affected by continuous read status SPI transactions, prolong the delay between the successive flash status read command by programming the OSPI_WCCTL.REPDLY field. This feature is implemented to free up the SPI bandwidth, if required. However, defining this delay is not always desired as the ready bit indication can come later what impacts the overall performance. This register must be setup while the controller is idle.

When the OSPI controller starts to service a STIG request, it sets the OSPI_FCCTL.STAT bit to indicate a command execution is in progress. When the OSPI controller is in the auto polling state, servicing a STIG request is different. Several devices are inaccessible after a program operation until the device has completed that write. Few of them have a possibility to suspend the programming page. It can be controlled by the OSPI_POLSTAT.STAT bit, which indicates active auto polling phase. After requesting a STIG, the OSPI controller issues an appropriate opcode to memory. While servicing a STIG (in auto polling phase), the OSPI_FCCTL.STAT bit remains steady and other parts of transfer such as address or dummy bits are disabled (to issue program suspend command, only opcode is needed).

SPI Command Translation

Requests issued by the DAC or STIG are translated into a sequence of byte transfers to send downstream (before serializing the flash device). These sequences depend on the requested transfer, except the following example (1-byte non-sequential read):

INSTRUCTION OPCODE > ADDRESS > MODEBYTE > DUMMY CYCLES > 1-DATA BYTE

NOTE: During data phase mode, data programmed in the OSPI_MBCTL register is driven on pins. If mode data is not enabled, the address phase is followed directly by dummy cycles. During the dummy cycle phase the

OSPI data pins (D0-D7) are three-stated (High-z). To ensure the correct signal level on the data pins during this phase, external pull-ups can be used on data pins.

For sequential accesses, an extra data byte per read is pushed to the flash device on the back of the above sequence, assuming that it can be done without any gap between each transferred byte.

The actual sequence sent to the flash device depends on the requested transfers (non-sequential or sequential), whether the device is configured in XIP mode or not, and the state of the OSPI_DRICTL and OSPI_DWICTL registers. For writes, the write enable latch (WEL) within the flash device must be high before a write sequence can be issued.

The OSPI controller automatically issues a WEL command before triggering a write command via the DAC (the program need not perform this operation). To increase flexibility and performance, turn off this feature by setting the OSPI_DWICTL.WELDIS bit. The opcode for WEL is 0x06 and common between the devices. However, the WEL operation is programmed using the OSPI_OE_LWR.XRDBYT/OSPI_OE_UP.FSTBYTWEL bits and (optionally) the OSPI_OE_LWR.XWRBYT/OSPI_OE_UP.XBYTWEL bits (flash device requires 2-byte command code for WEL).

When write requests from the DAC are not received and all outstanding requests have been sent, the flash device automatically starts the page program write cycle. Any incoming request at this time is held in wait state until the cycle is completed. The OSPI controller automatically polls the flash device legacy SPI status register to identify when the write cycle has completed. This is achieved by sending the Read Status Register (RDSR) opcode to the flash device and waiting until the device indicates that the write cycle is completed (the Write in Progress bit is cleared to zero and WEL bit is cleared to zero or device ready bit is set to one). The WREN and RDSR device instructions are only sent by the controller. For other specific instruction that the user determines must be sent to the device (for example, if the device needs to be unprotected before a write command is issued), must be separately handled by issuing flash commands via the STIG.

Hold and Reset Control

There is an option to trigger hold and reset features on the I/O of the flash device. The hold functionality is common across the devices and takes an alternative function of the DQ3 pin (applicable when device does not operate in quad SPI or DDR modes). The transfer can be held and resumed by the OSPI_CTL.HLD bit. Devices with hold feature on DQ3 need another dedicated pin for hardware reset. Devices without hold feature have an alternative reset on the DQ3 pin, which makes the additional reset pin redundant. The controller supports both variants. The OSPI_CTL.RSTCFG field allows the user to configure the hardware reset solution implemented in the device. After configuration, it is possible to trigger hold or reset features using I/O (OSPI_CTL.HLD or OSPI_CTL.RST bits).

NOTE: The OSPI controller does not support dedicated reset pin to control the reset of flash devices. Flash devices with reset functionality on DQ3 can be controlled directly via OSPI controller.

After hold activation, the controller is in waiting state. Any other operations must not be requested before de-asserting the OSPI_CTL.HLD bit. The hold feature is useful when any SPI transaction needs to be prolonged to adjust it into specific point in time. To check if the hold request is suspended, the OSPI_CTL.IDLE bit can be polled

for. If SPI is not in the idle state, the transfer is suspended. Software must reset the OSPI_CTL.HLD bit before any new SPI transaction. In case hold request is set before starting any transfer, it will be in hold state after it starts.

Hardware reset must be activated when CS is high (no valid transaction is present on SPI bus). It can be checked by polling the OSPI_CTL.IDLE bit. If the controller is in the idle state and no other transfer requests are queued, hardware reset can be triggered. Reset feature is useful when any write, program, or erase operation needs to be cancelled. No transfer request is permitted before driving the reset back to inactive. Triggering hold or reset on the DQ3 pin at the time the device is configured to work in Quad SPI or DDR mode, overwrites transfer data on the DQ3 with 0. This behavior is considered as a software error. Ensure that the flash device is introduced to suitable SPI Mode (by polling its Configuration Register) before triggering alternative DQ3 function.

Flash Instruction Type Support

To send correct read and write opcodes, software must initialize the OSPI_DRICTL and OSPI_DWICTL registers. These registers include fields to setup the required instruction opcodes that is intended to be used to access the flash (default is basic read and basic page program) as well as the instruction type, edge mode (DDR or SDR) and whether the instruction uses single, dual, quad, or octal pins for address and data transfers.

To ensure that the controller can operate from a reset state, the registers are reset to an opcode compatible with single I/O standard SPI devices. Though it is applicable for both reads and writes, the OSPI_DRICTL.INSTRTYP field appears only once (not included in the OSPI_DWICTL register). If software sets this to any value other than 0, the OSPI_DRICTL.ADDRTRNSFR/OSPI_DWICTL.ADDRTRNSFR/ OSPI_DRICTL.DATATRNSFR/OSPI_DWICTL.DATATRNSFR bits become don't care. It is made available to allow software to support less common flash instructions, where opcode, address, and data are sent on 2 or 4 data lines (opcode from several instructions are sent serially to the flash device, even for dual/quad instructions).

Dual Data Rate (DDR) Operations

The OSPI controller supports DDR mode of operation, in which some or all transfer phases happen in DDR mode, where the I/O lines are driven/sampled on both rising and falling edges of the clock.

In DDR mode, the OSPI controller supports the following modes:

- Dual Transfer Rate (DTR) mode, where command is driven in SDR mode and address/dummy cycles/data are driven in DDR mode.
- DTR protocol mode, where everything including command is driven in DDR mode.

For DTR mode, there are specific commands which are recognized by the flash as DTR commands. These are DTR Read commands which can be handled in STR Protocol (but in DTR Mode). This is achieved by setting the OSPI_CTL.DTREN bit to 0 and OSPI_DRICTL.DDREN bit to 1.

For DTR protocol mode, all normal commands can be sent in DDR fashion, provided the flash is already configured in a mode to accept the commands in DDR mode. Support for DTR protocol provides significant enhancement. This is enabled in the OSPI controller by setting the OSPI_DRICTL.DDREN bit to 1. It allows the device to work in DTR mode for each possible command (not only DTR read ones). It can also handle opcode phase in DTR mode, which improves the overall performance.

There are several devices (for example, Micron N25Q512A) that can handle read operations in DTR mode. They can issue and capture data on both rising and falling edges while working with a dedicated command type. This enables the controller to maintain same throughput twice the lower frequency of SPI_CLK for STR mode.

In MT25Q family of Micron devices, DTR protocol is implemented. It enables device to handle all commands in DTR mode. DTR Read commands detect DTR mode based on dedicated opcode. Therefore, opcode must be sent as STR. When DTR protocol is enabled, the device does not need opcode to detect edge mode, as it can recognize based on the volatile or nonvolatile bit in the flash configuration register.

The ***Read Configuration Examples*** table illustrates how software must configure the controller for selected specific read and write instruction supported by the different devices.

Table 23-3: Read Configuration Examples

Command	Opcode (Number of Lanes/ Edge Mode)	Address/ Dummy/ Mode (Number of Lanes/ Edge Mode)	Data (Number of Lanes/ Edge mode)	Instruction Type `OSPI_DRICTL.INSTRTYP`	Address Transfer Type `OSPI_DRICTL.ADDRTRNSFR`	Data Transfer Type `OSPI_DRICTL.DATATRNSFR`	DDR Bit Enable `OSPI_DRICTL.DDREN`
READ	1/SDR	1/SDR	1/SDR	0	0	0	0
FAST_READ	1/SDR	1/SDR	1/SDR	0	0	0	0
DTR FAST_READ	1/SDR	1/DDR	1/DDR	0	0	0	1
DOR (Dual output Fast Read)	1/SDR	1/SDR	2/SDR	0	0	1	0
DTR DOR (Dual output Fast Read)	1/SDR	1/DDR	2/DDR	0	0	1	1
DIOR (Dual I/O Fast Read)	1/SDR	2/SDR	2/SDR	0	1	1	0
DTR DIOR (Dual I/O Fast Read)	1/SDR	2/DDR	2/DDR	0	1	1	1
QOR (Quad output Fast Read)	1/SDR	1/SDR	4/SDR	0	0	2	0
DTR QOR (Quad output Fast Read)	1/SDR	1/DDR	4/DDR	0	0	2	1
QIOR (Quad I/O Fast Read)	1/SDR	4/SDR	4/SDR	0	2	2	0

Table 23-3: Read Configuration Examples (Continued)

Command	Opcode (Number of Lanes/ Edge Mode)	Address/ Dummy/ Mode (Number of Lanes/ Edge Mode)	Data (Number of Lanes/ Edge mode)	Instruction Type `OSPI_DRICTL.INSTRTYP`	Address Transfer Type `OSPI_DRICTL.ADDRTRNSFR`	Data Transfer Type `OSPI_DRICTL.DATATRNSFR`	DDR Bit Enable `OSPI_DRICTL.DDREN`
DTR QIOR (Quad I/O Fast Read)	1/SDR	4/DDR	4/DDR	0	2	2	1
OOR (Octal output Fast Read)	1/SDR	1/SDR	8/SDR	0	0	3	0
DTR OOR (Octal output Fast Read)	1/SDR	1/DDR	8/DDR	0	0	3	1
OIOR (Octal I/O Fast Read)	1/SDR	8/SDR	8/SDR	0	3	3	0
DTR OIOR (Octal I/O Fast Read)	1/SDR	8/DDR	8/DDR	0	3	3	1
DCFR (Dual Command Fast Read)	2/SDR	2/SDR	2/SDR	1	don't care	don't care	0
DTR DCFR (Dual Command Fast Read)	2/SDR	2/DDR	2/DDR	1	don't care	don't care	1
QCFR (Quad Command Fast Read)	4/SDR	4/SDR	4/SDR	2	don't care	don't care	0
DTR QCFR (Quad Command Fast Read)	4/SDR	4/DDR	4/DDR	2	don't care	don't care	1
OCFR (Octal Command Fast Read)	8/SDR	8/SDR	8/SDR	3	don't care	don't care	0
DTR OCFR (Octal Command Fast Read)	8/SDR	8/DDR	8/DDR	3	don't care	don't care	1

NOTE: This data is applicable for 3-byte and 4-byte address variants of the commands.

In DTR protocol, all transfer phases (including opcode) take DDR edge mode independent of the command under execution. DTR protocol is enabled by the OSPI_CTL.DTREN bit. It has higher priority than the OSPI_DRICTL.DDREN bit. Therefore, if the OSPI_CTL.DTREN bit is set, irrespective of value programmed in the OSPI_DRICTL.DDREN bit, all command, address, dummy cycles, and data are transferred in DDR mode.

Table 23-4: Write Configuration Examples

Command	Opcode (Number of Lanes)	Address/ Dummy/Mode (Number of Lanes)	Data (Number of Lanes)	Instruction **OSPI_DRICTL.INSTRTYP**	Address Transfer Type **OSPI_DWICTL.ADDRTRNSFR**	Data Transfer Type **OSPI_DWICTL.DATATRNSFR**
PP (Page Program)	1	1	1	0	0	0
DIFP (Dual Input Fast Program)	1	1	2	0	0	1
DIEFP (Dual Input Extended Fast Program)	1	2	2	0	1	1
QIFP (Quad Input Fast Program)	1	1	4	0	0	2
QIEFP (Quad Input Extended Fast Program)	1	4	4	0	2	2
OIFP (Octal Input Fast Program)	1	1	8	0	0	3
OIEFP (Octal Input Extended Fast Program)	1	8	8	0	3	3
DCPP (Dual Command Page Program)	2	2	2	1	don't care	don't care
QCPP (Quad Command Page Program)	4	4	4	2	don't care	don't care
OCPP (Octal Command Page Program)	8	8	8	3	don't care	don't care

NOTE: This data is applicable for both 3-byte or 4-byte address variants of the commands.

In DTR protocol, all transfer phases (including opcode) take DDR edge mode independent of the command under execution.

Data Sampling

The OSPI provides flexibility to configure the sampling point of read data with the SPI clock to meet setup and hold timings of the flash devices when operating at higher speed. The OSPI_RDC register provides an option to control the sampling point. In OSPI controller, data received on the OSPI pins is sampled by internal reference clock (OSPI_REFCLK). In STR mode, by default (when the OSPI_RDC.DLYRD = 0), the incoming data is on the first falling edge of the OSPI_REFCLK in second half of SPI clock. In DTR mode, it is on the first falling edge of the OSPI_REFCLK in second quarter of SPI clock.

The OSPI_RDC.SMPLEDG bit selects the edge of the OSPI_REFCLK, in which data from flash memory are sampled. This increases the sampling resolution by two times. The OSPI_RDC.DLYRD field controls the additional number of OSPI_REFCLK cycles that must be applied to the internal read data capture circuit. Large clock-to-out delay of the flash memory, trace delays, and other device delays may impose an upper limit on the flash clock frequency which is less for the flash memory to operate. To compensate this, software must set this register to a value that guarantees robust data captures.

The OSPI_RDC.SMPLEDG bit selects the edge of the SYSCLK, in which data from flash memory are sampled. This increases the sampling resolution by two times. The OSPI_RDC.DLYRD field controls the additional number of SYSCLK cycles that must be applied to the internal read data capture circuit. Large clock-to-out delay of the flash memory, trace delays, and other device delays may impose an upper limit on the flash clock frequency which is less for the flash memory to operate. To compensate this, software must set this register to a value that guarantees robust data captures.

For example, when the baud divider (OSPI_CTL.BAUD field) is programmed to 7, it results in divider of 16. Therefore, SPI_CLK: OSPI_REFCLK = 16:1 (every 1 SPI_CLK cycle has 16 OSPI_REFCLK cycles). When the OSPI_RDC.DLYRD bits are programmed to X,

In STR mode of operation, received data is captured on:

- (16/2) + X^{th} falling edge of OSPI_REFCLK if OSPI_RDC.SMPLEDG = 0
- (16/2) + X^{th} rising edge of OSPI_REFCLK if OSPI_RDC.SMPLEDG = 1

In DTR mode of operation, received data is captured on:

- (16/4) + X^{th} falling edge of OSPI_REFCLK if OSPI_RDC.SMPLEDG = 0
- (16/4) + X^{th} rising edge of OSPI_REFCLK if OSPI_RDC.SMPLEDG = 1

To improve the hold timing during transfers in DTR mode, the OSPI_RDC.DDRDLYRD delays the transmitted data by programmable number of OSPI_REFCLK cycles.

NOTE: The OSPI interface for Octal DTR mode may not work at higher frequencies for flash devices that require DQS.

PHY Module Architecture

The PHY Module is divided into the following four sub-blocks:

- Data Transmitter

  The data transmitter serializes the transmit data to assign complaint signal values into the controller output interface. The input data size is two bytes to cover the octal DDR scenario where two bytes are sent within a single reference clock cycle. The configuration interface covers selected SPI protocols (single, dual, quad, or octal) or command types (DDR, SDR). These values are necessary to calculate the number of bits that fit into a clock cycle and consequently what set value must be set by the hardware.

- Data Receiver

  The data receiver block samples data from flash device.

- Delay Line Module

  The delay line module block provides an appropriate delay for the input clock to ensure correct data transmitting and sampling. This block contains two separate delay paths for the OSPI clock, one feeding the external FLASH device and the other feeding the internal PHY sampling clock used for capturing data from the device when the PHY mode is enabled. Delay line values are configurable in software.

- Clock Arbiter
