  The clock arbiter handles gating the clock logic for clocks forwarded to the DLL inputs.

The ***PHY Module Block Diagram*** shows the sub-blocks in the PHY module. The sections following the diagram describe the architecture of the sub-blocks in more detail.

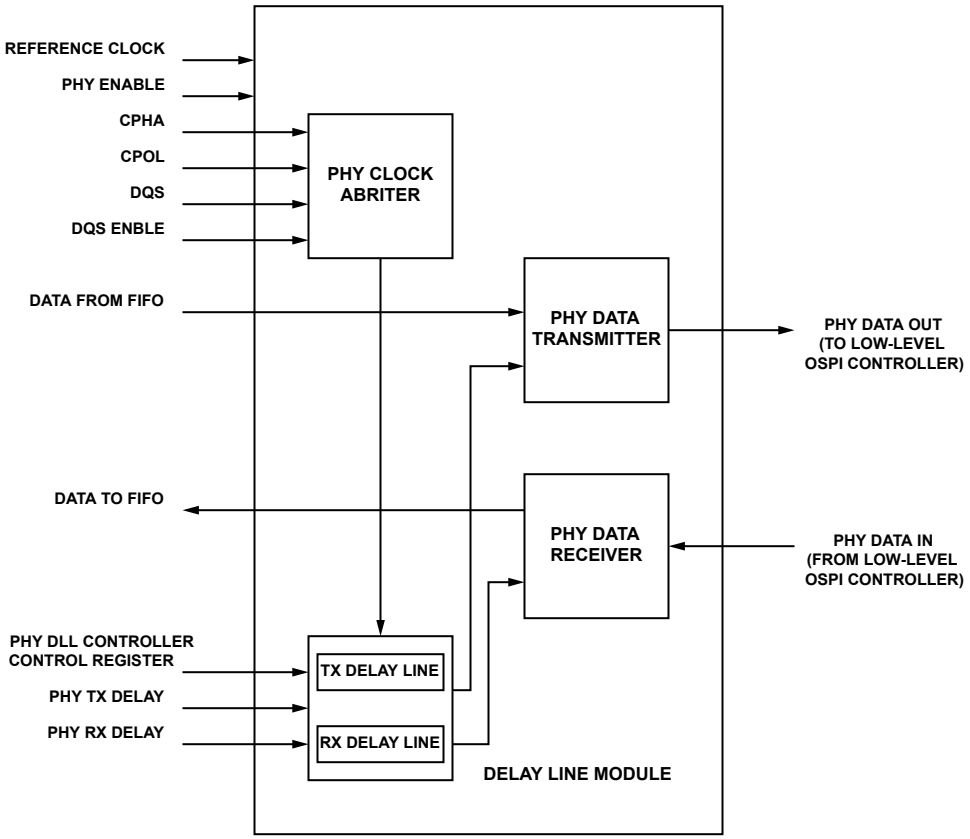

Figure 23-2: PHY Module Block Diagram

PHY Data Transmitter

The data transmitter latches queued data to transmit on both the negative and positive edges of the reference clock. Then data is chopped to fit into the output interface. With the PHY module, in the last stage of the TX data path data from both edges are connected, forwarded back to the low-level OSPI controller, and then put on the OSPI controller outputs if the PHY enable bit is asserted. Otherwise, the controller outputs generated by the low-level OSPI controller are selected.

PHY Data Receiver

In the data receiver module, data is sampled on both edges of the delayed reference clock (sampling clock) ensuring a wide range of the sampling window. Read data is gathered in shift registers and then merged into a byte-sized input FIFO. Data reception is programmable to work either with the delayed reference clock or with the DQS input signal from the flash device.

Delay Line Module

Due to the asynchronous nature of flash devices, it is important to address the timing requirements for capturing and receiving data between the controller and the flash. The PHY module contains logic to meet the timing requirements. The delay compensation circuit is designed with the following features:

- Programmable OSPI clock delay specified as a percentage of a clock cycle

- Programmable sampling clock delay specified as a percentage of a clock cycle
- Delay compensation circuit re-sync circuitry activated during refresh cycles to compensate for temperature and voltage drift

The delay compensation circuitry relies on a controller/target approach. The controller delay line is used to determine how many delay elements constitute a complete cycle. This count, along with the programmable fractional delay settings, determines the actual number of delay elements to program into the target delay lines. The controller and target delay lines are identical. This approach allows the memory controller to observe a clock and then delay other signals by a fixed percentage of that clock.

DLL Locking is controlled through the register interface. When the DLL is reset, the controller DLL performs a locking procedure starting with the DLL start point value in the `OSPI_PHYMCTL.INITDLY` bit field and the current frequency of operation. The DLL start point value must not exceed a delay of 1 and 1/4 cycles of delay, when calculated by estimating the worst case timing through a delay element at the highest frequency the DLL will be operating at. For example, if the maximum operating frequency is 200 MHz (period of 5 ns) and the worst case delay element has a 85 ps delay, then program the DLL start point to 5 / 0.085 = 58.8 = 59 elements = 0x3B.

With this setting, the controller DLL is will correctly lock for all frequencies below 200 MHz and in any process corner. If the delay provided by the delay line is enough to cover a full clock cycle, the controller DLL is in full clock mode. In this case, the DLL lock value in the `OSPI_DLLOB_LWR.LWRLOCK` bit field reports the number of delay element in one full clock cycle. The target delay line fractional setting uses this number to determine the number of delay elements to add to the target delay lines. For example, if the DLL lock value = 50 = 0x32, then the target delay line percentage = 25% = 0x20, and the target delay line delay value = 50 × 0.25 = 12.5 elements. The DLL Module will round the calculated value into an integer number of delay elements.

If the frequency of operation is such that the delay line is not long enough to accommodate a full cycle of delay, the controller DLL will automatically detect this and switch to half clock mode. In this mode, the controller DLL attempts to lock when the delay in the delay line reaches a half-clock cycle. If lock is achieved in half clock mode, the target delay lines are automatically adjusted to program a fractional delay of a full cycle. There is no need to change the target delay settings based upon the lock mode of the controller DLL. For example, if the DLL lock value = 50 = 0x32, then the target delay line percentage = 25% = 0x20, and the target delay line delay value = (50 2) × 0.25 = 25 elements. Do not work in half clock mode when using a loop-back sampling method or when the SPI clock is configured to SPI Mode 3 (CPHA =1, CPOL =1).

If the frequency of operation is such that the delay line is not long enough to capture a half-clock cycle of delay, the controller DLL will indicate lock and set the number of delays to the maximum length of the delay line. This is called saturation mode. There is no need to change the target delay settings in this mode. The target delay settings will be fixed at the fractional delay based upon the maximum delay of the delay line times 2. For example, if the DLL lock value = MAX = 128 = 0x80, and the target delay line percentage = 25% = 0x20, then the target delay line delay value = (128 × 2) × 0.25 = 64 elements.

PHY Clock Arbiter

The OSPI clock is generated only when the SPI control logic FSM indicates that an SPI transfer is ongoing. Conversely, the reference clock is continuously generated. This module generates a sampling clock that is ready to pass

through the RX delay line. It is generated when read data phase of SPI transfer is detected based on information from the SPI control module. The sampling clock is optionally sourced from DQS or loop-back input.

PHY Pipeline Mode

The PHY pipeline mode is for a direct read mode of operation. The flash command generator pipelines and puts a few expected sequential accesses into the TX FIFO causing the CS to stay active since the low-level OSPI controller controls the internal TX FIFO fill level. To correctly trigger a direct read in pipeline mode, first poll the `OSPI_CTL.IDLE` bit to determine that the TX FIFO is empty. The sequential data transfer is interrupted when non-sequential access occur or too many wait states are introduced by the SPB controller to keep the flash transaction continuous. Introducing wait states slows down the system data rate.

Enable this mode when following conditions are met:

- SYSCLK > 1.1 × OSPI_REFCLK

  NOTE: In PHY mode the reference clock is taken from the CDU CLKO10

- Accesses are only 32-bits in size

Programming Concepts

Software configures the OSPI controller before communicating with the flash device. The static configuration bits must be setup before the OSPI controller is enabled using the `OSPI_CTL.EN` field. To change the controller configuration, disable it before reconfiguring.

Configuring OSPI after Reset

The OSPI controller comes up with a state that is suitable to perform basic reads and writes using the DAC. Basic read (opcode 0x03) and write (opcode 0x02) instructions are supported by all target devices. The controller also wakes up with a baud rate divider setting of 32. When the reference clock operates at 500 MHz after reset, the effective SPI clock is 15.625 MHz. This must be slow enough to meet all timing requirements of all target devices without any further device programming.

When the target device does not use three address bytes, the `OSPI_DSCTL` register must be modified to the appropriate size. If software wants writes to the device and the number of bytes per device page is not equal to 256, the `OSPI_DSCTL` register must also be modified. The software must enable the write protect feature prior to enabling the OSPI controller. This blocks any AHB writes from taking effect. The `OSPI_WRPROT_LWR`, `OSPI_WRPROT_UP`, `OSPI_WRPROT_CTL`, and `OSPI_DSCTL.PGSZ` fields must be setup.

After reset, software can read from and write to the flash device. Enabling/disabling the controller and DAC is achieved by writing to the corresponding `OSPI_CTL` register fields. Maintain the default values of the baud rate divisor and default state of the `OSPI_CTL.CPOL`/ `OSPI_CTL.CPHA` bits. A write data value of 0x00780081 is recommended.

Programming Dummy Cycles

When programming the dummy cycles for OSPI reads (DAC and STIG-initiated reads) from the flash device, mode data should be considered as it impacts the actual number of dummy cycles seen on the bus. When mode data is not enabled, then the number of dummy cycles is that same as those set in dummy cycles field, respectively, for STIG or DAC operation.

However, when mode data is enabled, then in addition to the programmed number of dummy cycles, a few extra cycles are needed to transmit out the mode data. The number of cycles added depends on the bus mode of the OSPI. For example, when the address phase of the command is configured to be sent on a single line in STR mode, then the mode bits consume eight cycles. When the address phase of the command is configured to be sent on four lines in DTR mode, then the mode bits consume one cycle. These extra cycles should be considered when configuring the dummy cycles for the controller, so the overall dummy clock cycles match the dummy cycles provided in flash data sheet.

Configuring OSPI for Optimal Use

Software must accurately configure the controller to optimally access the flash.

To configure the controller:

1. Wait until pending STIG are completed or poll the `OSPI_CTL.IDLE` field.
2. Disable the `OSPI_CTL.DACEN` field. The OSPI controller can be completely disabled using the `OSPI_CTL.EN` field.
3. Update the `OSPI_DLY` register. This register allows the user to tweak how the chip select is driven after each flash access. This is required as each device may have different timing requirements. As the serial clock frequency is increased, these timing requirements become critical. The numbers programmed in this register are based on the period of OSPI_REFCLK.

   For example, an ATMEL device needs 50 ns minimum time before CS can be re-asserted after it has been de-asserted. By default, the controller provides a a minimum of one SCLK period. When the device is operating at 50 MHz, the SCLK period is only 20 ns. Therefore, additional 30 ns are required. As the register defines the number of OSPI_REFCLK cycles to add, if OSPI_REFCLK is running at 500 MHz (2 ns period), user must program a value of at least 15 to the `OSPI_DLY.DSRT` bits. This delay can be extended during auto-polling phase. Polling repetition delay can be defined in the `OSPI_WCCTL.REPDLY` field.
4. Update the `OSPI_DSCTL` register. The number of bytes per page is required to perform any write operation on flash. The number of bytes per device block is only required if the write protect feature is used.
5. Setup and enable the write protection registers (`OSPI_WRPROT_LWR`, `OSPI_WRPROT_UP`, and `OSPI_WRPROT_CTL`), if write protection features are required.
6. Enable the required interrupts using the `OSPI_IMSK` register.
7. Update the `OSPI_REMAPADDR` register to remap the DAC addresses to different address in flash.
8. Set the baud rate divisor in the `OSPI_CTL.BAUD` to define the required clock frequency of the target device.

9. Select the appropriate chip select signal to use through the OSPI_CTL.BAUD bits.
10. Update the OSPI_RDC register. This register delays when read data is captured and helps when read data path from the device to the controller is long and the device clock frequency is high.
11. Enable the OSPI controller and DAC using the OSPI_CTL register.

Configuring OSPI for DAC Read Operation

1. Configure the OSPI_DRICTL register:
    a. Program the desired opcode for Read command (0xBB for Dual SPI read).
    b. Configure th instruction type, address transfer type, and data transfer type as per the opcode.
    c. Configure the dummy cycles for the selected command opcode depending on the flash device.
    d. Set the Mode bit Enable if the mode data needs to be transferred during dummy cycles phase.
    e. Set the DDR enable bit if the command works in DTR mode.
2. If the operation requires dual opcode, set the OSPI_CTL.OPCODEEN bit.
3. Update the second byte for read opcode in the OSPI_OE_LWR.XRDBYT field.
4. To operate in DTR protocol mode, set the OSPI_CTL.DTREN bit.

   If this bit is set, the OSPI_DRICTL.DDREN bit has no effect and all phases of command including the op-code are done in DDR mode.
5. Update the OSPI_DSCTL.ADDRSZ field.
6. Update the OSPI_MBCTL.MODE field.
7. Enable the DAC mode using the OSPI_CTL.DACEN bit, if not enabled.
8. Start the read transfer by accessing the OSPI memory mapped space through core or MDMA accesses. Any access to address 0x60000000 will access the flash address 0x0 if address remapping is 0.
9. If using MDMA for the transfer, wait for the DMA to complete.

NOTE: For accesses through core, software need not check FIFO levels. All the FIFOs are internally maintained by DAC.

Configuring OSPI for DAC Write Operation

1. Configure the OSPI_DWICTL register:
    a. Program the desired opcode for write command like 0x02 for single SPI page program.
    b. Configure the address transfer type and data transfer type as per the opcode.
    c. Configure the dummy cycles for selected command opcode depending on the flash device.

2. Update the OSPI_DRICTL.INSTRTYP field as per the selected opcode.
3. Clear the OSPI_DWICTL.WELDIS bit to manually send the WEL (Write Enable) instruction to flash. Else, the controller automatically issues WEL to flash before sending any write command to flash.

   If WEL command for flash under use is not 0x06, update the OSPI_OE_UP.FSTBYTWEL field.
4. If the operation requires dual opcode, set the OSPI_CTL.OPCODEEN bit.
5. Update the second byte for read opcode in the OSPI_OE_LWR.XWRBYT field.
6. Update the number of address bytes the command expects in the OSPI_DSCTL.ADDRSZ field.
7. As the controller supports the automatic polling for write operation complete, update the OSPI_WCCTL register accordingly to enable the automatic polling for flash program operation complete.
   a. Enable the automatic polling by clearing the OSPI_WCCTL.DIS bit.
   b. Update Polling opcode and define polling bit index and polarity as per the flash device.
   c. Update polling count and polling repetition delay.
   d. Optionally, update the OSPI_POLLEXP register if polling expiration is enabled.
8. Enable the DAC mode using the OSPI_CTL.DACEN, if not enabled.
9. Start the read transfer by accessing the OSPI memory mapped space through core or MDMA accesses. Any access to address 0x60000000 will access the flash address 0x0 if address remapping is 0.
10. Wait for the DMA to complete, if using MDMA for the transfer.

NOTE: For accesses through core, software need not check FIFO levels. All FIFOs are internally maintained by DAC.

Issuing STIG Command

This is a typical method that software uses to access the flash device registers and perform erase operations. It can also be used to access the flash array (though only 8 data bytes can be read or written at a time), as defined in the OSPI_FCRD_LWR, OSPI_FCWD_LWR, OSPI_FCRD_UP and, OSPI_FCWD_UP registers.

To issue a STIG command:

1. Set the OSPI_IMSK.STIGREQ_MSK bit to enable the STIG command completion interrupt.
2. Update the OSPI_FCCTL.OPCODE and OSPI_FCCTL.DMY bits, as per the flash command that need to be executed via STIG.
3. Clear the OSPI_FCCTL.STIGBNKEN bit.
4. Set the OSPI_FCCTL.ADDREN bit, iwhen the command requires the address to be driven.

   When set:

a. Update the OSPI_FCCTL.ADDRSZ field according to the number of address bytes expected by the command.

b. Update the OSPI_FCA register with the desired flash address.

5. When the command expects the data to be sent to flash, set the OSPI_FCCTL.WREN bit.

   When set:

   a. Update the OSPI_FCCTL.WRSZ field according to the number of data bytes to be sent to flash.

   b. Update the OSPI_FCWD_LWR and OSPI_FCWD_UP registers with data to be sent to flash.

6. When the command expects the data to be received from the flash, set the OSPI_FCCTL.RDEN bit.

   When set, update the OSPI_FCCTL.RDSZ field according to the number of data bytes to expected from flash.

7. Update the OSPI_FCCTL.MODEEN bit, when the mode data are sent during dummy cycles.

   When set, update the OSPI_MBCTL.MODE field with desired mode data.

8. Set the OSPI_FCCTL.EXE bit to execute the STIG command.

9. Set the OSPI_ISTAT.STIGREQ bit (or wait for interrupt if enabled) indicating that the STIG command execution is completed.

10. When the command expects the data to be received from the flash, read the data from the OSPI_FCWD_LWR and OSPI_FCWD_UP registers.

NOTE: Do not set the OSPI_FCCTL.WREN and OSPI_FCCTL.RDEN bits simultaneously. A given command can either read data or send data to the flash, but not both at the same time.

With normal STIG command, only 8 bytes can be read at a time, but with support of STIG memory bank up to 16 bytes can be read in to STIG memory bank. This is controlled by the OSPI_FCCTL.STIGBNKEN bit and OSPI_FCMCTL register. Commands issued using this interface have a higher priority than all other read accesses coming from AHB, and interrupts any read commands being requested by the DAC.

To issue a STIG memory bank read command:

1. Set the OSPI_IMSK.STIGREQ_MSK bit to enable STIG command completion interrupt.

2. Update the OSPI_FCCTL.OPCODE and OSPI_FCCTL.DMY bits as per the flash command that need to be executed via STIG.

3. Set the OSPI_FCCTL.STIGBNKEN bit.

4. Set the OSPI_FCCTL.ADDREN bit, if the command requires the address to be driven.

   If set:

   a. Update the OSPI_FCCTL.ADDRSZ field according to the number of address bytes expected by the command.

b. Update the OSPI_FCA register with the desired flash address.

5. Update the OSPI_FCCTL.MODEEN bit, if the mode data are sent during dummy cycles.

   If set, update the OSPI_MBCTL.MODE field with the desired mode data.

6. Set the OSPI_FCCTL.EXE bit to execute the STIG command.
7. Set the OSPI_ISTAT.STIGREQ bit (or wait for interrupt if enabled) indicating that the STIG command execution is completed.

At this stage, 16 bytes of data read from the flash device are available in the STIG memory bank. To access this data, a STIG memory bank read must be issued. Each read can read one byte form STIG memory bank at a time. To read all data, 16 reads must be issued.

To read a data byte from STIG memory bank:

1. Set the OSPI_FCMCTL.BNKADDR field. This can be any value from 0 to 16.
2. Set the OSPI_FCMCTL.TRIGREQ bit to trigger the STIG memory bank read.
3. Poll the OSPI_FCMCTL.BNKREQ bit to clear.
4. Read the requested data byte from the OSPI_FCMCTL.BNKDATA.

Entering XIP mode

The controller supports XIP operations to minimize the latency for back-to-back reads or code execution.

If the flash device comes in XIP on power up, software cannot discover the state of XIP from POR via the Flash Status Register reads. The only operation of a flash device when XIP mode is enabled, is an XIP read. In such cases, software must be aware that if flash enters XIP from POR, the OSPI_MBCTL.MODE and OSPI_CTL.XIPIMM fields must be set. This makes the controller to enter XIP mode immediately and start communicating with the flash device in XIP mode on next read issued. Therefore, it does not require the read opcode to be transferred. To exit XIP mode, this bit must be set to 0. This takes effect in the attached device only after the next read instruction is executed. Software must ensure that at least one read instruction is requested after resetting this bit before it can be sure XIP mode in the device is exited.

OSPI_CTL.XIPRD: If it is not known that the flash device enters XIP from POR, and XIP from POR may be supported by the attached flash device, software can attempt to exit the XIP mode by issuing an XIP exit command using a STIG command. For this, software must be aware of the mode bit requirements of that device, as XIP entry and exit changes per device.

XIP mode is supported in several flash devices. However, flash manufacturers do not have a consistent standard approach. Most of them use signature bits that are sent to the device immediately following the address bytes. Few of them (such as Micron devices) use signature bits and require a flash device configuration register write to enable XIP.

The following section describes how software ensures entry into XIP mode for the flash devices compliant with the OSPI controller.

Micron N25Q, MT25Q, and MT35X Devices

XIP mode must first be enabled by setting the corresponding field of VCR within the flash device. The VCR can be written to using the OSPI_FCCTL register to issue a VCR write command.

1. Disable the DAC using the OSPI_CTL.DACEN bit to ensure that no new AHB read accesses are sent to the flash device.
2. Use STIG mode to issue a VCR write to flash memory.
3. Set XIP mode bits in the OSPI_MBCTL.MODE field to 8'b00000000.
4. Enable the OSPI controller XIP mode by setting the OSPI_CTL.XIPRD bit.
5. Re-enable the DAC.

Micron (Supporting Basic XIP Mode), Winbond, Spansion Devices

1. Disable the DAC using the OSPI_CTL.DACEN bit to ensure that no new AHB read accesses are sent to the flash device.
2. Set XIP mode bits in the OSPI_MBCTL.MODE to:
   - 8'b10000000, for Micron devices supporting basic XIP mode
   - 8'b00100000, for Winbond devices
   - 8'b10100000, for Spansion devices
3. Enable XIP mode by setting the OSPI_CTL.XIPRD bit.
4. Reenable the DAC.

Using PHY Mode

The OSPI PHY mode extends the architecture of the OSPI flash controller to allow the interfacing of high-speed flash devices and ensure the reliable data transfers at high speed. For non-PHY operations, the controller assumes that OSPI transfer clock is at least 4 times lower than the reference clock to ensure correct data transactions in SDR mode and 8 times lower for DDR transactions. This provides a comfortable regulation of data synchronization, but it is not effective from a dynamic power efficiency standpoint.

The PHY mode allows transfers at speeds that match the increasing reference clocks of emerging higher performance flash devices, including frequencies close to 200 MHz. The PHY module works with the OSPI flash controller to enable DDR or SDR transfers at the device frequencies. For example, when a given flash device operates at 200 MHz, the reference clock is also 200 MHz, eliminating the need for high speed peripheral clocks.

The default reference clock (OSPI_REFLK) for OSPI is SYSCLK, but to enable support for PHY mode the reference clock is selected from one of the options from CDU output clock 10 (Refer to the CDU chapter). By default, it is connected to SYSCLK which is suitable for non-PHY mode of operation. For PHY mode, the reference clock (OSPI_REFLK) is either SCLK0_0 or SCLK1_1.

To configure PHY mode, first implement the procedure described in the Configuring OSPI for Optimal Use section and then proceed with the following steps based on the DLL mode configuration:

DLL Bypass Mode

1. Enable the PHY mode by setting the `OSPI_CTL.PHYEN` bit and enable the DDR protocol with the `OSPI_CTL.DTREN` bit.

   NOTE: Ensure that the device is configured to work in DDR Protocol (do not confuse with DDR commands).

2. Calibrate the software using the following sub steps:

   a. Calculate how many delay elements are necessary to shift the reference clock period by 25% and program this value in the `OSPI_PHYCTL.TXDLY` bit field. This is the best case for DDR transfers from the set-up/hold timing standpoint. The delay may vary slightly in a real design.

   b. Resynchronize the DLLs by setting the `OSPI_PHYCTL.RESYNC` bit. If this has already been set by a previous resynchronization, toggle the bit to 0 and then back to 1 to trigger the re-synchronization DLL logic.

   c. Enable the PHY bypass mode by setting the `OSPI_PHYMCTL.BYPCTL` bit.

   d. Trigger a read request from a location where the value is predictable. Depending on the device, this is the parameter page, ID, status, data from the OTP region, or data from the location of the flash array.

   e. Check for data correctness by incrementing the value of the RX clock delay using the `OSPI_PHYCTL.RXDLY` bit field, resynchronizing the DLLs, triggering a valid read request, and then checking for the correct data and store information. Continue to check until the range boundary of the RX clock delay is achieved and then proceed to the next step.

3. Set the RX clock delay value with one from the middle of valid range based on the information in storage.
4. Resynchronize the DLLs
5. Set the device read instruction register for Octal Read DDR Configuration. Configure each transfer phase to work in octal mode and set the number of dummy cycles to a minimum of the number specified in the documentation of the device. More dummy cycles may be set to accommodate additional read path delays in actual systems data.
6. Enable pipeline mode by setting the `OSPI_CTL.PIPEPHYEN` bit.
7. Perform a sequential read of data consistent with the conditions indicated in the PHY Pipeline Mode section.
8. Poll for IDLE with the `OSPI_CTL.IDLE` bit and when it is asserted to high trigger the next transfer request.

DLL Controller Mode

1. Enable the PHY mode by setting the `OSPI_CTL.PHYEN` bit and enable the DDR protocol with the `OSPI_CTL.DTREN` bit.

NOTE: Ensure that the device is configured to work in DDR protocol (do not confuse with DDR commands).

2. Calibrate the software using the following sub steps:
   a. Drive the OSPI_CTL.RST bit low to reset the DLL.
   b. Calculate initial delay value for the controller DLL according to the PHY DLL controller control register bits[6:0] and write this value into the OSPI_PHYMCTL.INITDLY bit field.
   c. Set DLL reset bit (OSPI_CTL.RST) back to high. The controller delay line automatically starts the locking procedure with the configuration given once the DLL module is in reset state.
   d. Poll the OSPI_DLLOB_LWR.LOCK bit. When it is set, the lock is done.
   e. Resynchronize the DLLs by setting the OSPI_PHYCTL.RESYNC bit. If this has already been set by a previous resynchronization, toggle the bit to 0 and then back to 1 to trigger the re-synchronization DLL logic.
   f. Set the TX DLL delay bit field (OSPI_PHYCTL.TXDLY) and the RX DLL delay bit field (OSPI_PHYCTL.RXDLY) to the current percentage clock offsets. Wait 20 reference clock cycles for the new configuration to propagate before triggering the next SPI transfer.
   g. Trigger a read request from a location where the value is predictable. Depending on the device, this is the parameter page, ID, status, data from the OTP region, or data from the location of the flash array.
   h. Check for data correctness by incrementing the value of the RX clock delay using the OSPI_PHYCTL.RXDLY bit field, resynchronizing the DLLs, triggering a valid read request, and then checking for the correct data and store information. Continue to check until the range boundary of the RX clock delay is achieved and then proceed to the next step.
3. Set the RX clock delay value with one from the middle of valid range based on the information in storage.
4. Resynchronize the DLLs
5. Set the device read instruction register for octal read DDR configuration. Configure each transfer phase to work in octal mode and set the number of dummy cycles to a minimum of the number specified in the documentation of the device. More dummy cycles may be set to accommodate additional read path delays in actual systems data.
6. Enable pipeline mode by setting the OSPI_CTL.PIPEPHYEN bit.
7. Perform a sequential read of data consistent with the conditions indicated in the PHY pipeline Mode section.
8. Poll for IDLE with the OSPI_CTL.IDLE bit and when it is asserted to high trigger the next transfer request.

ADSP-SC59x OSPI Register Descriptions

Octal SPI (OSPI) contains the following registers.

Table 23-5: ADSP-SC59x OSPI Register List

Name	Description
OSPI_CTL	Octal SPI Control Register
OSPI_DLY	Device Delay Register
OSPI_DRICTL	Device Read Instruction Control Register
OSPI_DWICTL	Device Write Instruction Control Register
OSPI_DSCTL	Device Size Control Register
OSPI_DLLOB_LWR	DLL Observable Register (Lower)
OSPI_DLLOB_UP	DLL Observable Register (Upper)
OSPI_FCA	Flash Command Address Register
OSPI_FCCTL	Flash Command Control Register
OSPI_FCMCTL	Flash Command Control Memory Register
OSPI_FCRD_LWR	Flash Command Read Data Register (Lower)
OSPI_FCRD_UP	Flash Command Read Data Register (Upper)
OSPI_FCWD_LWR	Flash Command Write Data Register (Lower)
OSPI_FCWD_UP	Flash Command Write Data Register (Upper)
OSPI_IMSK	Interrupt Mask Register
OSPI_ISTAT	Interrupt Status Register
OSPI_WRPROT_LWR	Lower Write Protection Register
OSPI_MBCTL	Mode Bit Control Register
OSPI_MODID	Module ID Register
OSPI_POLLEXP	Polling Expiration Register
OSPI_OE_LWR	Opcode Extension Register (Lower)
OSPI_OE_UP	Opcode Extension Register (Upper)
OSPI_PHYCTL	PHY Control Register
OSPI_PHYMCTL	PHY DLL Master Control Register
OSPI_POLSTAT	Polling Flash Status Register
OSPI_RDC	Read Data Capture Register
OSPI_REMAPADDR	Remap Address Register
OSPI_WRPROT_UP	Upper Write Protection Register
OSPI_WRPROT_CTL	Write Protection Control Register
OSPI_WCCTL	Write Completion Control Register

Octal SPI Control Register

The OSPI_CTL register contains basic configuration fields of the controller.

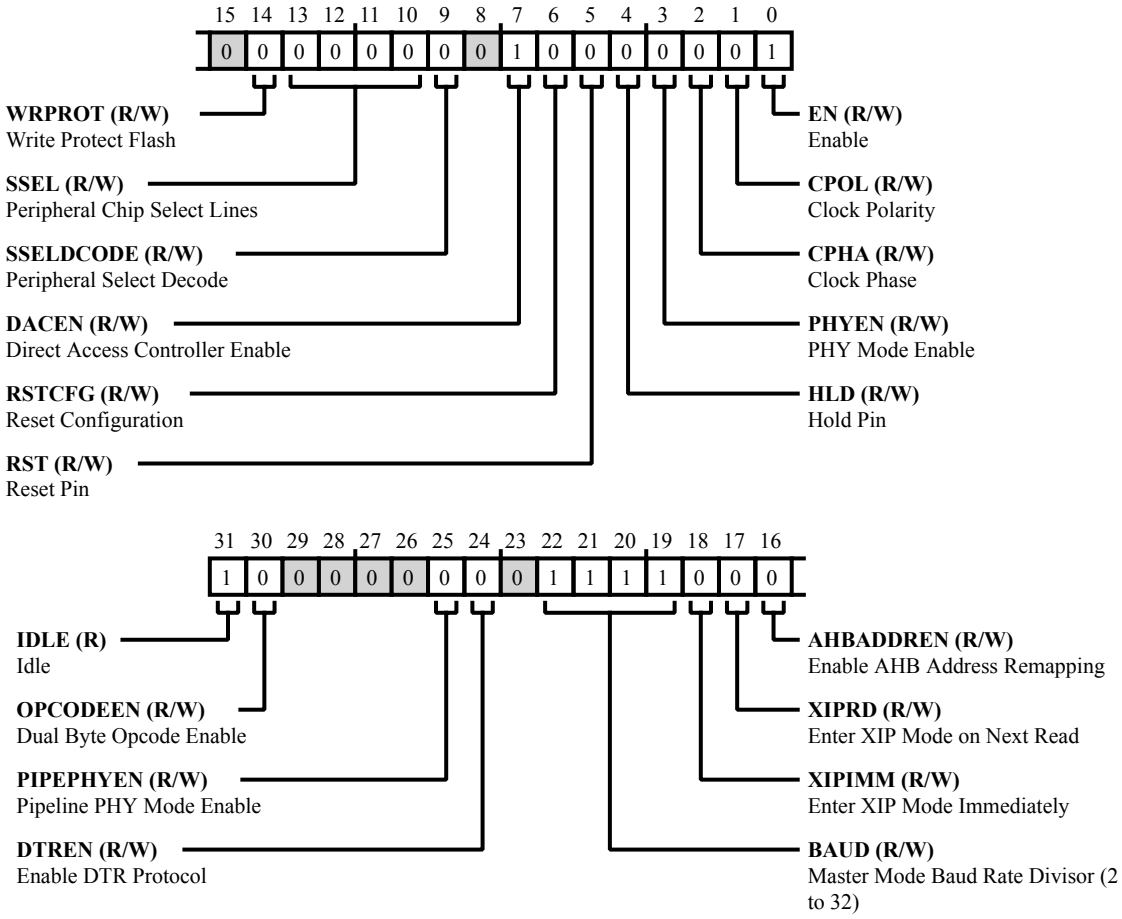

Figure 23-3: OSPI_CTL Register Diagram

Table 23-6: OSPI_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/NW)	IDLE	Idle. The OSPI_CTL.IDLE bit indicates an idle status. The serial interface and low level SPI pipeline are idle. This is a status read-only bit. Note: This is a re-timed signal. There is an inherent delay in generating this signal.

Table 23-6: OSPI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
30 (R/W)	OPCODEEN	Dual Byte Opcode Enable. The OSPI_CTL.OPCODEEN bit is set (=1) when the target Flash device supports dual byte opcode (Macronix MX25). It is applicable for Octal I/O mode or protocol only. It should be be cleared (=0) when the device is configured to work in another SPI mode. If enabled, the supplementing bytes are taken from the OSPI_OE_LWR and OSPI_OE_UP registers.
25 (R/W)	PIPEPHYEN	Pipeline PHY Mode Enable. The OSPI_CTL.PIPEPHYEN bit is relevant only for configuration with PHY module. It is asserted to 1 between consecutive PHY pipeline reads transfers and deasserted to 0 otherwise.
24 (R/W)	DTREN	Enable DTR Protocol. The OSPI_CTL.DTREN bit enables the DTR protocol. It must be set if the device is configured to work in DTR protocol.
22:19 (R/W)	BAUD	Master Mode Baud Rate Divisor (2 to 32). The OSPI_CTL.BAUD bit field selects the baud rate divisor. SPI Baud Rate = (Master Reference Clock)/ Baud Rate Divisor where, Baud Rate Divisor is: 4'b0000 = /2 4'b0001 = /4 4'b0010 = /6 4'b0011 = /8 4'b0100 = /10 ... 4'b1111 = /32

Table 23-6: OSPI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
18 (R/W)	XIPIMM	Enter XIP Mode Immediately. When XIP is enabled, clearing the `OSPI_CTL.XIPIMM` bit (= 0) causes the controller to exit XIP mode on the next read instruction. When the `OSPI_CTL.XIPIMM` bit is set (= 1), operate the device in XIP mode immediately. Use this register when the external device wakes up in XIP mode (as per the contents of its non-volatile configuration register). The controller assumes the next read instruction is passed to the device as an XIP instruction, and therefore does not require the read opcode to be transferred. Note: To exit XIP mode, the `OSPI_CTL.XIPIMM` bit should be cleared (=0). This takes effect in the attached device only after the next read instruction is executed. Software must ensure that at least one read instruction is requested after resetting the `OSPI_CTL.XIPIMM` bit (to ensure that XIP mode is exited).	
		0	If XIP is enabled, it causes the controller to exit XIP mode on the next read instruction
		1	Operate the device in XIP mode immediately
17 (R/W)	XIPRD	Enter XIP Mode on Next Read. When XIP is enabled, clearing the `OSPI_CTL.XIPRD` bit (= 0) causes the controller to exit XIP mode on the next read instruction. When XIP is disabled, setting the `OSPI_CTL.XIPRD` bit (= 1) informs the controller that the device is ready to enter XIP on the next read instruction. The controller sends the appropriate command sequence, including mode bits to cause the device to enter XIP mode. Use this register after the controller ensures that the Flash device is configured to enter XIP mode. Note: To exit XIP mode, the `OSPI_CTL.XIPRD` bit should be cleared (= 0). This takes effect in the attached device only after the next read instruction is executed. Software must ensure that at least one read instruction is requested after resetting the `OSPI_CTL.XIPRD` bit (to ensure that XIP mode is exited).	
		0	If XIP is enabled, it cause the controller to exit XIP mode on the next read instruction
		1	If XIP is disabled, this setting informs the controller that the device is ready to enter XIP on the next read instruction
16 (R/W)	AHBADDREN	Enable AHB Address Remapping. The `OSPI_CTL.AHBADDREN` bit enables the bus address remapping (direct access mode only). When set (=1), the incoming bus address is adapted and sent to the Flash device as (address + N), where N is the value stored in the remap address register.	

Table 23-6: OSPI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
14 (R/W)	WRPROT	Write Protect Flash. The `OSPI_CTL.WRPROT` bit, when set (=1), drives the write protect pin of the Flash. This is resynchronized to the generated memory clock, as necessary.	
13:10 (R/W)	SSEL	Peripheral Chip Select Lines. The `OSPI_CTL.SSEL` bit field indicates the peripheral chip select line. If `OSPI_CTL.SSELDCODE` = 0, ss[3:0] is output: ss[3:0] ..... SSEL[3:0] 4'bxxx0.....1110.....SSEL0 selected 4'bxx01.....1101.....SSEL1 selected 4'bx011.....1011.....SSEL2 selected 4'b0111.....0111.....SSEL3 selected 4'b1111.....1111.....No peripheral selected If `OSPI_CTL.SSELDCODE` = 1, ss[3:0] directly drives SSEL[3:0].	
9 (R/W)	SSELDCODE	Peripheral Select Decode. The `OSPI_CTL.SSELDCODE` bit indicates the peripheral select decode.	
		0	Only one of the 4 selects n_ss_out [3:0] is active
		1	Allows external 4:16 decode (n_ss_out = ss)
7 (R/W)	DACEN	Direct Access Controller Enable. The `OSPI_CTL.DACEN` bit enables the direct access controller. When the direct access controller and indirect access controller are disabled, all bus requests are completed with an error response.	
		0	Disable Direct Access Controller once current transfer of the data word is complete
		1	Enable Direct Access Controller
6 (R/W)	RSTCFG	Reset Configuration. The `OSPI_CTL.RSTCFG` bit indicates the reset pin configuration.	
		0	Reset Feature on DQ3 Pin of the Device
		1	Reset Feature on Dedicated Pin of the Device (Controlling the 5th bit Influences the Output)
5 (R/W)	RST	Reset Pin. The `OSPI_CTL.RST` bit, when set (=1), drives the reset pin of the Flash. When cleared (=0), it deactivates the reset pin.	

Table 23-6: OSPI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/W)	HLD	Hold Pin. The `OSPI_CTL.HLD` bit, when set (=1), drives the hold pin of the Flash. When cleared (=0), it deactivates the hold pin.	
3 (R/W)	PHYEN	PHY Mode Enable. When the `OSPI_CTL.PHYEN` bit is enabled, the controller is informed that PHY module is to be used for handling SPI transfers. This bit is relevant only for configuration with PHY module.	
2 (R/W)	CPHA	Clock Phase. The `OSPI_CTL.CPHA` bit selects the clock phase.	
		0	SPI clock is active outside the word
		1	SPI clock is inactive outside the word
1 (R/W)	CPOL	Clock Polarity. The `OSPI_CTL.CPOL` bit selects clock polarity outside SPI word.	
		0	OSPI clock is quiescent low
		1	OSPI clock is quiescent high
0 (R/W)	EN	Enable. The `OSPI_CTL.EN` bit enables OSPI operation.	
		0	Disable OSPI Module
		1	Enable OSPI Module

Device Delay Register

The OSPI_DLY register introduces relative delays in the generation of the master output signals. All timings are defined in cycles of the SPI REFERENCE CLOCK/ext_clk.

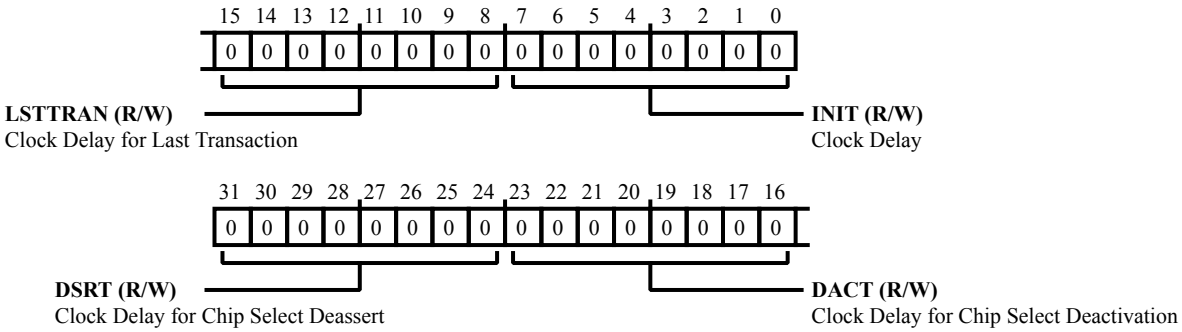

Figure 23-4: OSPI_DLY Register Diagram

Table 23-7: OSPI_DLY Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	DSRT	Clock Delay for Chip Select Deassert. The OSPI_DLY.DSRT field indicates the delay in the master reference clocks for the length that the master mode chip select outputs are deasserted between transactions. The minimum delay is always an SCLK period to ensure the chip select is not asserted again within an SCLK period.
23:16 (R/W)	DACT	Clock Delay for Chip Select Deactivation. The OSPI_DLY.DACT field indicates the delay in the master reference clocks between one chip select being deactivated and the activation of another. This is used to ensure a quiet period between the selection of two different slaves and requires the transmit FIFO to be empty.
15:8 (R/W)	LSTTRAN	Clock Delay for Last Transaction. The OSPI_DLY.LSTTRAN field indicates the delay in the master reference clocks between last bit of the current transaction and deasserting the device chip select (n_ss_out). By default, the chip select is deasserted on the cycle following the completion of the current transaction.
7:0 (R/W)	INIT	Clock Delay. The OSPI_DLY.INIT field indicates the delay in the master reference clocks between setting n_ss_out low and the first bit transfer.

Device Read Instruction Control Register

This register defines the configuration of Multiple-SPI READ instruction. This register should be setup while the controller is idle.

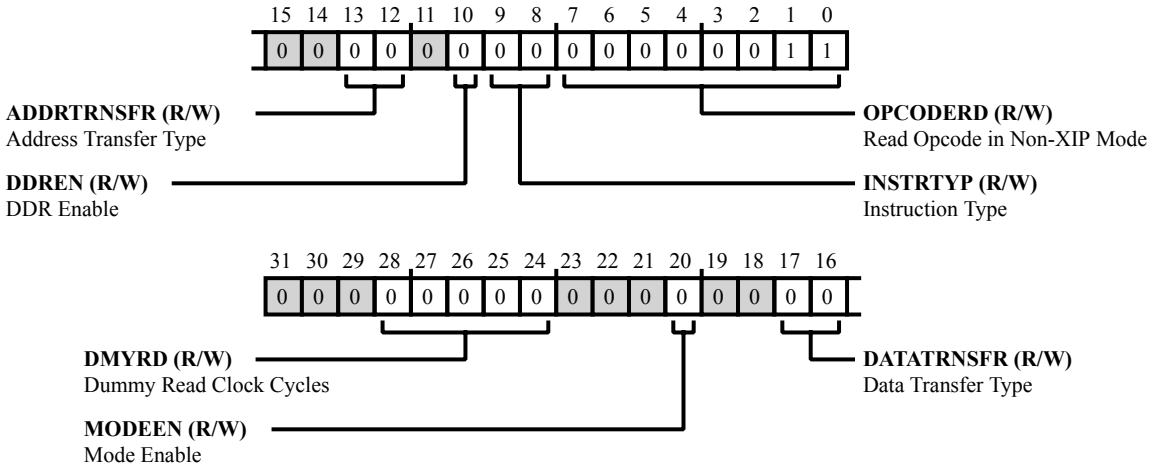

Figure 23-5: OSPI_DRICTL Register Diagram

Table 23-8: OSPI_DRICTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
28:24 (R/W)	DMYRD	Dummy Read Clock Cycles. The `OSPI_DRICTL.DMYRD` field indicates the number of dummy clock cycles required by the device for a read instruction.	
20 (R/W)	MODEEN	Mode Enable. The `OSPI_DRICTL.MODEEN` field is set (=1) to ensure that the `OSPI_MBCTL.MODE` bits are sent following the address bytes.	
17:16 (R/W)	DATATRNSFR	Data Transfer Type. The `OSPI_DRICTL.DATATRNSFR` field indicates the data transfer type for standard SPI modes.	
		0	SIO Mode. Data is shifted to the device on DQ0 only and from the device on DQ1 only.
		1	Used for Dual Input/Output instructions. For data transfers, DQ0 and DQ1 are used as both inputs and outputs.
		2	Used for Quad Input/Output instructions. For data transfers, DQ0, DQ1, DQ2, and DQ3 are used as both inputs and outputs.
		3	Used for Quad Input/Output instructions. For data transfers, DQ[7:0] are used as both inputs and outputs.

Table 23-8: OSPI_DRICTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
13:12 (R/W)	ADDRTRNSFR	Address Transfer Type. The `OSPI_DRICTL.ADDRTRNSFR` field indicates the address transfer type for standard SPI modes.	
		0	Addresses can be shifted to the device on DQ0 only.
		1	Addresses can be shifted to the device on DQ0 and DQ1 only.
		2	Addresses can be shifted to the device on DQ0, DQ1, DQ2, and DQ3.
		3	Addresses can be shifted to the device on DQ [7:0]
10 (R/W)	DDREN	DDR Enable. The `OSPI_DRICTL.DDREN` field indicates whether the opcode from the `OSPI_DRICTL.OPCODERD` field is compliant with one of the DDR read commands. Set the `OSPI_DRICTL.DDREN` field to 1 when opcode from bits 7 to 0 is compliant with DDR command. Master output data is issued by the controller in DDR fashion starting of the address SPI transfer phase. It is not applicable for STIG Mode.	
9:8 (R/W)	INSTRTYP	Instruction Type. The `OSPI_DRICTL.INSTRTYP` field indicates the instruction type.	
		0	Use standard SPI mode. Data is shifted to the device on DQ0 only and from the device on DQ1 only.
		1	Use DIO-SPI mode. Instruction sent on DQ0 and DQ1.
		2	Use QIO-SPI mode. Instruction sent on DQ0, DQ1, DQ2, and DQ3.
		3	Use OIO-SPI mode. Instruction sent on DQ[7:0].
7:0 (R/W)	OPCODERD	Read Opcode in Non-XIP Mode. The `OSPI_DRICTL.OPCODERD` field indicates the read opcode to use when not in XIP mode.	

Device Write Instruction Control Register

This register defines the configuration of Multiple-SPI WRITE (Program Page) instruction. This register should be setup while the controller is idle.

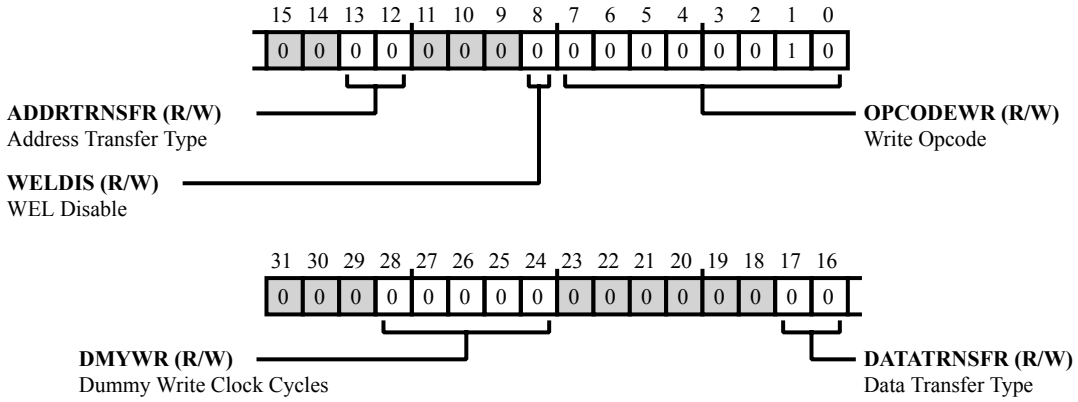

Figure 23-6: OSPI_DWICTL Register Diagram

Table 23-9: OSPI_DWICTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
28:24 (R/W)	DMYWR	Dummy Write Clock Cycles. The `OSPI_DWICTL.DMYWR` field indicates the number of dummy clock cycles required by the device for write instruction.	
17:16 (R/W)	DATATRNSFR	Data Transfer Type. The `OSPI_DWICTL.DATATRNSFR` field indicates the data transfer type for standard SPI modes.	
		0	SIO Mode. Data is shifted to the device on DQ0 only and from the device on DQ1 only.
		1	Used for Dual Input/Output instructions. For data transfers, DQ0 and DQ1 are used as both inputs and outputs.
		2	Used for Octal Input/Output Instructions. For data transfers, DQ0, DQ1, DQ2, and DQ3 are used as both inputs and outputs.
		3	Used for Octal Input/Output instructions. For data transfers, DQ[7:0] are used as both inputs and outputs.

Table 23-9: OSPI_DWICTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
13:12 (R/W)	ADDRTRNSFR	Address Transfer Type. The `OSPI_DWICTL.ADDRTRNSFR` field indicates the address transfer type for standard SPI modes.	
		0	Addresses can be shifted to the device on DQ0 only.
		1	Addresses can be shifted to the device on DQ0 and DQ1.
		2	Addresses can be shifted to the device on DQ0, DQ1, DQ2, and DQ3.
		3	Addresses can be shifted to the device on DQ [7:0].
8 (R/W)	WELDIS	WEL Disable. The `OSPI_DWICTL.WELDIS` bit disables the automatic issuing of the WEL command before a write operation for DAC or INDAC.	
7:0 (R/W)	OPCODEWR	Write Opcode. Write Opcode	

Device Size Control Register

This register allows the user to define the memory organization of using Flash Devices. This register should be setup while the controller is idle.

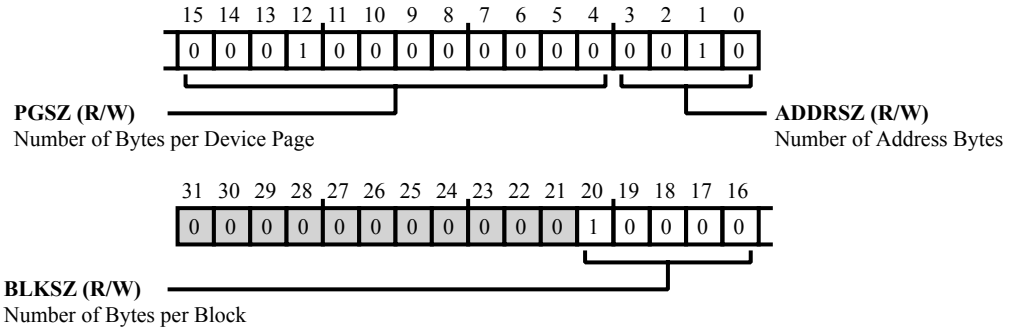

Figure 23-7: OSPI_DSCTL Register Diagram

Table 23-10: OSPI_DSCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
20:16 (R/W)	BLKSZ	Number of Bytes per Block. The controller uses the `OSPI_DSCTL.BLKSZ` field to perform write protection logic. The number of bytes per block must be a power of 2. 0: 1 byte 1: 2 bytes 3: 8 bytes ... 16: 65535 bytes and so on
15:4 (R/W)	PGSZ	Number of Bytes per Device Page. The controller uses the `OSPI_DSCTL.PGSZ` field to perform flash writes up to and across page boundaries.
3:0 (R/W)	ADDRSZ	Number of Address Bytes. The `OSPI_DSCTL.ADDRSZ` field indicates the address size for DAC mode. A value of 0 indicates 1 byte.

DLL Observable Register (Lower)

The OSPI_DLLOB_LWR register contains the DLL status. This register is synchronized into the APB domain by the octal-SPI flash controller and updates dynamically.

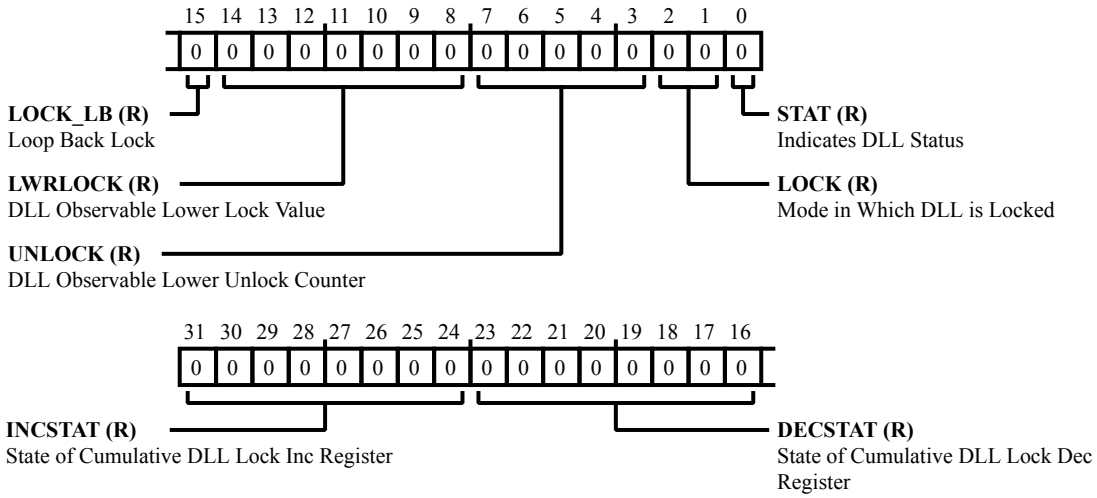

Figure 23-8: OSPI_DLLOB_LWR Register Diagram

Table 23-11: OSPI_DLLOB_LWR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/NW)	INCSTAT	State of Cumulative DLL Lock Inc Register. The OSPI_DLLOB_LWR.INCSTAT field indicates the state of the cumulative dll_lock_inc register.
23:16 (R/NW)	DECSTAT	State of Cumulative DLL Lock Dec Register. The OSPI_DLLOB_LWR.DECSTAT field indicates the state of the cumulative dll_lock_dec register.
15 (R/NW)	LOCK_LB	Loop Back Lock. The OSPI_DLLOB_LWR.LOCK_LB bit indicates that lock of loop back is done.
14:8 (R/NW)	LWRLOCK	DLL Observable Lower Lock Value. The OSPI_DLLOB_LWR.LWRLOCK field indicates the DLL encoder value from the master DLL to slave DLLs.
7:3 (R/NW)	UNLOCK	DLL Observable Lower Unlock Counter. The OSPI_DLLOB_LWR.UNLOCK field indicates the number of increments or decrements required for the master DLL to complete the locking process.
2:1 (R/NW)	LOCK	Mode in Which DLL is Locked. The OSPI_DLLOB_LWR.LOCK field indicates the mode in which the DLL has achieved the lock.

Table 23-11: OSPI_DLLOB_LWR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
0 (R/NW)	STAT	Indicates DLL Status.

DLL Observable Register (Upper)

The OSPI_DLLOB_UP register contains the DLL status. This register is synchronized into the APB domain by the octal-SPI flash controller and updates dynamically.

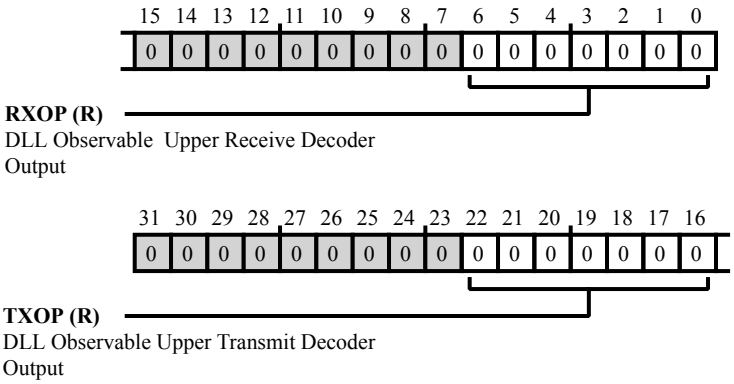

Figure 23-9: OSPI_DLLOB_UP Register Diagram

Table 23-12: OSPI_DLLOB_UP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
22:16 (R/NW)	TXOP	DLL Observable Upper Transmit Decoder Output. The OSPI_DLLOB_UP.TXOP field indicates the encoded value for the TX delay line for this slice.
6:0 (R/NW)	RXOP	DLL Observable Upper Receive Decoder Output. The OSPI_DLLOB_UP.RXOP field indicates the encoded value for the RX delay line for this slice.

Flash Command Address Register

This register allows the user to define the address of the command using by the STIG controller. This register should be setup while the controller is idle.

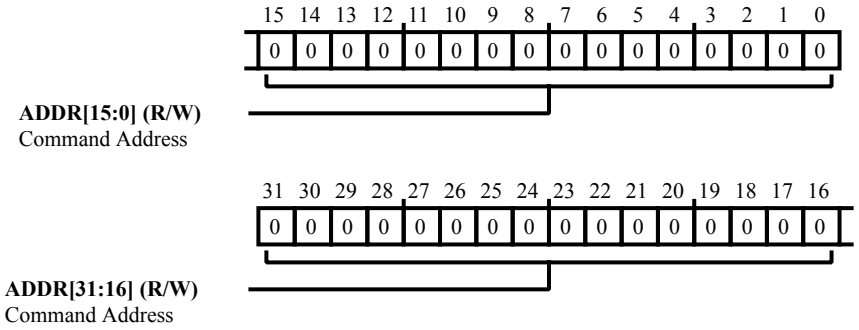

Figure 23-10: OSPI_FCA Register Diagram

Table 23-13: OSPI_FCA Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	ADDR	Command Address. The `OSPI_FCA.ADDR` field indicates the address used by the command specified in the `OSPI_FCCTL.OPCODE` field. This must be setup before triggering the STIG command using the `OSPI_FCCTL.EXE` field.

Flash Command Control Register

This register controls SPI transactions generated by STIG. It allows the user to define corresponding SPI frame to particular command, triggering the transfer and polling for its completion.

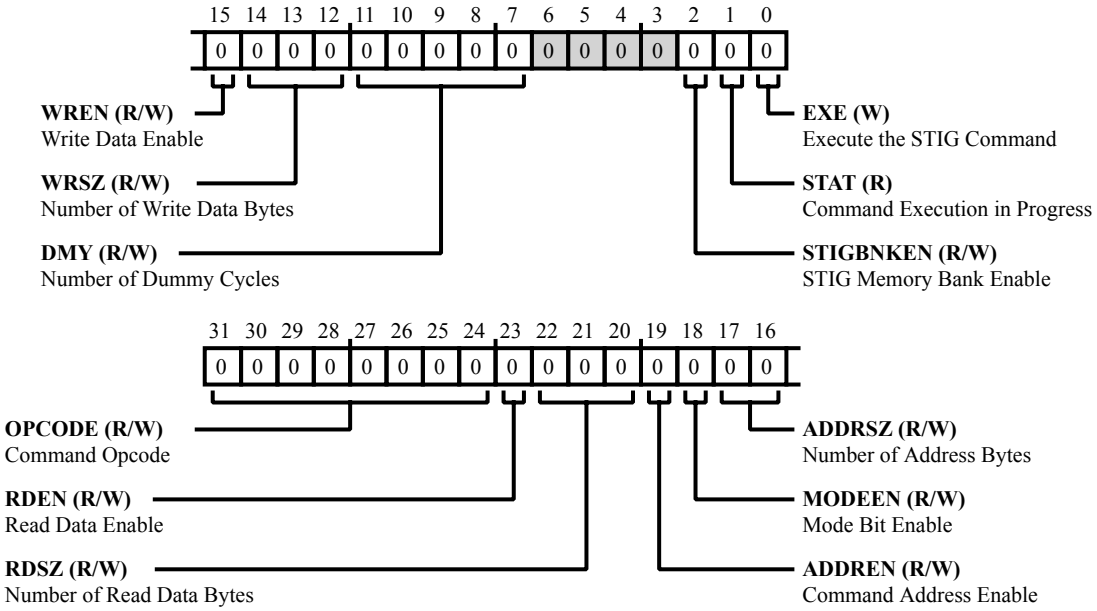

Figure 23-11: OSPI_FCCTL Register Diagram

Table 23-14: OSPI_FCCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	OPCODE	Command Opcode. The `OSPI_FCCTL.OPCODE` field must be configured before triggering the STIG command. For example, 0x20 maps to sub sector erase. Writing to the `OSPI_FCCTL.EXE` field launches the command. Note: Using this approach to issue commands to the device makes use of the instruction type of the `OSPI_DRICTL` and `OSPI_DWICTL` registers.
23 (R/W)	RDEN	Read Data Enable. When the `OSPI_FCCTL.RDEN` bit is set (=1), the command specified in the `OSPI_FCCTL.OPCODE` can read data bytes received from the device.
22:20 (R/W)	RDSZ	Number of Read Data Bytes. The `OSPI_FCCTL.RDSZ` field indicates the number of read data bytes; up to 8 data bytes can be read using this command. Configure the `OSPI_FCCTL.RDSZ` field to 0 for 1 byte and 7 for 8 bytes.

Table 23-14: OSPI_FCCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
19 (R/W)	ADDREN	Command Address Enable. When the OSPI_FCCTL.ADDREN bit is set (=1), the command specified in the OSPI_FCCTL.OPCODE field requires an address. This bit must be set before triggering the command via writing a 1 to the execute field.	
18 (R/W)	MODEEN	Mode Bit Enable. When the OSPI_FCCTL.MODEEN bit is set (=1), the OSPI_MBCTL.MODE field is sent following the address bytes.	
17:16 (R/W)	ADDRSZ	Number of Address Bytes. The OSPI_FCCTL.ADDRSZ field indicates the number of address bytes required (the address itself is programmed in the OSPI_FCA register. This field must be configured before triggering the command via bit 0 of this register.	
		0	1 address byte
		1	2 address bytes
		2	3 address bytes
		3	4 address bytes
15 (R/W)	WREN	Write Data Enable. When set (=1), the command specified in the OSPI_FCCTL.OPCODE field enables write data bytes to be sent to the device.	
14:12 (R/W)	WRSZ	Number of Write Data Bytes. The OSPI_FCCTL.WRSZ field indicates the number of write data bites; up to 8 data bytes may be written using this command. Configure to 0 for 1 byte, 7 for 8 bytes.	
11:7 (R/W)	DMY	Number of Dummy Cycles. The OSPI_FCCTL.DMY field indicates the number of dummy cycles required. This field should be configured before triggering the command via the OSPI_FCCTL.EXE field.	
2 (R/W)	STIGBNKEN	STIG Memory Bank Enable. The OSPI_FCCTL.STIGBNKEN bit must be set (=1) before triggering the flash memory bank transfer. It must be cleared (=0) before triggering any other operation. The OSPI_FCCTL.STIGBNKEN bit is set before triggering the command via OSPI_FCCTL.EXE field.	
1 (R/NW)	STAT	Command Execution in Progress.	
0 (RX/W)	EXE	Execute the STIG Command.	

Flash Command Control Memory Register

This register controls the Memory Bank accesses. It also defines the number of bytes intended to get by STIG access configured to use the STIG Memory Bank.

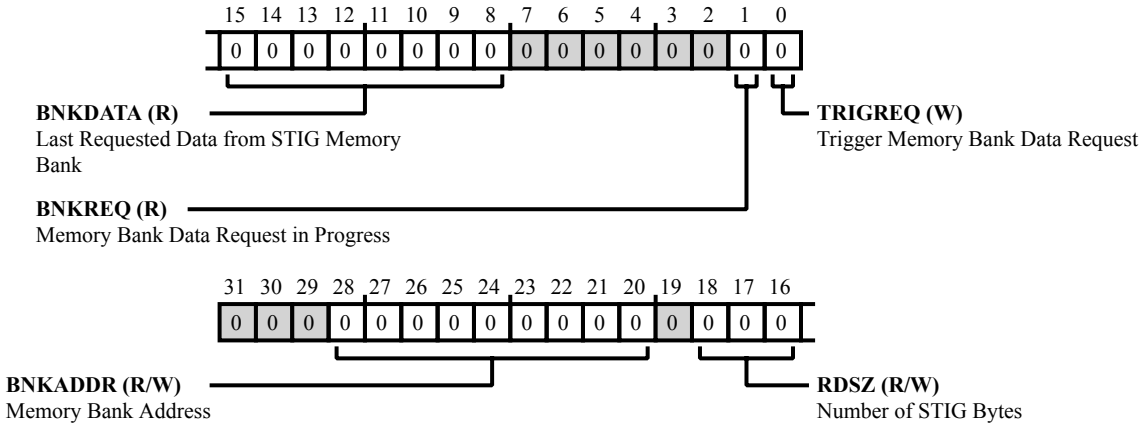

Figure 23-12: OSPI_FCMCTL Register Diagram

Table 23-15: OSPI_FCMCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
28:20 (R/W)	BNKADDR	Memory Bank Address. The `OSPI_FCMCTL.BNKADDR` field indicates the address of the memory bank from which data is read.
18:16 (R/W)	RDSZ	Number of STIG Bytes. The `OSPI_FCMCTL.RDSZ` field indicates the number of read bytes for the extended STIG.
15:8 (R/NW)	BNKDATA	Last Requested Data from STIG Memory Bank.
1 (R/NW)	BNKREQ	Memory Bank Data Request in Progress.
0 (RX/W)	TRIGREQ	Trigger Memory Bank Data Request. Trigger the Memory Bank data request. This bit is internally synchronized.

Flash Command Read Data Register (Lower)

This register keeps the last 4 bytes read by STIG SPI access.

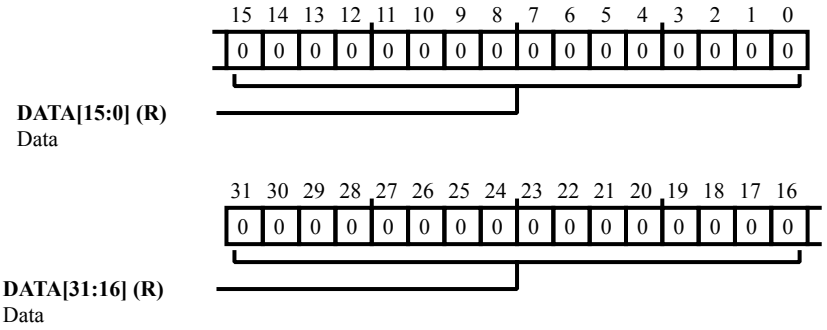

Figure 23-13: OSPI_FCRD_LWR Register Diagram

Table 23-16: OSPI_FCRD_LWR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	DATA	Data. The `OSPI_FCRD_LWR.DATA` field contains data that is returned by the flash device for any status or configuration read operation carried out by triggering the STIG event in the `OSPI_FCCTL` register. The register is valid when the `OSPI_FCCTL.STAT` bit is low.

Flash Command Read Data Register (Upper)

This register keeps the last but 4 bytes read by STIG SPI access. This register in conjunction with the Flash Command Read Data Register (Lower) enables the controller to keep 8 last bytes read from the Flash Device using STIG.

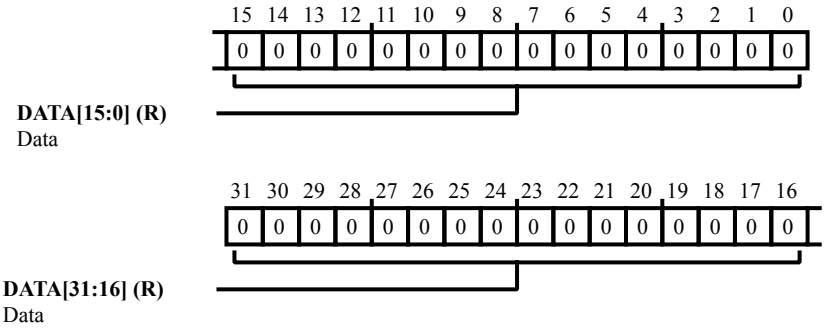

Figure 23-14: OSPI_FCRD_UP Register Diagram

Table 23-17: OSPI_FCRD_UP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	DATA	Data. The `OSPI_FCRD_UP.DATA` field contains data that is returned by the flash device for any status or configuration read operation carried out by triggering the STIG event in the `OSPI_FCCTL` register. The register is valid when the `OSPI_FCCTL.STAT` bit is low.

Flash Command Write Data Register (Lower)

The OSPI_FCWD_LWR register takes the first 4 bytes to be written by STIG.

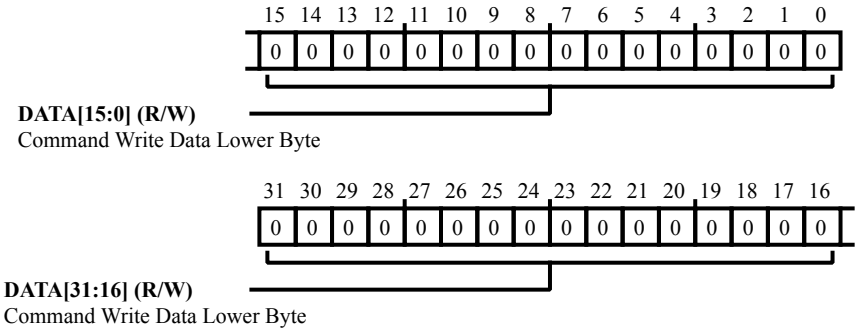

Figure 23-15: OSPI_FCWD_LWR Register Diagram

Table 23-18: OSPI_FCWD_LWR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	DATA	Command Write Data Lower Byte. The OSPI_FCWD_LWR.DATA field contains data written to the flash for any status or configuration write operation carried out by triggering the STIG event in the OSPI_FCCTL register. This field must be setup before triggering the command using the OSPI_FCCTL.EXE field.

Flash Command Write Data Register (Upper)

This register takes the bytes ranging from 5 to 8 to be written by STIG.

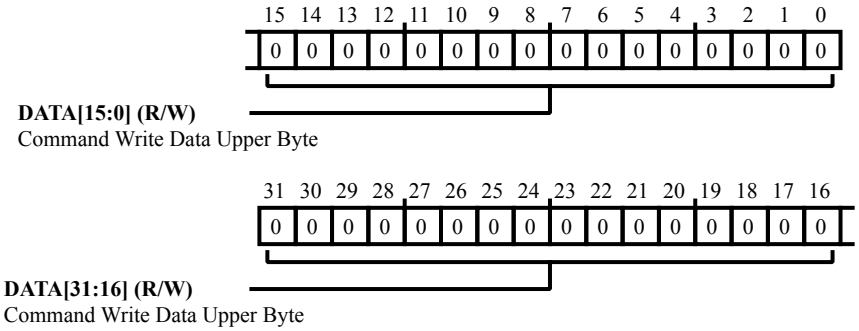

Figure 23-16: OSPI_FCWD_UP Register Diagram

Table 23-19: OSPI_FCWD_UP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	DATA	Command Write Data Upper Byte. The `OSPI_FCWD_UP.DATA` field contains data written to the flash for any status or configuration write operation carried out by triggering the event in the `OSPI_FCCTL` register. This field must be setup before triggering the command using the `OSPI_FCCTL.EXE` field.

Interrupt Mask Register

The OSPI_IMSK register allows the user to mask/unmask particular interrupt sources. This register must be setup when the controller is idle.

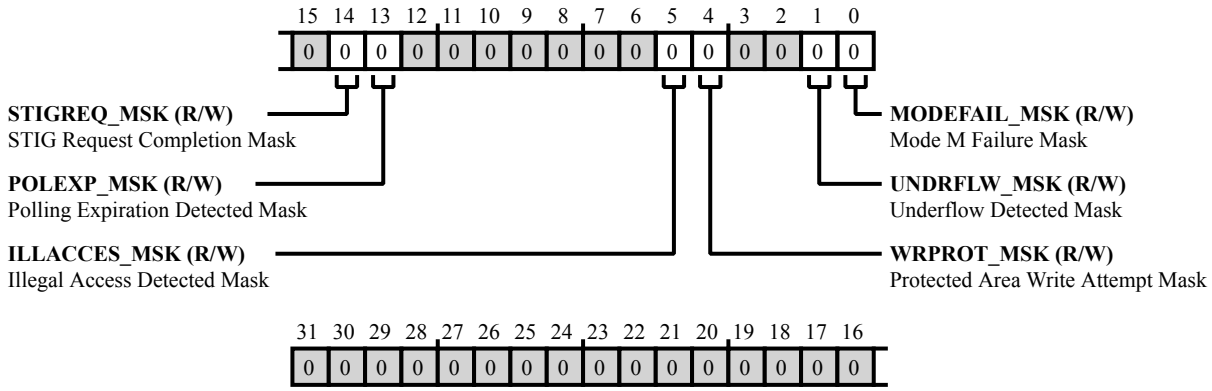

Figure 23-17: OSPI_IMSK Register Diagram

Table 23-20: OSPI_IMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
14 (R/W)	STIGREQ_MSK	STIG Request Completion Mask. 0 = the interrupt for the corresponding interrupt status register bit is disabled. 1 = the interrupt for the corresponding interrupt status register bit is enabled.
13 (R/W)	POLEXP_MSK	Polling Expiration Detected Mask. 0 = the interrupt for the corresponding interrupt status register bit is disabled. 1 = the interrupt for the corresponding interrupt status register bit is enabled.
5 (R/W)	ILLACCES_MSK	Illegal Access Detected Mask. 0 = the interrupt for the corresponding interrupt status register bit is disabled. 1 = the interrupt for the corresponding interrupt status register bit is enabled.
4 (R/W)	WRPROT_MSK	Protected Area Write Attempt Mask. 0 = the interrupt for the corresponding interrupt status register bit is disabled. 1 = the interrupt for the corresponding interrupt status register bit is enabled.
1 (R/W)	UNDRFLW_MSK	Underflow Detected Mask. 0 = the interrupt for the corresponding interrupt status register bit is disabled. 1 = the interrupt for the corresponding interrupt status register bit is enabled.
0 (R/W)	MODEFAIL_MSK	Mode M Failure Mask. 0 = the interrupt for the corresponding interrupt status register bit is disabled. 1 = the interrupt for the corresponding interrupt status register bit is enabled.

Interrupt Status Register

The status fields in the OSPI_ISTAT register are set when the described event occurs, and the interrupt is enabled in the OSPI_IMSK register. If any of these bit fields are set, the interrupt output is asserted high. The fields are each cleared by writing a 1 to the field.

Note: Bit fields [10:6] are valid only when legacy SPI mode is active.

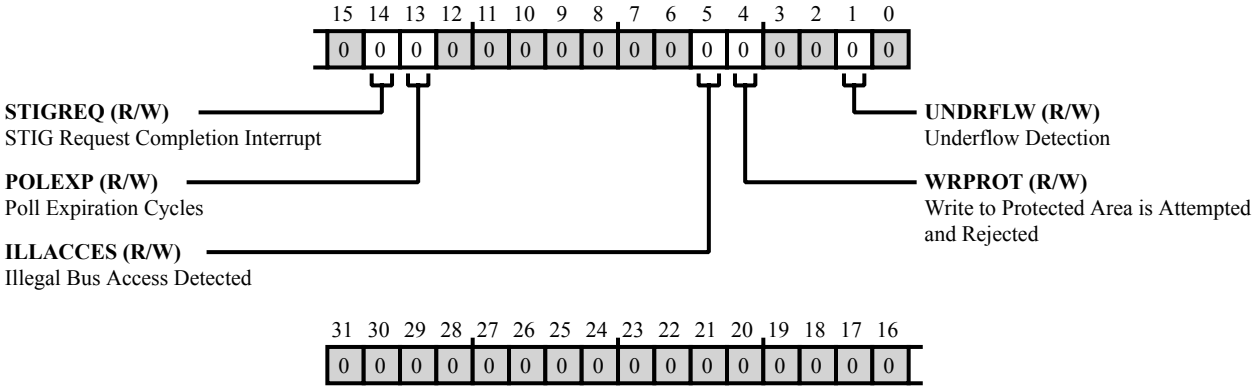

Figure 23-18: OSPI_ISTAT Register Diagram

Table 23-21: OSPI_ISTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
14 (R/W)	STIGREQ	STIG Request Completion Interrupt. The OSPI_ISTAT.STIGREQ bit indicates that the controller is ready to get another STIG request.
13 (R/W)	POLEXP	Poll Expiration Cycles. The OSPI_ISTAT.POLEXP bit indicates that the maximum number of programmed polls cycles has expired.
5 (R/W)	ILLACCES	Illegal Bus Access Detected. The OSPI_ISTAT.ILLACCES bit indicates that an illegal bus access has been detected. Bus wrapping bursts and the use of SPLIT/RETRY accesses cause the error interrupt to trigger.
4 (R/W)	WRPROT	Write to Protected Area is Attempted and Rejected. Write to protected area was attempted and rejected.

Table 23-21: OSPI_ISTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W)	UNDRFLW	Underflow Detection. The `OSPI_ISTAT.UNDRFLW` bit indicates that an underflow condition has been detected.	
		0	No underflow is detected.
		1	underflow is detected and an attempt to transfer data is made when the small TX FIFO is empty. This may occur when AHB write data is slowly provided to keep up with the requested write operation.

Lower Write Protection Register

The OSPI_WRPROT_LWR register allows the user to define lower boundary of the write protection area. This register should be setup while the controller is idle.

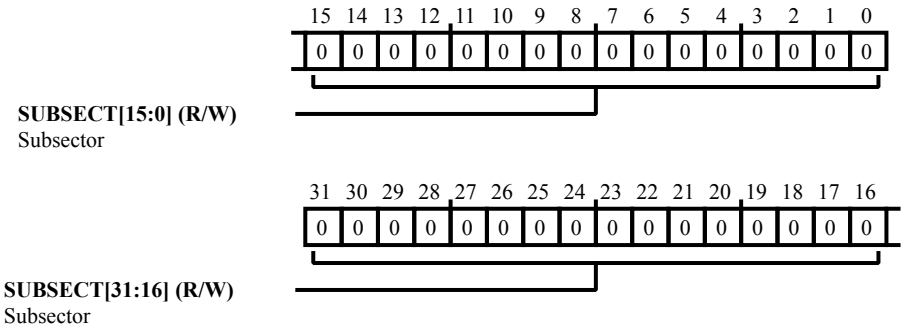

Figure 23-19: OSPI_WRPROT_LWR Register Diagram

Table 23-22: OSPI_WRPROT_LWR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	SUBSECT	Subsector. The OSPI_WRPROT_LWR.SUBSECT field defines the lower end of the address range to be protected. The address to be programmed must be OSPI memory map address (starting from 0x60000000) shifted by the value in the OSPI_DSCTL.BLKSZ. For example, if lower address of flash to be protected is 0x100 and the OSPI_DSCTL.BLKSZ= 4, the value to be programmed in this register must be 0x60000100 >> 4, which is 0x06000010.

Mode Bit Control Register

This register allows the user to define the mode bits for corresponding Flash Device. It also provides configuration for CRC aware SPI transfers. This register should be setup while the controller is idle.

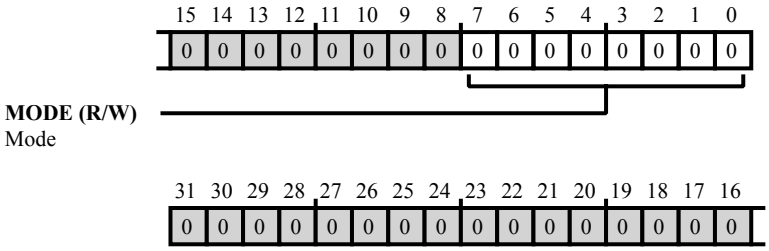

Figure 23-20: OSPI_MBCTL Register Diagram

Table 23-23: OSPI_MBCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	MODE	Mode. The `OSPI_MBCTL.MODE` field is sent to the device following the address bytes when the mode bit transmission is enabled.

Module ID Register

This register provides the IP release number and the configuration data.

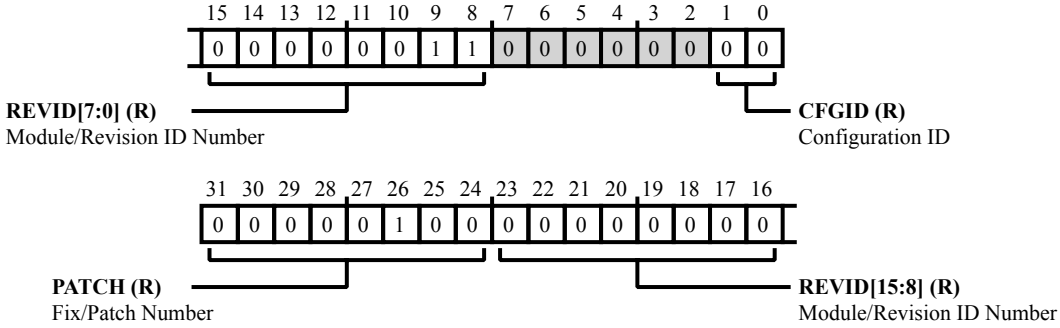

Figure 23-21: OSPI_MODID Register Diagram

Table 23-24: OSPI_MODID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/NW)	PATCH	Fix/Patch Number. The `OSPI_MODID.PATCH` field indicates the fix/patch number related to the `OSPI_MODID.REVID` field.
23:8 (R/NW)	REVID	Module/Revision ID Number. The `OSPI_MODID.REVID` field holds the module revision.
1:0 (R/NW)	CFGID	Configuration ID. The `OSPI_MODID.CFGID` field holds the configuration ID number.

Polling Expiration Register

This register defines maximum number of poll cycles. If the expected value of the bit being polled is not gotten after number defined in this register, the auto-polling is done on the next phase. The value stored in this register matters only if Write Completion Control Register bits[15] and Polling Flash Status Register bit[8] are set to "1". If auto-polling is not disabled by Write Completion Control Register bits[14], at least two auto-polling phases are queued before execution and popped after polled bit have taken expected value. This register should be setup while the controller is idle.

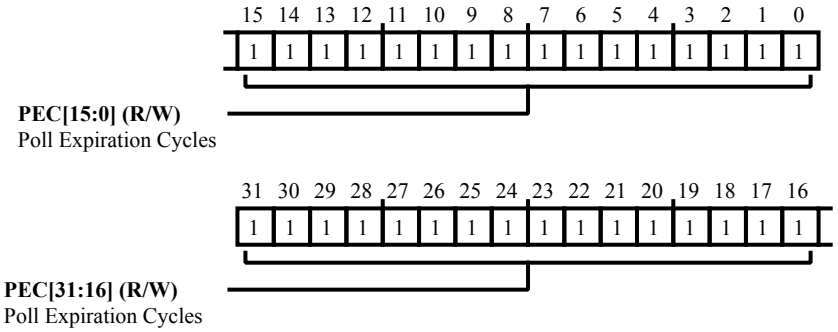

Figure 23-22: OSPI_POLLEXP Register Diagram

Table 23-25: OSPI_POLLEXP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	PEC	Poll Expiration Cycles. The `OSPI_POLLEXP.PEC` field defines the number of polls cycles before expiration.

Opcode Extension Register (Lower)

This register provides the supplementing opcodes for Dual Byte Opcode Mode activated by Octal-SPI Configuration Register bit[30].

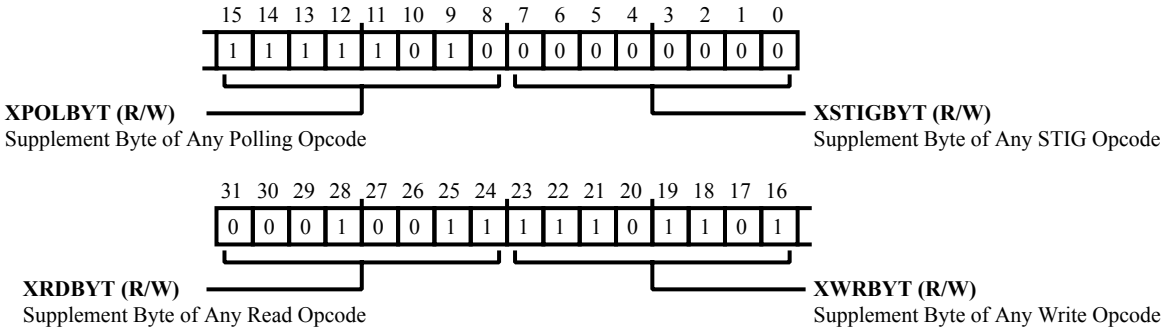

Figure 23-23: OSPI_OE_LWR Register Diagram

Table 23-26: OSPI_OE_LWR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	XRDBYT	Supplement Byte of Any Read Opcode.
23:16 (R/W)	XWRBYT	Supplement Byte of Any Write Opcode.
15:8 (R/W)	XPOLBYT	Supplement Byte of Any Polling Opcode.
7:0 (R/W)	XSTIGBYT	Supplement Byte of Any STIG Opcode.

Opcode Extension Register (Upper)

This register provides the supplementing opcodes for Dual Byte Opcode Mode activated by Octal-SPI Configuration Register bit[30]. Additionally, it allows the user to define the Write Enable Latch (WEL) command first byte opcode used for automatic WEL insertion before any AHB write access.

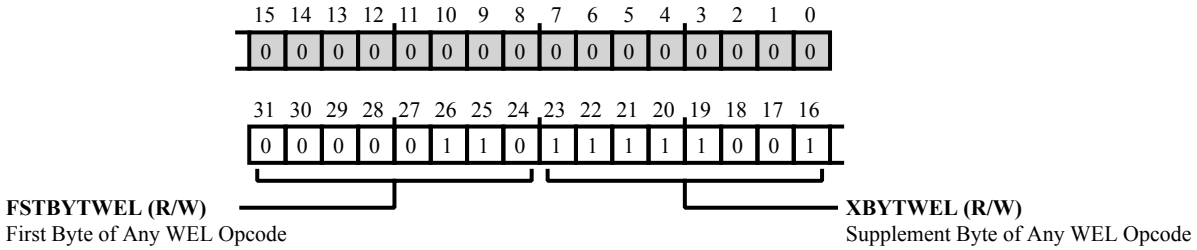

Figure 23-24: OSPI_OE_UP Register Diagram

Table 23-27: OSPI_OE_UP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	FSTBYTWEL	First Byte of Any WEL Opcode.
23:16 (R/W)	XBYTWEL	Supplement Byte of Any WEL Opcode.

PHY Control Register

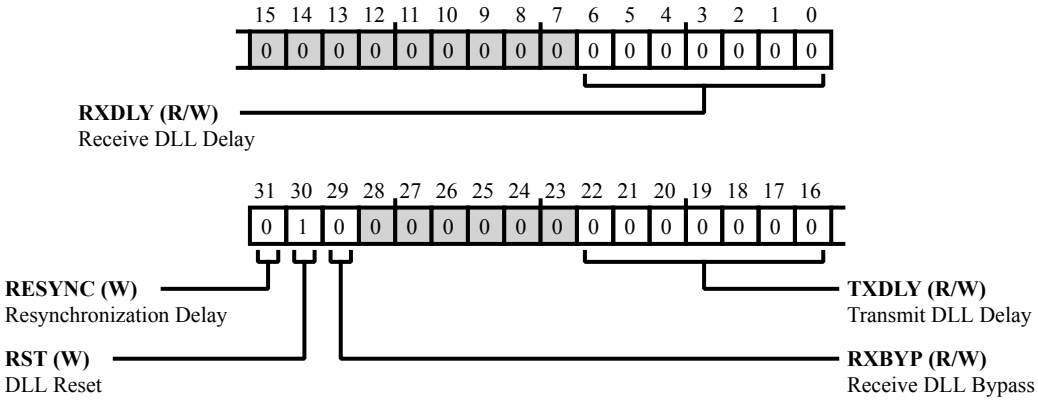

Figure 23-25: OSPI_PHYCTL Register Diagram

Table 23-28: OSPI_PHYCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (RX/W)	RESYNC	Resynchronization Delay. The `OSPI_PHYCTL.RESYNC` bit is used for resynchronization delay lines to update them with values from the `OSPI_PHYCTL.RXDLY` and `OSPI_PHYCTL.TXDLY` fields.
30 (RX/W)	RST	DLL Reset. The `OSPI_PHYCTL.RST` bit is used for reset of Delay Lines by software.
29 (R/W)	RXBYP	Receive DLL Bypass. The `OSPI_PHYCTL.RXBYP` field determines if RX DLL is bypassed.
22:16 (R/W)	TXDLY	Transmit DLL Delay. The `OSPI_PHYCTL.TXDLY` field determines the number of delay elements to insert on data path between ref_clk and spi_clk.
6:0 (R/W)	RXDLY	Receive DLL Delay. The `OSPI_PHYCTL.RXDLY` field determines the number of delay elements to insert on data path between ref_clk and rx_dll_clk.

PHY DLL Master Control Register

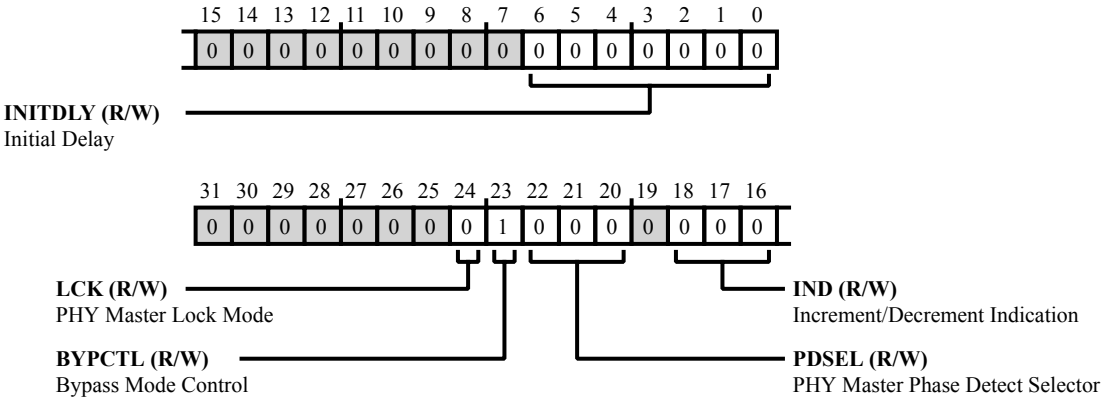

Figure 23-26: OSPI_PHYMCTL Register Diagram

Table 23-29: OSPI_PHYMCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
24 (R/W)	LCK	PHY Master Lock Mode. The `OSPI_PHYMCTL.LCK` bit indicates whether the master delay line locks on a full cycle or half cycle of delay.
23 (R/W)	BYPCTL	Bypass Mode Control. The `OSPI_PHYMCTL.BYPCTL` bit indicates the bypass mode of the master and slave DLLs.
22:20 (R/W)	PDSEL	PHY Master Phase Detect Selector. The `OSPI_PHYMCTL.PDSEL` field selects the number of delay elements to be inserted between the phase detect flip-flops.
18:16 (R/W)	IND	Increment/Decrement Indication. The `OSPI_PHYMCTL.IND` field indicates the number of consecutive increment or decrement indications.
6:0 (R/W)	INITDLY	Initial Delay. The `OSPI_PHYMCTL.INITDLY` field is the initial delay value for the DLL.

Polling Flash Status Register

This register provides auto-polling data. It acts as the extension for the Write Completion Control Register where full status is not available and any action can be taken only relying on the indication of single bit being polled for.

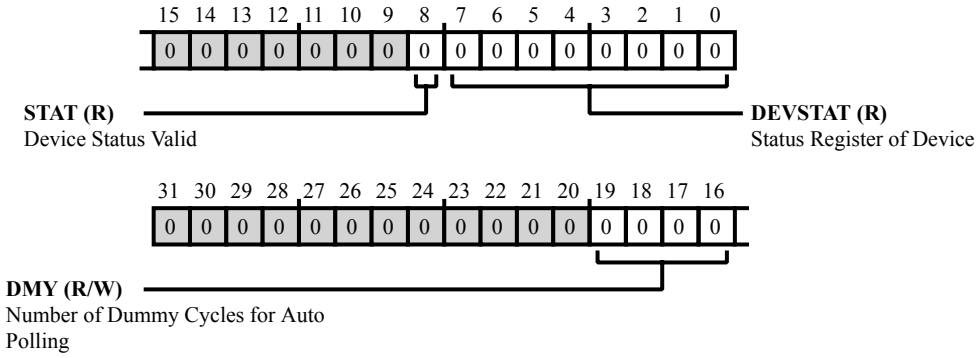

Figure 23-27: OSPI_POLSTAT Register Diagram

Table 23-30: OSPI_POLSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
19:16 (R/W)	DMY	Number of Dummy Cycles for Auto Polling. The `OSPI_POLSTAT.DMY` field indicates user-defined additional dummy cycles for read status during the auto-polling state. It may be necessary to add some cycles if the external delay of read data path shifts it outside the defined clock cycle.
8 (R/NW)	STAT	Device Status Valid. The `OSPI_POLSTAT.STAT` bit is set (=1) when value in bits from 7 to 0 is valid.
7:0 (R/NW)	DEVSTAT	Status Register of Device. The `OSPI_POLSTAT.DEVSTAT` field indicates the actual status register of the device.

Read Data Capture Register

This register is used to adjust SPI transfer conditions in order to fetch and capture data reliably. This register should be setup while the controller is idle.

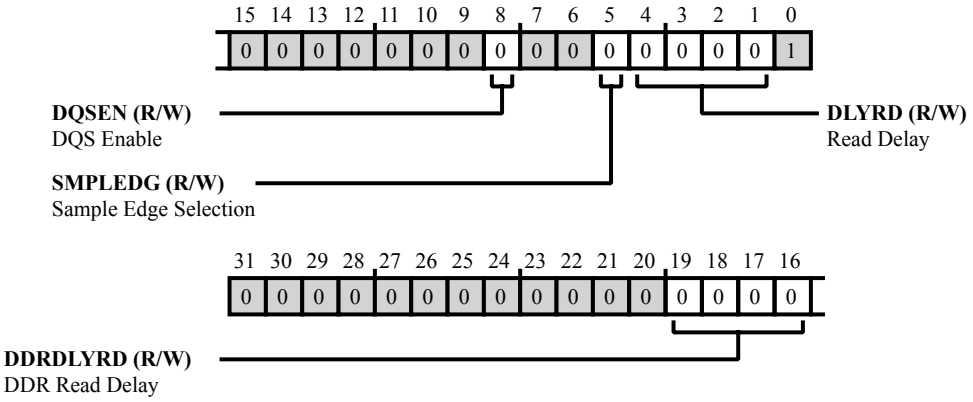

Figure 23-28: OSPI_RDC Register Diagram

Table 23-31: OSPI_RDC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
19:16 (R/W)	DDRDLYRD	DDR Read Delay. The `OSPI_RDC.DDRDLYRD` field indicates the delay of the transmitted data by the number of ref_clk cycles. This field is relevant only when DDR read Command is executed. Otherwise, it can be ignored.	
8 (R/W)	DQSEN	DQS Enable. If the `OSPI_RDC.DQSEN` bit is set (=1), the signal from DQS input is driven into RX DLL and is used for data capturing in PHY mode instead of internally generated gated ref_clk.	
5 (R/W)	SMPLEDG	Sample Edge Selection. The `OSPI_RDC.SMPLEDG` bit selects the edge on which data outputs from flash memory is sampled.	
		0	Data outputs from Flash are sampled on falling edge of the ref_clk.
		1	Data outputs from Flash are sampled on rising edge of the ref_clk.
4:1 (R/W)	DLYRD	Read Delay. The `OSPI_RDC.DLYRD` field indicates the delay of the read data capturing logic by the programmed number of OSPI_REFCLK cycles.	

Remap Address Register

This register allows the user to define the address offset for DAC accesses. This register should be setup while the controller is idle.

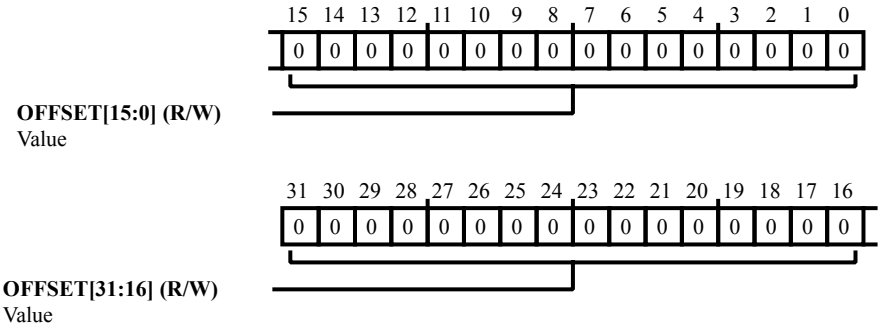

Figure 23-29: OSPI_REMAPADDR Register Diagram

Table 23-32: OSPI_REMAPADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	OFFSET	Value. The `OSPI_REMAPADDR.OFFSET` field is used to remap an incoming bus address to a different address used by the Flash.

Upper Write Protection Register

This register allows the user to define upper boundary of the write protection area. This register should be setup while the controller is idle.

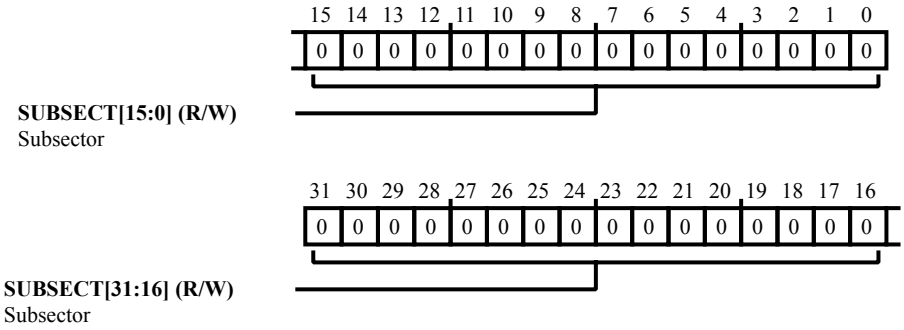

Figure 23-30: OSPI_WRPROT_UP Register Diagram

Table 23-33: OSPI_WRPROT_UP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	SUBSECT	Subsector. The `OSPI_WRPROT_UP.SUBSECT` field defines the upper end of the address range to be protected. The address to be programmed must be an OSPI memory map address (starting from 0x60000000) shifted by the value in the `OSPI_DSCTL.BLKSZ`. For example, if the upper address of flash to be protected is 0x100 and the `OSPI_DSCTL.BLKSZ`= 4, the value to be programmed in this register must be 0x60000100 >> 4, which is 0x06000010.

Write Protection Control Register

This register allows the user to define the configuration of write protection settings. This register should be setup while the controller is idle.

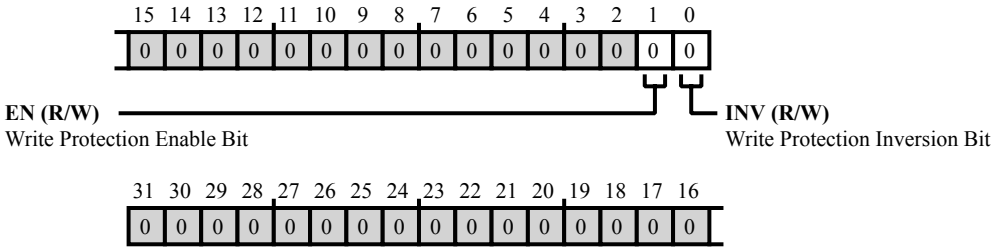

Figure 23-31: OSPI_WRPROT_CTL Register Diagram

Table 23-34: OSPI_WRPROT_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
1 (R/W)	EN	Write Protection Enable Bit. When set (=1), any AHB write access with an address within the protection region defined in the lower and upper write protection registers is rejected. An AHB error response is generated and an interrupt source triggered. When cleared (=0), the protection region is disabled.
0 (R/W)	INV	Write Protection Inversion Bit. When set (=1), the protection region defined in the lower and upper write protection registers is inverted meaning it is the region that the system is permitted to write to. When cleared (=0), the protection region defined in the lower and upper write protection registers is the region that the system is not permitted to write to.

Write Completion Control Register

The OSPI_WCCTL register defines how the controller polls the device following a write transfer.

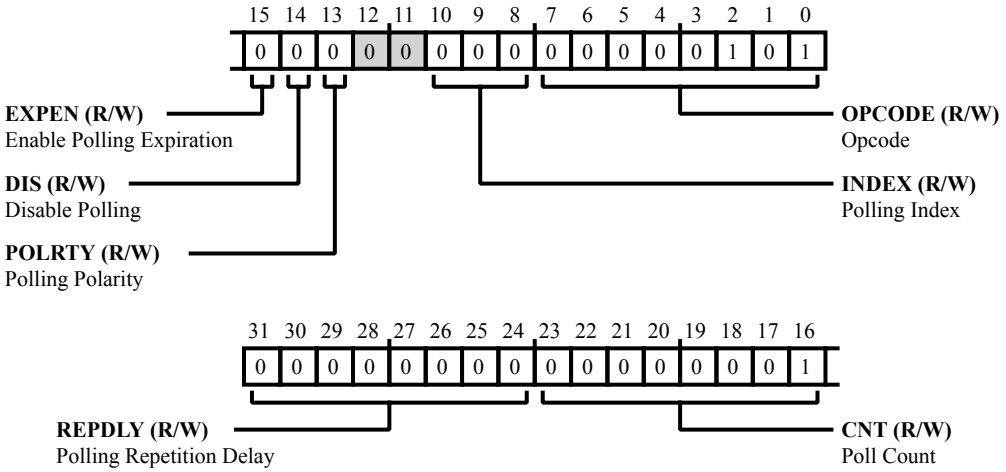

Figure 23-32: OSPI_WCCTL Register Diagram

Table 23-35: OSPI_WCCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:24 (R/W)	REPDLY	Polling Repetition Delay. The OSPI_WCCTL.REPDLY field defines the additional delay required to ensure that the Chip Select is deasserted during auto polling phase.	
23:16 (R/W)	CNT	Poll Count. The OSPI_WCCTL.CNT field defines the number of times the controller should expect to see a true result from polling in successive reads of the device register.	
15 (R/W)	EXPEN	Enable Polling Expiration. The OSPI_WCCTL.EXPEN bit is set (=1) to enable auto polling expiration.	
14 (R/W)	DIS	Disable Polling. The OSPI_WCCTL.DIS bit switches off automatic polling function.	
13 (R/W)	POLRTY	Polling Polarity. The OSPI_WCCTL.POLRTY bit defines the polling polarity.	
		0	Write transfer to the device will be complete if the polled bit is 0.
		1	Write transfer to the device will be complete if the polled bit is 1.

Table 23-35: OSPI_WCCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
10:8 (R/W)	INDEX	Polling Index. The `OSPI_WCCTL.INDEX` field defines the bit index that must be polled. A value of 010 means that bit 2 of the returned data is polled for. A value of 111 means that bit 7 of the returned data is polled for.
7:0 (R/W)	OPCODE	Opcode. The `OSPI_WCCTL.OPCODE` field defines the opcode that must be issued by the controller when it is automatically polling for device program completion. This command is issued followed all device write operations. By default, this polls the standard device status register using opcode 0x05.

24 Universal Asynchronous Receiver/Transmitter (UART)

The UART module is a full-duplex peripheral compatible with PC-style industry-standard UARTs. The UART converts data between serial and parallel formats. The serial communication follows an asynchronous protocol that supports various word lengths, stop bits, bit rates, and parity-generation options. Multiple events can generate interrupts.

The UART is logically compliant to EIA-232E, EIA-422, EIA-485 and LIN standards, but usually requires external transceiver devices to meet electrical requirements. In IrDA (Infrared Data Association) mode, the UART meets the half-duplex IrDA SIR (9.6/115.2 Kbps rate) protocol. In multi-drop bus mode, the UART meets the full-duplex MDB/ICP v2.0 protocol.

The UART module supports partial modem status and control functionality to allow for hardware flow control.

The UART is a DMA-capable peripheral with separate transmit and receive DMA controller channels. The use of DMA requires minimal software intervention as the DMA engine moves the data. The UART can also use a programmed core mode of operation. The core mode requires software management of the data flow using either interrupts or polling.

The UART can use one of the peripheral timers for a hardware-assisted auto-baud detection mechanism. The timers are external to the UART.

NOTE: The UARTs (UART0, UART1, and UART2) operate in the SCLK0 domain.

UART Features

Each UART includes the following features.

- 5–8 data bits
- Programmable extra stop bit and programmable extra half-stop bit
- Even, odd, and sticky parity bit options
- Extra 8-stage receive FIFO with programmable threshold interrupt request
- Flexible transmit and receive interrupt request timing

- Three interrupt outputs for receive, transmit, and status
- Independent DMA operation for receive and transmit
- Programmable automatic request to send (RTS)/clear to send (CTS) hardware flow control
- False start bit detection
- SIR IrDA operation mode
- MDB/ICP v2.0 operation mode
- Internal loopback
- Improved bit rate granularity
- LIN break command/Inter-frame gap transmission support

Table 24-1: UART Specifications

Feature	Availability
Protocol	
Controller-Capable	Yes
Target-Capable	Yes
Transmission Simplex	Yes
Transmission Half-Duplex	Yes
Transmission Full-Duplex	Yes
Access Type	
Data Buffer	Yes
Core Data Access	Yes
DMA Data Access	Yes
DMA Channels	2 (per UART Port)
DMA Descriptor	Yes
Boot Capable	Yes (Target Mode)
Local Memory	No
Clock Operation	SCLK0/16

UART Functional Description

The following sections provide details on the UARTs functionality.

ADSP-SC59x UART Register List

The Universal Asynchronous Receiver/Transmitter module (UART) is a full-duplex peripheral compatible with PC-style industry-standard UARTs. The UART converts data between serial and parallel formats. The serial communication follows an asynchronous protocol that supports various word length, stop bit, parity, and interrupt generation options. A set of registers governs UART operations. For more information on UART functionality, see the UART register descriptions.

UART Block Diagram

The ***UART Block Diagram*** figure shows a simplified block diagram of one UART module and how it interconnects to the processor system.

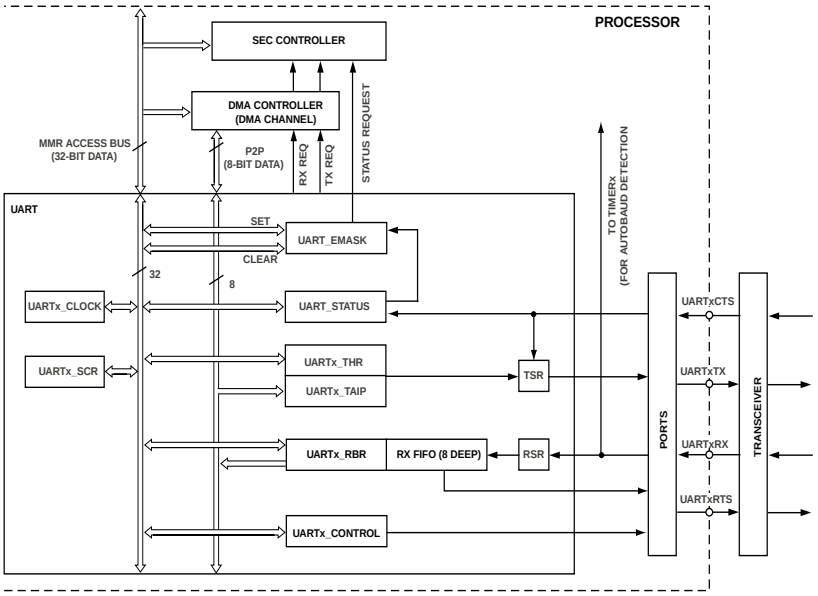

Figure 24-1: UART Block Diagram

UART Architectural Concepts

The following sections provide information about the UART architecture.

Internal Interface

The UART is a DMA-capable peripheral with support for separate transmit and receive DMA controller channels. It operates in either DMA or programmed core modes. The core mode requires software management of the data flow using either interrupts or polling. The DMA method requires minimal software intervention, as the DMA engine itself moves the data. The `UART_RBR` and `UART_THR` registers also connect to one of the peripheral DMA buses.

All UART registers are 32 bits, and the registers connect to the peripheral MMR bus. Not all MMRs can be used, and unused bits are zero-filled. The UART has three interrupt outputs described as follows.

- The transmit and receive request outputs can function as DMA requests and connect to the DMA controller. Therefore, if the DMA is not enabled, the DMA controller simply forwards the request to the system event controller (SEC).
- The status interrupt output connects directly to the SEC . On many processors, the alternative capture input () of one of the GP timers also senses the $\overline{\texttt{UART_RX}}$ pin. When configured in capture mode, the processor can then use the GP timer to detect the bit rate of the received signal.

External Interface

Each UART features a $\overline{\texttt{UART_RX}}$ (receive) pin and a $\overline{\texttt{UART_TX}}$ (transmit) pin available through the general-purpose ports. These two pins usually connect to an external transceiver device that meets the electrical requirements of full-duplex or half-duplex standards. For example, EIA-232, EIA-422, 4-wire EIA-485 for full-duplex or 2-wire EIA-485, LIN for half-duplex. Additionally, the UART features a pair of clear-to-send, input pins ($\overline{\texttt{UART_CTS}}$),

and request-to-send, output pins (UART_RTS) for hardware flow control. UART signals are multiplexed with other functions at the pin level.

Hardware Flow Control

To prevent the UART transmitter from sending data while the receiving counterpart is not ready, the UART features a UART_RTS/UART_CTS hardware flow control mechanism. The UART_RTS signal is an output that connects to the UART_CTS input of the communication partner. If data transfer is bidirectional, the figure shows the ***UART Hardware Flow Control*** handshake.

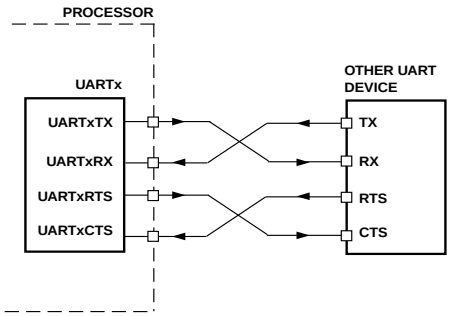

Figure 24-2: UART Hardware Flow Control

In both DMA and core mode, the receiver can deassert the UART_RTS signal to indicate that its receive buffer is almost full. Continued data transfers can cause an overrun error. The transmitter pauses when the UART_CTS input is in a deasserted state. In this state, the transmitter completes transmission of the data currently held in the transmit shift register (UART_TSR) but it does not continue with the data in the transmit hold register (UART_THR). If the UART_CTS pin is asserted again, the transmitter resumes and loads the content of UART_THR register into the UART_TSR register.

Bit Rate Generation

The peripheral clock (SCLK0) and the 16-bit divisor in the UART_CLK register characterize the sample clock. The UART uses the UART_CTL.EN bit to enable the clock. By default, every serial bit is oversampled 16 times. The bit clock is 1/16th of the sample clock. If not in IrDA mode, the bit clock can equal the sample clock if the UART_CLK.EDBO bit is set, so that the following equation applies:

$$\text{Bit Rate} = \text{SCLK0}/(16^{(1-\text{EDBO})} \times \text{Divisor})$$

The ***UART Bit Rate Examples with 100 MHz SCLK*** table provides example divide factors required to support standard baud rates at an SCLK0 of 100 MHz.

Table 24-7: UART Bit Rate Examples with 100 MHz SCLK0

Bit Rate (bits/sec)	EDBO = 0			EDBO = 1		
	DL	Actual	% Error	DL	Actual	% Error
2400	2604	2400.15	0.006	41667	2399.98	0.001
4800	1302	4800.31	0.006	20833	4800.08	0.002

Table 24-7: UART Bit Rate Examples with 100 MHz SCLK0 (Continued)

Bit Rate (bits/sec)	EDBO = 0			EDBO = 1		
	DL	Actual	% Error	DL	Actual	% Error
9600	651	9600.61	0.006	10417	9599.69	0.003
19200	326	19171.78	0.147	5208	19201.23	0.006
38400	163	38343.56	0.147	2604	38402.46	0.006
57600	109	57339.45	0.452	1736	57603.69	0.006
115200	54	115740.74	0.469	868	115207.37	0.006
921600	7	892857.14	3.119	109	917431.19	0.452
1500000	4	1562500	4.167	67	1492537.31	0.498
3000000	2	3125000	4.167	33	3030303.03	1.01
6250000	1	6250000	0	16	6250000	0

NOTE: Carefully select the SCLK0 frequencies. Even multiples of the bit rate can decrease the error percentage.

Setting the bit clock equal to the sample clock (`UART_CLK.EDBO` =1) improves the bit rate granularity and the bit clock matches with the bit rate of the communication partner. Use `UART_CLK.EDBO` mode only when bit rate accuracy is not acceptable in the `UART_CLK.EDBO`=0 mode.

The `UART_CLK.EDBO`=1 mode is not intended to increase the speed of operation beyond the electrical limitations of the UART transfer protocol.

Autobaud Detection

At the chip level, the $\overline{\texttt{UART_RX}}$ pin is typically routed to an alternate capture input (`TIMER_ACI[nn]`) of a general-purpose timer. When working in width capture mode, the processor uses this general-purpose timer to detect the bit rate applied to the $\overline{\texttt{UART_RX}}$ pin automatically by an external device. It often uses the capture capabilities of the timer to supervise the bit rate at run time. If the UART communicates with any device supplied by a weak clock oscillator that drifts over time, the processor can then readjust its UART bit rate dynamically, as required.

Often, the processor uses autobaud detection for initial bit rate negotiations where it is most likely a completer device waiting for the host to send a predefined autobaud character. This situation is common for UART booting. Do not enable the `UART_CTL.EN` bit while autobaud detection is in-process, to prevent the UART from starting a receive operation with incorrect bit rate matching. Alternatively, set the `UART_CTL.LOOP_EN` bit to disconnect the UART from its $\overline{\texttt{UART_RX}}$ pin.

A software routine can detect the pulse widths of serial stream bit cells. The sample base of the timer is synchronous with the UART operation (all derived from the same SCLK0). The UART uses pulse widths to calculate the bit rate divider as follows:

Divisor = `TIMER_TMR[n]_WID`/($16^{(1-\text{EDBO})}$ × Number of captured UART bits)

To increase the number of timer counts and the resolution of the captured signal, do not measure just the pulse width of a single bit. Instead, enlarge the pulse of interest over more bits. Traditionally, a NULL character (ASCII 0x00) is used in autobaud detection, as shown in the ***Autobaud Detection*** figure.

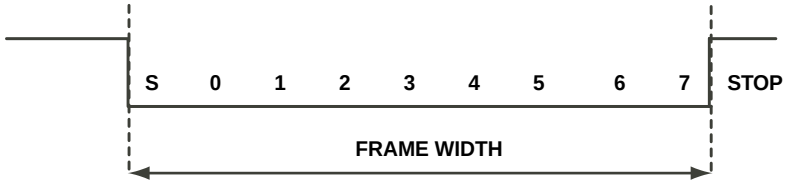

Figure 24-3: Autobaud Detection

Because the example frame encloses 8 data bits and 1 start bit, apply the following formula:

Divisor = `TIMER_TMR[n]_WID`/($16^{(1-EDBO)}$ × 9)

NOTE: For processor-specific mapping of timer alternate capture inputs to the UARTs of the processor, see "Width Capture (WIDCAP) Mode" in the "*General-Purpose Timer (TIMER)*" chapter.

Real receive signals often have asymmetrical falling and rising edges, and the sampling logic level is not exactly in the middle of the signal voltage range. At higher bit rates, such pulse-width-based autobaud detection does not always return adequate results without extra conditioning of the analog signal. Measure signal periods to work around this issue.

For example, predefine the ASCII character “@” (0x40) as the autobaud detection character and measure the period between two subsequent falling edges. As shown in the ***Autobaud Detection Character 0x40*** figure, measure the period between the falling edge of the start bit and the falling edge after bit 6. Since this period encloses 8 bits, apply the following formula:

Divisor = `TIMER_TMR[n]_PER`/($16^{(1-EDBO)}$ × 8)

or:

- Divisor = `TIMER_TMR[n]_PER`>> 7, if `UART_CLK.EDBO`=0
- Divisor = `TIMER_TMR[n]_PER`>> 3, if `UART_CLK.EDBO`=1

The ***Autobaud Detection Character 0x40*** figure shows the ASCII “@” (0x40) detection character.

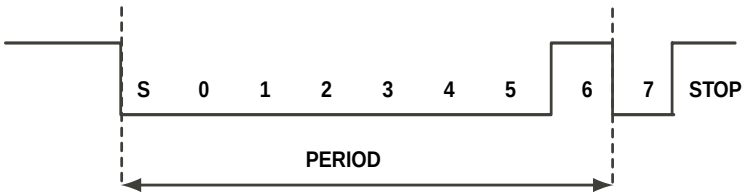

Figure 24-4: Autobaud Detection Character 0x40

UART Debug Features

The UART can automatically calculate and transmit a parity bit. The ***UART Parity*** table summarizes parity behavior assuming 8-bit data words (`UART_CTL.WLS`=b#11).

Table 24-8: UART Parity

PEN	STP	EPS	Data (hex)	Data (binary, LSB first)	Parity
0	x	x	x	x	None
1	0	0	0x60	0000 0110	1
1	0	0	0x57	1110 1010	0
1	0	1	0x60	0000 0110	0
1	0	1	0x57	1110 1010	1
1	1	0	x	x	1
1	1	1	x	x	0

The two force error bits, UART_CTL.FPE and UART_CTL.FFE, are intended for test purposes. They are useful for debugging software, especially in loopback mode.

The UART can be set to internal loopback mode (UART_CTL.LOOP_EN=1). Loopback mode disconnects the input of the receiver from the receive pin and internally redirects the transmit output to the receiver. The transmit pin remains active and continues to transmit data externally as well. Loopback mode also forces the UART_RTS pin to deassert, disconnects the UART_STAT.CTS bit from the UART_CTS input pin, and connects the internal version of UART_RTS to the UART_STAT.CTS bit.

Additionally, the UART_TX pin can be forced to zero asynchronously using the UART_CTL.SB bit.

UART Operating Modes

The following sections describe the main operating modes of the UART.

- UART Mode
- IrDA SIR Mode
- Multi-Drop Bus Mode

UART Mode

The UART mode follows an asynchronous serial communication protocol with these options:

- 1 start bit
- 5–8 data bits
- Address bit (available in MDB mode only)
- None, even, odd or sticky parity
- One, 1½, or two stop bits (1½ stop bits valid only in 5-bit word length)

The UART_CTL register controls the format of received and transmitted character frames. Data is always transmitted and received with the least significant bit (LSB) first.

The ***Bit Stream on a UART TX Pin Transmitting an "S" Character (0x53)*** figure shows a typical physical bit stream measured on a UART_TX pin.

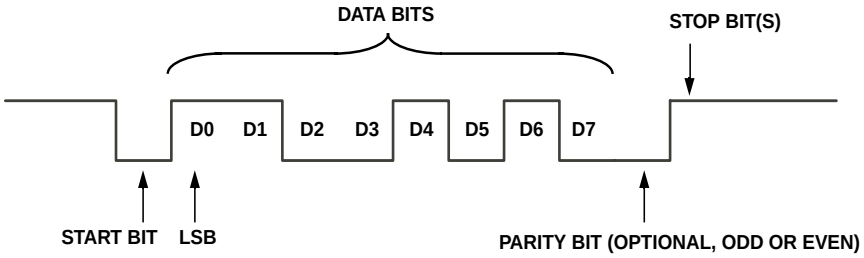

Figure 24-5: Bit Stream on a UART TX Pin Transmitting an "S" Character (0x53)

IrDA SIR Mode

The UART also supports serial data communication by way of infrared signals, according to the recommendations of the Infrared Data Association (IrDA). The physical layer known as IrDA SIR (9.6/115.2 Kbps rate) is based on return-to-zero-inverted (RZI) modulation. The UART does not support pulse position modulation.

Using the 16x data rate clock, RZI modulation is achieved by inverting and modulating the non-return-to-zero (NRZ) code normally transmitted by the UART. On the receive side, the UART uses a 16x clock to determine an IrDA pulse sample window, from which it recovers the RZI modulated NRZ code.

NOTE: The UART_CLK.EDBO bit is not valid in IrDA mode. Clear (=0) this bit in this mode.

Multi-Drop Bus Mode

The UART uses a protocol for point-to-point connections as well as in networks where the EIA-485 standard is representative of UART-based bus systems. The EIA-232 standard defines point-to-point connections. In such networks, node addressing is important.

In a multidrop bus (MDB) network, for example, an address bit enhances the UART frame. The address bit is inserted between the data bits and the optional parity bit. To configure the UART for MDB mode, set the mode of operation bits (UART_CTL.MOD [5:4]) to 01.

By convention, the address bit is transmitted low for regular data bytes. When set, it marks special address bytes that require the attention of all nodes on the network.

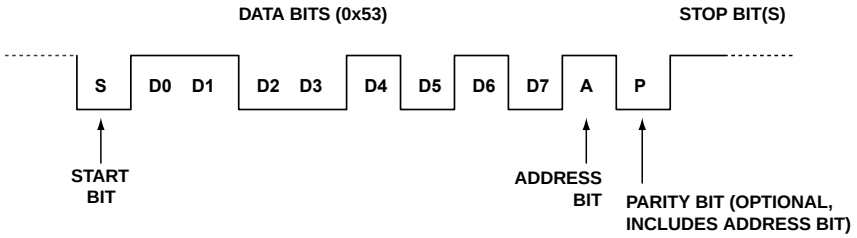

Figure 24-6: UART Frame with Address Bit

All transmit operations are processed through the transmit buffer register (UART_THR), so all DMA data transmissions clear the address bit. If data is written to the transmit address or insert pulse register (UART_TAIP) instead, the same transmit operation is initiated with the only exception that the address bit is sent high.

The UART uses the UART_STAT.ADDR bit of the receiver to signal whether the previously received frame had the address bit set or not. Hardware updates it every time a new frame is received. When the enable address word interrupt bit (UART_IMSK.EAWI) is set, the reception of an address byte triggers a special status interrupt request.

The address sticky bit (UART_STAT.ASTKY) is the sticky version of the UART_STAT.ADDR bit. Hardware sets it whenever the UART_STAT.ADDR bit is set. Software can clear the UART_STAT.ASTKY bit with a W1C operation.

In MDB mode, only address bytes progress to the receive FIFO by default. Data bytes are gated unless the UART_STAT.ASTKY bit is set. The receiver ignores all traffic on the UART bus. This way, the processor can go into low-power mode and interrupt activity does not load the processor every time a frame is transmitted on the UART bus. If, however, an address frame is transmitted, the receiver immediately samples all further traffic. A software routine can analyze the received data, decide whether it was of relevance for the local network node, and W1C the UART_STAT.ASTKY bit if it was not.

Software can overrule of the hardware address frame detection by setting the UART_STAT.ADDR bit and (indirectly) the UART_STAT.ASTKY bit with a W1S operation.

The MDB mode follows an asynchronous serial communication protocol with the following options.

- 1 start bit
- 5–8 data bits
- Address bit
- None, even, odd or sticky parity
- One, 1½, or two stop bits (1½ stop bits are valid only in 5-bit word length)

NOTE: If the address bit and parity bit are both enabled, the parity check and generation includes the address bit in its parity calculation.

UART Data Transfer Modes

The UART can transfer data using both the core and DMA. Receive and transmit paths operate independently except that the bit rate and the frame format are identical for both transfer directions. Transmit and receive channels are both buffered. The UART_THR register buffers the transmit shift register (UART_TSR) and the UART_RBR register buffers the receive shift register (UART_RSR).

UART Mode Transmit Operation (Core)

In core mode, the processor core moves data to and from the UART. A write to the UART_THR register initiates the transmit operation. If no former operation is pending, the UART_THR register passes the data immediately to the

UART_TSR register. There, it is shifted out at the bit rate characterized by the UART_CLK register, with start, stop, and parity bits appended as defined by the UART_CTL register.

The UART_THR register and the UART_TSR register can be modeled as a two-stage transmit buffer. The least significant bit (LSB) always transmits first. This bit is bit 0 of the value written to the UART_THR register.

UART Mode LIN Break Command

Some UART-based protocols demand synchronization methods that are not native to standard UART implementations. For example, the Local Interconnect Network (LIN) protocol requires a low-pulse of well-defined transmit length as a prologue to every multi-byte message. Its length must be at least 13 bit-times.

With previous UARTs, there were two options to implement this protocol:

- A null byte is transmitted with a temporarily lowered bit rate, or
- A software counter generates the period, and the asynchronous set break (SB) mechanisms pull the transmit pin low

Since both methods have their disadvantages, the newer UART introduces a new inter-frame gap technique.

The feature is not available in MDB or IrDA operating modes. However, in standard UART mode (bits UART_CTL.MOD [5:4] =00), a write to the UART_TAIP register initiates the transmission of an inter-frame pulse. If the transmit buffer is not empty, the UART first transmits all bytes in the queue. It only initiates with pulse generation after the last stop bit of the last byte has been shifted out.

The value written into the UART_TAIP register defines the nature and the duration of the transmitted pulse. Bits [6:0] control the duration in bit-times and bit [7] controls the value (duration = UART_TAIP[6:0] / UART_CLK[15:0]). If UART_TAIP[7] is set, and an active high pulse is issued, the number of stop bits is extended. If UART_TAIP[7] is cleared, a low pulse is generated. Invert the polarity using the UART_CTL.FCPOL bit. Writing a value of 13 into the UART_TAIP register generates the break command as required by the LIN protocol.

NOTE: If the UART_CTL.TPOLC bit is enabled, an inverted most-significant bit can be transmitted.

NOTE: If another transmission is pending (in the UART_TSR register), the UART_TAIP initiated pulse is queued until after all pending operations have finished and all stop bits are transmitted.

The transmission of break command/inter-frame gap precedes transmission of the number of stop bits as set in the UART_CTL.STB and UART_CTL.STBH bit fields.

The UART receiver can detect break commands through the break indicator (UART_STAT.BI) flag. This flag reports that an entire UART frame has been received in low state. It does not report whether the duration of the received low pulse was exact or at least 13 bit-times as LIN controllers transmit. Typically, the break indicator meets LIN requirements. The processor can use GP timers to determine the pulse width more precisely, if necessary.

Each $\overline{\text{UART_RX}}$ pin is also routed to a GP timer through its alternate capture input (TACI). This functionality is not only useful for bit rate detection (*autobaud*) but also helps to measure the pulse widths precisely on the $\overline{\text{UART_RX}}$ input. Additionally, the GP timers can issue an interrupt request or a fault condition when the received

pulse width is shorter than a bit time or longer than the worst-case break condition. The windowed watchdog width mode of the GP timers controls this functionality.

UART Mode Receive Operation (Core)

The receive operation uses the same data format as the transmit configuration except that one valid stop bit is always sufficient. The UART_CTL.STB and UART_CTL.STBH bits have no impact on the receiver.

The UART receiver senses the falling edges of the receive input. When it detects an edge, the receiver starts sampling the input according to settings in the UART_CLK register. The receiver samples the start bit (majority sampling) close to its midpoint. If sampled low, it assumes a valid start condition. Otherwise, it discards the detected falling edge.

After detection of the start bit, the received word is shifted into the UART_RSR register.

After the corresponding stop bit is received, the content of the UART_RSR register is transferred to the 8-deep receive FIFO and is accessible by reading the UART_RBR register.

The receive FIFOs and the UART_RBR register act as a 9-stage receive buffer. If the stop bit of the ninth word is received before software reads the UART_RBR register, an overrun error is reported. Overruns protect data in the UART_RBR register and the receive FIFO from being overwritten by further data until the software clears the UART_STAT.OE bit. However, the data in the UART_RSR register is immediately destroyed as soon as the overrun occurs.

The sampling clock is 16 times faster than the bit clock. The receiver oversamples every bit 16 times and makes a majority-decision based on the middle three samples. This functionality improves immunity against noise and hazards on the line. The receiver disregards spurious pulses of less than two times the sampling clock period.

Normally, the receiver samples every incoming bit at exactly the 7th, 8th, and 9th sample clock. If, however, the UART_CLK.EDBO bit is set to 1, the receiver samples bits approximately at 7/16th, 8/16th, and 9/16th of their period. This configuration achieves better bit rate granularity and accuracy as required at high operation speeds. Hardware design must ensure that the incoming signal is stable between 6/16th and 10/16th of the nominal bit period.

Reception starts when the UART receiver detects a falling edge on the $\overline{\text{UART_RX}}$ input pin. The receiver attempts to see a start bit. The data is shifted into the UART_RSR register. After the ninth sample of the first, the receiver processes the stop bit and copies the received data to the 8-stage receive FIFO. The UART_RSR recovers for further data reception.

The receiver samples data bits close to their midpoint. Because the receiver clock is typically asynchronous to the data rate of the transmitter, the sampling point can drift relative to the center of the data bits. The sampling point is synchronized again with each start bit, so the error accumulates only over the length of a single word. The polarity of received data is selectable, using the UART_CTL.RPOLC bit.

NOTE: The receiver checks for only a single stop bit. After the third sample of the first stop bit has been received (at time 9/16th of the stop bit duration), the receiver immediately acts (status update). It then prepares for new falling edge detection (start detection).

IrDA Transmit Operation

To generate the IrDA pulse transmitted by the UART, the normal NRZ output of the transmitter is first inverted if the UART_CTL.TPOLC bit is configured for active-low operation. In this configuration, a zero is transmitted as a high pulse of 16 UART clock periods and a one is transmitted as a low pulse for 16 UART clock periods. Then, six UART clock periods delay the leading edge of the pulse. Similarly, eight UART clock periods truncate the trailing edge of the pulse. For a 16-cycle UART clock period, this operation results in the final representation of the original zero as a high pulse of only 3/16 clock periods. The ***IrDA Transmit Pulse*** figure shows how the pulse is centered around the middle of the bit time. The final IrDA pulse is fed to the off-chip infrared driver.

This modulation approach ensures a pulse width output from the UART of three cycles high out of every 16 UART clock cycles. As shown in the ***IrDA Transmit Pulse*** figure, the error terms associated with the bit rate generator are small and well within the tolerance of most infrared transceiver specifications.

NOTE: In IrDA mode, writes to the UART_TAIP register are equivalent to writes to the UART_THR register.

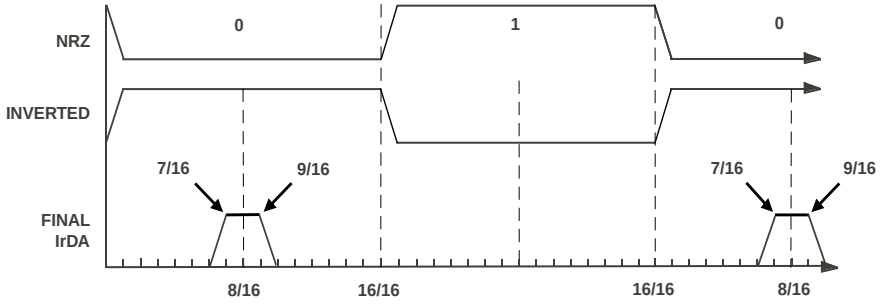

Figure 24-7: IrDA Transmit Pulse

IrDA Receive Operation

The IrDA receiver function is more complex than the transmit function. The receiver must discriminate the IrDA pulse and reject noise. The receiver looks for the IrDA pulse in a narrow window centered around the middle of the expected pulse.

Glitch filtering is accomplished by counting 16 system clocks from the time the receiver detects an initial pulse. If the pulse is absent when the counter expires, the receiver interprets it as a glitch. Otherwise, the receiver interprets it as a zero. This assessment is acceptable because glitches originating from on-chip capacitive cross-coupling typically do not last for more than a fraction of the system clock (SCLK0) period. Appropriate shielding avoids sources outside of the chip and not part of the transmitter. The only other source of a glitch is the transmitter itself. The processor relies on the transmitter to perform within specification. If the transmitter violates the specification, unpredictable results can occur. The 4-bit counter adds an extra level of protection at a minimal cost.

NOTE: Because SCLK0 can change across systems, the longest glitch tolerated is inversely proportional to the SCLK0 frequency.

A counter that is clocked at the 16x bit-time sample clock determines the receive sampling window. The sampling window is resynchronized with each start bit by centering the sampling window around the start bit.

The polarity of receive data is selectable, using the UART_CTL.RPOLC bit. The ***IrDA Receiver Pulse Detection*** figure provides examples of each polarity type.

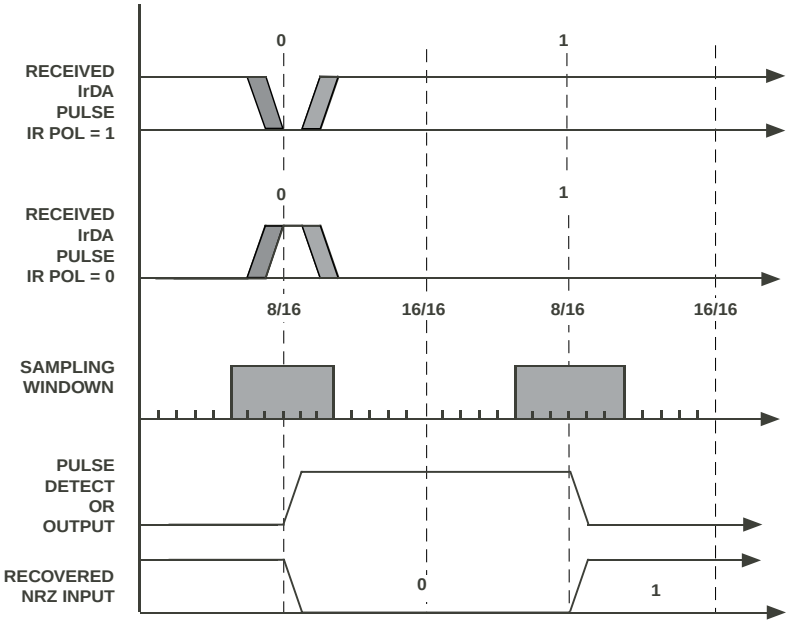

Figure 24-8: IrDA Receiver Pulse Detection

MDB Transmit Operation

In MDB mode, receive and transmit paths operate independently from each other, except for sharing bit rate and frame formats for both transfer directions.

Transmit operation is initiated by writing the UART_THR or UART_TAIP registers. A write to the UART_THR register transmits the written word with the appending address bit set low. A write to the UART_TAIP register transmits the written word with the appended address bit set high. The data is moved into the UART_TSR register, where it is shifted out at the bit rate programmed by the UART_CLK register, with start, stop, address, and parity bits appended, as required.

If DMA is enabled, the DMA engine always writes the data into the UART_THR register, and the written word is transmitted with the appending address bit set low.

The polarity of transmit data is selectable, using the UART_CTL.TPOLC bit.

MDB Receive Operation

Receive operations use the same data format as the transmit configuration, except that the number of stop bits is always assumed to be 1. After detection of the start bit, the received word is shifted into the UART_RSR register at the programmed bit.

Normally, the receiver samples every incoming bit at exactly the 7th, 8th, and 9th sample clock. If, however, the UART_CLK.EDBO bit is set, the receiver samples the bits approximately at 7/16th, 8/16th, and 9/16th of their period. This configuration achieves better bit rate granularity and accuracy needed at high operation speeds. Hardware design must ensure that the incoming signal is stable between 6/16th and 10/16th of the nominal bit period.

After the appropriate number of bits (including address, parity, and stop bits) is received, the UART_RSR register is transferred to the receive FIFO and accessible through the UART_RBR register.

The polarity of receive data is selectable, using the UART_CTL.RPOLC bit.

DMA Mode

In DMA mode, separate receive and transmit DMA channels move data between the UART and memory. The software does not have to move data; it just must set up the appropriate transfers either through the descriptor mechanism or through autobuffer mode.

DMA channels provide a 4-deep FIFO, resulting in total buffer capabilities of 6 words at the transmit side and 9 words at the receive side. In DMA mode, the bus activity and arbitration mechanism determine the latency. The processor loading and interrupt priorities do not determine the latency.

To enable UART DMA, first set up the system DMA control registers. Then, enable the UART_IMSK.ERBFI or UART_IMSK.ETBEI interrupts. This sequence is necessary because these interrupt request lines double as DMA request lines. With DMA enabled, once these requests are received, the DMA control unit generates a direct memory access. If DMA is not enabled, the UART interrupt is passed on to the system interrupt handling unit. The status interrupt for the UART goes directly to the system event controller (SEC), bypassing the DMA unit completely.

For transmit DMA, programs must set the DMA_CFG.SYNC bit. With this bit set, interrupt generation is delayed until the entire DMA FIFO is drained to the UART module. The UART transmit DMA interrupt service routine can disable the DMA or to clear the UART_IMSK.ETBEI control bit only when the DMA_CFG.SYNC bit is set. Otherwise, up to four data bytes can be lost.

When the UART_IMSK.ETBEI bit is set, an initial transmit DMA request is issued immediately. The program then clears the UART_IMSK.ETBEI bit through the DMA service routine.

In DMA transmit mode, the UART_IMSK.ETBEI bit enables the peripheral request to the DMA FIFO. The DMA_CFG.EN bit enables the strobe on the memory side. If the DMA count is less than the DMA FIFO depth, which is 4, then the DMA interrupt can be requested before the UART_IMSK.ETBEI bit is set. If this behavior is unwanted, set the DMA_CFG.SYNC bit.

Regardless of the DMA_CFG.SYNC setting, the DMA stream has not left the UART transmitter completely at the time the interrupt request is generated. Transmission can abort in the middle of the stream, causing data loss, when the UART clock was disabled without extra synchronization with the UART_STAT.TEMT bit.

The UART provides functionality to avoid resource-consuming polling of the UART_STAT.TEMT bit. The UART_IMSK_SET.EDTPTI bit enables the UART_STAT.TEMT bit to trigger a DMA interrupt. To delay the DMA completion interrupt until the last data word of a STOP DMA has left the UART, keep the DMA_CFG.INT bit cleared and set the UART_IMSK_SET.EDTPTI bit instead. Then, the normal DMA completion interrupt is suppressed. Later, the UART_STAT.TEMT event triggers a DMA interrupt after the last word of the DMA has left the UART transmit buffers. If DMA_CFG.INT and UART_IMSK.EDTPTI are set, when finishing STOP mode, the DMA requests two interrupts.

The DMA of the UART module supports 8-bit and 16-bit operation, but not 32-bit operation. It does not support sign-extension.

Mixing DMA and Core Modes

Switching from DMA mode to core operation dynamically requires some consideration, especially for transmit operations. By default, the interrupt timing of the DMA is synchronized with the memory side of the DMA FIFOs. Normally, the transmit DMA completion interrupt is generated after the last byte is copied from the memory into the DMA FIFO. The transmit DMA interrupt service routine is not yet permitted to disable the DMA_CFG.EN bit. The interrupt is requested when the DMA_STAT.IRQDONE bit is set. The DMA_STAT.RUN bit, however, remains set until the data has completely left the transmit DMA FIFO.

When planning to switch from a DMA to core mode, set the DMA_CFG.SYNC bit in the word of the last descriptor or work unit before handing over control. Then, after the interrupt request occurs, software can write new data into the UART_THR register as soon as the UART_STAT.THRE bit permits. If the DMA_CFG.SYNC bit cannot be set, software can poll the DMA_STAT.RUN bit instead. Alternatively, using the UART_IMSK.EDTPTI bit can avoid expensive status bit polling.

When switching from core to DMA operation, ensure that the first DMA request is issued properly. If the DMA is enabled while the UART is still transmitting, no precaution is required. If, however, the DMA is enabled after the UART_STAT.TEMT bit is high, pulse the UART_IMSK.ETBEI bit to initiate DMA transmission.

Setting Up Hardware Flow Control

The following steps show how to set up UART hardware flow control:

1. Configure automatic or manual hardware flow control for the receiver through the UART_CTL.ARTS bit, or the transmitter through the UART_CTL.ACTS bit.
2. Configure $\overline{\text{UART_CTS}}$ and $\overline{\text{UART_RTS}}$ polarity through the UART_CTL.FCPOL bit.

On reset, when the UART is not yet enabled and the port multiplexing has not been programmed, the $\overline{\text{UART_RTS}}$ pin is not driven. Some applications require a resistor to pull the UART_RTS signal to either state during reset.

UART Event Control

Status flags in the UART_STAT register are available to signal data reception, parity, and error conditions, if necessary.

DMA and Interrupt Multiplexing

See the *Direct Memory Access (DMA)* chapter for information on DMA multiplexing. Several interrupts and DMA channels in the UART can be multiplexed.

NOTE: To operate in interrupt mode without using DMA channels, set the UART_IMSK.ELSI bit. This configuration redirects receive and transmit requests to the status interrupt output. The status interrupt goes directly to the SEC without going through the DMA controller.

Interrupt Masks

Each UART features a set of interrupt mask registers: UART_IMSK, UART_IMSK_SET, and UART_IMSK_CLR. The UART_IMSK register supports read/write operations. Writing ones to the UART_IMSK_SET register enables interrupts, writing ones to the UART_IMSK_CLR register disables them. Reads from either register return the enabled bits. This way, different interrupt service routines can control transmit, receive, and status interrupt requests independently and easily.

The UART module uses the UART_IMSK registers to enable requests for system handling of empty or full states of data registers. Unless polling is used as a means of action, the UART_IMSK.ERBFI and UART_IMSK.ETBEI bits in this register are normally set.

Each UART module has three interrupt outputs. It uses one for transmission, one for reception, and one for reporting status events. The UART module routes transmit and receive requests through the DMA controller. The status request goes directly to the system event controller (SEC).

If the associated DMA channel is enabled, the request functions as a DMA request. If the DMA channel is disabled, it simply forwards the request to the SEC. A DMA channel must be associated with the UART module to enable transmit and receive interrupts. Otherwise, transmit and receive requests cannot be forwarded.

NOTE: To operate in interrupt mode without using DMA channels, set the UART_IMSK.ELSI bit. This configuration redirects receive and transmit requests to the status interrupt request output. The status interrupt goes directly to the SEC without going through the DMA controller.

Interrupt Servicing

Interrupt service routines (ISRs) perform UART writes and reads. Separate interrupt lines are provided for transmit, receive, and status. The UART_IMSK register group enables the independent interrupts individually. To enable UART transmit interrupts, set the UART_CTL.EN bit.

The ISRs evaluate the status bits in the UART_STAT register to determine the signaling interrupt source. The system event controller for the processor assigns and unmasks interrupts. The ISRs must clear the interrupt latches explicitly. To reduce interrupt frequency on the receive side in core mode, use the UART_IMSK.ERFCI status interrupt as an alternative to the regular UART_IMSK.ERBFI receive interrupt. Hardware must ensure that at least two (if UART_CTL.RFIT=0) or four (if UART_CTL.RFIT=1) words are available in the receive buffer by the time the interrupt is requested.

Transmit Interrupts

The UART module uses the UART_IMSK_SET.ETBEI bit to enable transmit interrupt requests.

The UART_THR and UART_TAIP registers are the same physical register, and both affect the signaling of the UART_STAT.TEMT, UART_STAT.TFI, and UART_STAT.THRE bits similarly.

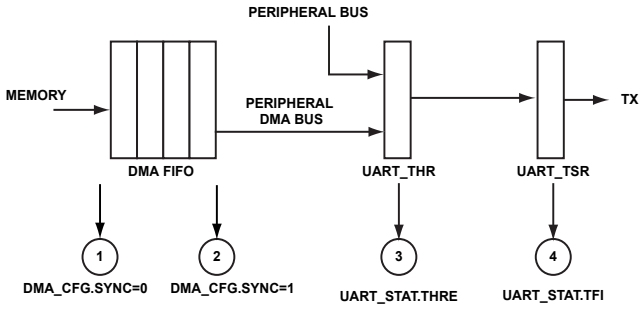

Figure 24-9: Transmit Interrupts

The UART module asserts the transmit request along with the `UART_STAT.THRE` bit, indicating that the transmit buffer is ready for new data. The `UART_STAT.THRE` bit resets to 1. When the `UART_IMSK_SET.ETBEI` bit is set, the UART module immediately issues an interrupt or DMA request. This way, no special handling of the first character is required when transmission of a string is initiated. Set the `UART_IMSK_SET.ETBEI` bit and let the interrupt service routine load the first character from memory and write it to the `UART_THR` register in the normal manner. ISRs can clear the `UART_IMSK.ETBEI` bit through the `UART_IMSK_CLR` register when the string transmission has completed.

Hardware clears the `UART_STAT.THRE` bit when new data is written to the `UART_THR` register. These write operations also clear the transmit interrupt request. However, they also initiate further transmission. If continued transmission is undesirable, the UART module can alternatively clear the transmit request through the `UART_IMSK_CLR.ETBEI` bit register. Transfers of data from the `UART_THR` register to the `UART_TSR` register reset this status flag in the `UART_STAT` register.

ISRs can interrogate the `UART_STAT.TEMT` bit to discover any ongoing transmission. The sticky counterpart of the `UART_STAT.TEMT` bit, `UART_STAT.TFI`, indicates when the transmit buffer has drained and can trigger a status interrupt. When data is pending in either one of these registers, the `UART_STAT.TEMT` flag is low. As soon as all data has left the `UART_TSR` register, the `UART_STAT.TEMT` bit goes high again and indicates that all pending transmit operations (including stop bits) have finished. Then, it is safe to disable the `UART_CTL.EN` bit or to three-state off-chip line drivers. Then, the UART module can generate an interrupt either through the status interrupt channel when the `UART_IMSK.ETFI` bit is set, or through the DMA controller when enabled by the `UART_IMSK.EDTPTI` bit.

When enabled by the `UART_IMSK.ETBEI` bit, the `UART_STAT.THRE` flag requests data along the peripheral command lines to the DMA controller (referred to as TXREQ). This signal is routed through the DMA controller. If the associated DMA channel is enabled, the TXREQ signal functions as a DMA request, otherwise the DMA controller simply forwards it to the SEC. Alternatively the `UART_IMSK.ETXS` bit can redirect the transmit interrupts to the UART status interrupt.

With interrupts disabled, the UART module can poll the status flags to determine when data is ready to move. Because polling is processor intensive; it is not typically used in real-time signal processing environments. Since read operations from `UART_STAT` registers have no side effects, different software threads can interrogate these registers without mutual impacts.

Polling the SEC_SSTAT[n] register without enabling the interrupts by the SEC_CCTL[n] register is an alternate method of operation to consider. Software can write up to two words into the UART_THR register before enabling the UART clock. As soon as the UART_CTL.EN bit is set, the UART module sends those two words.

Receive Interrupts

The UART module uses the UART_IMSK_SET.ERBFI bit to enable receive interrupt requests. If set, the UART_STAT.DR flag requests an interrupt on the dedicated RXREQ output, indicating that new data is available in the UART_RBR register. This signal is routed through the DMA controller. If the associated DMA channel is enabled, the RXREQ signal functions as a DMA request; otherwise the DMA controller simply forwards it to the SEC. Alternatively, if no DMA channel is assigned to the UART, the UART_IMSK.ERXS bit can redirect the receive interrupts to the UART status interrupt. When software reads the UART_RBR register, hardware clears the UART_STAT.DR bit again, which, in turn, clears the receive interrupt request.

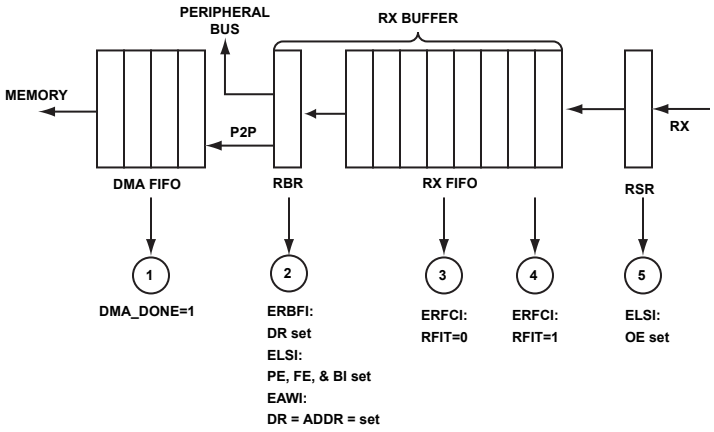

Figure 24-10: Receive Interrupts

Hardware updates the following:

- UART_STAT.DR bits
- UART_STAT.ADDR bits
- UART_STAT.ASTKY bits
- UART_STAT.PE bits
- UART_STAT.FE bits
- UART_STAT.BI bits
- UART_RBR register

The UART_STAT.OE bit is updated as soon as an overflow condition occurs (for example when a stop bit for a frame is received and the receive FIFO is full). When software does not read the UART_RBR register in time, the received data is protected from being overwritten by new data until software clears the UART_STAT.OE bit. Only the content of the UART_RSR register can be overwritten in the overrun case.

The UART module uses the UART_STAT.RFCS bit to monitor the state of the 8-deep receive FIFO. It uses the UART_CTL.RFIT bit to control the behavior of the buffer. If UART_CTL.RFIT is zero, the UART_STAT.RFCS bit is set when the receive buffer holds four or more words. If UART_CTL.RFIT is set, the UART_STAT.RFCS bit is set when the receive buffer holds seven or more words. Hardware clears the UART_STAT.RFCS bit when a core or DMA reads the UART_RBR register and when the buffer is flushed below the level of four (UART_CTL.RFIT=0) or seven (UART_CTL.RFIT=1). If the associated interrupt bit UART_IMSK.ERFCI is enabled, a status interrupt request is reported when the UART_STAT.RFCS bit is set.

If errors are detected during reception, an interrupt can be requested from the status interrupt output. This status interrupt request goes directly to the SEC. The bit enables status interrupt requests.

The controller detects the following error conditions, shown with their associated bits in the UART_STAT register.

- Overrun error (UART_STAT.OE bit)
- Parity error (UART_STAT.PE bit)
- Framing error or invalid stop bit (UART_STAT.FE bit)
- Break indicator (UART_STAT.BI bit)

Status Interrupts

The UART module uses status interrupt channels for the following purposes:

- Line status interrupt requests
- Flow control interrupt requests
- Receive FIFO threshold interrupt requests
- Transmission finished interrupt request

The UART module uses the UART_IMSK.ELSI bit to enable the line status interrupts. If set, the status interrupt request is asserted with one of the UART_STAT.BI, UART_STAT.FE, UART_STAT.PE, or UART_STAT.OE receive errors bits. A W1C operation to the UART_STAT register clears the error bits. Once all error conditions are cleared, the interrupt request deasserts.

The UART module uses the UART_IMSK_SET.ERFCI bit to enable the receive FIFO count interrupt. If set, a status interrupt request is generated when the UART_STAT.RFCS is active. The UART_STAT.RFCS bit indicates a receive buffer threshold level. If the UART_CTL.RFIT bit is cleared, software can safely read two words out of the UART_RBR register by the time the UART_STAT.RFCS interrupt occurs.

If the UART_CTL.RFIT bit is set, software can safely read four words. The interrupt request and the UART_STAT.RFCS bit are cleared when the UART_RBR is read enough of times, so that the receive buffer drains below the threshold of two (UART_CTL.RFIT=0) or four (UART_CTL.RFIT=1). Because in DMA mode a status service routine may not be permitted to read UART_RBR, this interrupt is only recommended in core mode. In DMA mode, use this functionality for error recovery only.

The UART module uses the UART_IMSK_SET.EDSSI bit to enable the flow control interrupts. If active, a status interrupt is generated when the sticky UART_STAT.SCTS bit register is set, indicating that the UART_CTS input of the transmitter been reasserted. A W1C operation to the UART_STAT.SCTS bit clears the interrupt request.

The UART module uses the UART_IMSK_SET.ETFI bit to enable the transmission finished interrupt. If active, a status interrupt request is asserted when the UART_STAT.TFI bit is set. The UART_STAT.TFI is the sticky version of the UART_STAT.TEMT bit, indicating that a byte that started transmission has finished. A W1C operation to the UART_STAT.TFI bit clears the interrupt request.

Multi-Drop Bus Events

Several status bits and interrupt features in the UART_STAT and UART_IMSK registers facilitate efficient data handling in multi-drop bus mode. These features include the address (UART_STAT.ADDR) bit, the address sticky (UART_STAT.ASTKY) bit and the enable address word interrupt (UART_IMSK.EAWI). One of the key features of the multi-drop bus protocol is its address bit. The address bit signifies to the completer that the requester is transmitting an address word (all read it) or a data word (only the addressed target reads its). The UART hardware provides an efficient method of handling the situation described with the use of UART_STAT.ASTKY bit.

NOTE: The UART module uses the UART_STAT.ASTKY bit in multi-drop bus mode to indicate when an address operation for a peripheral is occurring. The UART_STAT.ASTKY bit is a sticky version of the UART_STAT.ADDR bit. Hardware sets the bit whenever the UART_STAT.ADDR bit is set. Only software clears it with a W1C operation. With the UART_STAT.ASTKY bit set, words are received iregardless of the mode bit or address bit setting. With the UART_STAT.ASTKY bit cleared, only address words (mode bit =1) are received and words with mode bit =0 are ignored in MDB mode. This bit does not affect reception in non-MDB modes. (Words with mode bit =0 are not moved from the UART_RSR register to the receive FIFO.)

UART Programming Model

The following sections provide basic procedures for configuring various UART operations.

Detecting Autobaud

To detect Autobaud:

1. Ensure that the timer is disabled.
2. Configure the following bits: UART_CTL.MOD =00, UART_CTL.LOOP_EN =1, UART_CTL.WLS =11 (8-bit data), and UART_CTL.EN =1
3. Configure the following bits: TIMER_TMR[n]_CFG.TMODE =1101, TIMER_TMR[n]_CFG.OUTDIS =1, TIMER_TMR[n]_CFG.IRQMODE =10 and enable the timer.
4. Send test data through the host device and wait for the timer interrupt and disable the timer.

   The bit rate can be derived from the timer period register value according to the formula provided in the Autobaud Detection section.

Using Common Initialization Steps

When using the core or the DMA to execute transfers, the following steps are common to all UART modes.

1. All UART signals are multiplexed and compete with other functions at pin level. First, program the port registers according to the guidelines in the PORT chapter.
2. Program the UART_CLK register. Refer to Bit Rate Generation topic.
3. Program the UART_CTL register and enable the UART clock.

Using Core Transfers

Write data into the UART_THR register, when the UART_STAT.THRE bit is set, to initiate a core transmit operation. If the UART_STAT.DR bit is set, received data can be read from the UART_RBR register.

Using DMA Transfers

1. Make sure that the UART_IMSK.ETBEI or the UART_IMSK.ERBFI bits are cleared before configuring the DMA.
2. Configure the dedicated DMA channel.
3. Set the UART_IMSK.ETBEI or UART_IMSK.ERBFI bits to start the transfer.

Using Interrupts

Each UART features three interrupt signal outputs.

1. Enable individual interrupts in the system event controller (SEC)
2. Register IRQ handlers.
3. Use the interrupts mask registers to enable specific IRQ events.

Setting Up Hardware Flow Control

1. Configure automatic or manual hardware flow control for the receiver through the UART_CTL.ARTS bit, or the transmitter through the UART_CTL.ACTS bit.
2. Configure $\overline{\text{UART_CTS}}$ and $\overline{\text{UART_RTS}}$ polarity through the UART_CTL.FCPOL bit.

ADSP-SC59x UART Register Descriptions

UART (UART) contains the following registers.

Table 24-9: ADSP-SC59x UART Register List

Name	Description
UART_CLK	Clock Rate Register

Table 24-9: ADSP-SC59x UART Register List (Continued)

Name	Description
UART_CTL	Control Register
UART_IMSK	Interrupt Mask Register
UART_IMSK_CLR	Interrupt Mask Clear Register
UART_IMSK_SET	Interrupt Mask Set Register
UART_RBR	Receive Buffer Register
UART_RSR	Receive Shift Register
UART_RXCNT	Receive Counter Register
UART_SCR	Scratch Register
UART_STAT	Status Register
UART_TAIP	Transmit Address/Insert Pulse Register
UART_THR	Transmit Hold Register
UART_TSR	Transmit Shift Register
UART_TXCNT	Transmit Counter Register

Clock Rate Register

The UART_CLK register divides the system clock (SCLK0) down to the bit clock.

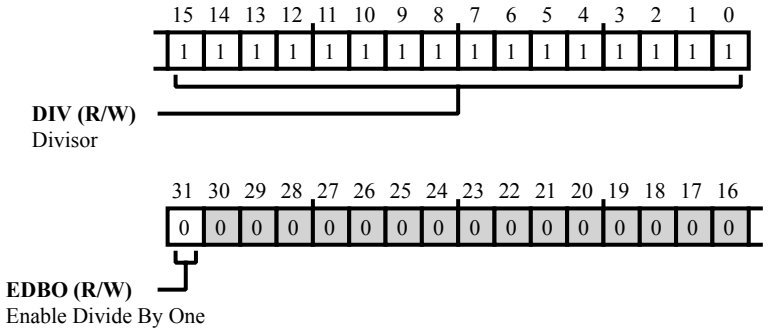

Figure 24-11: UART_CLK Register Diagram

Table 24-10: UART_CLK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	EDBO	Enable Divide By One. The UART_CLK.EDBO bit enables the bypassing of the divide-by-16 prescaler in bit clock generation. This functionality improves bit rate granularity, especially at high bit rates. Do not set this bit in IrDA mode. Note: Properly select the SCLK frequencies. Even multiples of bit rate decrease the error percentage. Setting the bit clock equal to the sample clock (UART_CLK.EDBO =1) improves the bit rate granularity and the bit clock matches with the bit rate of the communication partner. The disadvantage is that the power dissipation is higher and sample points are not always accurate. Therefore, use UART_CLK.EDBO=1 mode only when bit rate accuracy is not acceptable in the UART_CLK.EDBO=0 mode. The UART_CLK.EDBO=1 mode is not intended to increase the speed of operation beyond the electrical limitations of the UART transfer protocol.	
		0	Bit clock prescaler = 16
		1	Bit clock prescaler = 1
15:0 (R/W)	DIV	Divisor. The UART_CLK.DIV provides the divisor for the UART's clock bit rate calculation. The bit rate is defined by: Bit Rate = SCLK0 / ($16^{(1-EDBo)}$ x UART_CLK.DIV)	

Control Register

The UART_CTL register provides enable and disable control for UART and IrDA mode of operation. It also provides UART line control, permitting selection of the format of received and transmitted character frames. Modem feature control also is available from this register, including partial modem functionality to allow for hardware flow control and loopback mode.

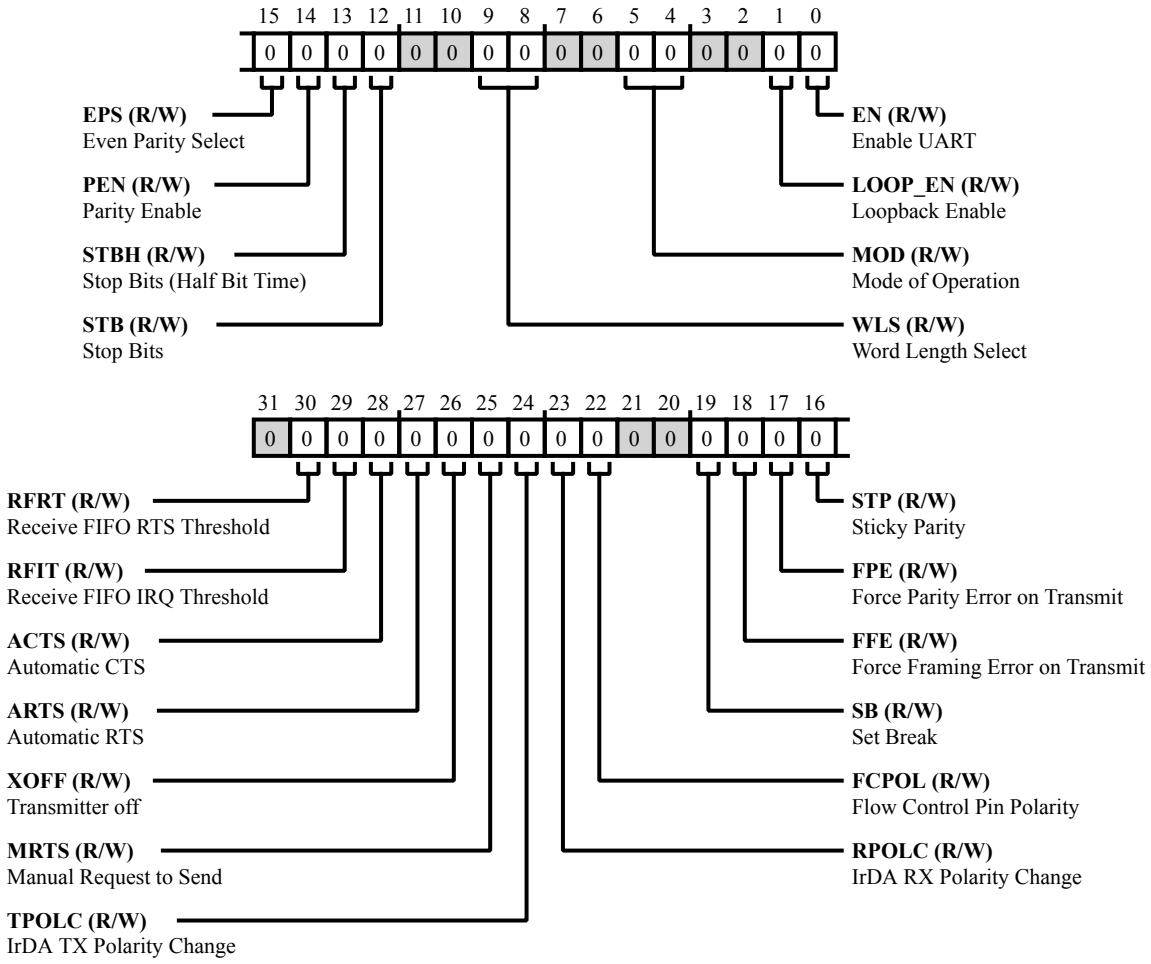

Figure 24-12: UART_CTL Register Diagram

Table 24-11: UART_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
30 (R/W)	RFRT	Receive FIFO RTS Threshold. The UART_CTL.RFRT bit controls UART_RTS pin assertion and deassertion timing. This bit is ignored if UART_CTL.ARTS is cleared. If set, the UART_RTS pin is deasserted when the receive buffer already holds seven words and an eighth start bit is detected. It is reasserted when the FIFO contains seven words or less. If cleared, the UART_RTS pin is deasserted when the RX buffer already holds four words and a fifth start bit is detected. The UART_RTS pin is reasserted when the RX buffer contains no more than 4 words.	
		0	Deassert RTS if RX FIFO word count > 4; assert if <= 4
		1	Deassert RTS if RX FIFO word count > 7; assert if <= 7
29 (R/W)	RFIT	Receive FIFO IRQ Threshold. The UART_CTL.RFIT bit controls the timing of the UART_STAT.RFCS bit. If UART_CTL.RFIT is cleared, the receive threshold is two. If UART_CTL.RFIT is set, the threshold is four words in the receive buffer.	
		0	Set RFCS=1 if RX FIFO count >= 4
		1	Set RFCS=1 if RX FIFO count >= 7
28 (R/W)	ACTS	Automatic CTS. The UART_CTL.ACTS bit must be set to enable the UART_CTS input pin for UART_TX handshaking. If enabled, the UART_STAT.CTS bit holds the value (if UART_CTL.FCPOL is set) or complement value (if UART_CTL.FCPOL is cleared) of the UART_CTS input pin. The UART_STAT.CTS bit can be used to determine whether the external device is ready to receive data (if UART_STAT.CTS is set) or whether it is busy (if UART_STAT.CTS is cleared). If UART_CTL.ACTS is cleared, the UART_TX handshaking protocol is disabled, and the UART_TX line transmits data whenever there is data to send, regardless of the value of UART_CTS. Software can pause ongoing transmission by setting the UART_CTL.XOFF bit.	
		0	Disable TX handshaking protocol
		1	Enable TX handshaking protocol
27 (R/W)	ARTS	Automatic RTS. The UART_CTL.ARTS bit must be set to enable the UART_RTS input pin for UART_TX handshaking. If set, the hardware guarantees a minimal UART_RTS pin deassertion pulse width of at least the number of data bits defined by the UART_CTL.WLS bit field. If cleared, the UART_RTS pin is not generated automatically by hardware. The UART_RTS pin can still be manually controlled by the UART_CTL.MRTS bit, and software is responsible for UART_RTS pulse width control (if needed).	
		0	Disable RX handshaking protocol.
		1	Enable RX handshaking protocol.

Table 24-11: UART_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
26 (R/W)	XOFF	Transmitter off. The UART_CTL.XOFF bit (if set) turns off transmission (XOFF) by preventing the content of THR from being continued to TSR. When set, this bit turns on transmission (XON). The state of the UART_CTL.XOFF bit is ignored if the UART_CTL.ACTS bit is set.	
		0	Transmission ON, if ACTS=0
		1	Transmission OFF, if ACTS=0
25 (R/W)	MRTS	Manual Request to Send. The UART_CTL.MRTS bit controls the state of the UART_RTS output pin when the UART_CTL.ARTS bit is cleared. When UART_CTL.MRTS is cleared, the UART deasserts the UART_RTS pin, signaling to the external device that the UART is not ready to receive. When UART_CTL.MRTS is set, the UART asserts the UART_RTS pin, signaling to the external device that the UART is ready to receive.	
		0	Deassert RTS pin when ARTS=0
		1	Assert RTS pin when ARTS=0
24 (R/W)	TPOLC	IrDA TX Polarity Change. The UART_CTL.TPOLC bit selects the active low or high polarity for IrDA communications. This bit is effective only in IrDA mode. If set, in IrDA mode, the UART_TX pin idles high. In UART or MDB mode, it is inverted-NRZ. If cleared, in IrDA mode, the UART_TX pin idles low. In UART or MDB mode, it is NRZ.	
		0	Active-low TX polarity setting
		1	Active-high TX polarity setting
23 (R/W)	RPOLC	IrDA RX Polarity Change. The UART_CTL.RPOLC bit selects the active low or high polarity for IrDA communications. This bit is effective only in IrDA mode. If set, in IrDA mode, the UART_RX pin idles high. In UART or MDB mode, it is inverted-NRZ. If cleared, in IrDA mode, the UART_RX pin idles low. In UART or MDB mode, it is NRZ.	
		0	Active-low RX polarity setting
		1	Active-high RX polarity setting

Table 24-11: UART_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
22 (R/W)	FCPOL	Flow Control Pin Polarity. The UART_CTL.FCPOL bit selects the polarities of the UART_CTS and UART_RTS pins. When the UART_CTL.FCPOL bit is cleared, the UART_RTS and UART_CTS pins are active low, and the UART is halted when the UART_RTS and UART_CTS pin state is high. When UART_CTL.FCPOL bit is set, the UART_RTS and UART_CTS pins are active high, and the UART is halted when the UART_RTS and UART_CTS pin state is low.	
		0	Active low CTS/RTS
		1	Active high CTS/RTS
19 (R/W)	SB	Set Break. If set, the UART_CTL.SB bit forces the UART_TX pin to low asynchronously, regardless of whether or not data is currently transmitted. This bit functions even when the UART clock is disabled. Because the UART_TX pin normally drives high, it can be used as a flag output pin, if the UART is not used. (For example, if UART_CTL.TPOLC is cleared, drive UART_TX pin low; or if UART_CTL.TPOLC is set, drive UART_TX pin high.)	
		0	No force
		1	Force TX pin to 0
18 (R/W)	FFE	Force Framing Error on Transmit. The UART_CTL.FFE bit is intended for test purposes. This bit is useful for debugging software, especially in loopback mode.	
		0	Normal operation
		1	Force error
17 (R/W)	FPE	Force Parity Error on Transmit. The UART_CTL.FPE bit is intended for test purposes. This bit is useful for debugging software, especially in loopback mode.	
		0	Normal operation
		1	Force parity error

Table 24-11: UART_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/W)	STP	Sticky Parity. The UART_CTL.STP bit controls whether the parity is generated by hardware based on the data bits or whether it is set to a fixed value. If this bit is cleared, the hardware calculates the parity bit value based on the data bits. Then, the EPS bit determines whether odd or even parity mode is chosen. If this bit is set, odd parity is used. That means that the total count of logical-1 data bits including the parity bit must be an odd value. Even parity is chosen by UART_CTL.STP cleared and UART_CTL.EPS set. Then, the count of logical-1 bits must be a even value. If the UART_CTL.STP bit is set, hardware parity calculation is disabled. In this case, the sent and received parity equals the inverted UART_CTL.EPS bit.	
		0	No forced parity
		1	Force (Stick) parity to defined value (if PEN=1)
15 (R/W)	EPS	Even Parity Select.	
		0	Odd parity
		1	Even parity
14 (R/W)	PEN	Parity Enable. The UART_CTL.PEN bit enables parity transmission and parity check. The UART_CTL.PEN bit inserts one additional bit between the most significant data bit and the first stop bit. The polarity of this so-called parity bit depends on data and the UART_CTL.STP and UART_CTL.EPS control bits. Both transmitter and receiver calculate the parity value. The receiver compares the received parity bit with the expected value and issues a parity error if they do not match. If the UART_CTL.PEN bit is cleared, the UART_CTL.STP and the UART_CTL.EPS bits are ignored.	
		0	Disable
		1	Enable parity transmit and check
13 (R/W)	STBH	Stop Bits (Half Bit Time).	
		0	0 half-bit-time stop bit
		1	1 half-bit-time stop bit
12 (R/W)	STB	Stop Bits. The UART_CTL.STB bit controls how many stop bits are appended to transmitted data.	
		0	1 stop bit
		1	2 stop bits

Table 24-11: UART_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9:8 (R/W)	WLS	Word Length Select. The UART_CTL.WLS field determines whether the transmitted and received UART word consists of 5, 6, 7, or 8 data bits.	
		0	5-bit word
		1	6-bit word
		2	7-bit word
		3	8-bit word
5:4 (R/W)	MOD	Mode of Operation. The UART_CTL.MOD selects the UART operation mode (UMOD).	
		0	UART mode
		1	MDB mode
		2	IrDA SIR mode
1 (R/W)	LOOP_EN	Loopback Enable. The UART_CTL.LOOP_EN bit enables UART loopback mode. When set, this bit disconnects the input of the receiver from the UART_RX pin, and internally redirects the transmit output to the receiver. The UART_TX pin remains active and continues to transmit data externally as well. Loopback mode also forces the UART_RTS pin to its deassertive state, disconnects the UART_CTS bit from the UART_CTS input pin, and directly connects the UART_CTL.MRTS bit to the UART_STAT.CTS bit. In loopback mode, setting the UART_CTL.MRTS bit sets the UART_STAT.CTS bit and enables the transmitter of the UART. Clearing the UART_CTL.MRTS bit clears the UART_STAT.CTS bit and disables the transmitter of the UART.	
		0	Disable
		1	Enable
0 (R/W)	EN	Enable UART. The UART_CTL.EN enables the UART clocks. This bit also resets the state machine and control registers when cleared. Using this bit to disable the UART -- when not used -- reduces power consumption.	
		0	Disable
		1	Enable

Interrupt Mask Register

The UART_IMSK register indicates the interrupt mask status (unmasked, if set, or masked, if cleared) of the UART status interrupt requests. This register is not a data register. Instead, it is controlled by the UART_IMSK_SET and UART_IMSK_CLR register pair. Writing ones to the UART_IMSK_SET register enables (unmasks) interrupt requests, and writing ones to the UART_IMSK_CLR register disables (masks) them. Reads from either register return the enabled bits.

The UART_IMSK register is used to enable requests for system handling of empty or full states of UART data registers. Unless polling is used as a means of action, the UART_IMSK.ERBFI and UART_IMSK.ETBEI bits are normally set. Setting this register without enabling system DMA causes the UART to notify the processor of the data inventory state using interrupts. For proper operation in this mode, system interrupts must be enabled, and appropriate interrupt handling routines must be present.

Each UART features three separate interrupt channels to handle the data transmit, data receive, and line status events independently, regardless of whether DMA is enabled or not. If no DMA channels are assigned to the UART, set the UART_IMSK.ELSI bit to reroute the transmit and receive interrupts to the status interrupt request output.

With system DMA enabled, the UART uses DMA to transfer data to or from the processor. Dedicated DMA channels are available for receive and transmit operations. Line error handling can be configured independently from the receive or transmit setup.

The DMA of the UART is enabled by first setting up the system DMA control registers and then enabling the UART_IMSK.ERBFI and UART_IMSK.ETBEI interrupts. This configuration is because the interrupt request lines double as DMA request lines. Depending on whether DMA is enabled or not, upon receiving these requests, the DMA control unit either generates a direct memory access or passes the UART interrupt on to the system interrupt handling unit(s). However, the error interrupt for the UART goes directly to the system interrupt handling unit(s), bypassing the DMA unit completely.

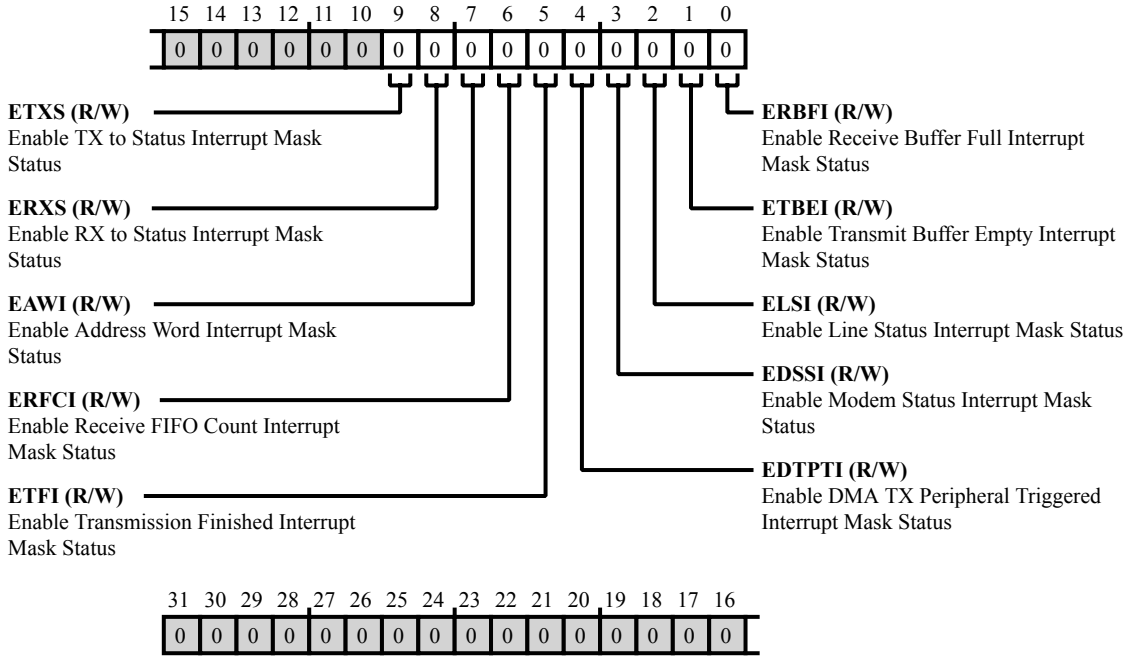

Figure 24-13: UART_IMSK Register Diagram

Table 24-12: UART_IMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W)	ETXS	Enable TX to Status Interrupt Mask Status. If set (interrupt unmasked), the `UART_IMSK.ETXS` bit indicates re-direction of the TX interrupt requests to status interrupt output. If cleared, TX interrupt requests are routed to normal interrupt outputs.	
		0	Interrupt is masked
		1	Interrupt is unmasked
8 (R/W)	ERXS	Enable RX to Status Interrupt Mask Status. If set (interrupt unmasked), the `UART_IMSK.ERXS` bit indicates re-direction of RX interrupt requests to status interrupt output. If cleared, RX interrupt requests are routed to normal interrupt outputs.	
		0	Interrupt is masked
		1	Interrupt is unmasked

Table 24-12: UART_IMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	EAWI	Enable Address Word Interrupt Mask Status. If set (interrupt unmasked), the UART_IMSK.EAWI bit indicates generation of a status interrupt request when an Address word in MDB-mode is present in the UART_RBR. A received word is an address word if the UART_STAT.ADDR bit is set.	
		0	Interrupt is masked
		1	Interrupt is unmasked
6 (R/W)	ERFCI	Enable Receive FIFO Count Interrupt Mask Status. If set (interrupt unmasked), the UART_IMSK.ERFCI bit indicates enabling of the receive buffer threshold interrupt request if signaled by the UART_STAT.RFCS bit. Read the UART_RBR register sufficient times to clear the interrupt request.	
		0	Interrupt is masked
		1	Interrupt is unmasked
5 (R/W)	ETFI	Enable Transmission Finished Interrupt Mask Status. If set (interrupt unmasked) the UART_IMSK.ETFI bit indicates enabling of interrupt generation on the status interrupt channel when the transmit buffer register, the transmit address register, and the transmit shift register are all empty as indicated by the UART_STAT.TFI. The UART_IMSK.ETFI interrupt can be used to avoid expensive polling of the UART_STAT.TEMT bit, when the UART clock or line drivers should be disabled after transmission has completed. W1C the UART_STAT.TFI bit to clear the interrupt request. In DMA operation, the UART_IMSK.ETFI bits functionality might be preferred.	
		0	Interrupt is masked
		1	Interrupt is unmasked
4 (R/W)	EDTPTI	Enable DMA TX Peripheral Triggered Interrupt Mask Status. If set (interrupt unmasked), the UART_IMSK.EDTPTI bit indicates enabling of the DMA completion interrupt request to be delayed until the data has left the UART completely. This bit is required for DMA transmit operation only. If set, the UART can generate a DMA interrupt request by the time the UART_STAT.TEMT bit goes high after the last DMA data word is transmitted. When UART_IMSK.EDTPTI is set, usually the DMA_CFG.INT field is cleared to 00 in a STOP mode DMA. This set up suppresses the normal completion interrupt request, and the UART_STAT.TEMT event is signaled through the DMA controller and triggers the DMA interrupt. If both (DMA_CFG.INT not 00 and UART_IMSK.EDTPTI set), two interrupts are requested at the end of a STOP mode DMA.	
		0	Interrupt is masked
		1	Interrupt is unmasked

Table 24-12: UART_IMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	EDSSI	Enable Modem Status Interrupt Mask Status. If set (interrupt unmasked), the UART_IMSK.EDSSI bit indicates enabling of a modem status interrupt request on the same status interrupt channel when the UART_STAT.SCTS bit is set. This indicates UART_CTS pin re-assertion. Write-1-to-clear (W1C) the UART_STAT.SCTS bit to clear the interrupt request.	
		0	Interrupt is masked
		1	Interrupt is unmasked
2 (R/W)	ELSI	Enable Line Status Interrupt Mask Status. If set (interrupt unmasked), the UART_IMSK.ELSI bit indicates that redirection of TX and RX interrupt requests to the status interrupt output of the UART by OR'ing them with the UART_STAT.OE, UART_STAT.PE, UART_STAT.FE, and UART_STAT.BI interrupt requests. Set this bit when no DMA channel is associated with the UART. Enabling UART_IMSK.ELSI disables the RX/TX interrupt channels and negates the UART_IMSK.EDTPTI bit.	
		0	Interrupt is masked
		1	Interrupt is unmasked
1 (R/W)	ETBEI	Enable Transmit Buffer Empty Interrupt Mask Status. If set (interrupt unmasked), the UART_IMSK.ETBEI bit indicates generation of a TX interrupt request if the UART_STAT.THRE bit is set.	
		0	Interrupt is masked
		1	Interrupt is unmasked
0 (R/W)	ERBFI	Enable Receive Buffer Full Interrupt Mask Status. If set (interrupt unmasked), the UART_IMSK.ERBFI indicates generation of an RX interrupt request if the UART_STAT.DR bit is set.	
		0	Interrupt is masked
		1	Interrupt is unmasked

Interrupt Mask Clear Register

The UART_IMSK indicates interrupt mask status (unmasked if set, masked if cleared) of UART status interrupts. This register is not a data register. Instead it is controlled by the UART_IMSK_SET and UART_IMSK_CLR register pair. Writing ones to UART_IMSK_SET enables (unmasks) interrupt requests, and writing ones to UART_IMSK_CLR disables (masks) them. Reads from either register return the enabled bits. For more information, see the UART_IMSK register description.

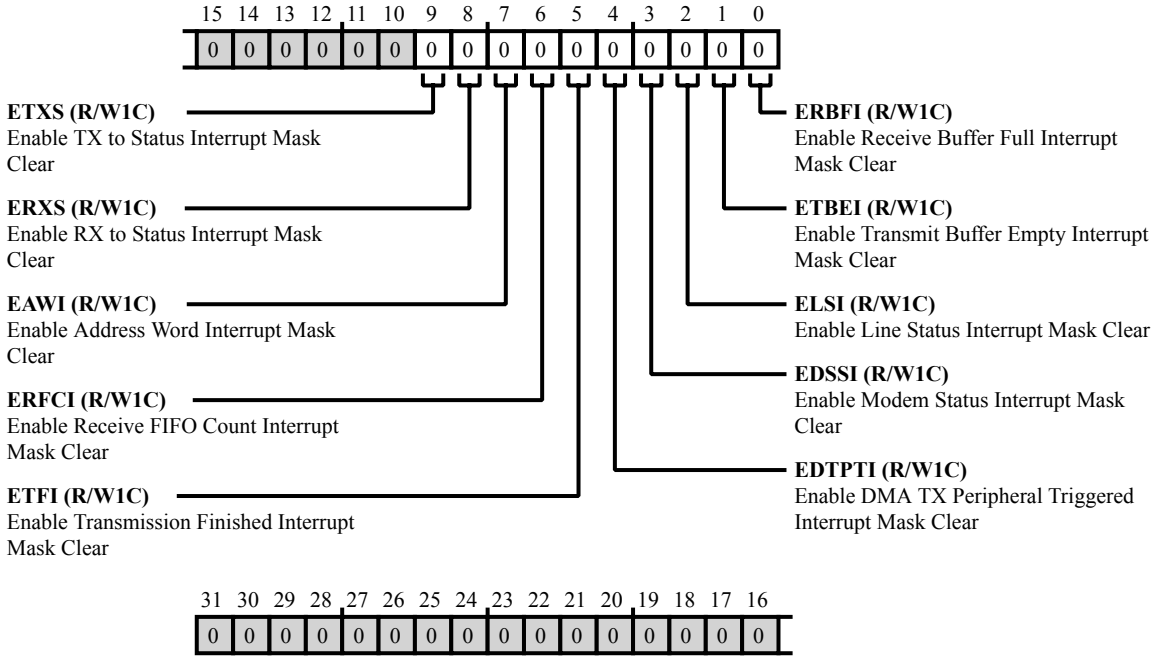

Figure 24-14: UART_IMSK_CLR Register Diagram

Table 24-13: UART_IMSK_CLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W1C)	ETXS	Enable TX to Status Interrupt Mask Clear.	
		0	No action
		1	Mask interrupt
8 (R/W1C)	ERXS	Enable RX to Status Interrupt Mask Clear.	
		0	No action
		1	Mask interrupt
7 (R/W1C)	EAWI	Enable Address Word Interrupt Mask Clear.	
		0	No action
		1	Mask interrupt

Table 24-13: UART_IMSK_CLR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6 (R/W1C)	ERFCI	Enable Receive FIFO Count Interrupt Mask Clear.	
		0	No action
		1	Mask interrupt
5 (R/W1C)	ETFI	Enable Transmission Finished Interrupt Mask Clear.	
		0	No action
		1	Mask interrupt
4 (R/W1C)	EDTPTI	Enable DMA TX Peripheral Triggered Interrupt Mask Clear.	
		0	No action
		1	Mask interrupt
3 (R/W1C)	EDSSI	Enable Modem Status Interrupt Mask Clear.	
		0	No action
		1	Mask interrupt
2 (R/W1C)	ELSI	Enable Line Status Interrupt Mask Clear.	
		0	No action
		1	Mask interrupt
1 (R/W1C)	ETBEI	Enable Transmit Buffer Empty Interrupt Mask Clear.	
		0	No action
		1	Mask interrupt
0 (R/W1C)	ERBFI	Enable Receive Buffer Full Interrupt Mask Clear.	
		0	No action
		1	Mask interrupt

Interrupt Mask Set Register

The UART_IMSK indicates interrupt request mask status (unmasked if set, masked if cleared) of UART status interrupts. This register is not a data register. Instead it is controlled by the UART_IMSK_SET and UART_IMSK_CLR register pair. Writing ones to UART_IMSK_SET enables (unmasks) interrupt requests, and writing ones to UART_IMSK_CLR disables (masks) them. Reads from either register return the enabled bits. For more information, see the UART_IMSK register description.

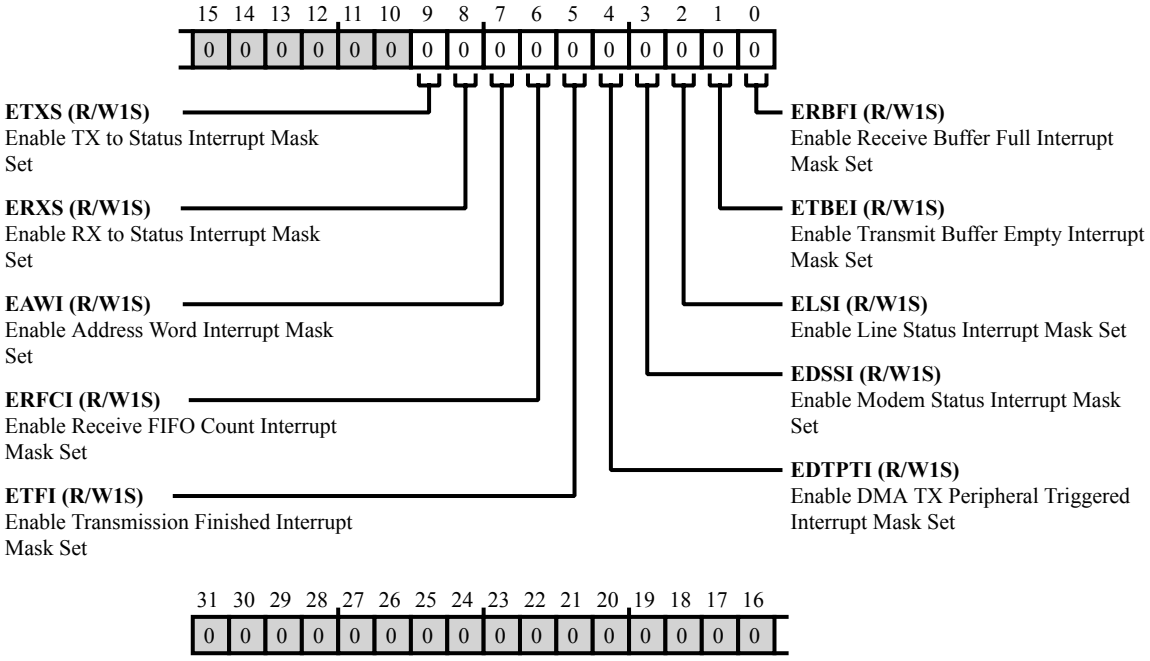

Figure 24-15: UART_IMSK_SET Register Diagram

1 (R/W1S)	ETBEI	Enable Transmit Buffer Empty Interrupt Mask Set.	
		0	No action
		1	Unmask interrupt
0 (R/W1S)	ERBFI	Enable Receive Buffer Full Interrupt Mask Set.	
		0	No action
		1	Unmask interrupt

Receive Buffer Register

The read-only UART_RBR register is the UART's receive buffer. It is updated when there is pending data in the receive FIFO. Newly available data is signaled by the UART_STAT.DR bit.

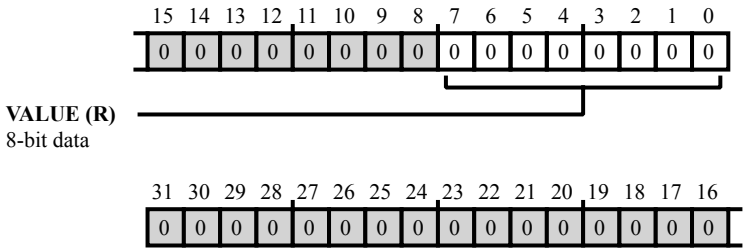

Figure 24-16: UART_RBR Register Diagram

Table 24-15: UART_RBR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/NW)	VALUE	8-bit data.

Receive Shift Register

The read only UART_RSR register which returns the content of the UART's receive shift register.

The frame data is moved into this shift register after polarity inversion, if any (including the native polarity inversion in the IrDA case).

In the case of the longest frame (MDB, with parity mode, and 8 bit data word-length), the start bit may be shifted out and not available for reading at the end of the frame reception. This register is NOT reset at the start of frame. If read, in the middle of a frame reception, data corresponding the previous frame may not have entirely shifted out (for example, the read data that have been read may NOT correspond entirely to the frame being received).

Because the UART is receiving only 1 stop bit, the UART_RSR contains only 1 stop bit even if more than one stop bit is present in the actual transfer. This register may be considered as storing the 10 most recently received bits (taking into consideration the stop bit receive limitation above).

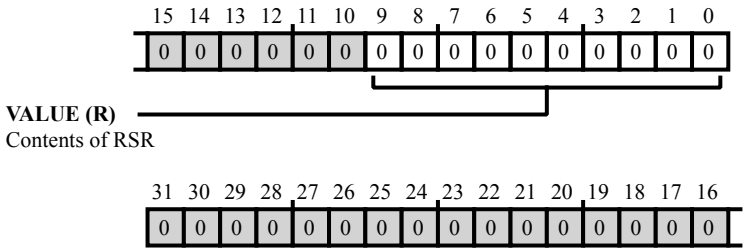

Figure 24-17: UART_RSR Register Diagram

Table 24-16: UART_RSR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
9:0 (R/NW)	VALUE	Contents of RSR.

Receive Counter Register

The UART_RXCNT register returns the content of 16-bit counter in the UART receiver. This count is used for baud rate clock generation (the lower [15:0] is the count data).

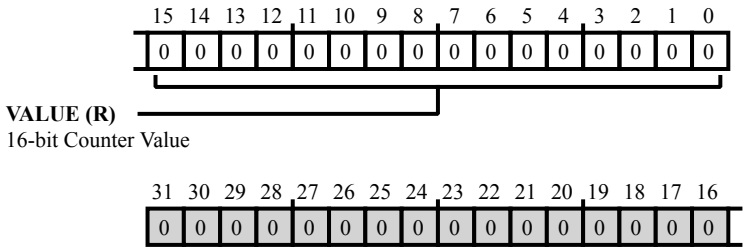

Figure 24-18: UART_RXCNT Register Diagram

Table 24-17: UART_RXCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	VALUE	16-bit Counter Value.

Scratch Register

The UART_SCR registers contain 8-bit scratch pad data. These registers are used for general purpose data storage and do not control the UART hardware in any way.

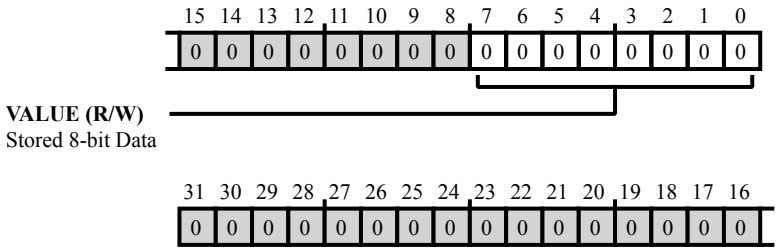

Figure 24-19: UART_SCR Register Diagram

Table 24-18: UART_SCR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	VALUE	Stored 8-bit Data.

Status Register

The UART_STAT register contains the UART line status and UART modem status, as indicated by the current states of the UART's UART_CTS pin and internal receive buffers. Writes to this register can perform write-one-to-clear (W1C) operations on most status bits. Reading this register has no side effects.

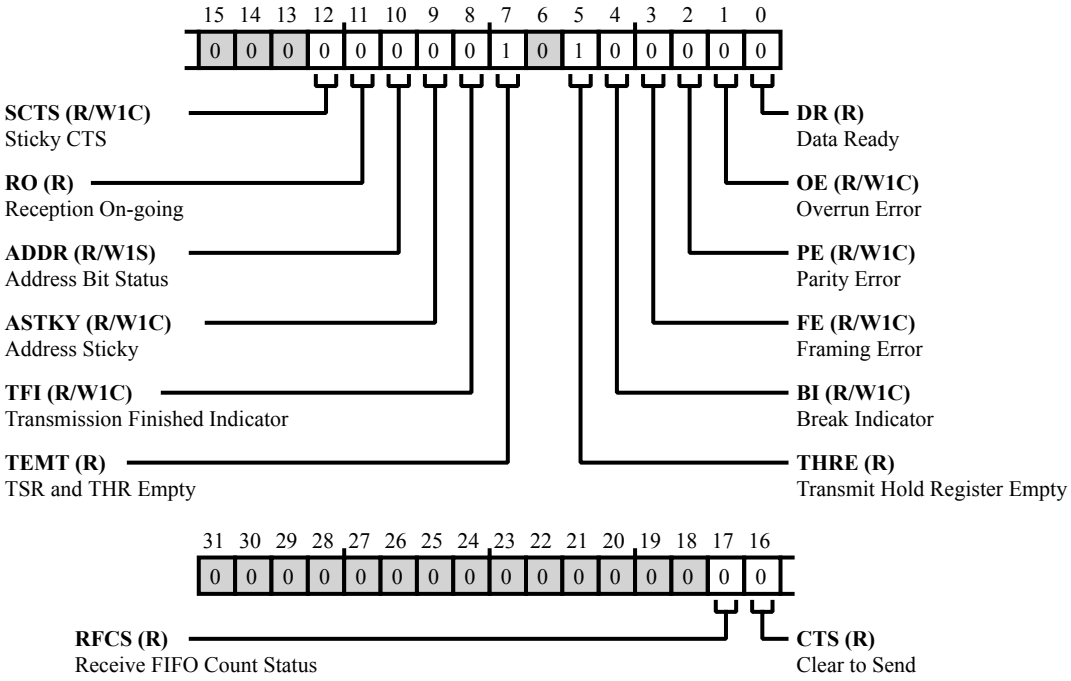

Figure 24-20: UART_STAT Register Diagram

Table 24-19: UART_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/NW)	RFCS	Receive FIFO Count Status. The UART_STAT.RFCS bit is set when the receive buffer holds more or equal entries than a certain threshold. The threshold is controlled by the UART_CTL.RFIT bit. If UART_CTL.RFIT is cleared, the threshold is four entries. If UART_CTL.RFIT is set, the threshold is seven entries. The UART_STAT.RFCS bit is cleared when the UART_RBR register is read sufficient times until the buffer is drained below the threshold. The UART_STAT.RFCS bit can trigger a status interrupt request if enabled by the UART_IMSK_SET.ERFCI bit.	
		0	RX FIFO has less than 4 (7) entries when RFIT=0 (1)
		1	RX FIFO has at least 4 (7) entries when RFIT=0 (1)

Table 24-19: UART_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/NW)	CTS	Clear to Send. The UART_STAT.CTS bit holds the value (if UART_CTL.FCPOL set) or the complement value (if UART_CTL.FCPOL cleared) of the UART_CTS input pin. The UART_CTL.ACTS bit must be set to enable this feature. The core can read the value of the UART_STAT.CTS bit to determine whether the external device is ready to receive (UART_STAT.CTS set) or if it is busy (UART_STAT.CTS cleared). If UART_CTL.ACTS is cleared, the UART_TX handshaking protocol is disabled, and the UART transmits data as long as there is data to transmit, regardless of the value of UART_STAT.CTS. When UART_CTL.ACTS is cleared, the software can pause transmission temporarily by setting the XOFF bit. Note that in loopback mode (UART_CTL.LOOP_EN set), the UART_STAT.CTS bit is disconnected from the UART_CTS input pin. Instead, the bit is directly connected to the UART_CTL.MRTS bit.	
		0	Not clear to send (External device not ready to receive)
		1	Clear to send (External device ready to receive)
12 (R/W1C)	SCTS	Sticky CTS. The UART_STAT.SCTS bit is a sticky bit that is set when UART_STAT.CTS transitions from 0 to 1. The UART_STAT.SCTS bit is cleared by software with a W1C operation. This bit can trigger a line status interrupt request if enabled by the UART_IMSK_SET.EDSSI bit.	
		0	CTS has not transitioned from low to high
		1	CTS has transitioned from low to high
11 (R/NW)	RO	Reception On-going.	
		0	No data reception in progress
		1	Data reception in progress
10 (R/W1S)	ADDR	Address Bit Status. The UART_STAT.ADDR bit is used to mirror the address bit of the word in UART_RBR in multi-drop bus protocol, and is enabled only in MDB mode. The UART_STAT.ADDR bit is updated by hardware upon detecting a received word with the address bit in UART_RBR set or cleared. Additionally, software can set the ADDR bit with a write-1-to-set (W1S) operation.	
		0	Address bit is low
		1	Address bit is high

Table 24-19: UART_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W1C)	ASTKY	Address Sticky. The UART_STAT.ASTKY bit is used in multi-drop bus mode to indicate whether a peripheral is currently being addressed. This bit is a sticky version of the UART_STAT.ADDR bit and is set by hardware when setting the UART_STAT.ADDR bit. The UART_STAT.ASTKY bit can only be cleared by software with a write-one-to-clear (W1C) operation. With the UART_STAT.ASTKY bit set, words will be received irrespective of the UART_CTL.MOD bit or UART_STAT.ADDR bit selection. With the UART_STAT.ASTKY bit cleared, only address words (UART_CTL.MOD bit set) will be received and words with UART_CTL.MOD bit cleared are ignored (not moved from the RSR to the RX FIFO) in MDB mode. The UART_STAT.ASTKY bit does not affect reception in non-MDB modes.	
		0	ADDR bit has not been set
		1	ADDR bit has been set
8 (R/W1C)	TFI	Transmission Finished Indicator. The UART_STAT.TFI bit is a sticky version of the UART_STAT.TEMT bit. While UART_STAT.TEMT is automatically cleared by hardware when new data is written to the UART_THR register, the sticky UART_STAT.TFI bit remains set, until it is cleared by software (W1C). The UART_STAT.TFI bit enables more flexible transmit interrupt request timing.	
		0	TEMT did not transition from 0 to 1
		1	TEMT transition from 0 to 1
7 (R/NW)	TEMT	TSR and THR Empty. The UART_STAT.TEMT bit indicates that the UART_THR and UART_TAIP registers and the UART_TSR register are empty. In this case, the program is permitted to write to the UART_THR and UART_TAIP registers twice without losing data. The UART_STAT.TEMT bit can also be used as indicator that pending UART transmission is completed. At that time, it is safe to disable the UART_CTL.EN bit or to three-state the off-chip line driver.	
		0	Not empty TSR/THR
		1	TSR/THR Empty

Table 24-19: UART_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (R/NW)	THRE	Transmit Hold Register Empty. The UART_STAT.THRE bit indicates that the UART transmit channel is ready for new data and software can write to the UART_THR and UART_TAIP registers. Writes to the UART_THR and UART_TAIP registers clear the UART_STAT.THRE. The bit is set again when the UART_THR and UART_TAIP registers are empty and ready to accept data.	
		0	Not empty THR/TAIP
		1	Empty THR/TAIP
4 (R/W1C)	BI	Break Indicator. The UART_STAT.BI bit indicates that the first stop bit is sampled low and the entire data word, including parity bit, consists of low bits only. (This condition indicates that UART_RX was held low for more than the maximum word length.) The UART_STAT.BI bit is updated simultaneously with the UART_STAT.DR bit, that is, by the time the first stop bit is received or when data is loaded from the receive FIFO to the UART_RBR register. The bit is sticky and can be cleared by W1C operations.	
		0	No break interrupt
		1	Break interrupt this indicates UARTxRX was held low(RPOLC=0) / high (RPOLC=1) for more than the maximum word length
3 (R/W1C)	FE	Framing Error. The UART_STAT.FE bit indicates that the first stop bit is sampled. This bit is updated simultaneously with the UART_STAT.DR bit, that is, by the time the first stop bit is received or when data is loaded from the receive FIFO to the UART_RBR register. The UART_STAT.FE bit is sticky and can be cleared by W1C operations. Note that invalid stop bits can be simulated by setting the UART_CTL.FFE bit.	
		0	No error
		1	Invalid stop bit error
2 (R/W1C)	PE	Parity Error. The UART_STAT.PE bit indicates that the received parity bit does not match the expected value. This bit is updated simultaneously with the UART_STAT.DR bit, that is, by the time the first stop bit is received or when data is loaded from the receive FIFO to the UART_RBR register. The UART_STAT.PE bit is sticky and can be cleared by W1C operations. Note that invalid parity bits can be simulated by setting the UART_CTL.FPE bit.	
		0	No parity error
		1	Parity error

Table 24-19: UART_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W1C)	OE	Overrun Error. The UART_STAT.OE bit indicates that further data is received while the internal receive buffer was full. This bit is set when sampling the stop bit of the sixth data word. To avoid overruns, read the UART_RBR register in time. In DMA receive mode, overruns are very unlikely to happen ever. After an overrun occurs, the UART_RBR and receive FIFO are protected from being overwritten by new data until the UART_STAT.OE bit is cleared by software. The content of the UART_RSR register is lost as soon as the overrun occurs. The UART_STAT.OE bit is sticky and can be cleared by W1C operations.	
		0	No overrun
		1	Overrun error
0 (R/NW)	DR	Data Ready. The UART_STAT.DR bit indicates that data is available in the receiver and can be read from the UART_RBR register. The bit is set by hardware when the receiver detects the first valid stop bit. The bit is cleared by hardware when the UART_RBR register is read.	
		0	No new data
		1	New data in RBR

Transmit Address/Insert Pulse Register

The UART_TAIP register and the UART_THR register share the same physical register, but UART_TAIP has different effect than the UART_THR register when UART_TAIP is written to in MDB and UART modes.

In MDB mode, data written to the UART_TAIP register is transmitted as an address frame (as with the UART_CTL.MOD bit set).

In UART mode, a write to UART_TAIP causes a pulse of value UART_TAIP [7] for a duration of UART_TAIP [6:0] x bit time. (There is additional inversion if the UART_CTL.TPOLC bit is set).

Bit time is defined by the UART_CLK register. The transmission of the pulse is followed by stop bit transmission as specified by the UART_CTL.STB and UART_CTL.STBH bits. This could be used for supporting line break command and inter-frame gap.

In IrDA mode, writes to UART_TAIP is treated the same as writes to UART_THR.

Accesses to the UART_TAIP register have the same affects as the UART_THR register with respect to the UART_STAT.THRE, UART_STAT.TEMT, and UART_STAT.TFI flags.

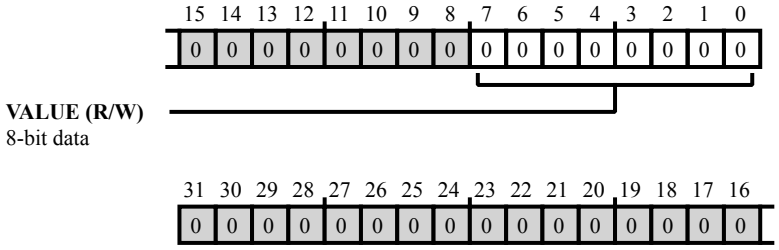

Figure 24-21: UART_TAIP Register Diagram

Table 24-20: UART_TAIP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	VALUE	8-bit data.

Transmit Hold Register

The write-only UART_THR register is the UART's transmit buffer. The UART_STAT.THRE bit indicates whether data can be written to UART_THR. Writes to this register automatically propagate to the internal UART_TSR register as soon as UART_TSR is ready. Then, transmit operation is initiated immediately.

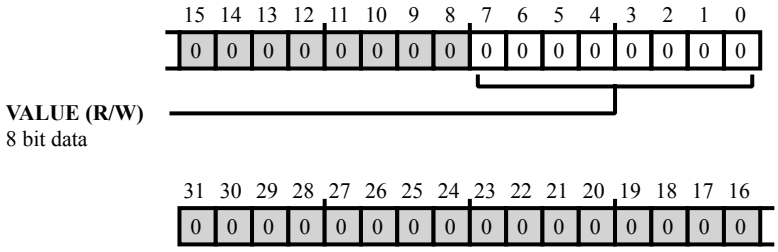

Figure 24-22: UART_THR Register Diagram

Table 24-21: UART_THR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	VALUE	8 bit data.

Transmit Shift Register

The read only UART_TSR register which returns the content of the UART's transmit shift register.

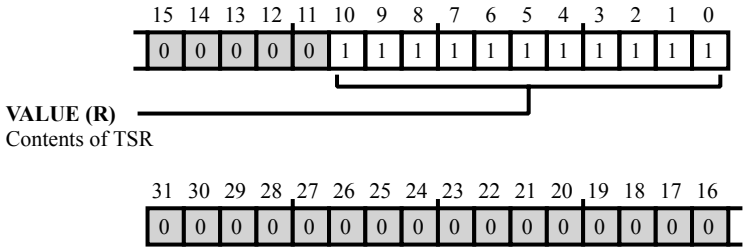

Figure 24-23: UART_TSR Register Diagram

Table 24-22: UART_TSR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
10:0 (R/NW)	VALUE	Contents of TSR.

Transmit Counter Register

The UART_TXCNT read only register returns the content of 16-bit counter in the UART transmitter. This count is used for baud rate clock generation (the lower [15:0] is the count data).

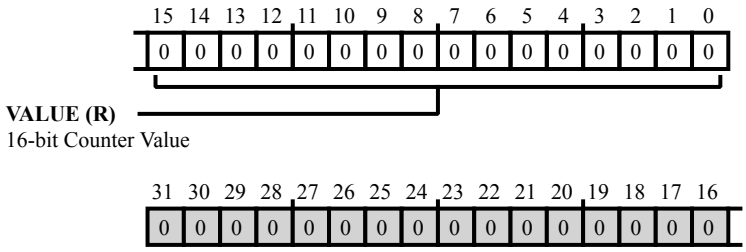

Figure 24-24: UART_TXCNT Register Diagram

Table 24-23: UART_TXCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	VALUE	16-bit Counter Value.

25 Enhanced Parallel Peripheral Interface (EPPI)

The Enhanced Parallel Peripheral Interface (EPPI) is a half-duplex, bidirectional port with a dedicated clock pin and three frame sync (FS) pins. It can support direct connections to active TFT LCDs, parallel A/D and D/A converters, video encoders and decoders, image sensor modules and other general-purpose peripherals. Each EPPI has two DMA channels associated with it. Moreover, in some modes, an EPPI can use an extra DMA channel.

EPPI Features

The EPPI module supports the following features.

- Programmable data length from 8 bits to up to 24 bits per clock cycle (depending on the product model)
- Bidirectional and half-duplex port
- Internal or external clock source
- Clock gating by an external device asserting the clock gating control signal
- Various framed and non-framed operating modes, as well as internal or external frame syncs
- Various general-purpose modes with 0, 1, 2, and 3 frame sync modes for both receive and transmit
- Ignores premature external frame syncs for data consistency
- SMPTE274M and SMPTE 296M high definition format support
- ITU-656, SMPTE 296M and SMPTE 274M status word error detection and correction for ITU-656 receive modes
- ITU-656, SMPTE 296M and SMPTE 274M receive modes – active video only, vertical blanking only, and entire field
- ITU-656, SMPTE 296M and SMPTE 274M preamble and status word decode
- Optional packing and unpacking of data to or from 32 bits from or to 8, 16 bits and 24 bits. If packing or unpacking is enabled, endianness can be altered to change the order of packing or unpacking of bytes/words
- Optional sign extension or zero-fill and alternate even or odd data sample filter for receive modes

- RGB888 to RGB666 or RGB565 conversion for transmit modes
- 4:2:2 YCrCb data Tx/Rx interleaving or de-interleaving modes
- Configurable LCD data enable (DEN) output available on frame sync 3
- Delayed start of PPI frame syncs
- Data clipping and mirroring
- Horizontal and vertical windowing for general purpose 2 and 3 frame sync modes
- Preamble, blanking and stripping support
- Multiplexing dual input

EPPI Functional Description

The EPPI has the following functionality.

RGB data formats

For transmit modes, the EPPI can convert RGB888 data in memory to either RGB565 or RGB666 at the output using bits in the Control register.

Data clipping

The EPPI contains two registers to define the lower and upper limits for the Luma and Chroma components. This functionality is used for clipping data values during 8-bit, 10-bit, 12-bit, or 16-bit transmit modes.

Data mirroring

A data mirroring feature is available which mirrors the EPPI data bits 15–0. This functionality is available in both transmit and receive modes.

Windowing

The EPPI supports windowing for general-purpose input modes.

Preamble, blanking and stripping support

The EPPI can embed blanking information and clip active data to be transmitted. This functionality is available for single channel data, interleaved data, and parallel data and supports data lengths equal to 16 bits, 20 bits or 24 bits.

ADSP-SC59x EPPI Register List

The EPPI is a half-duplex, bidirectional parallel port. It comprises a clock pin, 3 frame sync pins, and a set of data pins. For more information on EPPI functionality, see the EPPI register descriptions.

Table 25-1: ADSP-SC59x EPPI Register List

Name	Description
EPPI_CLKDIV	Clock Divide Register
EPPI_CTL	Control Register
EPPI_CTL2	Control Register 2 Register
EPPI_EVENCLIP	Clipping Register for EVEN (Luma) Data Register
EPPI_FRAME	Lines Per Frame Register
EPPI_FS1_DLY	Frame Sync 1 Delay Value Register
EPPI_FS1_PASPL	FS1 Period Register / EPPI Active Samples Per Line Register
EPPI_FS1_WLHB	FS1 Width Register / EPPI Horizontal Blanking Samples Per Line Register
EPPI_FS2_DLY	Frame Sync 2 Delay Value Register
EPPI_FS2_PALPF	FS2 Period Register / EPPI Active Lines Per Field Register
EPPI_FS2_WLVB	FS2 Width Register / EPPI Lines Of Vertical Blanking Register
EPPI_HCNT	Horizontal Transfer Count Register
EPPI_HDLY	Horizontal Delay Count Register
EPPI_IMSK	Interrupt Mask Register
EPPI_LINE	Samples Per Line Register
EPPI_ODDCLIP	Clipping Register for ODD (Chroma) Data Register
EPPI_STAT	Status Register
EPPI_VCNT	Vertical Transfer Count Register
EPPI_VDLY	Vertical Delay Count Register

ADSP-SC59x EPPI Interrupt List

Table 25-2: ADSP-SC59x EPPI Interrupt List

Interrupt ID	Name	Description	Sensitivity	DMA Channel
218	EPPI0_CH0_DMA	EPPI0 Channel 0 DMA	Level	28
219	EPPI0_CH1_DMA	EPPI0 Channel 1 DMA	Level	29
220	EPPI0_STAT	EPPI0 Status	Level

Trigger ID	Name	Description	Sensitivity
19	EPPI0_CH0_DMA	EPPI0 Channel 0 DMA	Pulse
20	EPPI0_CH1_DMA	EPPI0 Channel 1 DMA	Pulse

RGB Data Formats

For transmit modes, the EPPI can convert RGB888 data in memory to RGB666 at the output when the EPPI_CTL.RGBFMTEN bit is set and the EPPI_CTL.DLEN value is equal to 18 bits. Similarly, the EPPI can convert RGB888 data in memory to RGB565 at the output when the EPPI_CTL.RGBFMTEN bit is set and EPPI_CTL.DLEN is equal to 16 bits.

This conversion is performed as follows:

- If EPPI_CTL.PACKEN =1, the EPPI first unpacks according to the EPPI_CTL.SWAPEN bit setting, and the three 32-bit data words from the DMA are broken into four 24-bit data words to be transmitted out, as described earlier.
- If EPPI_CTL.PACKEN =0, the EPPI takes the lower 24 bits of the 32-bit DMA as the data to be transmitted. Then, the EPPI truncates this 24-bit data word to the required data width. It removes the lower 2 bits of G and the lower 2 bits or 3 bits of R and B.

Data Clipping

The EPPI contains two registers to define the lower and upper limits for the Luma and Chroma components. It uses these registers for clipping data values during 8-bit, 10-bit, 12-bit, or 16-bit transmit modes. All data values for odd samples which are less than the value in the EPPI_ODDCLIP.LOWODD bit field are replaced with the value in the EPPI_ODDCLIP.LOWODD field. All data values for even samples which are less than the value in the EPPI_EVENCLIP.LOWEVEN field are replaced with the value in the EPPI_EVENCLIP.LOWEVEN field.

In the same manner, all data values for odd samples which are more than the value in the EPPI_ODDCLIP.HIGHODD bit field are replaced with the value in the EPPI_ODDCLIP.HIGHODD field. All data values for even samples which are more than the values in the EPPI_EVENCLIP.HIGHEVEN field are replaced with the values in the EPPI_EVENCLIP.HIGHEVEN field.

Depending on the programmed EPPI length, only the corresponding bits (least aligned) are considered for clipping. For example, if the EPPI is programmed in 10-bit mode, bits 9:0 and bits 25:16 constitute the clipping thresholds. The higher bits are ignored. The EPPI supports 8-bit, 10-bit, 12-bit, and 16-bit clipping thresholds.

For the 4:2:2 YCrCb color space, Luma and Chroma typically have different lower and upper thresholds. Separate thresholds can be required for even and odd data samples. For monochrome (Y only) or some non-video clipping applications, the value in the EPPI_ODDCLIP.LOWODD field can be the same as the value in the EPPI_EVENCLIP.LOWEVEN field. The value in the EPPI_ODDCLIP.HIGHODD field can be the same as the value in the EPPI_EVENCLIP.HIGHEVEN field.

In GP 0 FS mode with internal blanking generation, clipping is valid only for the active video part of the transmitted data. ITU-R 656 preambles, status words, and blanking data bypass the clipping logic.

When the EPPI is programmed in 16-bit or 24-bit mode with the EPPI_CTL.SPLTWRD bit set, the YDATA (luma data) gets the clipping threshold levels of the EPPI_EVENCLIP register. The CDATA (chroma data) gets the clipping threshold levels of the EPPI_ODDCLIP register.

The clipping registers are ignored when the EPPI_CTL.RGBFMTEN bit is set.

Data Mirroring

To increase the pin multiplexing options for the EPPI data pins, a data mirroring feature is available which mirrors the EPPI data bits 15:0. This feature is available in both transmit and receive modes. It is enabled by setting the EPPI_CTL.DMIRR bit.

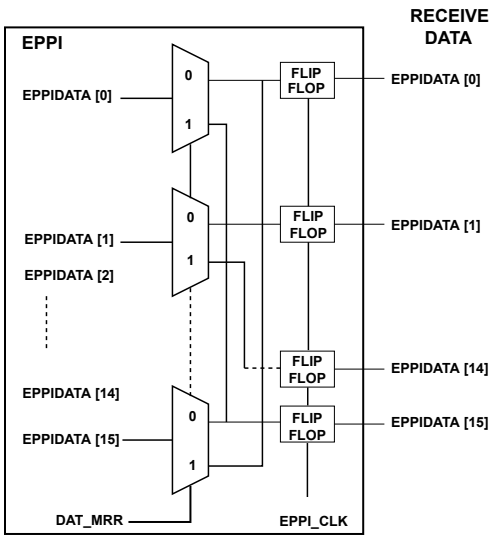

Figure 25-1: Data Mirroring Receive

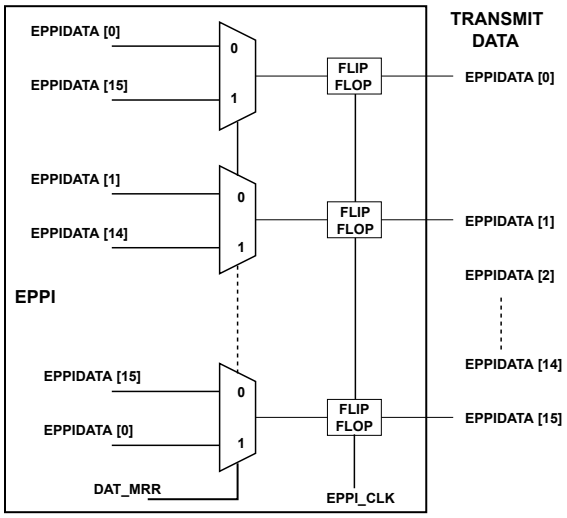

Figure 25-2: Data Mirroring Transmit

Windowing

The EPPI supports windowing for general-purpose input modes. The module can be configured to bring in a region of interest instead of the entire frame of data, which helps reduce bandwidth requirements.

Preamble, Blanking and Stripping Support

The EPPI supports embedding blanking information and clipping of active data for transmission. This functionality is available for single-channel data, interleaved data, and parallel data and supports a data length (`EPPI_CTL.DLEN`) of 16 bits or 24 bits.

Support of preamble generation or detection and stripping of blanking information is also provided for ITU656 mode and the SMPTE 274M and 296M HD formats. The ***Video Mode Comparison*** table shows the SMPTE standards in comparison with the ITU656 modes. Preambles for SMPTE and ITU656 modes are identical. Extension of preamble to 12 bits is also supported.

Table 25-5: Video Mode Comparison

Video Mode	Frame Rate	Frame Resolution	Active Video Resolution	Sampling Frequency (MHz)	Remarks
ITU656 (NTSC)	30	1716x525	720x480	27.02	Y-C interleaved
ITU656 (PAL)	25	1728x625	720x576	27.00	Y-C interleaved
SMPTE 296M	30	3300x750	1280x720	74.25	Y,C separate
	60	1650x750	1280x720	74.25	Y,C separate

Table 25-5: Video Mode Comparison (Continued)

Video Mode	Frame Rate	Frame Resolution	Active Video Resolution	Sampling Frequency (MHz)	Remarks
SMPTE 274M	30	2200x1125	1920x1080	74.25	Y,C separate
	60	2200x1125	1920x1080	148.50	Y,C separate
	25	2640x1125	1920x1080	74.25	Y,C separate
	50	2640x1125	1920x1080	148.50	Y,C separate
	24	2750x1125	1920x1080	74.25	Y,C separate

See the clock operating conditions section of the data sheet for the maximum sampling frequency for this product.

EPPI Definitions

The following definitions are helpful when using the EPPI module.

ITU-R BT.-656

Description of a digital video protocol for interfaces and data stream format required to send uncompressed PAL or NTSC standard definition TV (525 or 625 lines) signals.

YUV422

YUV is a color space where luminance (Y) and chrominance (UV) components define the pixels. The suffix signifies how the chrominance components have been decimated and provide formatting information. In this case, the YUV422 format has the chrominance decimated by two, meaning only half of each chrominance component is available. Typical YUV422 formatting interleaves the luminance and chrominance (for example, U1Y1V1Y2U2Y3V2Y4).

RGB888

RGB is a color space where three color values, one red (R), one green (G) and one blue (B), define the pixels. The suffix signifies the bit widths for these color components. In this case, RGB888 means that each red, green, and blue value is 8 bits.

RGB565

RGB is a color space where three color values, one red (R), one green (G) and one blue (B) define the pixels. The suffix signifies the bit widths for these color components. In this case, RGB565 means that the red (R) and blue (B) are 5 bits each while the green (G) is 6 bits. When packed together, each RGB565 pixel can be represented in a 16-bit data word. LCD display panels commonly use this format.

SMPTE 274M

An HD standard defining the spatial resolution (image sample structure) and frame rates for 1920x1080.

SMPTE 296M

An HD standard for defining the spatial resolution (image sample structure) and frame rates for 1280x720.

EPPI Block Diagram

The ***EPPI Block Diagram*** figure shows the functional blocks within the EPPI.

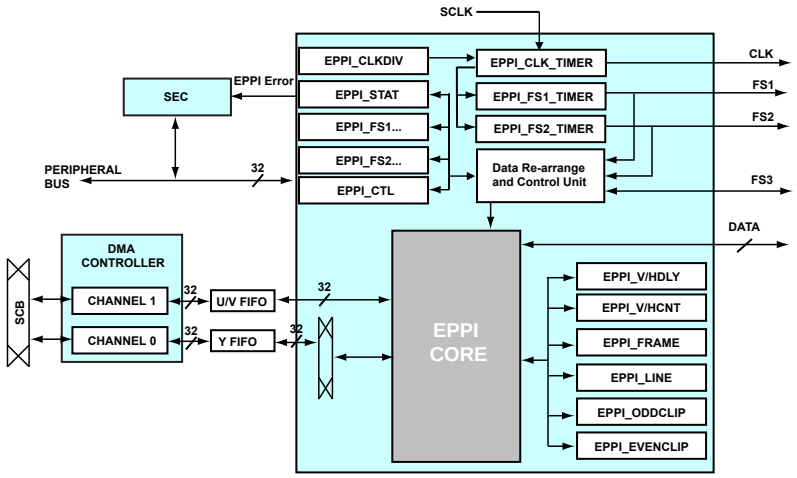

Figure 25-3: EPPI Block Diagram

EPPI Architectural Concepts

The following sections describe the architectural concepts.

- Reset Operation
- Frame Sync Polarity and Sampling Edge
- Direct Memory Access (DMA)
- EPPI Clock

Reset Operation

On a hardware reset, the entire EPPI is reset. All MMRs return to their default values. EPPI interrupt and DMA requests become inactive and internally generated `EPPI_CLK` and frame syncs are aborted.

In software, write 0 to the `EPPI_CTL.EN` bit to reset and reconfigure the EPPI. When disabled in this manner, only the `EPPI_STAT` register is cleared to its reset value. Interrupts and DMA requests become inactive and internally generated clock and frame syncs are aborted.

Frame Sync Polarity and Sampling Edge

The EPPI_CTL.POLS and EPPI_CTL.POLC bits provide a mechanism to select the active level of the frame syncs and the sampling or driving edge of the EPPI clock, respectively. This functionality allows the EPPI to connect to data sources and receivers with a wide array of control signal polarities. Often, the remote data source or receiver also offer configurable signal polarities. In these cases, the EPPI_CTL.POLS and EPPI_CTL.POLC bits add flexibility.

Table 25-6: Frame Sync Polarity Selections and Frame Sync Pin States

Bit Setting	Frame Sync 2	Frame Sync 1
POLS = b#00	Active high	Active high
POLS = b#01	Active high	Active low
POLS = b#10	Active low	Active high
POLS = b#11	Active low	Active low

Table 25-7: Clock Polarity Selections and Receive/Transmit Pin States

	Receive		Transmit	
Bit Setting	Sample Data	Sample/Drive Syncs	Drive Data	Sample/Drive Syncs
POLC = b#00	Falling edge	Falling edge	Rising edge	Rising edge
POLC = b#01	Falling edge	Rising edge	Rising edge	Falling edge
POLC = b#10	Rising edge	Falling edge	Falling edge	Rising edge
POLC = b#11	Rising edge	Rising edge	Falling edge	Falling edge

Direct Memory Access (DMA)

The EPPI has a native DMA controller with two channels. A local arbiter arbitrates between these channels and requests are forwarded to the system crossbar. The EPPI has one connection to the fabric.

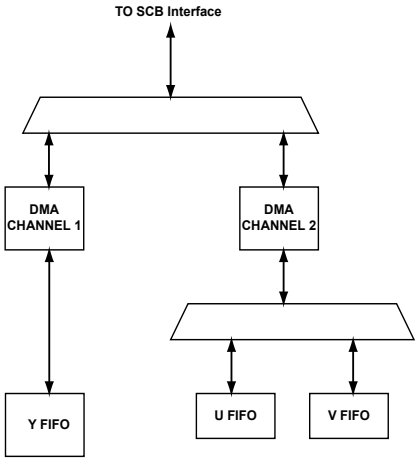

Figure 25-4: EPPI DMA Interface

The EPPI must be used with DMA. Configuring the EPPI DMA channels is a necessary step toward using the EPPI interface. The channels can be configured for either transmit or receive operation, plus have a maximum throughput of (EPPI_CLK) x (32 bits/transfer). In modes where data lengths permit, packing can increase transfer bandwidth.

The DMA engine generates interrupts at the completion of a row, frame, or partial-frame transfer. The DMA engine also coordinates the source or destination point for the data that is transferred through the EPPI.

The 2D DMA capability allows the processor to be interrupted at the end of a line or after a frame of video is transferred, or if a DMA error occurs. The DMA_XCNT and DMA_YCNT registers allow for flexible data interrupt points. For example, assume the DMA_XMOD = DMA_YMOD =1. If a data frame contains 320 × 240 bytes (240 rows of 320 bytes each), the following conditions hold.

- Setting DMA_XCNT =320, DMA_YCNT = 240, and DMA_CFG.INT =1 interrupts on every row transferred, for the entire frame.
- Setting DMA_XCNT =320, DMA_YCNT =240, and DMA_CFG.INT =2 interrupts only on the completion of the frame (when 240 rows of 320 bytes have been transferred).
- Setting DMA_XCNT =38,400 (320 x 120), DMA_YCNT =2, and DMA_CFG.INT =1 causes an interrupt when half of the frame is transferred, and again when the whole frame is transferred.

The following is the general procedure for setting up DMA operation with the EPPI.

1. Configure the DMA registers as appropriate for the desired DMA operating mode.
2. Enable the DMA channel for operation.
3. Configure appropriate EPPI registers.
4. Enable the EPPI by writing 1 to the EPPI_CTL.EN bit.

EPPI Clock

The EPPI can be supplied with an external clock, or the clock can be generated internally and supplied to external devices. For information on the maximum PPI_CLK specification in internal and external clock modes, see the product-specific data sheet.

When using an external EPPI_CLK, there can be up to two cycles latency before valid data is received or transmitted.

The internal clock can be generated from SCLK0 when the EPPI_CTL.ICLKGEN bit is set. The value in the EPPI_CLKDIV register determines the generated clock frequency. The internally generated EPPI clock frequency is:

$f_{PCLK} = f_{SCLK0}/(EPPI_CLKDIV + 1)$

where:

f_{PCLK} – frequency of internally generated EPPI clock

f_{SCLK} – frequency of SCLK0

EPPI_CLKDIV – Clock division value programmed in the EPPI_CLKDIV register.

The ***Relationship Between CLKDIV and the Ratio of SCLK0 to EPPI Clock*** table gives a few examples.

Table 25-8: Relationship Between CLKDIV and the Ratio of SCLK0 to EPPI Clock

CLKDIV15–0	EPPI/SCLK0 Clock Ratio
0x0002	1:3
0x0003	1:4
0x0004	1:5
0x0005	1:6
...	...

EPPI Operating Modes

The EPPI supports various receive and transmit modes of operation which include the detection and generation of preamble data. Specifically, the EPPI supports data formats described in the specifications ITU656, SMPTE 274M and SMPTE 296M. In addition to these modes, the EPPI also supports general-purpose receive and transmit using up to three frame syncs (FS).

The control register (EPPI_CTL) includes most of the bits used for configuring operating modes. The “Register Descriptions” section of this chapter provides complete descriptions of these bits.

ITU-R 656 Modes

The EPPI supports three input modes and one output mode for ITU-R 656 framed data. This section describes these modes.

ITU-R 656 Background

In ITU-R 656 mode, the horizontal (H), vertical (V), and field (F) signals are sent as an embedded part of the video data stream. The signals are sent in a series of bytes that form a control word. ITU-R 656 was formerly known as CCIR-656.

The letter H is used to distinguish between the *start of active video* (SAV) and *end of active video* (EAV) signals. These signals indicate the beginning and end of active video data in each line. The SAV occurs on a 1-to-0 transition of H, and EAV occurs on a 0-to-1 transition of H. The space between EAV and SAV is filled with horizontal blanking data. Therefore, H = 1 during the horizontal blanking portion of the data stream, and H = 0 during the active video portion of the data stream.

The letter V is used to denote the vertical blanking portion of the data stream. A transition in V can occur only in the EAV sequence. When V = 1, the data stream contains vertical blanking data, and when V = 0, the data stream contains active video data.

The letter F is used to distinguish Field 1 from Field 2. Interlaced video has two fields in a frame of data. It requires each field to be handled uniquely, and alternate rows of each field combined to create the actual video image.

For interlaced video, F = 0 represents Field 1 (*Odd Field*) and F = 1 represents Field 2 (*Even Field*). Progressive video makes no distinction between Field 1 and Field 2, and F is always 0 for progressive video. Interlaced video requires each field to be handled uniquely because alternate rows of each field combine to create the actual video image.

An entire field of video is comprised of active video plus horizontal blanking (the space between an EAV and SAV code) and vertical blanking (the space where V = 1). A field of video commences on a transition of the F bit.

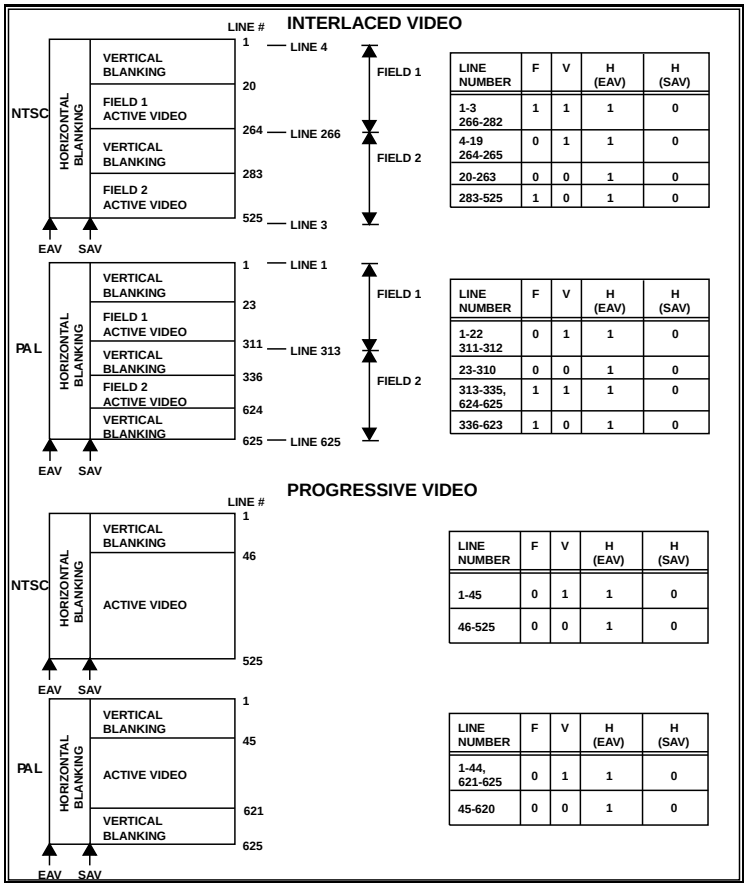

Figure 25-5: Typical Video Frame Partitioning for NTSC/PAL Systems in Interlaced and Progressive ITU-R BT.656 Systems

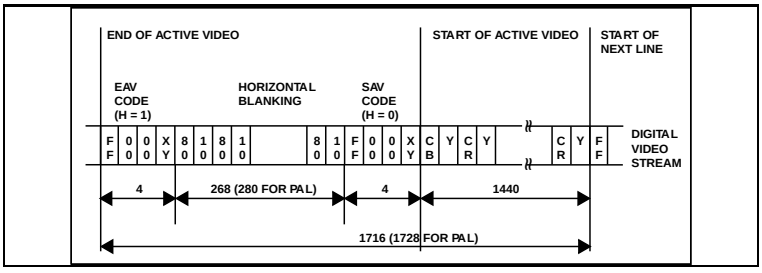

Figure 25-6: ITU-R 656 8-Bit Parallel Data Stream from NTSC (PAL) Systems

NOTE: Refer to the ***Control Sequences for 8-Bit and 10-Bit ITU-R 656 Video*** table. There is a defined preamble of three data elements (for example, in the case of 8-bit video: 0xFF, 0x00, 0x00), followed by the XY status word. The status word contains four protection bits for error detection and correction excluding the

F (field), V (vertical blanking), and H (horizontal blanking) bits. F and V are only allowed to change as part of EAV sequences (that is, transition from H = 0 to H = 1).

The bit definitions are as follows:

- F = 0 for field 1
- F = 1 for field 2
- V = 1 during vertical blanking
- V = 0 when not in vertical blanking
- H = 0 at SAV
- H = 1 at EAV
- P3 = V XOR H
- P2 = F XOR H
- P1 = F XOR V
- P0 = F XOR V XOR H

P3–P0 are protection bits that enable 1-bit and 2-bit error detection, and 1-bit error correction at the receiver. The EPPI corrects the error if it detects 1-bit errors in F, V, or H. Errors in the protection bits themselves are detected but not corrected.

Table 25-9: Control Sequences for 8-Bit and 10-Bit ITU-R 656 Video

	8-Bit Data								10-Bit Data	
	D9 (MSB	D8	D7	D6	D5	D4	D3	D2	D1	D0
Preamble	1	1	1	1	1	1	1	1	1	1
	0	0	0	0	0	0	0	0	0	0
	0	0	0	0	0	0	0	0	0	0
Control Byte	1	F	V	H	P3	P2	P1	P0	0	0

The EPPI_STAT register contains 2 bits, EPPI_STAT.ERRDET and EPPI_STAT.ERRNCOR, that are used to report the status of error detected and error not corrected, respectively.

The EPPI_STAT.ERRDET bit is set whenever an error is detected in the status word. However, this bit does not generate an interrupt. The EPPI_STAT.ERRNCOR bit is set when more than a 1-bit error is detected in the status word. An interrupt is generated when the EPPI_STAT.ERRNCOR bit is set. It can be cleared by clearing the EPPI_STAT.ERRNCOR and EPPI_STAT.ERRDET bits. Both bits are sticky and W1C.

In many applications, video streams other than the standard NTSC/PAL formats (for example, CIF, QCIF) can be employed. The processor interface is flexible enough to accommodate different row and field lengths. In general, as

long as the incoming video has the proper EAV/SAV codes, the EPPI can read it in. A CIF image could be formatted to be 656-compliant, where EAV and SAV values define the range of the image for each line. The V and F codes are used to delimit fields and frames.

The following sections provide descriptions of EPPI operations.

Table 25-10: Operating Modes and Generic EPPI Operation

		How to configure	Useful for	How to configure in ITU R 656 Tx Mode
ITU-R BT.656 Rx	Entire field	DIR= 0 XFRTYPE = b#01		
	Active video	DIR = 0 XFRTYPE = b#00

	Rx	DIR = 0 XFRTYPE = b#11 FSCFG = b#11		

ITU-R 656 Input Modes

In the ITU-R 656 input modes, the video source provides the clock or the system supplies it externally.

As shown in the ***ITU-R 656 Input Submodes*** figure and described in the following sections, there are three submodes supported for ITU-R 656 inputs: entire field, active video only, and vertical blanking interval only.

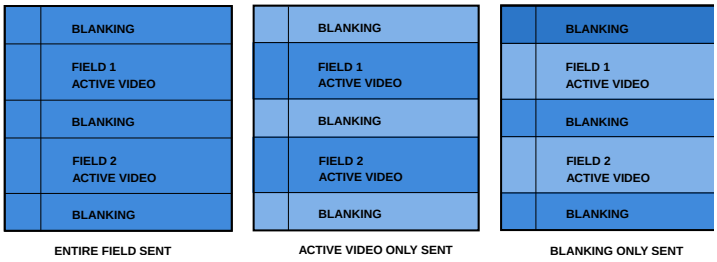

Figure 25-7: ITU-R 656 Input Submodes

Entire Field

In this mode, the EPPI reads the entire incoming bit stream. This stream includes active video as well as control byte sequences and ancillary data that can be embedded in horizontal and vertical blanking intervals.

Data transfer starts immediately after Field 1 synchronization occurs. The transfer does not include the first EAV code that contains the F = 0 assignment for interlaced video or the V = 0 assignment for progressive video.

Active Video

The EPPI uses this mode when only the active video portion of a field is of interest. The EPPI ignores (does not read in) all data between EAV and SAV, as well as all data present when V = 1. Furthermore, the control byte sequences are not stored to memory. The EPPI filters the sequences. After the start of Field 1 synchronizes, the EPPI ignores incoming samples until it sees an SAV.

In active video mode, programs must specify the number of total (active plus vertical blanking) lines per frame in the `EPPI_FRAME` register. Programs must specify the number of total (active plus horizontal blanking plus 8) samples per line in the `EPPI_LINE` register.

In this mode, any input data sequence that is considered part of the preamble is not sent to memory such as in 8-bit ITU mode. If 0xFF or 0x00 appear in the input data stream, these values are considered part of the preamble. The part of the preamble can appear individually and not be tagged along with the preamble sequence FF, 00, 00. This functionality also applies to vertical blanking interval mode.

Vertical Blanking Interval (VBI)

In this mode, data transfer is only active while V = 1 is in the control byte sequence. This functionality indicates that the video source is in the midst of the vertical blanking interval (VBI), which is sometimes used for ancillary data transmission. The ITU-R 656 recommendation specifies the format for these ancillary data packets, but the EPPI is not equipped to decode the packets themselves. Software must handle this task. Horizontal blanking data is logged where it coincides with the rows of the VBI.

The VBI is split into two regions within each field. The EPPI considers these two separate regions as one contiguous space. However, frame synchronization begins at the start of Field 1, which does not necessarily correspond to the

start of vertical blanking. For instance, in 525/60 systems, the start of Field 1 (F = 0) corresponds to line 4 of the VBI.

In VBI mode, the program must specify the number of total (active plus vertical blanking) lines per frame in the EPPI_FRAME register. The program must specify the number of total (active plus horizontal blanking plus 8) samples per line in the EPPI_LINE register.

In this mode, any input data sequence that is considered as part of the preamble is not sent to memory such as in 8-bit ITU mode. If 0xFF or 0x00 appears in the input data stream, these values are considered part of the preamble. The part of the preamble can appear individually, and not be tagged along with the preamble sequence FF, 00, 00. This functionality applies to active video mode too.

ITU-R 656 Output in General-Purpose Transmit Modes

In GP transmit mode, the EPPI frames an ITU-R 656 output stream with the proper preambles and blanking intervals by setting the EPPI_CTL.BLANKGEN bit. The EPPI fetches active data from memory through the DMA channel, saving DMA bandwidth. The EPPI generates and embeds the proper preamble, status word (EAV and SAV sequences), and blanking data along with the active video from memory. Program the EPPI_FS1_PASPL, EPPI_FS2_WLVB, EPPI_FS2_PALPF, and EPPI_FS1_WLHB registers to perform the desired functions. The EPPI can also drive out the frame syncs using the EPPI_CTL.FSCFG bit setting.

The ***16-Bit Transmit with Internal Blanking Generation*** figure shows the bit stream format in 16-bit transmit modes with blanking generation (EPPI_CTL.BLANKGEN enabled). Each 16-bit data sample consists of 8-bit luma (Y) and 8-bit chroma (Cr or Cb) components. During transmission, the chroma data and blanking bytes of value 0x80 are placed on the upper half (MSBs) of the data lines. The luma data and blacking bytes of value 0x10 are placed on the lower half (LSBs) of the data lines.

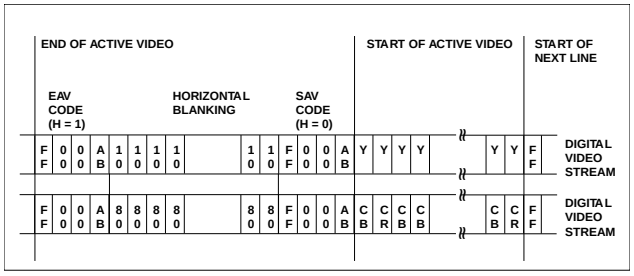

Figure 25-8: 16-Bit Transmit with Internal Blanking Generation

The ***Generated Blanking Preamble Sequence*** figure shows the data transmitted by the EPPI in this mode. After the EPPI is enabled, and if the EPPI FIFO is not empty, the transmission starts by sending out an EAV sequence for a vertical blanking line. For interlaced video, F starts at 1. For progressive video, F is always 0.

NOTE: Internal blanking generation functionality is valid only when the data length is 8, 10, or 16 bits and when the EPPI is in GP transmit modes. The EPPI_CTL.BLANKGEN bit generates preambles even in GP 2FS mode.

The internal blanking generation functionality of the ITU-R 656 output mode can also be bypassed by clearing the EPPI_CTL.BLANKGEN bit. (For example, if sending ancillary data in the blanking interval). The EPPI_CTL.BLANKGEN bit generates preambles even in GP 2FS mode.

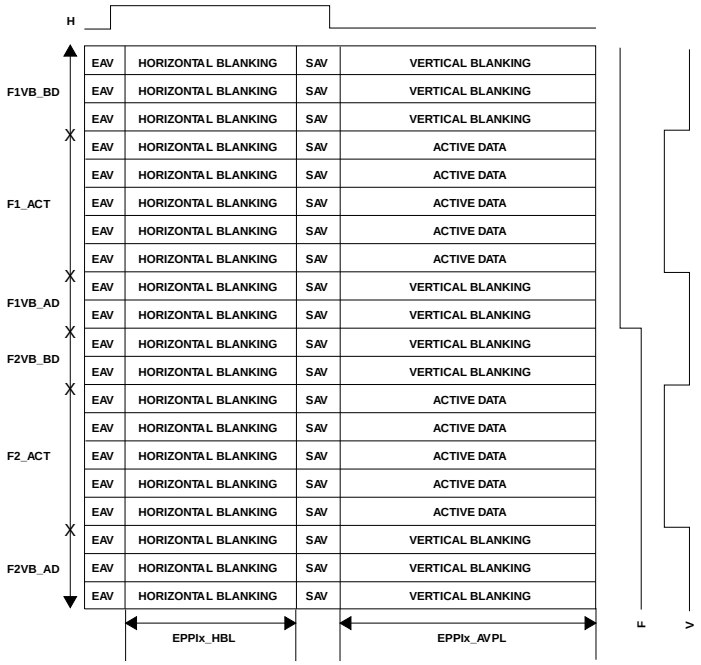

Figure 25-9: Generated Blanking Preamble Sequence

Frame Synchronization in ITU-R 656 Modes

For interlaced video, the start of frame synchronization occurs when a high-to-low transition is detected in F, the field indicator. For progressive video, the start of frame synchronization occurs when a high-to-low transition is detected in V, the vertical blanking indicator. These transitions in F and V can occur only in the EAV sequence. A start of line is detected on a low-to-high transition in H, the horizontal blanking indicator, which occurs in the EAV sequence as well.

For interlaced video, the start of frame corresponds to the start of field 1. Therefore, up to two fields can be ignored before the EPPI receives data. (For example, if field 1 started before the EPPI-to-camera channel was established). For progressive video, the start of frame corresponds to the start of active video.

Because all H and V signaling is embedded in the data stream in ITU-R 656 modes, the EPPI ignores the count registers (`EPPI_HCNT`, `EPPI_VCNT`). However, the EPPI still uses the `EPPI_FRAME` register to check for synchronization errors. Therefore, program this MMR with the number of lines expected in each frame of video.

The EPPI monitors the number of EAV-to-SAV transitions that occur from the start of a frame until it decodes the end of frame condition. (For example, a transition from F = 1 to F = 0 for interlaced video and a transition from V = 1 to V = 0 for progressive video).

At the end of frame condition, the actual number of lines processed is compared against the value in `EPPI_FRAME`. If there is a mismatch, a frame track error is asserted in the `EPPI_STAT` register. For example, if an SAV transition was missed, the current field only has NUM_ROWS – 1 rows. But resynchronization occurs at the start of the next frame. When the EPPI receives the entire field, the field status bit is toggled in the `EPPI_STAT` register. This way, an interrupt service routine (ISR) can discern which field was previously read in.

General-Purpose EPPI Modes

The general-purpose (GP) EPPI modes accommodate a wide variety of data capture and transmission applications.

Each EPPI has three bidirectional frame sync pins. The EPPI internally generates frame syncs, or an external device communicating with the EPPI generates them.

GP modes differ based on the number of frame syncs used and the EPPI supports GP 0 FS—GP 3 FS modes.

All the GP modes, except 0 FS mode, support horizontal windowing. GP modes with 2 and 3 frame syncs also support vertical windowing.

For GP transmit modes with internal clock or frame syncs, the EPPI starts generating the clock or frame syncs only when the EPPI FIFO is full for the first time. For GP 0 FS transmit mode, the EPPI only starts transmitting when the EPPI FIFO is full for the first time.

General-Purpose 0 Frame Sync Mode

This mode is useful for applications where periodic frame syncs are not used to frame the data.

After the initial trigger, the EPPI receives or transmits data samples on every clock cycle. However, if the `EPPI_CTL.SKIPEN` bit is set for receive mode, the EPPI receives only alternate data samples.

The `EPPI_LINE`, `EPPI_FRAME`, `EPPI_HCNT`, `EPPI_HDLY`, `EPPI_VCNT`, and `EPPI_VDLY` registers are not valid for GP 0 FS mode. Therefore, windowing is not possible in this mode. Also, line and frame track errors are not applicable in this mode.

GP 0 FS receive mode is further divided into two submodes; internal trigger (`EPPI_CTL.FLDSEL` bit =0) and external trigger (`EPPI_CTL.FLDSEL` bit =1). The submodes are based on how the processor initiates data transmission or reception. GP 0 FS transmit mode is always internally triggered. DMA handles all subsequent data manipulation.

- ***Frame synchronization in GP 0 FS external trigger mode.*** When the EPPI is programmed in external trigger mode, it does not generate the `EPPI_FS1` signal and the external device must provide a trigger. The EPPI starts receiving the data as soon as an `EPPI_FS1` signal assertion is detected. After that, the DMA handles all subsequent data manipulation and any activity on `EPPI_FS1` is ignored.
- ***Frame synchronization in GP 0 FS internal trigger mode.*** When the EPPI is programmed in internal trigger mode, it starts receiving or transmitting data as soon as the EPPI clock is enabled and synchronized. There can be up to four PPI clock cycles of latency before valid data is received or transmitted.

General-Purpose 1 Frame Sync Mode

This mode is useful for interfacing the EPPI with analog-to-digital converters (ADCs), digital-to-analog converters (DACs), and other general-purpose devices. This mode works for both transmit and receive.

The `EPPI_FRAME`, `EPPI_VDLY`, and `EPPI_VCNT` registers have no effect in GP 1 FS mode. As a result, frame track errors and vertical windowing are not available.

General-Purpose 2 Frame Sync Mode

This mode is useful for video applications that use two hardware synchronization signals, HSYNC and VSYNC. The HSYNC signal can be connected to EPPI_FS1 and the VSYNC signal can be connected to EPPI_FS2.

Data Enable in General-Purpose 2 Frame Sync Transmit Mode

The EPPI_FS3 pin functions as a data enable (DEN) pin, when EPPI is configured in GP 2 FS transmit mode and generating the frame sync internally. The bits EPPI_CTL.MUXSEL and EPPI_CTL.CLKGATEN are not enabled. The functionality of the DEN pin is described in the following two cases.

Case 1

Blanking generation is configured using the EPPI_CTL.BLANKGEN bit. EPPI data length (EPPI_CTL.DLEN bit) is configured for 8, 10, or 16-bit transfers. The EPPI_FS3 pin asserts during the *active data* regions, aligned with EPPI_CLK according to the clock polarity (EPPI_CTL.POLC bit) settings. For this mode, the pin EPPI_FS3 is driven based on the EPPI_CTL.POLC setting. The pin EPPI_FS3 is driven out on the same EPPI clock edge that drives out data. The frame sync polarity (EPPI_CTL.POLS) setting does not apply here—EPPI_FS3 is always active high in this mode.

Case 2

Blanking generation (EPPI_CTL.BLANKGEN =0) is disabled. Or blanking generation is enabled, but the EPPI data length (EPPI_CTL.DLEN bit) is configured for a transfer size other than 8, 10, or 16 bits. The EPPI_FS3 pin asserts at the start of the active data region on each line, aligned with EPPI_CLK according to the EPPI_CTL.POLC bit settings. For this mode, the pin EPPI_FS3 is driven based on the EPPI_CTL.POLC setting. The EPPI_FS3 signal is driven out on the same EPPI clock edge that drives out data.

The EPPI_CTL.POLS bit setting does not apply for case 2. The EPPI_FS3 signal is always active high in this mode. Once asserted, EPPI_FS3 stays asserted for the number of clock cycles per line configured in the EPPI_HCNT register, then it deasserts. This behavior on each line continues for the total number of lines programmed in the EPPI_VCNT register per frame. The behavior repeats at the start of subsequent video frames.

In case 2, if transmission of valid data is held off due to delays programmed in the EPPI_HDLY or EPPI_VDLY registers, the assertion of EPPI_FS3 is also held off. The delay is on a per-line or per-frame basis.

General-Purpose 3 Frame Sync Mode

This mode is useful for video applications that use three synchronization signals for hardware: HSYNC, VSYNC, and FIELD. The HSYNC connects to the EPPI_FS1 pin, VSYNC connects to the EPPI_FS2 pin, and FIELD connects to the EPPI_FS3 pin.

GP 3 FS mode is similar in operation to GP 2 FS mode. However, the start of frame synchronization in GP 3 FS also considers the state of the EPPI_FS3 pin. All the windowing register settings (EPPI_FRAME, EPPI_LINE, EPPI_HDLY, EPPI_HCNT, EPPI_VDLY, and EPPI_VCNT registers), as well as data reception or transmission and error generation are the same as for GP 2 FS mode. In addition, for GP 3 FS mode with internal frame syncs, the EPPI_CTL.FLDSEL bit setting specifies the condition under which the transfer begins.

The EPPI generates the EPPI_FS3 signal and toggles during every assertion of EPPI_FS2 or a combination of EPPI_FS2 and EPPI_FS1. The toggle depends on the EPPI_CTL.FLDSEL bit setting. The EPPI skips an EPPI_FS2 signal when the EPPI_FS3 value is high. Because of this condition, program the EPPI_FS2 period value to half of the total number of pixels in the frame as in GP 3 FS mode. When in GP 2 FS mode, program the EPPI_FS2 period with the value equal to the number of pixels per frame.

Supported Data Formats

The following sections describe EPPI receive and transmit data formats.

Receive Data Formats

The ***EPPI Receive Data Formats*** table provides information about EPPI configuration for specific use models for receive data.

Table 25-11: EPPI Receive Data Formats

Input Data Width	Use Model	Splitting/Packing Options
8	NTSC/PAL data	EPPI_CTL.SPLTEO =1 EPPI_CTL.SUBSPLTODD =1 if necessary to separate chroma components
	RGB sensor	No splitting possible. EPPI_CTL.PACKEN =1 – Four EPPI words are packed to 32-bit DMA data. EPPI_CTL.PACKEN =0 – Each EPPI word is sent as 8-bit data on the 32-bit DMA bus. This transfer consumes 4 times the DMA bandwidth of the 8-bit case with EPPI_CTL.PACKEN =1;
	ADCs	Gives I (in phase) and Q (quadrature) components. EPPI_CTL.SPLTEO =1 EPPI_CTL.SUBSPLTODD =0 since there are only two components.

Table 25-11: EPPI Receive Data Formats (Continued)

Input Data Width	Use Model	Splitting/Packing Options
10	NTSC/PAL data	Each EPPI word is zero filled or sign extended to 16 bits. EPPI_CTL.SPLTEO =1. EPPI_CTL.SUBSPLTODD =1 if necessary to separate chroma components.
	RGB sensor	No splitting possible. EPPI_CTL.PACKEN =1. Two EPPI words are zero filled or sign extended to 16 bits and packed to 32-bit DMA data. EPPI_CTL.PACKEN =0. Each EPPI word can be zero filled or sign extended to 16 bits and sent as a 16-bit data on the 32-bit DMA bus. This transfer consumes double the bandwidth of the 10-bit case with EPPI_CTL.PACKEN =1;
	ADCs	Each EPPI word is zero filled or sign extended to 16 bits. EPPI_CTL.SPLTEO =1 SEPPI_CTL.SUBSPLTODD = 0 since there are only two components.
12	RGB sensor	No splitting possible. EPPI_CTL.PACKEN =1. Two EPPI words are zero filled or sign extended to 16 bits and packed to 32-bit DMA data. EPPI_CTL.PACKEN =0. Each EPPI word can be zero filled or sign extended to 16 bits and sent as a 16-bit data on the 32-bit DMA bus. This transfer consumes double the bandwidth of the 12-bit case with EPPI_CTL.PACKEN =1;
	ADCs	Each EPPI word is zero filled or sign extended to 16 bits. EPPI_CTL.SPLTEO =1 EPPI_CTL.SUBSPLTODD =0 since there are only two components.
14	ADCs	Each EPPI word is zero filled or sign extended to 16 bits. EPPI_CTL.SPLTEO =1 EPPI_CTL.SUBSPLTODD =0 since there are only two components.

Table 25-11: EPPI Receive Data Formats (Continued)

Input Data Width	Use Model	Splitting/Packing Options
16	8-bit luma/chroma pair for NTSC or HD	EPPI_CTL.SPLTEO =1, EPPI_CTL.SPLTWRD =1, EPPI_CTL.SUBSPLTODD =1 if necessary to separate chroma components.
	16-bit luma/chroma pair for NTSC or HD	EPPI_CTL.SPLTEO =1, EPPI_CTL.SPLTWRD =0, EPPI_CTL.SUBSPLTODD =1 if necessary to separate chroma components.
	RGB565 sensor	No splitting possible. EPPI_CTL.PACKEN =1. Two EPPI words are packed to a 32-bit DMA data. EPPI_CTL.RGBFMTEN is valid only in transmit modes. So, RGB565 cannot be byte aligned in memory. EPPI_CTL.PACKEN =0. Each EPPI word is sent as a 16-bit data on the 32-bit DMA bus. This transfer consumes double the bandwidth of the 16-bit case with EPPI_CTL.PACKEN =1
	8-bit ADCs I/Q pair	EPPI_CTL.SPLTEO =1, EPPI_CTL.SPLTWRD =1, EPPI_CTL.SUBSPLTODD =0.
	16-bit ADCs I/Q pair	EPPI_CTL.SPLTEO =1, EPPI_CTL.SPLTWRD =0, EPPI_CTL.SUBSPLTODD =0.

Transmit Data Formats

The ***EPPI Transmit Data Formats*** table provides information about EPPI configuration for specific use models for transmit data.

Table 25-12: EPPI Transmit Data Formats

Output Data Width	Use Model	Splitting/Packing Options
8	NTSC/PAL data	EPPI_CTL.SPLTEO =1 EPPI_CTL.SUBSPLTODD =1 if the chroma components (U and V) come in separate DMA words.
	Serial RGB for lower-resolution LCDs	No splitting possible. EPPI_CTL.PACKEN =1. The 32-bit DMA data is unpacked to drive four EPPI words. EPPI_CTL.PACKEN =0. The lowest 8 bits of the DMA data is driven on the EPPI data and the rest of the 24 bits are discarded. This transfer consumes 4 times the DMA bandwidth of the 8-bit case with EPPI_CTL.PACKEN =1.
10	NTSC/PAL data	EPPI_CTL.SPLTEO =1 EPPI_CTL.SUBSPLTODD =1 if the chroma components (U and V) come in separate DMA words.
	DACs	EPPI_CTL.SPLTEO =1, EPPI_CTL.SUBSPLTODD =0.

Table 25-12: EPPI Transmit Data Formats (Continued)

Output Data Width	Use Model	Splitting/Packing Options
12	DACs	EPPI_CTL.SPLTEO =1, EPPI_CTL.SUBSPLTODD =0.
14	DACs	EPPI_CTL.SPLTEO =1, EPPI_CTL.SUBSPLTODD =0.
16	8-bit luma/chroma pair for NTSC or HD	EPPI_CTL.SPLTEO =1, EPPI_CTL.SPLTWRD =1, EPPI_CTL.SUBSPLTODD =1 if the chroma components (U and V) come in separate DMA words.
	16-bit luma/chroma pair for NTSC or HD	EPPI_CTL.SPLTEO =1, EPPI_CTL.SPLTWRD =0, EPPI_CTL.SUBSPLTODD =1 if the chroma components (U and V) come in separate DMA words.
	RGB565 LCD	No splitting possible. EPPI_CTL.RGBFMTEN =1. Takes RGB888 data from the memory and drops the LSBs from each component to drive out RGB565 data.
	8-bit ADCs I/Q pair	EPPI_CTL.SPLTEO =1, EPPI_CTL.SPLTWRD =1, EPPI_CTL.SUBSPLTODD = 0
	16-bit ADCs I/Q pair	EPPI_CTL.SPLTEO =1, EPPI_CTL.SPLTWRD =0, EPPI_CTL.SUBSPLTODD =1
18	RGB666 LCD	No splitting possible. EPPI_CTL.RGBFMTEN =1. Takes RGB888 data from the memory and drops the 2 LSBs from each component to drive out RGB666 data.

Data Transfer Modes

The following sections describe EPPI data transfer modes, including receive or transmit data packing, sign extension, zero fill, receive or transmit split modes, clock gating, delayed start, and data consistency management.

Data Packing for Receive Modes

For receive modes, if the EPPI_CTL.PACKEN bit =1 and the DMA is 32 bits, the EPPI packs the incoming data into 32-bit words based on the EPPI_CTL.DLEN and EPPI_CTL.SWAPEN bit settings. When EPPI_CTL.SWAPEN =0, the EPPI puts the first data in the least significant bits and when EPPI_CTL.SWAPEN =1, the EPPI puts the first data in the most significant bits. The packing options for the EPPI_CTL.DLEN bits are as follows.

- When EPPI_CTL.DLEN =8, four 8-bit words can be packed into one 32-bit word.
- When EPPI_CTL.DLEN =16, two 16-bit words can be packed into one 32-bit word.
- For EPPI_CTL.DLEN values that are more than 8 bits but less than 16 bits, two such words are either sign-extended or zero-filled to 16 bits and packed into one 32-bit word.
- When EPPI_CTL.DLEN =18, the EPPI sign-extends or zero-fills the 18-bit data to 24 bits and packs four 24-bit words into three 32-bit words.

- When EPPI_CTL.DLEN =24, the EPPI packs four 24-bit words into three 32-bit words.

When EPPI_CTL.PACKEN =0, the EPPI receives the incoming data and sends it on the bus as-is. If EPPI_CTL.DLEN is less than or equal to 16 bits, the DMA is a 16-bit DMA; otherwise it is a 32-bit DMA.

Data Packing for Transmit Modes

For transmit modes, if the EPPI_CTL.DLEN bit =1 and the DMA is a 32-bit DMA, the EPPI unpacks the 32-bit word according to the EPPI_CTL.DLEN and EPPI_CTL.SWAPEN bit settings.

If EPPI_CTL.SWAPEN =1, the EPPI transmits the most significant bits as the first data, and if EPPI_CTL.SWAPEN =0, the EPPI transmits the least significant bits as the first data. The unpacking options for the EPPI_CTL.DLEN bits are as follows.

- When EPPI_CTL.DLEN =8, the EPPI transmits one 32-bit word from memory as four 8-bit data words.
- For EPPI_CTL.DLEN values greater than 8 bits but less than or equal to 16 bits, the EPPI transmits one 32-bit word from memory as two 16-bit data words.
- When EPPI_CTL.DLEN =18 or 24, the EPPI transmits three 32-bit words from memory as four data words.

Sign-Extended and Zero-Filled Data

The following list describes the bit settings and functionality for sign-extending and zero-filling data.

- For EPPI_CTL.DLEN equal to 10, 12 or 14, data is zero-filled or sign-extended to 16 bits.
- For EPPI_CTL.DLEN equal to 18 bits, data is zero-filled or sign-extended to 24 bits if packing is enabled, and zero-filled or sign-extended to 32 bits if packing is disabled.
- For EPPI_CTL.DLEN equal to 24 bits, data is zero-filled or sign-extended to 32 bits if packing is disabled.
- For EPPI_CTL.DLEN equal to 8 bits, data is zero-filled or sign-extended to 16 bits if packing is disabled.
- If EPPI_CTL.SIGNEXT =1, then the data is sign-extended, otherwise it is zero-filled.

Split Receive Modes

The control register has three control bits for split receive modes: EPPI_CTL.SPLTEO, EPPI_CTL.SUBSPLTODD, and EPPI_CTL.DMACFG. Packing is not valid in split modes.

- If EPPI_CTL.SPLTEO =1, the EPPI splits the incoming data stream into two substreams, an even stream, and an odd stream, and packs them separately.
- The EPPI_CTL.SUBSPLTODD bit is available only when EPPI_CTL.SPLTEO =1. When EPPI_CTL.SUBSPLTODD =1, the EPPI subsplits the odd substream, and packs the streams separately.
- The EPPI_CTL.DMACFG bit is also available only if EPPI_CTL.SPLTEO =1. If EPPI_CTL.DMACFG =1, the EPPI uses two DMA channels and if EPPI_CTL.DMACFG =0, the EPPI uses only one DMA channel.

Split Transmit Modes

The EPPI_CTL register has three control bits for split transmit modes: EPPI_CTL.SPLTEO, EPPI_CTL.SUBSPLTODD, and EPPI_CTL.DMACFG. The DMA is always a 32-bit DMA. Packing is not valid in split modes.

- If EPPI_CTL.SPLTEO =1, the EPPI receives the Luma (Y3Y2Y1Y0) and interleaved Chroma (Cr1Cb1Cr0Cb0) data as 32 bits from the DMA channel. The EPPI interleaves the data to form a 4:2:2 YCrCb data stream to transmit.
- The EPPI_CTL.SUBSPLTODD bit is available only when EPPI_CTL.SPLTEO =1. In this case, if EPPI_CTL.SUBSPLTODD =1, the EPPI receives the Luma (Y3Y2Y1Y0) and deinterleaved Chroma (Cb3Cb2Cb1Cb0 and Cr3Cr2Cr1Cr0). The EPPI interleaves the data to form a 4:2:2 YCrCb data stream to transmit. (The EPPI does not decimate the chroma data when formatting it into 4:2:2.)
- The EPPI_CTL.DMACFG bit is also valid only if EPPI_CTL.SPLTEO =1. If EPPI_CTL.DMACFG =1, the EPPI uses two DMA channels and if EPPI_CTL.DMACFG =0, the EPPI uses only one DMA channel.

Clock Gating

In ITU-R BT.656 and GP 0/1/2 FS modes, EPPI_FS3 becomes a clock-gating input. This functionality is valid for both internally and externally sourced EPPI_CLK, in both receive and transmit modes. This clock gating signal must be synchronous with EPPI_CLK. The external device on the rising edge of EPPI_CLK must drive the clock gating signal. Its function is to hold the sync and data lines in their current state until EPPI_FS3 is driven low. There are no additional latency cycles upon coming out of clock gating mode.

When clock gating is not required, the EPPI_FS3 pin must either be tied to ground or configured to operate as another of its multiplexed functions.

In GP 2 FS transmit mode with internally generated frame syncs, the EPPI_FS3 pin functions as a data enable signal.

Support for Delayed Start of EPPI Frame Syncs

The EPPI supports a delayed start of the EPPI_FS1 and EPPI_FS2 frame syncs. The EPPI_FS1_DLY and EPPI_FS2_DLY registers are programmable registers corresponding to EPPI_FS1 (HSYNC) and EPPI_FS2 (VSYNC).

The delay programmed in these registers applies to the first active edge of the internally generated frame sync. The delay starts from the first EPPI_CLK edge. The delay counter runs only for the first time and then shuts off until the EPPI is reenabled. (The delay counter is the period counter itself, since they do not run together.) Program the delay registers prior to the first EPPI_CLK edge (similar to the width and period registers). The ***EPPI Delayed Frame Sync Generation*** figure shows the functioning of EPPI_FS1 and EPPI_FS2.

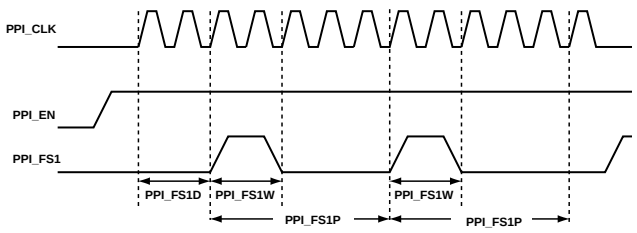

Figure 25-10: EPPI Delayed Frame Sync Generation

Ignoring Premature External Frame Syncs for Data Consistency

Once a frame has started with a VSYNC followed by an HSYNC (or both coming together), a line is tracked. When the count expires, the state machine waits at the end of line for an HSYNC to come. With the arrival of the HSYNC, the state machine starts tracking the next line, and so on.

The number of lines tracked is counted separately. Once the end of a frame is reached, the state machine waits there for the next VSYNC/HSYNC combination. The next frame starts once they are sampled. Unfortunately, every incoming FS (VSYNC or HSYNC) resets the respective counters and the tracking starts all over (even if the FS signals are premature). The result is incomplete data (or frames) to enter memory through the PxP interface.

To correct this problem, the EPPI waits for a frame or line completion before considering any incoming FS as valid.

- Single FS mode and line tracking in dual FS mode – When a line is in progress, when HSYNC is detected prematurely, it is ignored. A line track underflow event is generated.
- Dual FS mode – If a VSYNC is received when a frame is in progress, it is ignored. A frame track underflow error (`EPPI_STAT.FTERRUNDR`) is generated.

Ignoring the FS ensures that once a frame starts, the amount of data that goes into the memory/PxP interface corresponds exactly to the programmed data size in a frame.

NOTE: Even when the premature FS is a valid FS, the state machine loses at most one frame, and it recovers in the subsequent FS. The FS to number of data going into the memory relationship is always maintained as programmed.

When data underflow errors occur at the DMA interface, the EPPI does the following.

- If a premature line sync is detected, an LT underflow error is generated (`EPPI_STAT.LTERRUNDR` =1). All further line track errors are ignored until the EPPI detects the next valid line sync.
- If a premature frame sync is detected, an FT underflow error is generated (`EPPI_STAT.FTERRUNDR` =1). All further frame track and line track errors are ignored until the EPPI detects the next valid frame sync.

EPPI Event Control

The following sections describe how EPPI manages events.

EPPI Status, Error, and Interrupt Signals

The EPPI generates error interrupts (flagged in the EPPI_STAT register) when any one of the following error conditions occur.

- EPPI_STAT.YFIFOERR (YFIFO underflow or overflow)
- EPPI_STAT.CFIFOERR (CFIFO underflow or overflow)
- EPPI_STAT.LTERROVR (line track overflow error)
- EPPI_STAT.LTERRUNDR (line track underflow error)
- EPPI_STAT.FTERROVR (frame track overflow error)
- EPPI_STAT.FTERRUNDR (frame track underflow error)
- EPPI_STAT.ERRNCOR (ITU preamble error not corrected)

A W1C (write-1-to-clear) operation clears the error conditions. Each of the individual conditions which cause an EPPI error interrupt can be masked. The interrupt mask register (EPPI_IMSK) allows the masking of individual conditions which cause error interrupts.

There is only one interrupt line from each EPPI so all interrupts are internally OR'ed and sent as a single interrupt to the core. The EPPI_STAT register must then be read to discover specific errors. The following sections describe these errors in detail.

Frame and Line Track Errors

In external frame sync mode, the EPPI uses line track error (EPPI_STAT.LTERROVR and EPPI_STAT.LTERRUNDR) and frame track error (EPPI_STAT.FTERROVR and EPPI_STAT.FTERRUNDR) status bits to monitor the line and frame synchronization errors. The EPPI updates the bits when there is a mismatch detected in the HSYNC and VSYNC as compared to the programmed values in EPPI_LINE and EPPI_FRAME count registers.

Line Track Errors

The line track overflow (EPPI_STAT.LTERROVR) and underflow errors (EPPI_STAT.LTERRUNDR) generate a maskable interrupt as soon as the EPPI identifies them and not at the next frame sync.

- When the frame sync has not arrived when the EPPI_LINE counter expires, then the EPPI_STAT.LTERROVR error is generated.
- When the EPPI_LINE counter is running and a frame sync is detected, the EPPI_STAT.LTERRUNDR error is generated. A W1C operation clears both interrupts.

Frame Track Errors

The frame track overflow (EPPI_STAT.FTERROVR) and underflow errors (EPPI_STAT.FTERRUNDR) generate a maskable interrupt as soon as the EPPI identifies them. When the EPPI_FRAME.VALUE counter expires, the EPPI_STAT.FTERROVR error is reported before the next frame sync arrives.

When the EPPI_FRAME counter is running and a frame sync is detected, then an EPPI_STAT.FTERRUNDR is reported.

Both errors generate an error interrupt. Perform a W1C operation to clear the interrupts at their respective locations in the status register.

A premature frame sync results in a frame track under run error. But the error is logged (register bit set) only after the subsequent blanking period (if any) elapses.

Preamble Error Not Corrected Error

The EPPI supports data embedded frame syncs in ITU and SMPTE formats. In these formats, the module can receive an erroneous preamble which is not correctable. The EPPI_STAT.ERRNCOR error signals when this event occurs.

EPPI Programming Model

The following sections describe programming techniques, including receiving or transmitting ITU-R 656 frames; configuring transfers in GP0, GP1, GP2, and GP3 modes; and managing EPPI mode configurations.

Receiving ITU-R 656 Frames

The EPPI supports the reception of ITU-R 656 compliant frames.

1. Configure the EPPI to receive either full ITU-R 656 frame, active video, or blanking information by configuring the EPPI_CTL.XFRTYPE bits.
2. In both active video mode and in VBI (vertical blanking information) mode, specify the number of total (active plus vertical blanking) lines per frame in the EPPI_FRAME register. Specify the number of total (active plus horizontal blanking plus 8) samples per line in the EPPI_LINE register.
3. Configure DMA descriptors to move the data to memory.
4. Enable DMA.
5. Enable the EPPI.
6. To program the EPPI in internal clock mode, follow the procedure above with the EPPI_CTL.ICLKGEN bit =0. After enabling the EPPI, add a delay of 200 SCLK0 cycles (worst case) to ensure the EPPI FIFO becomes full. Then switch to internal clock mode by setting the EPPI_CTL.ICLKGEN bit =1.

Depending on the EPPI configuration, either the full ITU-R 656 frame is moved to memory or only the active video or only the blanking information.

Transmitting ITU-R 656 Frames in GP Transmit Modes

The EPPI can take active video from memory and generate the proper preambles and blanking information to produce valid ITU-R 656 video frames for transmission.

1. Provide active data frame in memory.
2. Set the EPPI_CTL.BLANKGEN bit so the EPPI generates blanking information.
3. Configure the EPPI_FS1_WLHB, EPPI_FS1_PASPL, EPPI_FS2_WLVB, EPPI_FS2_PALPF registers accordingly.
4. Configure the rest of the EPPI settings.
5. Configure DMA to fetch active frame data from memory buffers.
6. Enable DMA.
7. Enable the EPPI.
8. To program the EPPI in internal clock mode, follow the procedure above with the EPPI_CTL.ICLKGEN bit =0. After enabling the EPPI, add a delay of 200 SCLK0 cycles (worst case) to ensure the EPPI FIFO becomes full. Then switch to internal clock mode by setting the EPPI_CTL.ICLKGEN bit =1.

The EPPI takes the active data from memory, generates the blanking information, and transmits an ITU-R 656 frame

Configuring Transfers in GP 0 FS Mode

The EPPI can be configured to not use periodic frame syncs to frame the data.

1. Configure the EPPI to operate in GP 0 FS mode by setting EPPI_CTL.XFRTYPE = b#11 and EPPI_CTL.FSCFG = b#00.
2. When receiving, configure the EPPI to trigger on internally or externally by setting the EPPI_CTL.FLDSEL field appropriately. When transmitting, the EPPI always generates a trigger internally.
3. Configure DMA to move the data to or from memory.
4. Enable DMA.
5. Enable EPPI.
6. To program the EPPI in internal clock mode, follow the procedure above with the EPPI_CTL.ICLKGEN bit =0. After enabling the EPPI, add a delay of 200 SCLK0 cycles (worst case) to ensure the EPPI FIFO becomes full. Then switch to internal clock mode by setting the EPPI_CTL.ICLKGEN bit =1.

The DMA descriptions control the amount of data transferred. The frame syncs from the EPPI do not control the amount.

Configuring Transfers in GP 1 FS Mode

The GP 1 FS mode is useful for interfacing the EPPI with analog-to-digital converters (ADCs), digital-to-analog converters (DACs), and other general-purpose devices. This mode works for both transmit and receive.

NOTE: The EPPI_FRAME, EPPI_VDLY, and EPPI_VCNT registers have no effect in GP 1 FS mode. As a result, frame track errors and vertical windowing are not possible in this mode.

1. Configure GP 1 FS mode by setting the EPPI_CTL.XFRTYPE bit =b#11 and the EPPI_CTL.FSCFG bit =b#01. An external device can provide the frame syncs or the EPPI can source the frame syncs.
2. Program the EPPI_LINE register to contain the number clock cycles expected between two assertions of the EPPI_FS1 signal to monitor the line track errors. Program the EPPI_LINE register before the EPPI_HCNT register.
3. Program the EPPI_HDLY register to contain the number of clock cycles to wait after the assertion of EPPI_FS1. For example, the start of frame.
4. Program the EPPI_HCNT register to contain the number of data samples to receive or transmit for each frame.
5. Configure DMA to move the data to or from memory.
6. Enable DMA.
7. Enable the EPPI.
8. To program the EPPI in internal clock mode, follow the procedure above with the EPPI_CTL.ICLKGEN bit =0. After enabling the EPPI, add a delay of 200 SCLK0 cycles (worst case) to ensure the EPPI FIFO becomes full. Then, switch to internal clock mode by setting the EPPI_CTL.ICLKGEN bit =1.

Data moves in or out of memory. A frame sync frames the data for every line.

Configuring Transfers in GP 2 FS Mode

GP 2 FS mode is useful for video applications that use two hardware synchronization signals, HSYNC and VSYNC. The HSYNC connects to the EPPI_FS1 signal and VSYNC connects to the EPPI_FS2 signal.

1. Configure the EPPI to operate in GP 2 FS mode by setting the EPPI_CTL.XFRTYPE bit =b#11 and the EPPI_CTL.FSCFG bit =b#10. An external device can provide the frame syncs or the EPPI can source the frame syncs.
2. Program the EPPI_FRAME register to contain the number of expected lines per frame. The value can be equal to the number of EPPI_FS1 signal assertions expected between the start of each frame sync. The EPPI uses the value to monitor frame track errors. Program the EPPI_FRAME register before the EPPI_VCNT register.
3. Program the EPPI_LINE register to contain the number of clock cycles expected between two assertions of the EPPI_FS1 signal to monitor line track errors. Program the EPPI_LINE register before the EPPI_HCNT register.
4. Program the EPPI_HDLY register to configure the number of clock cycles to wait after the assertion of the EPPI_FS1 signal. (For example, the start of the line).
5. Program the EPPI_HCNT register to contain the number of data samples to receive or transmit for each line.

6. Program the EPPI_VDLY register to contain the number of lines to wait after the start of frame is detected.
7. Program the EPPI_VCNT register to contain the number of lines to receive or transmit.
8. If setting up the EPPI for transmit, the data enable (DEN) pin behaves according to the enabling of the blanking generation and the data length setting (DLEN). See Data Enable in General-Purpose 2 Frame Sync Transmit Mode for more details.
9. Enable DMA.
10. Enable the EPPI.
11. To program the EPPI in internal clock mode, follow the procedure above with the EPPI_CTL.ICLKGEN bit =0. After enabling the EPPI, add a delay of 200 SCLK0 cycles (worst case) to ensure the EPPI FIFO becomes full. Then switch to internal clock mode by setting the EPPI_CTL.ICLKGEN bit =1.

Data moves in or out of memory. A frame sync frames the data for every line and frame.

Configuring Transfers in GP 3 FS Mode

GP 3 FS mode is useful for video applications that use three synchronization signals for hardware: HSYNC, VSYNC, and FIELD. The HSYNC connects to EPPI_FS1, VSYNC connects to EPPI_FS2, and FIELD connects to EPPI_FS3.

1. Configure the EPPI to operate in GP 3 FS mode by setting the EPPI_CTL.XFRTYPE bit =b#11 and the EPPI_CTL.FSCFG bit =b#11. An external device can provide the frame syncs or the EPPI can source the frame syncs.
2. Configure the windowing registers according to steps in GP 2 FS mode.
3. Enable DMA.
4. Enable the EPPI.
5. To program the EPPI in internal clock mode, follow the procedure above with the EPPI_CTL.ICLKGEN bit =0. After enabling the EPPI, add a delay of 200 SCLK0 cycles (worst case) to ensure the EPPI FIFO becomes full. Then switch to internal clock mode by setting the EPPI_CTL.ICLKGEN bit =1.

Data moves in or out of memory. A frame sync frames the data for every line and frame. Operation and results are like the operation in GP 2 FS mode, but the EPPI also uses the EPPI_FS3 signal.

Configuring the EPPI to Use the Windowing Feature

Windowing is a useful feature for applications where the region of interest is smaller than the active video stream (for example, sensor calibration, auto-focusing, and others). It can result in significant DMA bandwidth reduction. The EPPI supports windowing for GP input modes.

1. Program the EPPI_FRAME register with the number of lines the frame contains.

2. Program the EPPI_LINE register with the number of samples per line in the frame.
3. Program the EPPI_VDLY register with the number of lines to wait after the start of a new frame before starting to read or transmit data.
4. Program the EPPI_VCNT register with the number of lines to read in or write out after EPPI_VDLY number of lines from the start of the frame.
5. Program the EPPI_HDLY register with the number of clock cycles to delay after the assertion of EPPI_FS1 is detected for the start of a new line.
6. Program the EPPI_HCNT register with the number of samples to read in or write out after EPPI_HDLY number of cycles have expired since the assertion of EPPI_FS1.

EPPI Mode Configuration

This section describes EPPI mode configurations, including support for all EPPI transmit and receive modes.

Configuring 8-Bit Receive Mode

For 8-bit non-split receive mode and if EPPI_CTL.PACKEN =1, the EPPI packs 4 bytes of incoming data into a 32-bit word. Alternate even or odd samples can be skipped based on the EPPI_CTL.SKIPEN and EPPI_CTL.SKIPEO bits. The first incoming data can be placed either in the least significant bit positions or in the most significant bit positions, based on the EPPI_CTL.SWAPEN bit setting.

Table 25-13: 8-Bit Receive Mode with Packing Enabled

Pin Data (8 bits)	DMA DATA SKIPEN=0 SKIPEO =X SWAPEN=0 SIGNEXT=X	DMA DATA SKIPEN=0 SKIPEO=X SWAPEN=1 SIGNEXT=X	DMA DATA SKIPEN=1 SKIPEO=1 SWAPEN=0 SIGNEXT=X	DMA DATA SKIPEN=1 SKIPEO=0 SWAPEN=0 SIGNEXT=X	DMA DATA SKIPEN=1 SKIPEO=1 SWAPEN=1 SIGNEXT=X	DMA DATA SKIPEN=1 SKIPEO=0 SWAPEN=1 SIGNEXT=X
0x11						
0x22						
0x33						
0x44	0x4433 2211	0x1122 3344				
0x55

0xFF			0xFFDD BB99		0x99BB DDFF	
0x00	0x00FF EEDD	0xDDE EFF00		0x00EE CCAA		0xAACC EE00

If `EPPI_CTL.PACKEN`=0, the DMA is a 16-bit DMA and the EPPI either sign-extends or zero-fills the bytes of incoming data into a 16-bit word. The `EPPI_CTL.SWAPEN` bit has no effect if `EPPI_CTL.PACKEN`=0.

Table 25-14: 8-Bit Receive Mode with Packing Disabled

Pin Data (8 bits)	DMA DATA SKIPEN=0 SKIPEO=X SWAPEN=X SIGNEXT=0	DMA DATA SKIPEN=0 SKIPEO=X SWAPEN=X SIGNEXT=1	DMA DATA SKIPEN=1 SKIPEO=1 SWAPEN=X SIGNEXT=0	DMA DATA SKIPEN=1 SKIPEO=0 SWAPEN=X SIGNEXT=1

0xAA	0x00AA	0xFFAA	0x00AA	
0xBB	0x00BB	0xFFBB		0xFFBB

Configuring 10/12/14-Bit Receive Modes

For 10, 12, or 14-bit non-split receive modes, the EPPI first either zero-fills or sign-extends the incoming data into a 16-bit word. The action depends on the setting of the `EPPI_CTL.SIGNEXT` bit. If `EPPI_CTL.PACKEN` =1, the EPPI then packs two of these words into one 32-bit word. Alternate even or odd samples can be skipped based on the `EPPI_CTL.SKIPEN` and `EPPI_CTL.SKIPEO` bits. The first incoming data can be placed either in the least significant bit positions or in the most significant bit positions, based on the `EPPI_CTL.SWAPEN` bit setting.

Configuring 16-Bit Receive Mode

For 16-bit non-split receive mode, if `EPPI_CTL.PACKEN` =1, the EPPI packs two 16-bit incoming data into one 32-bit word. Alternate even or odd samples can be skipped based on the `EPPI_CTL.SKIPEN` and

EPPI_CTL.SKIPEO bits. The first incoming data can be placed either in the least significant bit positions or in the most significant bit positions, based on the EPPI_CTL.SWAPEN bit setting.

Configuring 18-Bit Receive Mode

For 18-bit non-split receive mode, if EPPI_CTL.PACKEN =0, the EPPI zero-fills or sign-extends the incoming data into a 32-bit word. If EPPI_CTL.PACKEN =1, the EPPI first zero-fills or sign-extends the incoming data to 24 bits, and then packs four such 24-bit data words into three 32-bit words. Alternate even or odd samples can be

skipped based on the EPPI_CTL.SKIPEN and EPPI_CTL.SKIPEO bits. The EPPI_CTL.SWAPEN bit has no effect.

When the bits settings are `EPPI_CTL.SPLTEO` =1, `EPPI_CTL.SUBSPLTODD` =1 and `EPPI_CTL.DMACFG` =0, the EPPI packs the second Chroma component sent over the DMA bus completely before the Luma component. However, it is intentionally held until that previous word is moved out. This functionality allows the separation of Luma and Chroma values into individual buffers when using 2D-DMA. The second Chroma component is U0U1U2U3 in the ***8-bit Split Receive Mode with SKIPEN = 0 and SWAPEN = 0*** and ***8-bit Split Receive Mode with SKIPEN = 0 and SWAPEN = 1*** tables. The Luma component is Y4Y5Y6Y7 in the ***8-bit Split Receive Mode with SKIPEN = 0 and SWAPEN = 1*** table.

Configuring 10/12/14/16-Bit Split Receive Mode with SPLTWRD=0

For 16-bit split receive mode, the `EPPI_CTL.PACKEN` bit is not valid. The EPPI always packs two 16-bit words into one 32-bit word. For 10, 12, or 14-bit split receive modes, the EPPI first either sign-extends or zero-fills the incoming data into a 16-bit word. The EPPI then packs two of these words into one 32-bit word to send to the DMA.

Table 25-25: 16-bit Split Receive Mode with SPLTWRD = 0, SKIPEN = 0 and SWAPEN = 0

Pin Data (16 bits)	**SPLTEO=1 SUBSPLTODD=0 SWAPEN=0 SKIPEN=0 SKIPEO=X**			**SPLTEO=1 SUBSPLTODD=1 SWAPEN=0 SKIPEN=0 SKIPEO=X**

Configuring 16-Bit Split Receive Mode with SPLTWRD=1

For 16-bit split receive mode, the `EPPI_CTL.PACKEN` bit is not valid. The EPPI always packs two 16-bit words into one 32-bit word. The `EPPI_CTL.SPLTWRD` bit is only valid when the `EPPI_CTL.DLEN` bit =16 bits.

Table 25-27: 16-bit Split Receive Mode with SPLTWRD = 1, SKIPEN = 0 and SWAPEN = 0

Pin Data (16 bits)	SPLTEO=1 SUBSPLTODD=0 SWAPEN=0 SKIPEN=0 SKIPEO=X			SPLT_EVEN_ODD=1 SUBSPLTODD=1 SWAPEN=0 SKIPEN=0 SKIPEO=X

Configuring 8-Bit Transmit Mode

For 8-bit non-split transmit mode, if the `EPPI_CTL.PACKEN` bit =1, the DMA is a 32-bit DMA and the EPPI unpacks the 32-bit word from memory into 4 bytes to transmit. The EPPI transmits either the MSBs or the LSBs as the first data, depending on the `EPPI_CTL.SWAPEN` bit setting. If `EPPI_CTL.PACKEN` =0, the DMA is a 16-bit DMA and the EPPI transmits the lower 8 bits. The `EPPI_CTL.SWAPEN` bit has no effect when `EPPI_CTL.PACKEN` =0.

Table 25-28: 8-bit Transmit Mode with Packing Enabled

DMA Data (32 bits)	Pin Data when SWAPEN=0	Pin Data when SWAPEN=1
0x11223344	0x44	0x11
0x55667788	0x33	0x22
	0x22	0x33
	0x11	0x44
	0x88	0x55
	0x77	0x66
	0x66	0x77

	0x55	0x88

Table 25-29: Data Sent in 8-bit Transmit Mode with Packing Disabled

DMA Data (16 bits)	Pin Data SWAPEN=X
0x1234	0x34
0x2345	0x45
0x3456	0x56

Configuring 10/12/14-Bit Transmit Modes

For 10, 12, or 14-bit non-split transmit modes, if the `EPPI_CTL.PACKEN` bit =1, the DMA is a 32-bit DMA. The EPPI unpacks the 32-bit word from memory into two 16-bit data words. The EPPI then transmits the required LSBs from each data word. The EPPI transmits either the most significant word or the least significant word as the first data, depending on the `EPPI_CTL.SWAPEN` bit setting. If `EPPI_CTL.PACKEN` =0, the DMA is a 16-bit DMA and the EPPI transmits the required LSBs. The `EPPI_CTL.SWAPEN` bit has no effect when the `EPPI_CTL.PACKEN` bit =0.

Table 25-30: 10-bit Transmit Mode with Packing Enabled

DMA Data (32 bits)	Pin Data when SWAPEN=0	Pin Data when SWAPEN=1
0x1111 2222	0x222	0x111
0x3333 4444	0x111	0x222
	0x044	0x333
	0x333	0x044

Table 25-31: 10-bit Transmit Mode with Packing Disabled

0x1234	0x234
0x2345	0x345
0x3456	0x056
0x4567	0x167

Configuring 16-Bit Transmit Mode

For 16-bit non-split transmit mode, if the `EPPI_CTL.PACKEN` bit =1, the DMA is a 32-bit DMA. The EPPI unpacks the 32-bit word from memory into two 16-bit data words to transmit. The EPPI transmits either the MSBs or the LSBs as the first data, depending on the `EPPI_CTL.SWAPEN` bit setting. If the `EPPI_CTL.PACKEN` bit =0, the DMA is a 16-bit DMA and the EPPI transmits the data as is. The `EPPI_CTL.SWAPEN` has no effect when `EPPI_CTL.PACKEN` bit =0.

Table 25-32: 16-bit Transmit Mode with Packing Enabled

DMA Data (32 bits)	Pin Data when SWAPEN=0	Pin Data when SWAPEN=1
0x1111 2222	0x2222	0x1111
0x3333 4444	0x1111	0x2222
	0x4444	0x3333
	0x3333	0x4444

Table 25-33: 16-bit Transmit Mode with Packing Disabled

DMA Data (16 bits)	Pin Data SWAPEN=X
0x1234	0x1234
0x2345	0x2345
0x3456	0x3456

Configuring 18-Bit Transmit Mode

For 18-bit transmit mode, if the `EPPI_CTL.PACKEN` bit =1, the DMA is a 32-bit DMA and the EPPI unpacks the 32-bit word from memory. In this mode, when `EPPI_CTL.RGBFMTEN` is set, the least significant 2 bits of R, G, and B are dropped.

Table 25-34: 18-bit Transmit Mode with Packing Enabled

DMA Data	Pin Data (18-bits)	
	RGBFMTEN=0	RGBFMTEN=1
0x0123 4567	0x3 4567	0x0 8459

Configuring 10/12/14/16-Bit Transmit Mode with SPLTWRD=0

For 16-bit split transmit mode, the `EPPI_CTL.PACKEN` bit is not valid. The EPPI always unpacks the 32-bit DMA data into two 16-bit words to transmit. For 10, 12, or 14-bit split transmit modes, the EPPI first unpacks the data in the same way as for 16-bit transmit mode. But, the EPPI transmits only the required number of LSBs.

		Y_3		Y_1
		U_0		U_0
		Y_2		Y_2

Configuring 16-Bit Split Transmit Mode with SPLTWRD=1

For 16-bit split transmit mode, the `EPPI_CTL.PACKEN` bit is not valid. The EPPI always unpacks the 32-bit DMA data into two 16-bit words to transmit. The `EPPI_CTL.SPLTWRD` bit is only valid when the `EPPI_CTL.DLEN` bit =16 bits.

Table 25-44: 16-bit Split Transmit Mode with SPLTWRD = 1, SUBSPLTODD = 0, and SWAPEN = 0

DMACFG = 1			DMACFG = 0

EPPI Programming Concepts

This section provides information on SMPTE programming.

SMPTE Modes Programming

The programming model of SMPTE modes is like ITU Modes. All programming modes pertaining to ITU modes such as XFRTYPE, FSCFG, FLDSEL, and BLANKGEN also hold true for SMPTE modes The only difference is that because ITU modes use Y-Cr/Cb interleaved data and SMPTE use parallel Y-Cr/Cb data, SPLTWRD could be set while operating in SMPTE modes. The ***Programming Modes for SMPTE Formats*** table describes the programming modes for different SMPTE formats.

Table 25-46: Programming Modes for SMPTE Formats

SMPTE Format	SMPTE Channel Width	EPPI Input Bit Width	EPPI Mode	Remarks
296M	8	16 Cr/Cb - [15:8] Y - [7:0]	DLEN = 16 bits SPLTWRD = 1	SIGNEXT not supported
	8	16 Cr/Cb - [15:8] Y - [7:0]	DLEN = 16 bits SPLTWRD = 1	SIGNEXT not supported

ADSP-SC59x EPPI Register Descriptions

Enhanced Parallel Peripheral Interface (EPPI) contains the following registers.

Table 25-47: ADSP-SC59x EPPI Register List

Name	Description
EPPI_CLKDIV	Clock Divide Register
EPPI_CTL	Control Register
EPPI_CTL2	Control Register 2 Register
EPPI_EVENCLIP	Clipping Register for EVEN (Luma) Data Register
EPPI_FRAME	Lines Per Frame Register
EPPI_FS1_DLY	Frame Sync 1 Delay Value Register
EPPI_FS1_PASPL	FS1 Period Register / EPPI Active Samples Per Line Register
EPPI_FS1_WLHB	FS1 Width Register / EPPI Horizontal Blanking Samples Per Line Register
EPPI_FS2_DLY	Frame Sync 2 Delay Value Register
EPPI_FS2_PALPF	FS2 Period Register / EPPI Active Lines Per Field Register
EPPI_FS2_WLVB	FS2 Width Register / EPPI Lines Of Vertical Blanking Register
EPPI_HCNT	Horizontal Transfer Count Register
EPPI_HDLY	Horizontal Delay Count Register
EPPI_IMSK	Interrupt Mask Register
EPPI_LINE	Samples Per Line Register
EPPI_ODDCLIP	Clipping Register for ODD (Chroma) Data Register
EPPI_STAT	Status Register
EPPI_VCNT	Vertical Transfer Count Register
EPPI_VDLY	Vertical Delay Count Register

Clock Divide Register

The EPPI_CLKDIV register provides the divisor for EPPI internal clock generation. The generated clock frequency is given by following formula:

EPPI_CLK = (SCLK0) / (EPPI_CLKDIV + 1)

Note that a value of 0xFFFF is invalid for the EPPI_CLKDIV register.

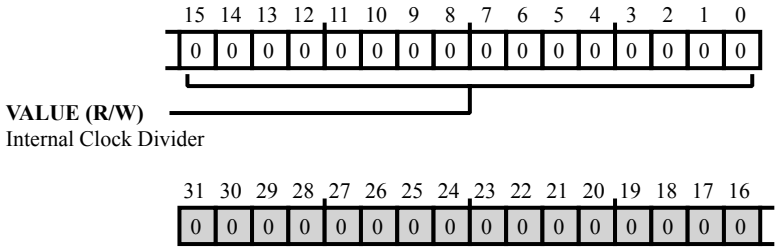

Figure 25-11: EPPI_CLKDIV Register Diagram

Table 25-48: EPPI_CLKDIV Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Internal Clock Divider.

Control Register

The EPPI_CTL register configures the EPPI for operating mode, control signal polarities, and data width of the port.

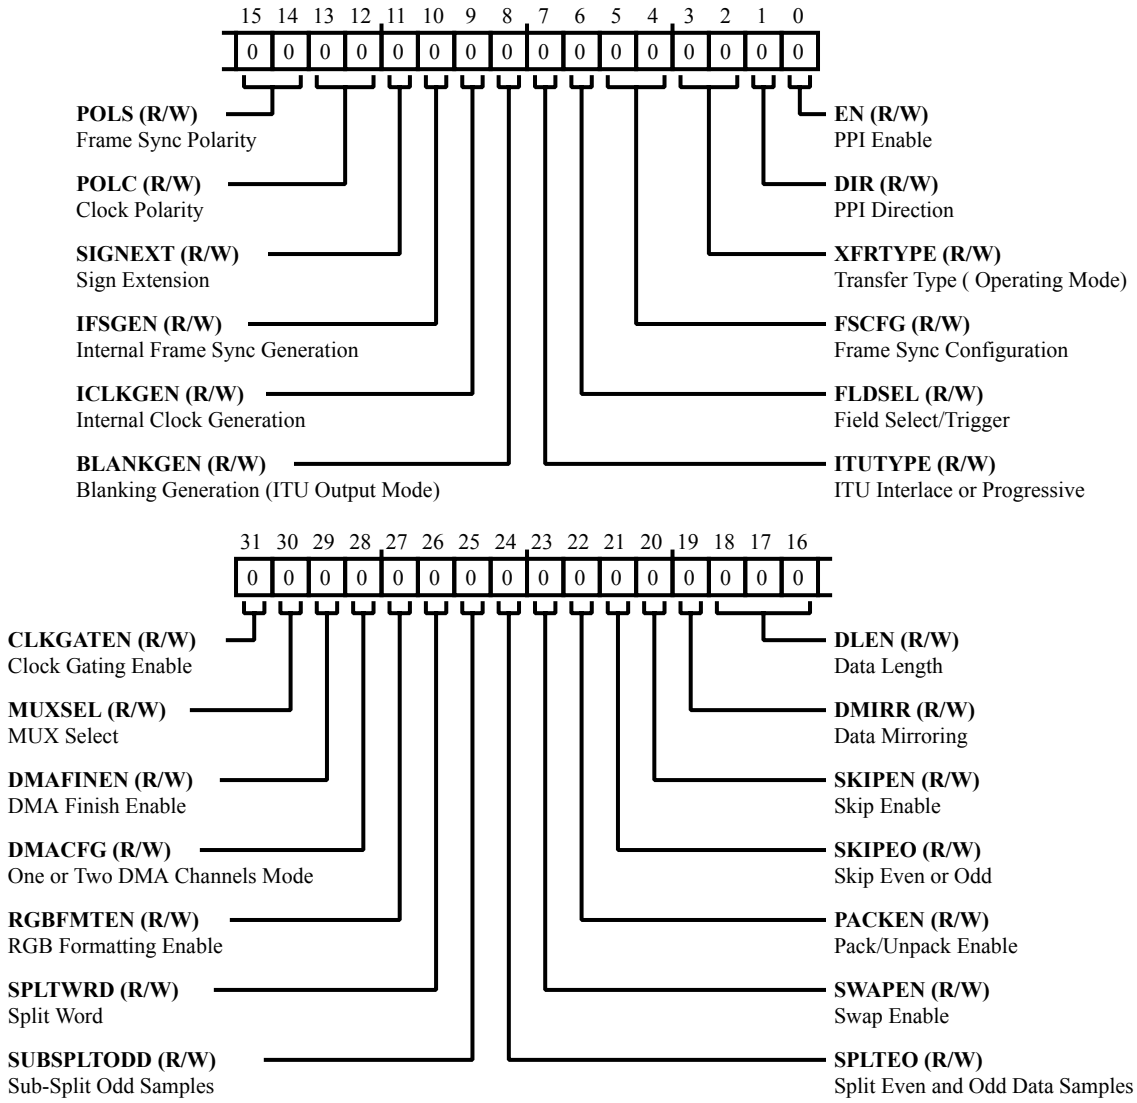

Figure 25-12: EPPI_CTL Register Diagram

Table 25-49: EPPI_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	CLKGATEN	Clock Gating Enable. The EPPI_CTL.CLKGATEN bit enables using the EPPI_FS3 pin as a clock gating pin. When EPPI_CTL.CLKGATEN is set, the EPPI_FS3 pin acts as a clock gating signal, and both the internal and external clock are gated. Note that the EPPI_FS3 pin gating signal is active low, and the EPPI_CTL.CLKGATEN selection is ignored if EPPI_CTL.MUXSEL is set or EPPI_CTL.FSCFG equals 0x3.	
		0	Disable
		1	Enable
30 (R/W)	MUXSEL	MUX Select. The EPPI_CTL.MUXSEL bit enables multiplexing of a primary and alternate camera using the EPPI main data and clock lines. For more information on this feature, see the EPPI functional description.	
		0	Normal Operation
		1	Multiplexed Operation
29 (R/W)	DMAFINEN	DMA Finish Enable. The EPPI_CTL.DMAFINEN bit selects whether or not the EPPI sends a finish command (010) through the DDE COMMAND line soon after a frame/line is received completely.	
		0	No Finish Command
		1	Enable Send Finish Command
28 (R/W)	DMACFG	One or Two DMA Channels Mode. The EPPI_CTL.DMACFG bit is valid only if EPPI_CTL.SPLTEO is set. If EPPI_CTL.DMACFG is set, the EPPI uses two DMA channels. And, if EPPI_CTL.DMACFG is cleared, the EPPI uses only one DMA channel.	
		0	PPI Uses One DMA Channel
		1	PPI Uses Two DMA Channels
27 (R/W)	RGBFMTEN	RGB Formatting Enable. For 16- or 18-bit transmit modes only, the EPPI_CTL.RGBFMTEN bit enables conversion of RGB888 from memory into RGB666 output data (18-bit transmit) or enables conversion of RGB888 from memory into RGB565 output data (16-bit transmit). Note that EPPI_CTL.SPLTEO and EPPI_CTL.RGBFMTEN should never be set simultaneously.	
		0	Disable RGB Formatted Output
		1	Enable RGB Formatted Output

Table 25-49: EPPI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
26 (R/W)	SPLTWRD	Split Word. The EPPI_CTL.SPLTWRD bit selects split word data placement when the data length (EPPI_CTL.DLEN) selects 16-, 20-, or 24-bit data words. For all other EPPI_CTL.SPLTWRD values, the set or clear selections for EPPI_CTL.SPLTWRD produce the same result (act as though EPPI_CTL.SPLTWRD is cleared). For EPPI_CTL.SPLTWRD set, the EPPI_CTL.DLEN values below result in the following combinations of split words: DLEN Cr/Cb data Y data 16 PPI_DATA[15:8] PPI_DATA[7:0] 20 PPI_DATA[19:10] PPI_DATA[9:0] 24 PPI_DATA[23:12] PPI_DATA[11:0]	
		0	PPI_DATA has (DLEN-1) bits of Y or Cr or Cb
		1	PPI_DATA Contains 2 Elements per Word
25 (R/W)	SUBSPLTODD	Sub-Split Odd Samples. The EPPI_CTL.SUBSPLTODD bit is valid only if EPPI_CTL.SPLTEO is set. If EPPI_CTL.SUBSPLTODD is set, the EPPI sub-splits the odd sub-stream, and packs them separately.	
		0	Disable
		1	Enable
24 (R/W)	SPLTEO	Split Even and Odd Data Samples. If EPPI_CTL.SPLTEO is set, the EPPI splits the incoming data stream into two sub-streams, an even stream and an odd stream, and packs them separately.	
		0	Do Not Split Samples
		1	Split Even/Odd Samples
23 (R/W)	SWAPEN	Swap Enable. The EPPI_CTL.SWAPEN selects whether or not to swap the order of the first data (most-significant bits versus least-significant bits) of the DMA word. For receive modes, the EPPI puts the first data in the most significant bits (if set) or puts the first data in the least significant bits (if cleared) of the DMA word. For transmit modes, the EPPI transmits the most significant bits in the DMA word as the first data (if set) or transmits the least significant bits in the DMA word as the first data (if cleared).	
		0	Disable
		1	Enable

Table 25-49: EPPI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
22 (R/W)	PACKEN	Pack/Unpack Enable. The EPPI_CTL.PACKEN select whether or not packing is enabled (for receive modes) and unpacking is enabled (for transmit modes). When this bit is set, EPPI transfer DMA is 32-bits wide. When this bit is cleared and the EPPI_CTL.DLEN is less than or equal to 16 bits, EPPI transfer DMA is 16-bits wide. For receive modes, if this bit is set, then the EPPI packs the incoming data into 32-bit words. If this bit is cleared, then the EPPI does not do any packing. For transmit modes, if this bit is set, then the EPPI always unpacks the 32-bit data from DMA. If this bit is not set, the EPPI does not do any unpacking.	
		0	Disable
		1	Enable
21 (R/W)	SKIPEO	Skip Even or Odd. The EPPI_CTL.SKIPEO bit selects whether even (if set) or odd (if cleared) samples are skipped if sample skipping is enabled (EPPI_CTL.SKIPEN is set). This feature only is useful for receive modes.	
		0	Skip Odd Samples
		1	Skip Even Samples
20 (R/W)	SKIPEN	Skip Enable. The EPPI_CTL.SKIPEN bit enables skipping alternate samples. This feature only is useful for receive modes.	
		0	No Samples Skipping
		1	Skip Alternate Samples
19 (R/W)	DMIRR	Data Mirroring. The EPPI_CTL.DMIRR field enables mirroring (bit reversing) of the data coming in or going out on the EPPI data pins. Pin Data (DAT_MRR=0) PPI Data (DAT_MRR=1) 15 15 0 14 14 1 .... 1 1 14 0 0 15	
		0	No Data Mirroring
		1	Data Mirroring
18:16 (R/W)	DLEN	Data Length. The EPPI_CTL.DLEN bits select the data length for the EPPI. Note that the 20 bits data length selection is valid only for SMPTE modes (EPPI_CTL.SPLTWRD set).	

Table 25-49: EPPI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		0	8 bits
		1	10 bits
		2	12 bits
		3	14 bits
		4	16 bits
		5	18 bits
		6	20 bits
		7	24 bits
15:14 (R/W)	POLS	Frame Sync Polarity. The `EPPI_CTL.POLS` selects whether the frame syncs' polarity is active low versus active high.	
		0	FS1 and FS2 are active high
		1	FS1 is active low. FS2 is active high
		2	FS1 is active high. FS2 is active low
		3	FS1 and FS2 are active low
13:12 (R/W)	POLC	Clock Polarity. The `EPPI_CTL.POLC` selects the rising versus falling edge for sampling data and sampling/driving syncs.	
		0	Clock/Sync Polarity Mode 0. For receive mode: Sample data on falling edge and sample/drive syncs on falling edge. For transmit mode: Drive data on rising edge and sample/drive syncs on rising edge.
		1	Clock/Sync Polarity Mode 1. For receive mode: Sample data on falling edge and sample/drive syncs on rising edge. For transmit mode: Drive data on rising edge and sample/drive syncs on falling edge.
		2	Clock/Sync Polarity Mode 2. For receive mode: Sample data on rising edge and sample/drive syncs on falling edge. For transmit mode: Drive data on falling edge and sample/drive syncs on rising edge.
		3	Clock/Sync Polarity Mode 3. For receive mode: Sample data on rising edge and sample/drive syncs on rising edge. For transmit mode: Drive data on falling edge and sample/drive syncs on falling edge.

Table 25-49: EPPI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W)	SIGNEXT	Sign Extension. The EPPI_CTL.SIGNEXT select whether (for receive modes when EPPI_CTL.DLEN selecting 16 bit data length) the data is sign extended or zero filled. Not that EPPI_CTL.SPLTWRD is removed from this shared bit.	
		0	Zero Filled
		1	Sign Extended
10 (R/W)	IFSGEN	Internal Frame Sync Generation. The EPPI_CTL.IFSGEN bit selects whether the frame syncs are generated internally or are supplied by an external device.	
		0	External Frame Sync
		1	Internal Frame Sync
9 (R/W)	ICLKGEN	Internal Clock Generation. The EPPI_CTL.ICLKGEN bit selects whether the EPPI_CLK is generated internally or is supplied by an external device.	
		0	External Clock
		1	Internal Clock
8 (R/W)	BLANKGEN	Blanking Generation (ITU Output Mode). The EPPI_CTL.BLANKGEN enables ITU output with internal blanking. In GP 8, 10 transmit bit modes (when EPPI_CTL.SPLTWRD is cleared) and 16-, 20-, and 24-bit transmit modes (when EPPI_CTL.SPLTWRD is set), EPPI_CTL.BLANKGEN selects whether or not the EPPI generates blanking and generates preamble and insertion with active data from memory.	
		0	Disable
		1	Enable
7 (R/W)	ITUTYPE	ITU Interlace or Progressive. The EPPI_CTL.ITUTYPE selects interlaced or progressive operation for ITU656 mode. This selection is valid for both TX and RX modes.	
		0	Interlaced
		1	Progressive

Table 25-49: EPPI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6 (R/W)	FLDSEL	Field Select/Trigger. The EPPI_CTL.FLDSEL bits configure the EPPI field and trigger selection. These are valid for GP modes (EPPI_CTL.XFRTYPE =0x3) and ITU656 active video mode (EPPI_CTL.XFRTYPE cleared).	
		0	Field Mode 0. Read field 1 (for ITU656 active video mode). Set internal trigger (for GP RX mode). FS3 is toggled on FS2 assertion followed by FS1 assertion (when the EPPI_CTL.FSCFG bit selects sync mode 3 and the EPPI_CTL.IFSGEN bit selects internal frame sync).
		1	Field Mode 1 Read field 1 and field 2 (ITU656 active video mode). Set external trigger (GP RX mode). FS3 is toggled on FS2 assertion (when the EPPI_CTL.FSCFG bit selects sync mode 3 and the EPPI_CTL.IFSGEN bit selects internal frame sync).
5:4 (R/W)	FSCFG	Frame Sync Configuration. The EPPI_CTL.FSCFG bits configure the EPPI frame syncs. These are valid only for GP modes (EPPI_CTL.XFRTYPE =0x3). The output of the frames syncs also depends on whether the EPPI transfer direction is transmit and the EPPI is in ITU output mode (EPPI_CTL.BLANKGEN is set).	
		0	Sync Mode 0. FS0 driven in GP mode. FS0 not driven in ITU output mode.
		1	Sync Mode 1. FS1 driven in GP mode. HSYNC driven on FS1 in ITU output mode.
		2	Sync Mode 2. FS2 driven in GP mode. HSYNC driven on FS1 and VSYNC driven on FS1 in ITU output mode.
		3	Sync Mode 3. FS3 driven in GP mode. HSYNC driven on FS1, VSYNC driven on FS2, and FIELD driven on FS3 in ITU output mode.

Table 25-49: EPPI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3:2 (R/W)	XFRTYPE	Transfer Type (Operating Mode). The EPPI_CTL.XFRTYPE bits select the EPPI operating mode. In receive mode (EPPI_CTL.DIR cleared), the EPPI modes include ITU656 active video only mode, ITU656 entire field mode, ITU656 vertical blanking only mode, and non-ITU656 mode (GP mode). For transmit mode (EPPI_CTL.DIR set), the EPPI_CTL.XFRTYPE bits have no effect, and the EPPI (in transmit mode) is always in GP mode.	
		0	ITU656 Active Video Only Mode
		1	ITU656 Entire Field Mode
		2	ITU656 Vertical Blanking Only Mode
		3	Non-ITU656 Mode (GP Mode)
1 (R/W)	DIR	PPI Direction. The EPPI_CTL.DIR bit selects whether the EPPI is in receive mode (if cleared) or in transmit mode (if set).	
		0	Receive Mode
		1	Transmit Mode
0 (R/W)	EN	PPI Enable. The EPPI_CTL.EN bit enables or disables the EPPI.	
		0	Disable
		1	Enable

Control Register 2 Register

The EPPI_CTL2 register controls HSYNC finish signal generation.

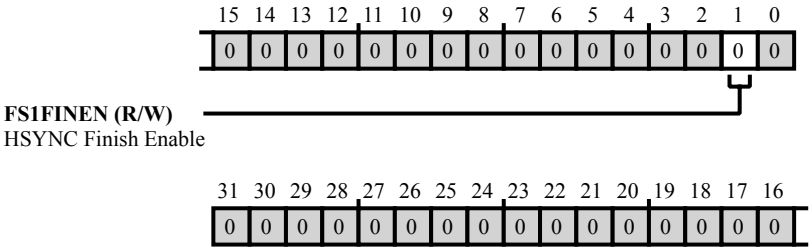

Figure 25-13: EPPI_CTL2 Register Diagram

Table 25-50: EPPI_CTL2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W)	FS1FINEN	HSYNC Finish Enable. The EPPI_CTL2.FS1FINEN bit selects whether (if set) the EPPI sends a finish command (010) through the DDE COMMAND line soon after a LINE is received completely or (if cleared) the EPPI sends a finish command (010) through the DDE COMMAND line soon after a FRAME is received completely. Note that the EPPI_CTL.DMAFINEN bit must be set for the EPPI to generate either of the finish commands.	
		0	Finish sent after frame RX done. PPI sends a finish command (010) through the DDE COMMAND line soon after a FRAME is received completely
		1	Finish sent after frame/line RX done. PPI sends a finish command (010) through the DDE COMMAND line soon after a frame/line is received completely.

Clipping Register for EVEN (Luma) Data Register

The EPPI_EVENCLIP register selects the clipping threshold for luma data, which provides clipping of individual video components.

The high even and low even spaces in EPPI_EVENCLIP are 16-bits wide and (depending on the EPPI_CTL.DLEN bit selection) only the corresponding video component bits are considered for clipping.

For example, if the EPPI is programmed in 10-bit mode, bits [9:0] and bits [25:16] constitute the clipping thresholds. The higher bits are (in this case) ignored.

Using the this method, 8-, 10-, 12- and 16-bit clipping thresholds can be set.

Note that when the EPPI is programmed in 16-, 20-, or 24-bit mode with the EPPI_CTL.SPLTWRD bit set, the luma data gets the clipping threshold levels of the EPPI_EVENCLIP register, and the chroma data gets the clipping threshold levels of the EPPI_ODDCLIP register.

Also, note that the EPPI_EVENCLIP and EPPI_ODDCLIP registers are ignored when the EPPI_CTL.RGBFMTEN bit is set.

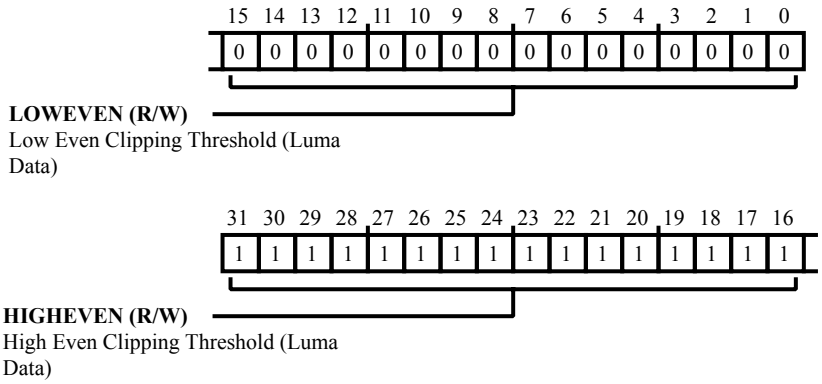

Figure 25-14: EPPI_EVENCLIP Register Diagram

Table 25-51: EPPI_EVENCLIP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/W)	HIGHEVEN	High Even Clipping Threshold (Luma Data). The EPPI_EVENCLIP.HIGHEVEN bit field selects the clipping threshold for luma data. The high even spaces are 16-bits wide and (depending on the EPPI_CTL.DLEN selection) only the corresponding video component bits are considered for clipping.
15:0 (R/W)	LOWEVEN	Low Even Clipping Threshold (Luma Data). The EPPI_EVENCLIP.LOWEVEN bit field selects the clipping threshold for luma data. The low even spaces are 16-bits wide and (depending on the EPPI_CTL.DLEN selection) only the corresponding video component bits are considered for clipping.

Lines Per Frame Register

The EPPI_FRAME register tracks the frame track overflow and underflow errors. This register should be programmed with the number of lines expected per frame. Any write to the EPPI_FRAME register will also write the same value to the EPPI_VCNT register. But, any write to the EPPI_VCNT register does not affect the EPPI_FRAME register value. So the EPPI_FRAME register should be programmed before the EPPI_VCNT register.

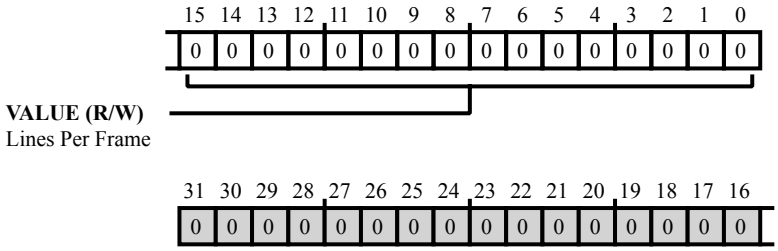

Figure 25-15: EPPI_FRAME Register Diagram

Table 25-52: EPPI_FRAME Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Lines Per Frame. The EPPI_FRAME.VALUE holds the number of lines expected per frame of data.

Frame Sync 1 Delay Value Register

The EPPI_FS1_DLY register selects the delay count (based on the period of the EPPI_CLK clock) between the first rising edge of EPPI_CLK after the EPPI is enabled and the first active edge of the associated frame sync when the internal frame sync is used.

Note that if the EPPI_FS1_DLY or EPPI_FS2_DLY registers are programmed with value 0, the EPPI operates as though 0 value is 1, and the first frame sync transition occurs after the completion of one period value of the respective counters.

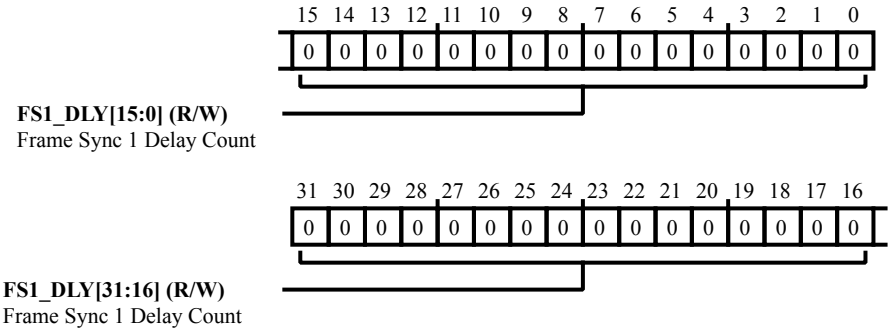

Figure 25-16: EPPI_FS1_DLY Register Diagram

Table 25-53: EPPI_FS1_DLY Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	FS1_DLY	Frame Sync 1 Delay Count. The EPPI_FS1_DLY.FS1_DLY bit field selects the delay count.

FS1 Period Register / EPPI Active Samples Per Line Register

The EPPI_FS1_PASPL register content varies depending on whether the EPPI is in GP1/2/3 FS modes or in GP transmit mode.

In GP 1, 2, or 3 FS modes, the EPPI_FS1_PASPL register is used for the generation of frame sync 1. The register contains the period required for EPPI_FS1 based on the EPPI_CLK clock.

In GP transmit mode with the EPPI_CTL.BLANKGEN bit set, this register contains the number of samples of active video or vertical blanking samples per line. When used for blanking generation, only the lower 16 bits are valid.

Note that a value of 0 for this register is illegal. If programmed as 0, the EPPI regards the EPPI_FS1_PASPL register as containing 1.

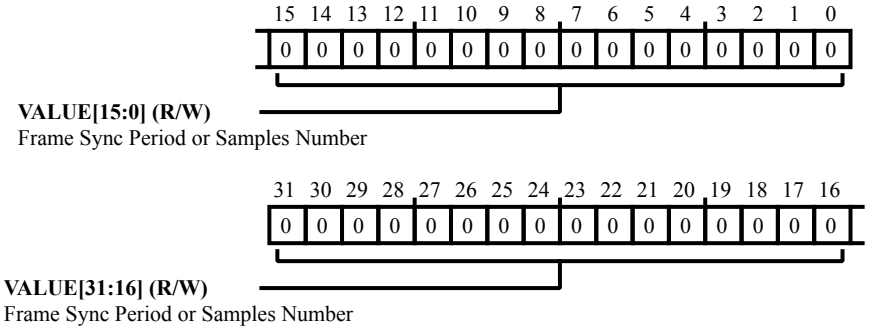

Figure 25-17: EPPI_FS1_PASPL Register Diagram

Table 25-54: EPPI_FS1_PASPL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Frame Sync Period or Samples Number. In GP 1, 2, or 3 FS modes, the EPPI_FS1_PASPL.VALUE bit field is used for the generation of frame sync 1 and contains the period required for EPPI_FS1 based on the EPPI_CLK clock. In GP transmit mode with the EPPI_CTL.BLANKGEN bit set, this bit field contains the number of samples of active video or vertical blanking samples per line.

FS1 Width Register / EPPI Horizontal Blanking Samples Per Line Register

The EPPI_FS1_WLHB register's content varies depending on whether the EPPI is in GP1/2/3 FS modes or in GP transmit mode.

In GP 1, 2 or 3 FS modes, EPPI_FS1_WLHB is used for the generation of frame sync 1. The register contains the width required for EPPI_FS1 based on the EPPI_CLK clock.

In GP transmit mode with the EPPI_CTL.BLANKGEN bit set, this register contains the number of samples of horizontal blanking per line. When used for blanking generation, only the lower 16 bits are valid.

Note that a value of 0 for the EPPI_FS1_WLHB register is illegal. If programmed as 0, the EPPI regards the EPPI_FS1_WLHB register as containing 1.

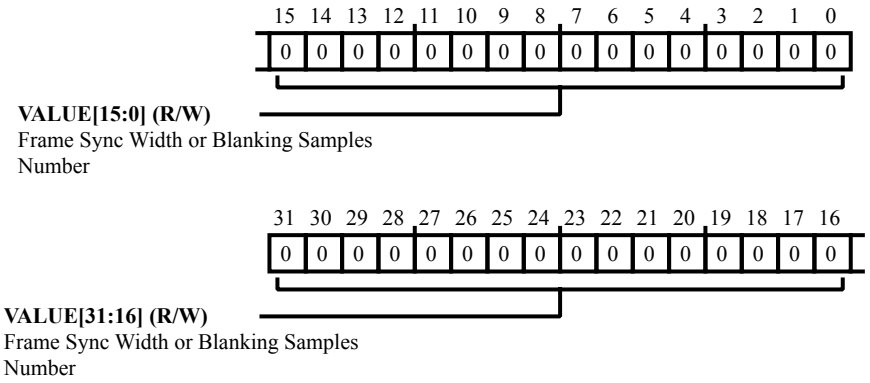

Figure 25-18: EPPI_FS1_WLHB Register Diagram

Table 25-55: EPPI_FS1_WLHB Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Frame Sync Width or Blanking Samples Number. The EPPI_FS1_WLHB.VALUE bit field content varies depending on whether the EPPI is in GP1/2/3 FS modes or in GP transmit mode. In GP 1, 2 or 3 FS modes, the EPPI_FS1_WLHB.VALUE bit field is used for the generation of frame sync 1. The register contains the width required for EPPI_FS1 based on the EPPI_CLK clock. In GP transmit mode with EPPI_CTL.BLANKGEN set, this bit field contains the number of samples of horizontal blanking per line.

Frame Sync 2 Delay Value Register

The EPPI_FS2_DLY register selects the delay count (based on the period of the EPPI_CLK clock) between the first rising edge of EPPI_CLK after EPPI enabled and the first active edge of the associated frame sync when the internal frame sync is used.

Note that if the EPPI_FS1_DLY or EPPI_FS2_DLY registers are programmed with the value 0, the EPPI operates as though 0 value is 1, and the first frame sync transition occurs after the completion of one period value of the respective counters.

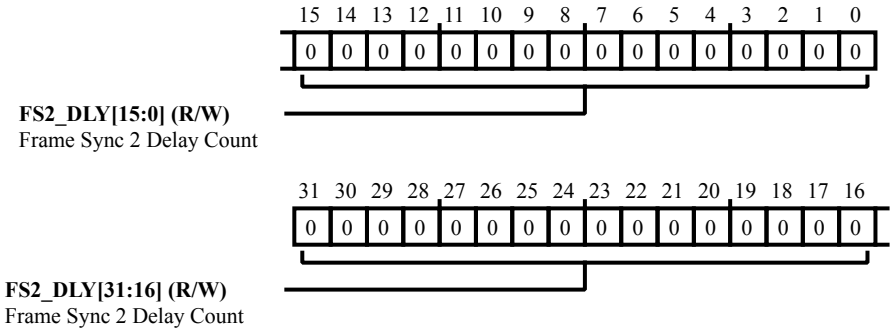

Figure 25-19: EPPI_FS2_DLY Register Diagram

Table 25-56: EPPI_FS2_DLY Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	FS2_DLY	Frame Sync 2 Delay Count. The EPPI_FS2_DLY.FS2_DLY bit field selects the delay count.

FS2 Period Register / EPPI Active Lines Per Field Register

The EPPI_FS2_PALPF register content varies depending on whether the EPPI is in GP2/3 FS modes or in GP transmit mode.

In GP 2 or 3 FS modes, EPPI_FS2_PALPF is used for the generation of frame sync 2. This register contains the period required for EPPI_FS2 based on the EPPI_CLK clock.

In GP transmit mode with the EPPI_CTL.BLANKGEN bit set, this register contains the number of lines of active video per field.

Note that a value of 0 for the EPPI_FS2_PALPF.F1ACT or EPPI_FS2_PALPF.F2ACT bits is illegal. If either is programmed as 0, the EPPI regards the 0 value fields as containing 1.

Also, note that for progressive video, the EPPI_FS2_PALPF.F2ACT bit is ignored.

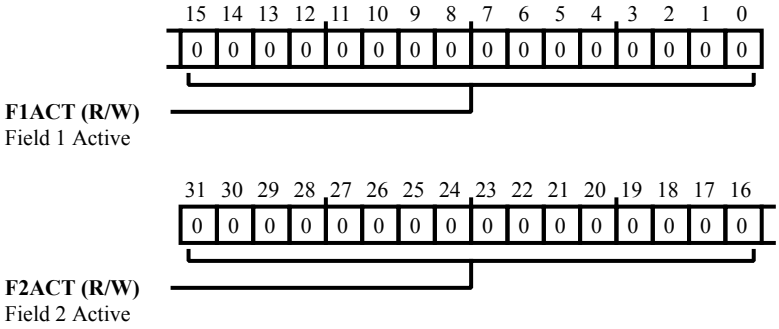

Figure 25-20: EPPI_FS2_PALPF Register Diagram

Table 25-57: EPPI_FS2_PALPF Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/W)	F2ACT	Field 2 Active. The EPPI_FS2_PALPF.F2ACT bit field contains the number of lines of active data in field 2.
15:0 (R/W)	F1ACT	Field 1 Active. The EPPI_FS2_PALPF.F1ACT bit field contains the number of lines of active data in field 1.

FS2 Width Register / EPPI Lines Of Vertical Blanking Register

The EPPI_FS2_WLVB register content varies depending on whether the EPPI is in GP2/3 FS modes or in GP transmit mode.

In GP 2 or 3 FS modes, the EPPI_FS2_WLVB register is used for the generation of frame sync 2. The register contains the width required for EPPI_FS2 based on the EPPI_CLK clock.

In GP transmit mode with the EPPI_CTL.BLANKGEN bit set, this register contains the number or lines of vertical blanking.

Note that for progressive video, the EPPI_FS2_WLVB.F2VBBD and EPPI_FS2_WLVB.F2VBAD bits are ignored.

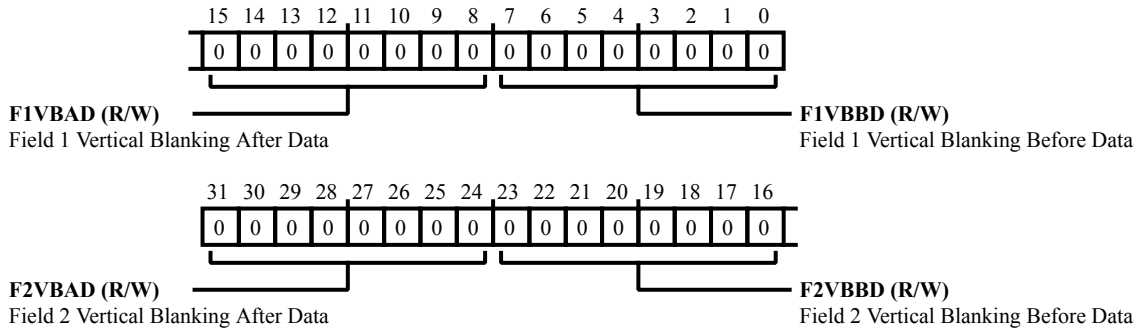

Figure 25-21: EPPI_FS2_WLVB Register Diagram

Table 25-58: EPPI_FS2_WLVB Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	F2VBAD	Field 2 Vertical Blanking After Data. The EPPI_FS2_WLVB.F2VBAD bit field contains the number of lines of vertical blanking after field 2.
23:16 (R/W)	F2VBBD	Field 2 Vertical Blanking Before Data. The EPPI_FS2_WLVB.F2VBBD bit field contains the number of lines of vertical blanking before field 2.
15:8 (R/W)	F1VBAD	Field 1 Vertical Blanking After Data. The EPPI_FS2_WLVB.F1VBAD bit field contains the number of lines of vertical blanking after field 1.
7:0 (R/W)	F1VBBD	Field 1 Vertical Blanking Before Data. The EPPI_FS2_WLVB.F1VBBD bit field contains the number of lines of vertical blanking before field 1.

Horizontal Transfer Count Register

The EPPI_HCNT register holds the number of samples to read in or write out per line, after EPPI_HDLY number of cycles have expired since the assertion of EPPI_FS1. Any write to the EPPI_LINE register modifies the EPPI_HCNT register. But, any write to the EPPI_HCNT register does not affect the EPPI_LINE register value. So the EPPI_HCNT register should be programmed after the EPPI_LINE register.

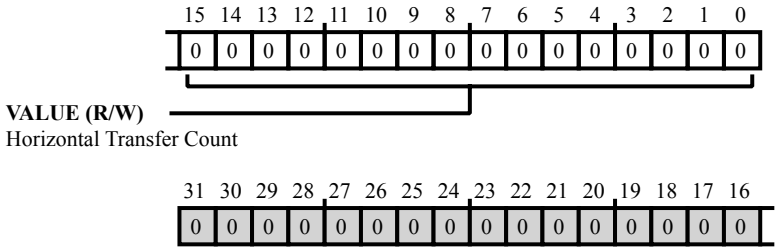

Figure 25-22: EPPI_HCNT Register Diagram

Table 25-59: EPPI_HCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Horizontal Transfer Count. The EPPI_HCNT.VALUE holds the number of samples to read in or write out per line, after EPPI_HDLY number of cycles have expired since the last assertion of EPPI_FS1.

Horizontal Delay Count Register

The EPPI_HDLY register contains the number of clock cycles to delay after the assertion of EPPI_FS1 is detected before starting to read or write data.

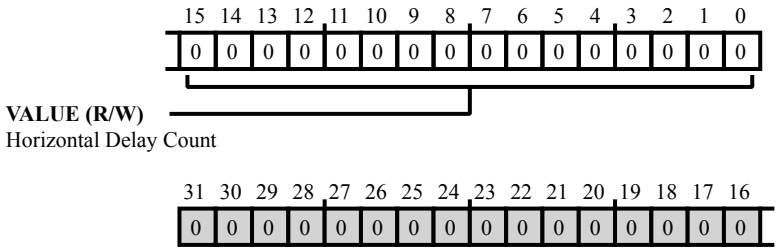

Figure 25-23: EPPI_HDLY Register Diagram

Table 25-60: EPPI_HDLY Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Horizontal Delay Count. The EPPI_HDLY.VALUE holds the number of EPPI_CLK cycles to delay after assertion of EPPI_FS1 before starting to read or write data.

Interrupt Mask Register

The EPPI_IMSK register permits the masking (if associated bit is set) of EPPI error interrupts for YFIFO underflow or overflow, CFIFO underflow or overflow, line track overflow error, line track underflow error, frame track overflow error, frame track underflow error, and ERR_NCOR (ITU preamble error not corrected. These conditions are flagged in the EPPI_STAT register and cleared by write-1-to-clear.

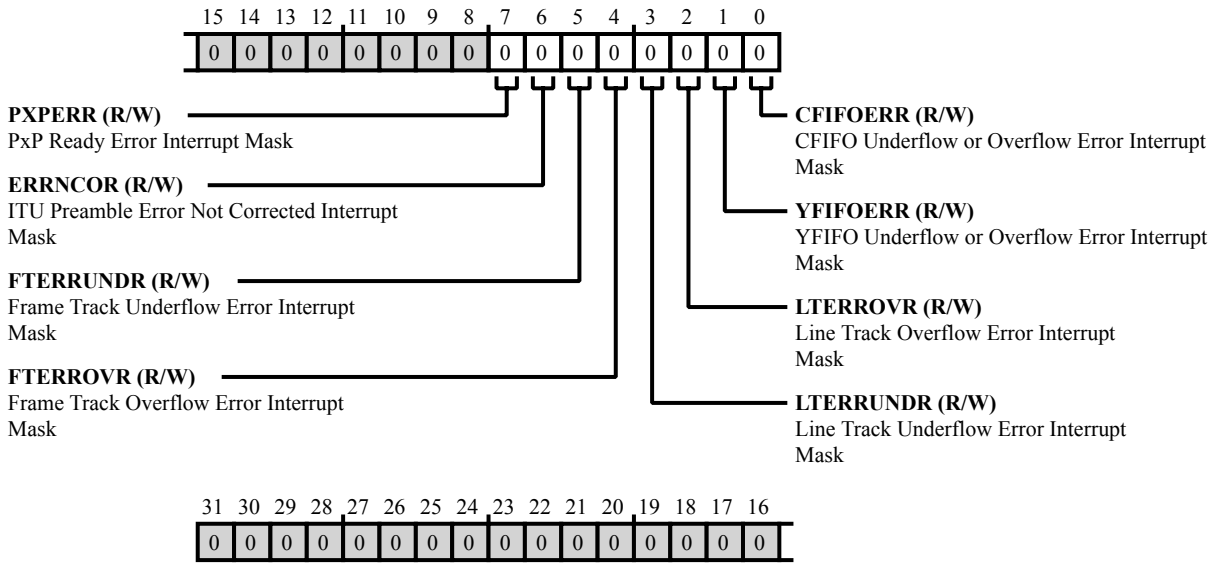

Figure 25-24: EPPI_IMSK Register Diagram

Table 25-61: EPPI_IMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	PXPERR	PxP Ready Error Interrupt Mask.	
		0	Unmask Interrupt
		1	Mask Interrupt
6 (R/W)	ERRNCOR	ITU Preamble Error Not Corrected Interrupt Mask.	
		0	Unmask Interrupt
		1	Mask Interrupt
5 (R/W)	FTERRUNDR	Frame Track Underflow Error Interrupt Mask.	
		0	Unmask Interrupt
		1	Mask Interrupt
4 (R/W)	FTERROVR	Frame Track Overflow Error Interrupt Mask.

		1	Mask Interrupt
0 (R/W)	CFIFOERR	CFIFO Underflow or Overflow Error Interrupt Mask.	
		0	Unmask Interrupt
		1	Mask Interrupt

Samples Per Line Register

The EPPI_LINE register tracks the line track overflow and underflow errors. This register should be programmed with the number of samples expected per line. Any write to the EPPI_LINE register will also write the same value to the EPPI_HCNT register. However, any write to the EPPI_HCNT register does not affect the EPPI_LINE register value. So the EPPI_LINE register should be programmed before the EPPI_HCNT register.

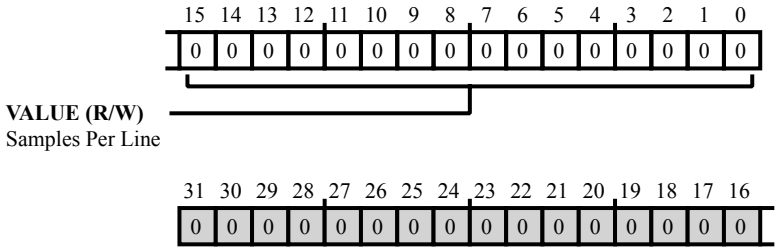

Figure 25-25: EPPI_LINE Register Diagram

Table 25-62: EPPI_LINE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Samples Per Line. The EPPI_LINE.VALUE holds the number of samples expected per line.

Clipping Register for ODD (Chroma) Data Register

The EPPI_ODDCLIP register selects the clipping threshold for chroma data, which provides clipping of individual video components.

The high odd and low odd spaces in EPPI_ODDCLIP are 16-bits wide and (depending on the EPPI_CTL.DLEN bit selection) only the corresponding video component bits are considered for clipping.

For example, if the EPPI is programmed in 10-bit mode, bits [9:0] and bits [25:16] constitute the clipping thresholds. The higher bits are (in this case) ignored.

Using the this method, 8-, 10-, 12- and 16-bit clipping thresholds can be set.

Note that when the EPPI is programmed in 16-, 20-, or 24-bit mode with the EPPI_CTL.SPLTWRD bit set, the luma data gets the clipping threshold levels of the EPPI_EVENCLIP register, and the chroma data gets the clipping threshold levels of the EPPI_ODDCLIP register.

Also, note that the EPPI_EVENCLIP and EPPI_ODDCLIP registers are ignored when the EPPI_CTL.RGBFMTEN bit is set.

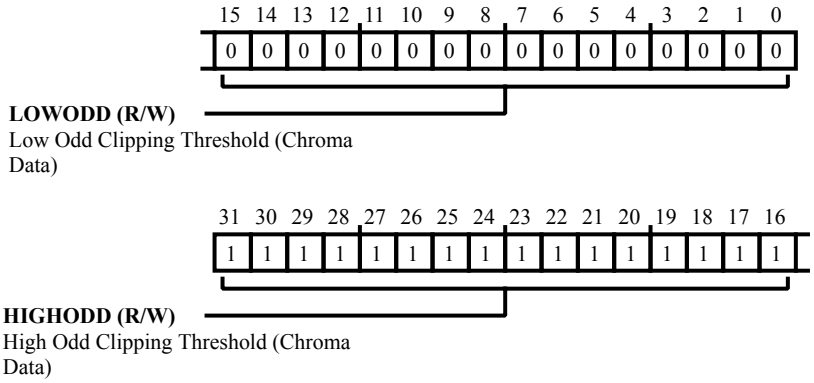

Figure 25-26: EPPI_ODDCLIP Register Diagram

Table 25-63: EPPI_ODDCLIP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/W)	HIGHODD	High Odd Clipping Threshold (Chroma Data). The EPPI_ODDCLIP.HIGHODD bit field selects the clipping threshold for luma data. The high odd spaces are 16-bits wide and (depending on the EPPI_CTL.DLEN selection) only the corresponding video component bits are considered for clipping.
15:0 (R/W)	LOWODD	Low Odd Clipping Threshold (Chroma Data). The EPPI_ODDCLIP.LOWODD bit field selects the clipping threshold for luma data. The low add spaces are 16-bits wide and (depending on the EPPI_CTL.DLEN selection) only the corresponding video component bits are considered for clipping.

Status Register

The EPPI_STAT register contains bits that provide information about the current operating state of the EPPI.

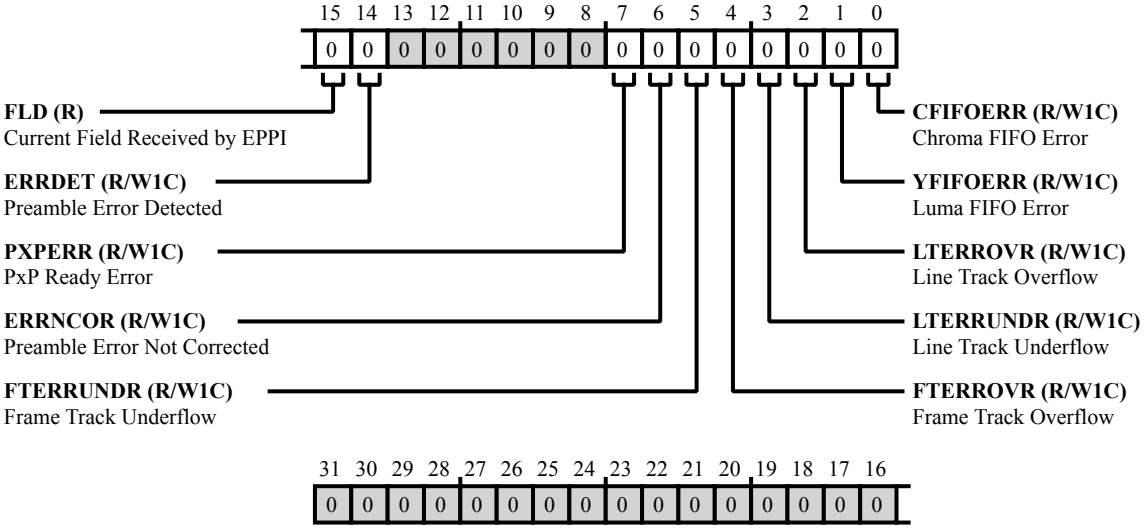

Figure 25-27: EPPI_STAT Register Diagram

Table 25-64: EPPI_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/NW)	FLD	Current Field Received by EPPI. The EPPI_STAT.FLD bit indicates whether the current field being received by the PPI is field 1 (if clear) or field 2 (if set).	
		0	Field 1
		1	Field 2
14 (R/W1C)	ERRDET	Preamble Error Detected. The EPPI_STAT.ERRDET bit is useful only in ITU receive modes and indicates if an error has been detected in the status word of EAV or SAV sequences (if set) or not (if clear).	
		0	No Preamble Error Detected
		1	Preamble Error Detected
7 (R/W1C)	PXPERR	PxP Ready Error. The EPPI_STAT.PXPERR bit is valid only in the RX mode. This bit indicates whether the incoming PPI data overflows the PxP interface (if set) or not (if clear). This bit is sticky and must be cleared by software by writing 1 to it.	

Table 25-64: EPPI_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6 (R/W1C)	ERRNCOR	Preamble Error Not Corrected. The `EPPI_STAT.ERRNCOR` bit is useful only in the ITU receive modes and indicates if an error in the status word of EAV or SAV sequences can not be cleared (if set) or not (if clear). This bit is sticky and must be cleared by software by writing 1 to it.	
		0	No uncorrected preamble error has occurred
		1	Preamble error detected but not corrected
5 (R/W1C)	FTERRUNDR	Frame Track Underflow. The `EPPI_STAT.FTERRUNDR` bit indicates whether a frame track underflow error has occurred (if set) or not (if clear). This bit is sticky and must be cleared by software by writing 1 to it.	
		0	No Error Detected
		1	Error Occurred
4 (R/W1C)	FTERROVR	Frame Track Overflow. The `EPPI_STAT.FTERROVR` bit indicates whether a frame track overflow error has occurred (if set) or not (if clear). This bit is sticky and must be cleared by software by writing 1 to it.	
		0	No Error Detected
		1	Error Occurred
3 (R/W1C)	LTERRUNDR	Line Track Underflow. The `EPPI_STAT.LTERRUNDR` bit indicates whether a line track underflow error has occurred (if set) or not (if clear). This bit is sticky and must be cleared by software by writing 1 to it.	
		0	No Error Detected
		1	Error Occurred
2 (R/W1C)	LTERROVR	Line Track Overflow. The `EPPI_STAT.LTERROVR` bit indicates whether a line track overflow error has occurred (if set) or not (if clear). This bit is sticky and must be cleared by software by writing 1 to it.	
		0	No Error Detected
		1	Error Occurred

Table 25-64: EPPI_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W1C)	YFIFOERR	Luma FIFO Error. For RX modes, the `EPPI_STAT.YFIFOERR` bit indicates whether the Luma FIFO has overflowed (if set) or not (if clear). For TX modes, this bit indicates whether the Luma FIFO has underflowed (if set) or not (if clear). This bit is sticky and must be cleared by software by writing 1 to it.	
		0	No Error Detected
		1	Error Occurred
0 (R/W1C)	CFIFOERR	Chroma FIFO Error. For RX modes, the `EPPI_STAT.CFIFOERR` bit indicates whether the chroma FIFO has overflowed (if set) or not (if clear). For TX modes, this bit indicates whether the chroma FIFO has underflowed (if set) or not (if clear). This bit is sticky and must be cleared by software by writing 1 to it.	
		0	No Error Detected
		1	Error Occurred

Vertical Transfer Count Register

The EPPI_VCNT register holds the number of lines to read in or write out, after EPPI_VDLY number of lines from the start of frame. Any write to the EPPI_FRAME register modifies the EPPI_VCNT register. However, any write to the EPPI_VCNT register does not affect the EPPI_FRAME register value. So the EPPI_VCNT register should be programmed after the EPPI_FRAME register.

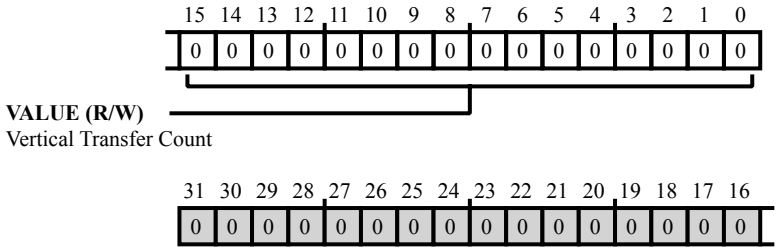

Figure 25-28: EPPI_VCNT Register Diagram

Table 25-65: EPPI_VCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Vertical Transfer Count. The EPPI_VCNT.VALUE holds the number of lines to read in or write out, after EPPI_VDLY number of lines from the start of frame.

Vertical Delay Count Register

The EPPI_VDLY register contains the number of lines to wait after the start of a new frame before starting to read/transmit data.

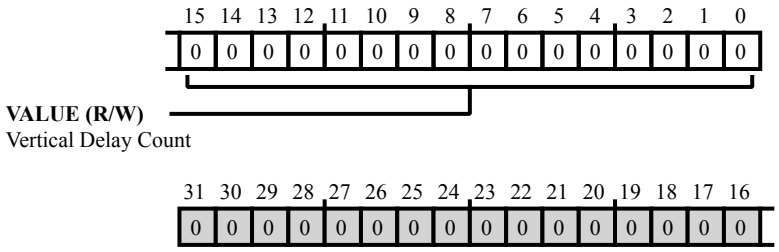

Figure 25-29: EPPI_VDLY Register Diagram

Table 25-66: EPPI_VDLY Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Vertical Delay Count. The EPPI_VDLY.VALUE holds the number of lines to wait after the start of a new frame before starting to read/transmit data.

26 General-Purpose Timer (TIMER)

The general-purpose timer (GP Timer) module serves as a collection of system timers that support various system-level functions. These functions include:

- Synchronized PWM waveform output capability
- External signal capture
- External event count
- General time-base functionality

Additionally, interrupt requests can be generated upon completion of timer events. Moreover, GP timers can act both as trigger requesters and trigger completers.

GP Timer Features

Each timer can be individually configured in any of these modes:

- Pin interrupt capture mode
- Windowed watchdog mode
- Pulse-width count and capture (WDTH_CAP) mode
- External Event (EXT_CLK) mode
- Pulse-width modulation (PWM_OUT) mode

Other features include:

- Synchronous operation
- Consistent management of period and pulse width values
- Autobaud detection for UART module (where available)
- Graceful bit pattern termination when stopping
- Support for center-aligned PWM patterns
- Error detection on implausible pattern values

- All read and write accesses to 32-bit registers are atomic
- Every timer has its dedicated interrupt request output

ADSP-SC59x TIMER Register List

The General-Purpose Timer block (TIMER) provides timers that may be used for external event capture and measurement, system timing, and PWM waveform generation. A set of registers governs TIMER operations. For more information on TIMER functionality, see the TIMER register descriptions.

Table 26-1: ADSP-SC59x TIMER Register List

Name	Description
TIMER_BCAST_DLY	Broadcast Delay Register
TIMER_BCAST_PER	Broadcast Period Register
TIMER_BCAST_WID	Broadcast Width Register
TIMER_DATA_ILAT	Data Interrupt Latch Register
TIMER_DATA_IMSK	Data Interrupt Mask Register
TIMER_ERR_TYPE	Error Type Status Register
TIMER_RUN	Run Register

Timer Block Diagram

The ***Timer Block Diagram*** shows all of the possible clock sources.

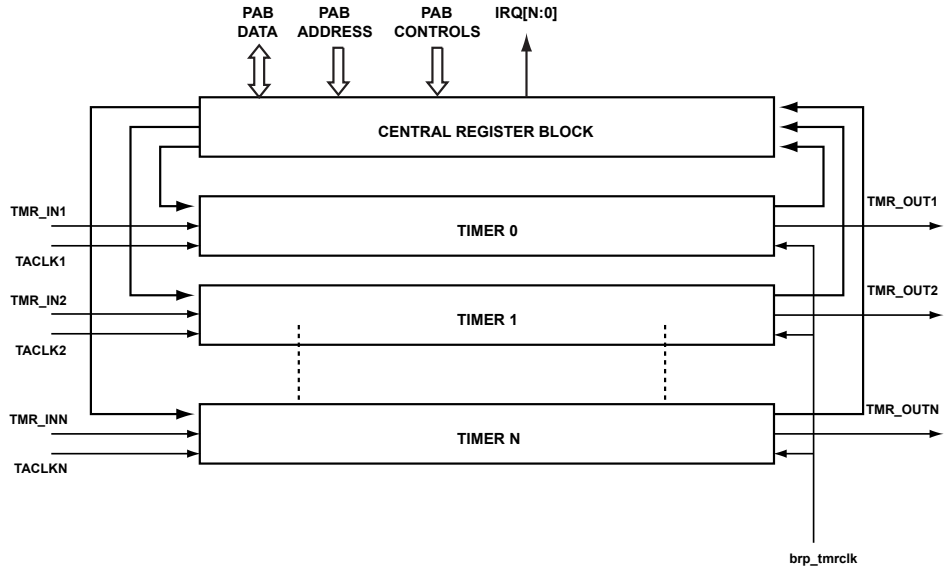

Figure 26-1: Timer Block Diagram

Internal Interface

The processor core always accesses the timer registers through the MMR access bus. Hardware ensures that all read and write operations from and to 32-bit timer registers are atomic. Every timer has a dedicated data interrupt request. There is also one common timer status and error interrupt request output that connects to the system event controller. Whenever a data interrupt request is generated, a data trigger generator pulse is also driven out, if

enabled. Each timer has an individual trigger input line, and each timer can be either started or stopped as a trigger receiver.

In total, the GP timer module can have up to (N + 1) interrupt request output lines and N data trigger lines.

Internal Timer Connections

The Timers support alternate inputs for the clock/capture (see External Interface). Some signals have internal default alternate connections according to the ***Timer Signal Routing*** table.

Table 26-5: Timer Signal Routing

Timer Signal	Connection
TM0_ACLK0	SYS_CLKIN0
TM0_ACI5	DAI0_PB04
TM0_ACLK5	DAI0_PB03
TM0_ACI6	DAI1_PB04
TM0_ACLK6	DAI1_PB03
TM0_ACI07	CNT0_TO
TM0_ACLK7	SYS_CLKIN1
TM0_ACI8	DAI0_PB06
TM0_ACLK8	DAI0_PB05
TM0_ACI9	DAI1_PB06
TM0_ACLK9	DAI1_PB05
TM0_ACI14	DAI0 Group C
TM0_ACI15	DAI1 Group C

External Interface

Each GP timer module can support up to 16 individual timers. However, most processors have less than this number. The exact number of timers available on a given processor is available in the data sheet for the processor.

Every timer has one main input/output signal (`TIMER_TMR[nn]`) and, usually, one auxiliary input pin, used as an alternate capture input (`TIMER_ACI[nn]`). Each timer can either run with a time base of SCLK0 or can reference an external clock on one of two (`TIMER_ACLK[nn]`) pins. The TMR_ALT_CLK0 signal maps to individual alternate clock ((`TIMER_ACLK[nn]`) pins for one or more timers. For instance, a TM_ACLK3 pin would provide an alternate site to supply an external signal that would serve as reference clock for TMR3. Likewise, the TMR_ALT_CLK1 signal from each timer unit connects internally to provide a single global timer clock pin (`TIMER_CLK`) for the GP timer module. It is used as an additional time base.

GP Timer Operating Modes

The following sections provide information on the various operating modes of the GP timer.

General Operation

The core of every timer is a 32-bit counter that can be interrogated through the read-only TIMER_TMR[n]_CNT register. Once the module enables a timer, it loads the timer TIMER_TMR[n]_CNT register with a starting value.

A timer can operate in one of several different modes, configured through the TIMER_TMR[n]_CFG register for that timer. These modes are: PWMOUT, EXTCLK, WIDCAP, WATCHDOG, PININT, and IDLE. The ***Timer Mode Descriptions*** table summarizes the modes.

Table 26-6: Timer Mode Descriptions

Timer Mode	Description
PWMOUT	Generates single or continuous PWM waveforms with programmable pulse width, period, and delay
EXTCLK	Counts edges of an externally applied waveform
WIDCAP	Captures pulse width or period of an externally applied waveform
WATCHDOG	Monitors pulse width or period of an external signal and compares against a window of acceptable values, optionally generating an interrupt when it falls inside or outside of that window
PININT	Can generate an interrupt request on an active edge applied to a timer pin
IDLE	Idle; no activity

Period, Width and Delay Register Interaction

When the timer is started, writes to the buffer registers are immediately copied through to the double-buffered period, pulse width, and delay registers. These values are then ready for use in the first timer period. When a timer is already running, software can write new values to the TIMER_TMR[n]_PER, TIMER_TMR[n]_WID, and TIMER_TMR[n]_DLY registers. The written values are buffered and do not update into the registers until the end of the current period. (The update occurs when the value in the TIMER_TMR[n]_CNT register equals the value in the TIMER_TMR[n]_PER register.)

If new values are not written to these registers, the value from the previous period is reused. Writes to these registers are atomic; it is not possible for the high word to be written without the low word also being written. Values written to the period, pulse width, and delay registers are always stored in the buffer registers. Reads from the same register always return the current, active value of period, pulse width, or delay value. Written values are not readback until they become active.

The usage of the TIMER_TMR[n]_PER, TIMER_TMR[n]_WID, and TIMER_TMR[n]_DLY registers varies, depending on the mode of the timer specified by the TIMER_TMR[n]_CFG.TMODE bits. See the ***Usage of the Period, Width, and Delay Registers in Different Timer Modes*** table for more information.

Table 26-7: Usage of the Period, Width, and Delay Registers in Different Timer Modes

Timer Mode	**TIMER_TMR[n]_PER**	**TIMER_TMR[n]_WID**	**TIMER_TMR[n]_DLY**
IDLE	Not writable	Not writable	Not writable

Table 26-7: Usage of the Period, Width, and Delay Registers in Different Timer Modes (Continued)

Timer Mode	TIMER_TMR[n]_PER	TIMER_TMR[n]_WID	TIMER_TMR[n]_DLY
WATCHDOG	Update on-the-fly. New value takes effect either at timer start or when an asserting edge on the input signal is sensed.	Read-only. Retains value of last measured width or period of the input signal.	Update on-the-fly. New value takes effect either at timer start or when an asserting edge on the input signal is sensed.
WIDCAP	Read-only. Period value captured at the appropriate time and updated from its buffer register simultaneously with the Width register.	Read-only. Width value captured at the appropriate time and updated from its buffer register simultaneously with the Period register.	Not used
PWMOUT	Update on-the-fly. New value takes effect either at timer start or at the end of the current period. A write followed by immediate read returns the current operating values.	Update on-the-fly. New value takes effect either at timer start or at the end of the current period. A write followed by immediate read returns the current operating values.	Update on-the-fly. New value takes effect either at timer start or at the end of the current period. A write followed by immediate read returns the current operating values.
EXTCLK	Can be updated on-the-fly.	Not used	Not used
PININT	Not used	Not used	Not used

If any of the period, pulse width, and delay registers are not used, then programs cannot write into that register. For example, in WIDCAP mode, the delay registers are not used. So, the program is not allowed to write any value to the TIMER_TMR[n]_DLY register. To prevent undesired operation, program the TIMER_TMR[n]_CFG.TMODE bits before programming the period, width, or delay registers.

If a program changes the TIMER_TMR[n]_CFG.TMODE bits from a status register to writable register (for example in PWMOUT mode), hardware does not clear these registers. These values are automatically overwritten by new values specified by software.

In PWMOUT mode with small periods, there may not be enough time between updates from the buffer registers to write these registers. The next period can use one old value and one new value. To prevent (width + pulse delay) > period errors, write the width and delay registers before the period register when decreasing the values. Write the period register before the width and delay registers when increasing the value.

Single-Pulse PWMOUT Mode

In single-pulse PWMOUT mode, the timer generates a single pulse on the TIMER_TMR[nn] pin. This mode is frequently used to implement a precise delay, often with generating an output trigger. The timer module uses the value in the TIMER_TMR[n]_DLY register to control the assertion of a pulse. The value in the TIMER_TMR[n]_WID register defines the pulse width. The TIMER_TMR[n]_PER is not used and cannot be written in this mode. After completion of the pulse, the timer is automatically stopped, and optionally generates an interrupt. The timer uses the TIMER_TMR[n]_CFG.PULSEHI bit to control pulse polarity.

The timer can be configured to generate a data interrupt request after satisfying various conditions specified by the TIMER_TMR[n]_CFG.IRQMODE bits.

It is not necessary to clear the relevant TIMER_RUN bit to stop the timer cleanly. At the end of the pulse, the timer stops automatically and the corresponding TIMER_RUN bit is cleared. To generate multiple discrete pulses (as opposed to a continuous PWM waveform), write a 1 to the appropriate TIMER_RUN bit, and wait for the timer to stop. Then, write another 1 to the same TIMER_RUN bit.

Continuous PWMOUT Mode

In continuous PWMOUT mode, the timer generates a repetitive pulse with a well-defined period, duty cycle, and pulse position. The TIMER_TMR[n]_DLY, TIMER_TMR[n]_PER, and TIMER_TMR[n]_WID registers are programmed with the values of the required PWM pulse. After the timer is started, the counter counts towards the value programmed in the TIMER_TMR[n]_PER register. Initially, the TIMER_TMR[nn] pin remains in a deasserted state. The pin toggles to an asserted state when the value in the TIMER_TMR[n]_CNT register equals the value in the TIMER_TMR[n]_DLY register.

The timer can control the assertion sense of the TIMER_TMR[nn] pin with the TIMER_TMR[n]_CFG.PULSEHI bit. The TIMER_TMR[nn] pin holds this value for the number of clock cycles specified in the TIMER_TMR[n]_WID register. Then, the pin deasserts and holds this value until the completion of the programmed period. The same waveform is generated repeatedly until the timer is disabled.

The timer can be configured to generate a data interrupt request after satisfying any of various conditions specified by the TIMER_TMR[n]_CFG.IRQMODE bits.

It is important to guarantee that the programmed period is greater than or equal to the sum of width and delay. Similarly, delay must be less than period. Violating either of these criteria results in an unpredictable waveform on the TIMER_TMR[nn] pin until the situation is rectified by writing proper values to these registers.

The maximum frequency possible to generate on the TIMER_TMR[nn] pin is achieved by setting TIMER_TMR[n]_PER to 2 and TIMER_TMR[n]_WID to 1. This operation makes the TIMER_TMR[nn] pin toggle each SCLK0 clock cycle (assuming the timer is configured to clock internally), producing a duty cycle of 50%.

When the TIMER_STOP_CFG.TMR[nn] bit of a timer is 0, the timer treats a stop operation as a stop-is-pending condition. When terminated with this setting, the timer automatically completes the current waveform and then stops cleanly, remaining in a deasserted state. This funtionality prevents truncation of the current pulse and unwanted PWM patterns at the TIMER_TMR[nn] pin. The processor can determine when the timer stops running by polling the corresponding TIMER_RUN.TMR[nn] bit until it reads 0 or by waiting for the last interrupt (if enabled).

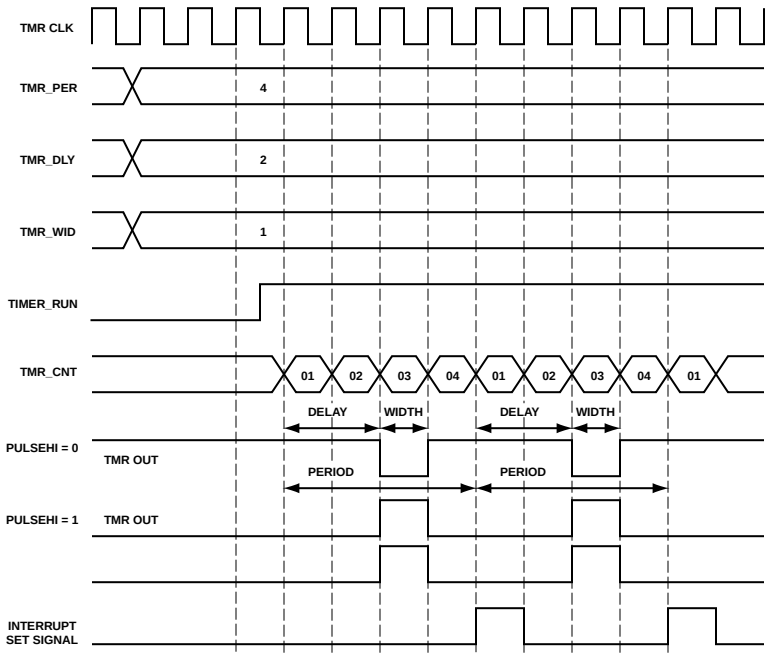

Figure 26-2: Signal Generation in Continuous PWMOUT Mode

The TIMER_TMR[n]_CFG register cannot be reconfigured until after the timer stops and the TIMER_RUN register reads 0.

Programs can force a timer to stop immediately in PWMOUT mode by writing a 1 to the TIMER_STOP_CFG register followed by writing a 1 to the TIMER_RUN_CLR register. (Or a program can stop a timer by writing a 0 to the appropriate TIMER_RUN.TMR[nn] bit.) This operation stops the timer whether the pending stop is waiting for the end of the current period or the end of the current pulse width. The timer can use this feature to regain immediate control of a timer during an error recovery sequence.

Use this feature carefully, as it can corrupt the PWM pattern generated at the TIMER_TMR[nn] pin, though after such a stop the pin deasserts automatically. Each timer samples its TIMER_RUN.TMR[nn] bit at the end of each period. It stops cleanly at the end of the first period after the TIMER_RUN.TMR[nn] bit is low. A timer that is disabled and then restarted (before the end of the current period), continues to run as if nothing happened. Typically, the program disables a PWMOUT timer and then waits for it to stop itself.

Width Capture (WIDCAP) Mode

The timer uses WIDCAP mode, often called capture mode, to measure pulse widths on the TIMER_TMR[nn] or (TIMER_ACI[nn]) inputs. The polarity (active high or low) of the input signal can be selected with the TIMER_TMR[n]_CFG.PULSEHI bit. The ***Timer Signal Flow in Width Capture Mode*** figure shows the control signal flow for WIDCAP_CAP mode.

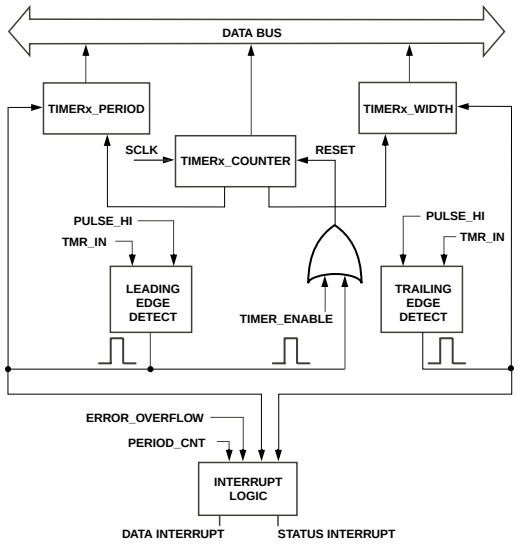

Figure 26-3: Timer Signal Flow in Width Capture Mode

NOTE: SCLK in the ***Timer Signal Flow in Width Capture Mode*** figure is SCLK0.

In this mode, the timer uses the `TIMER_TMR[n]_CFG.TINSEL` bit to select between the `TIMER_TMR[nn]` or(`TIMER_ACI[nn]`) input. The internally clocked timer is used to determine the period and pulse width of the externally applied rectangular waveforms.

When a timer is enabled in this mode, the timer resets the count in its `TIMER_TMR[n]_CNT` register to 0x0000 0001. It does not start counting until it detects a leading edge on the selected input pin.

When the timer detects the first leading edge, it starts incrementing. When it detects a trailing edge of a waveform, it captures the current 32-bit value of its `TIMER_TMR[n]_CNT` register into its width buffer register. At the next leading edge, the timer transfers the current 32-bit value of its `TIMER_TMR[n]_CNT` register into its period buffer register. The `TIMER_TMR[n]_CNT` register is reset to 0x0000 0001 again, and the timer continues counting and capturing until it is disabled.

In this mode, programs can measure both the pulse width and the pulse period of a waveform. The timer does not use the `TIMER_TMR[n]_DLY` register in this mode. The timer uses the `TIMER_TMR[n]_CFG.PULSEHI` bit to control the definition of leading edge and trailing edge of the `TIMER_TMR[nn]` /(`TIMER_ACI[nn]`) pin.

In WIDCAP mode, the following events always occur at the same time as one unit:

1. The `TIMER_TMR[n]_PER` register is updated from the period buffer register.
2. The `TIMER_TMR[n]_WID` register is updated from the width buffer register.
3. The `TIMER_DATA_ILAT.TMR[nn]` bit is set (if enabled).
4. A timer data trigger pulse is generated (if enabled).

The `TIMER_TMR[n]_CFG.TMODE` bit 0 controls the point in time at which this set of events is executed. Taken together, these four events are called a measurement report. The `TIMER_STAT_ILAT` register is not set at a

measurement report. A measurement report occurs, at most, once per input signal period. The current TIMER_TMR[n]_CNT value is always copied to the width buffer and period buffer registers at the trailing and leading edges of the input signal, respectively. But these values are not visible to software. A measurement report event samples the captured values into visible registers and sets the timer interrupt request to signal that the TIMER_TMR[n]_PER and the TIMER_TMR[n]_WID registers are ready to be read.

When the TIMER_TMR[n]_CFG.TMODE bit =b#1011, the measurement report occurs just after the width buffer register captures its value at a falling edge. Then, the TIMER_TMR[n]_WID register reports the pulse width measured in the pulse that has ended, but the TIMER_TMR[n]_PER register reports the pulse period measured at the end of the previous period. If only the first trailing edge has occurred, then the first period value has not yet been measured at the first measurement report. So, the period value is not valid. A read of the TIMER_TMR[n]_PER value in this case returns 0. See the ***Example of Width Capture Deasserted Mode (TMODE=b#1011)*** figure for more information.

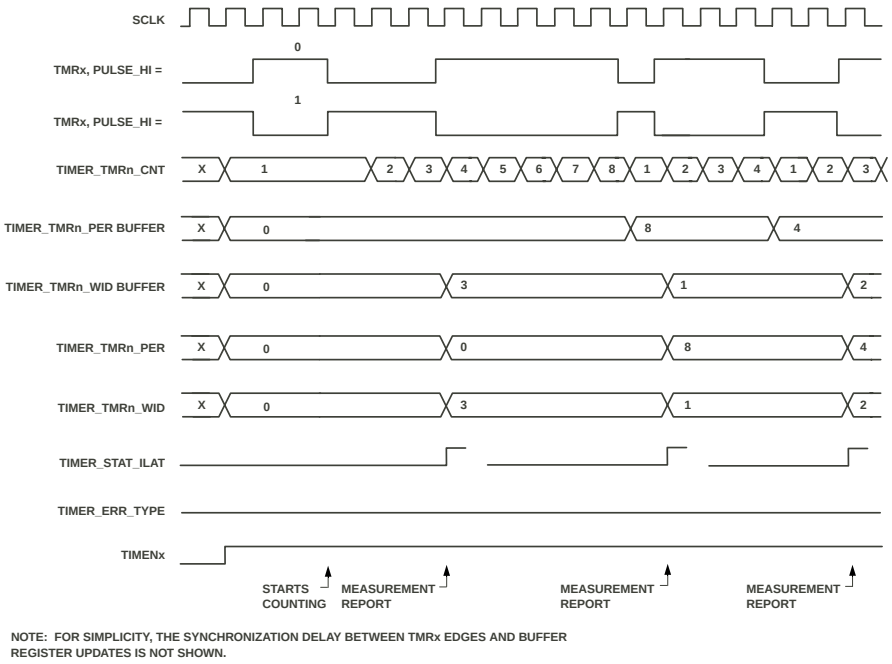

Figure 26-4: Example of Width Capture Deasserted Mode (TMODE=b#1011)

NOTE: SCLK in the ***Example of Width Capture Deasserted Mode (TMODE=b#1011)*** figure is SCLK0.

When the TIMER_TMR[n]_CFG.TMODE bit =b#1010, the measurement report occurs just after the period buffer register captures its value at a leading edge. Then, the TIMER_TMR[n]_PER and TIMER_TMR[n]_WID registers report the pulse period and pulse width measured in the period that has ended. Refer to the ***Example of Width Capture Asserted Mode (TMODE=b#1010)*** figure for more information.

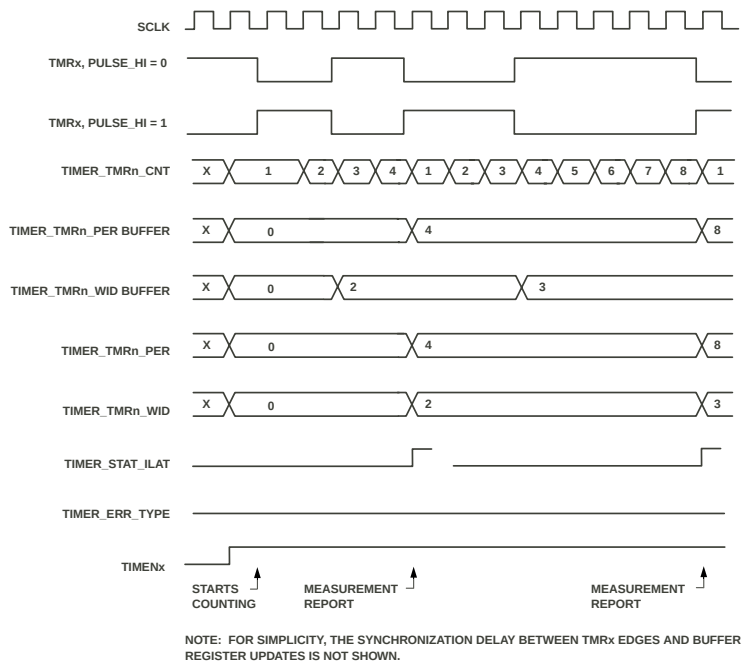

Figure 26-5: Example of Width Capture Asserted Mode (TMODE=b#1010)

NOTE: SCLK in the ***Example of Width Capture Asserted Mode (TMODE=b#1010)*** figure is SCLK0.

To measure the pulse width of a waveform that has only one leading edge and one trailing edge, set `TIMER_TMR[n]_CFG.TMODE` = b#1011. When `TIMER_TMR[n]_CFG.TMODE` = b#1010, no period value is captured in the period buffer register. Instead, the timer generates an error report interrupt request (if enabled) when the `TIMER_TMR[n]_CNT` range is exceeded and the counter wraps around. In this case, both the `TIMER_TMR[n]_PER` and `TIMER_TMR[n]_WID` registers read 0 (because no measurement report occurred to copy the value captured in the width buffer register to the `TIMER_TMR[n]_WID` register).

When using the `TIMER_TMR[n]_CFG.TMODE` bit =b#1010 mode to measure the width of a single pulse, programs can disable the timer after taking the interrupt that ends the measurement interval. When desired, restart the timer as appropriate in preparation for another measurement. This procedure prevents the timer from freely running after the width measurement and logging errors generated by the timer count overflowing.

Width Capture Mode Overflow

A timer status interrupt request (when enabled) is generated when the `TIMER_TMR[n]_CNT` register wraps around from 0xFFFF FFFF to 0 in the absence of a leading edge. At that point, the `TIMER_STAT_ILAT` bit is set and the `TIMER_ERR_TYPE` bits change to indicate a count overflow due to a period greater than the range of the counter. This indication is referred to as an error report. A data interrupt request in WIDCAP mode indicates that a new measurement is ready to be read (a measurement report). Similarly, an interrupt request on the timer status interrupt line (shared interrupt request for all timers) indicates an overflow error when generated in this mode.

The `TIMER_TMR[n]_PER` and `TIMER_TMR[n]_WID` registers are never updated at the time an overflow error is signaled. If the timer overflows and the `TIMER_TMR[n]_CFG.TMODE` bit =b#1010, the `TIMER_TMR[n]_PER` and `TIMER_TMR[n]_WID` registers are not updated. If the timer overflows and the

TIMER_TMR[n]_CFG.TMODE bit =b#1011, the TIMER_TMR[n]_PER and TIMER_TMR[n]_WID registers are updated only if a trailing edge is detected at a previous measurement report.

Software can count the number of error reports between measurement report interrupt requests to measure input signal periods longer than 0xFFFF FFFF. Each error report interrupt request adds a full 2^{32}SCLK0 counts to the total for the period, but the width is ambiguous. Ensure that if software monitors only the status interrupt request, then status interrupt requests from all other timers are masked.

Refer to the ***Example Timing for Width Capture Followed by Period Overflow (TMR_CFG.TMODE=b#1010)*** figure. The period is 0x1 0000 0004, but the pulse width could be either 0x0 0000 0002 or 0x1 0000 0002.

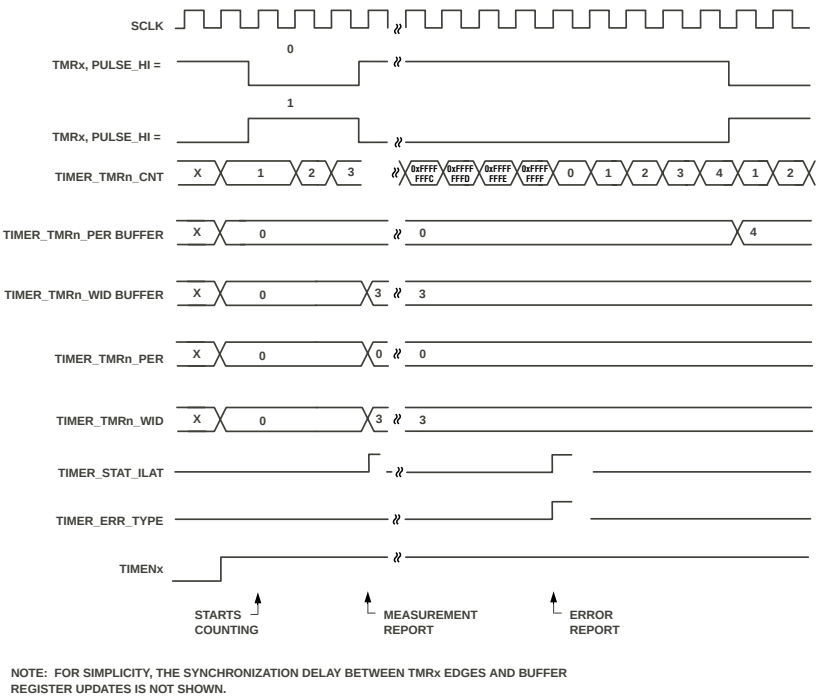

Figure 26-6: Example Timing for Width Capture Followed by Period Overflow (TMR_CFG.TMODE=b#1010)

NOTE: SCLK in the ***Example Timing for Width Capture Followed by Period Overflow*** figure is SCLK0.

The waveform applied to the TIMER_TMR[nn] (or (TIMER_ACI[nn])) pin is not required to have a 50% duty cycle. The minimum input low time is little more than one SCLK0 period. The minimum input high time is a little more than one SCLK0 period. (Refer to the product data sheet for details.) The maximum TIMER_TMR[nn] input frequency is less than SCLK0/2, with a 50% duty cycle. Under these conditions, the WIDCAP mode timer measures: period =2 and pulse width =1.

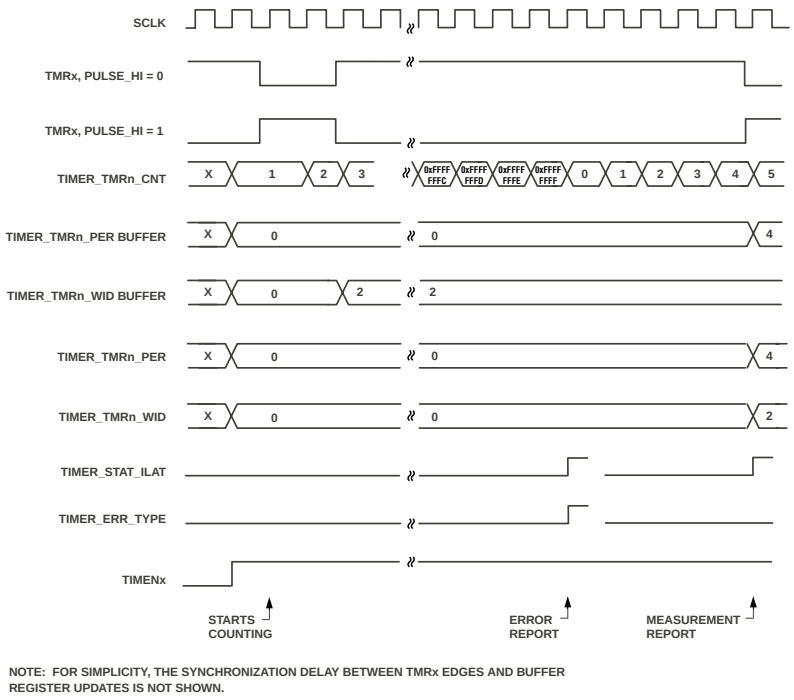

Figure 26-7: Example Timing for Width Capture Followed by Period Overflow (TMR_CFG.TMODE=b#1011)

NOTE: SCLK in the ***Example Timing for Width Capture Followed by Period Overflow*** figure is SCLK0.

Windowed Watchdog (WATCHDOG) Modes

In windowed watchdog (WATCHDOG) modes, a timer can take inputs from one of the `TIMER_TMR[nn]` pins or the `TIMER_ACI[nn]` pins. With this mode, the timer can monitor pulse width (width watchdog mode) or pulse period (period watchdog mode) on the input line. It also compares the measured value against a minimum required value and maximum allowed value and generates an interrupt request appropriately. The timer uses the `TIMER_TMR[n]_CFG.PULSEHI` bit to select polarity of the input signal.

The waveform applied to the input pin in watchdog mode is not required to have a 50% duty cycle. The minimum input pulse low time, high time, and total period specifications are available in the product data sheet.

Windowed Watchdog Width Mode

In windowed watchdog width mode, the timer counter monitors the pulse width of an input signal on one of the `TIMER_TMR[nn]` pins or one of the alternate clock pins (`TIMER_ACLK[nn]`). Program the minimum pulse width (p_{MIN}) in the `TIMER_TMR[n]_DLY` register and the maximum pulse width (p_{MAX}) in the `TIMER_TMR[n]_PER` register. Both values are programmed in terms of number of clock cycles (SCLK0 or alternate clock). The timer can generate an interrupt if the deasserting pulse edge occurs:

- Inside the window (p_{MIN} < pulse width ≤ p_{MAX}), or
- Outside the window (pulse width ≤ p_{MIN} or pulse width > p_{MAX})

After enabling the timer in this mode, it always starts counting at the asserting edge of the input signal. Any pulse that is already active when the timer is enabled is ignored.

With the TIMER_TMR[n]_CFG.IRQMODE bit =b#11, the timer generates an interrupt if the timed pulse width exceeds p_{MAX}, or if the pulse width is less than p_{MIN}. After attaining p_{MAX}, the pulse stays at an active level, and the counter keeps on counting until it sees a deasserting edge. When the input pulse is not active, the counter holds its current value until it again sees an asserting edge, or it restarts. An interrupt can also be generated for when the pulse occurs within the specified window condition, by setting TIMER_TMR[n]_CFG.IRQMODE =b#10.

In this mode, a trailing edge on the input pin triggers capturing of pulse width into the TIMER_TMR[n]_WID register. During the inactive portion of the input signal, the internal counter does not increment. The ***Watchdog Width Mode Timing*** figure shows the signal flow in this mode.

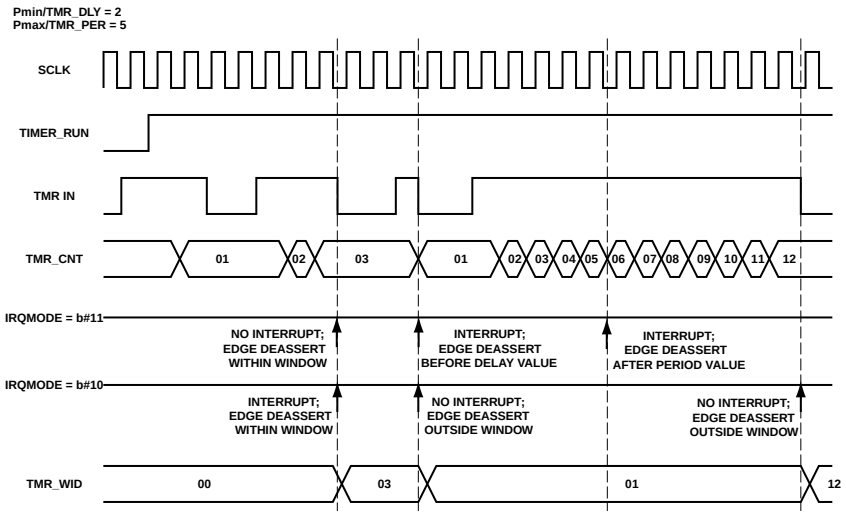

Figure 26-8: Watchdog Width Mode Timing

NOTE: SCLK in the ***Watchdog Width Mode Timing*** figure is SCLK0.

To check only the upper limit on pulse width (p_{MAX} but not p_{MIN}), then program p_{MIN} as 0 or 1. In such a case, it is better to use TIMER_TMR[n]_CFG.IRQMODE =b#11. With TIMER_TMR[n]_CFG.IRQMODE = b#10, a pulse width of 1 clock cycle results in an interrupt. For details, see the ***Windowed Watchdog Width Mode Interpretation*** table.

Table 26-8: Windowed Watchdog Width Mode Interpretation

Timer Delay	Timer Period	Incoming Pulse Width	IRQMODE= b#10	IRQMODE= b#11	Error Interrupt?
0 or 1	Anything ≥ 1	PW = 1	Interrupt at deasserting edge of input signal	No Interrupt	No Error Interrupt
		PW ≤ TMR_PER	Interrupt at deasserting edge of input signal	No Interrupt	No Error Interrupt
		PW > TMR_PER	No Interrupt	Interrupt when pulse width exceeds Pmax (Period Register) Value	No Error Interrupt
> 1 but ≤ (Period -1)	Anything > 1	PW ≤ TMR_DLY	No Interrupt	Interrupt at deasserting edge of input signal	No Error Interrupt
		TMR_DLY < PW≤ TMR_PER	Interrupt at deasserting edge of input signal	No Interrupt	No Error Interrupt
		PW > TMR_PER	No Interrupt	Interrupt when pulse width exceeds Pmax (Period Register) Value	No Error Interrupt
≥ Period	-	PW ≤ TMR_PER	Undefined	Undefined	No Error Interrupt
	-	PW > TMR_PER	Undefined	Undefined	b#11 Error Type
-	0	-	Undefined	Undefined	b#10 Error Type

Windowed Watchdog Period Mode

In this mode, the timer monitors the number of clock cycles between two consecutive rising or falling edges of an input signal on one of the `TIMER_TMR[nn]` or `TIMER_ACI[nn]` pins. Program the required minimum number of clock cycles (t_{MIN}) in the `TIMER_TMR[n]_DLY` register and the required maximum allowed number of clock cycles (t_{MAX}) in the `TIMER_TMR[n]_PER` register. Both values are programmed in terms of number of clock cycles (SCLK0) or alternate time clock (`TIMER_ACLK[nn]`). The timer can generate an interrupt when two consecutive occurrences of an active edge are:

- Within a specified window (t_{MIN} < Pulse Period ≤ t_{MAX}), or
- Outside a specified window (pulse width ≤ (t_{MIN} or t_{MAX} < pulse width)

When the `TIMER_TMR[n]_CFG.IRQMODE` bit =b#11 and the pulse period > t_{MAX} or is ≤ t_{MIN}, the timer generates an interrupt (if unmasked). After attaining the t_{MAX} value, the counter keeps on counting until it sees an active edge on the input line. An interrupt can also be generated for when the pulse occurs within the specified

window condition, by setting `TIMER_TMR[n]_CFG.IRQMODE` =b#10. Refer to the ***Watchdog Period Mode Timing*** figure for timer functionality in period watchdog mode.

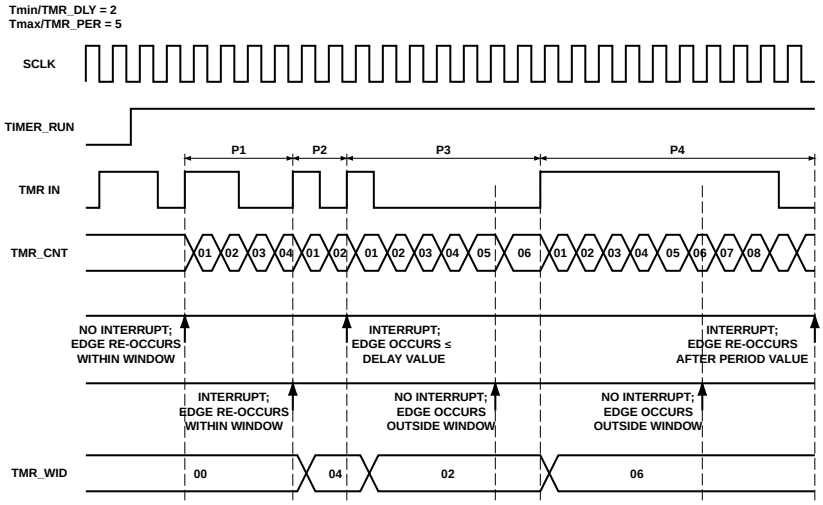

Figure 26-9: Watchdog Period Mode Timing

NOTE: SCLK in the ***Watchdog Period Mode Timing*** figure is SCLK0.

To check only the upper limit on period (the t_{MAX} value, not the t_{MIN} value), program t_{MIN} as 0 or 1. For details, refer to the ***Windowed Watchdog Period Mode Interpretation*** table.

Table 26-9: Windowed Watchdog Period Mode Interpretation

Timer Delay	Timer Period	Incoming Pulse Width	IRQMODE=b#10	IRQMODE =b#11	Error Interrupt?
0 or 1	Anything ≥ 2	Pulse Period ≤ TMR_PER	Interrupt at deasserting edge of input signal	No Interrupt	No Error Interrupt
		Pulse Period > TMR_PER	No Interrupt	Interrupt when pulse period crosses Pmax (Period Register) value	No Error Interrupt
> 1 but ≤ Period -1	Anything ≥ 2	Pulse Period ≤ TMR_DLY	No Interrupt	Interrupt at deasserting edge of input signal	No Error Interrupt
		TMR_DLY < Pulse Period ≤TMR_PER	Interrupt at deasserting edge of input signal	No Interrupt	No Error Interrupt
		Pulse Period > TMR_PER	No Interrupt	Interrupt when pulse width exceeds Pmax (Period Register) value	No Error Interrupt

Table 26-9: Windowed Watchdog Period Mode Interpretation (Continued)

Timer Delay	Timer Period	Incoming Pulse Width	IRQMODE=b#10	IRQMODE =b#11	Error Interrupt?
≥ Period	-	Pulse Period < TMR_PER	Undefined	Undefined	No Error Interrupt
		Pulse Period ≥ TMR_PER	Undefined	Undefined	b#11 Error Type
-	0 or 1	-	Undefined	Undefined	b#10 Error Type

Pin Interrupt (PININT) Mode

In PININT mode, any active edges on either the `TIMER_TMR[nn]` pin or the (`TIMER_ACI[nn]`) pin can cause an edge-based interrupt, if enabled. (The timer uses the `TIMER_TMR[n]_CFG.TINSEL` register to select the pin). The event on the input pin can set the `TIMER_DATA_ILAT.TMR[nn]` bit and issue a system interrupt request. Program the `TIMER_TMR[n]_CFG.PULSEHI` bit to change active edge polarity.

Since the interrupt request is generated in the SCLK0 clock domain, the width of the input signal must be more than one SCLK0 period. Along with generating the interrupt request, the timer also generates a trigger pulse (configured using the `TIMER_TRG_MSK` register). Due to the configuration of polarity, glitches can cause the generation of an undesired interrupt request at the input. To avoid this problem, programs must ensure that interrupt requests are unmasked only after configuring the desired polarity.

External Clock (EXTCLK) Mode

The timer uses EXTCLK mode, sometimes referred to as the counter mode, to count external events (signal edges), on either the `TIMER_TMR[nn]` or (`TIMER_ACI[nn]`) input pin. The timer works as a counter clocked by an external source (the signal at the pin), which can be asynchronous to SCLK0. The current count in the `TIMER_TMR[n]_CNT` register represents the number of leading-edge events detected. The `TIMER_TMR[n]_PER` register is programmed with the value of the maximum timer external count before stopping or issuing an interrupt request or trigger.

The `TIMER_TMR[n]_CFG.PULSEHI` bit determines the polarity of the leading edge on the input pin. The timer uses the `TIMER_TMR[n]_CFG.TINSEL` bit to select whether the event is counted on the `TIMER_TMR[nn]` or on the (`TIMER_ACI[nn]`) pin. The `TIMER_STAT_ILAT.TMR[nn]` and `TIMER_ERR_TYPE` bits are set if *one* of these conditions is met:

- `TIMER_TMR[n]_CNT` wraps around from 0xFFFF FFFF to 0
- The period = 0 at startup
- `TIMER_TMR[n]_CNT` register rolls over (from count = period to count = 0x1)

The `TIMER_TMR[n]_WID` and `TIMER_TMR[n]_DLY` registers are unused in this mode and must not be written.

The ***EXTCLK Mode Control Flow*** figure shows a flow diagram for EXTCLK mode.

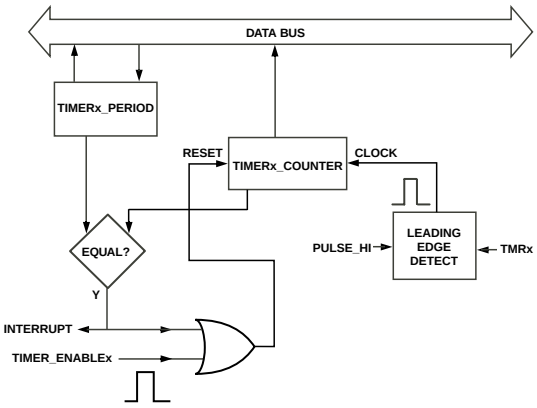

Figure 26-10: EXTCLK Mode Control Flow

The waveform applied to the input pin is not required to have a 50% duty cycle. The minimum input pulse low time, high time, and total period specifications are available in the product data sheet. Program the period to any value from 1 to (2^{32} – 1), inclusive.

After the timer has started, it resets the `TIMER_TMR[n]_CNT` register to 0x0 and then waits for the first leading edge on the input pin. This edge causes `TIMER_TMR[n]_CNT` to be incremented to the value 0x1, and every subsequent leading edge increments it by one. After the `TIMER_TMR[n]_CNT` register reaches the value programmed in the `TIMER_TMR[n]_PER` register, the corresponding `TIMER_DATA_ILAT` bit is set, and an interrupt and trigger are both generated (if enabled). The next leading-edge reloads the `TIMER_TMR[n]_CNT` register with 0x1, and the timer continues counting until it is disabled.

GP Timer Programming Concepts

Using the features, operating modes, and event control for the GP timer to their greatest potential requires an understanding of some GP timer-related concepts.

Setting Up Constantly Changing Timer Conditions

This task shows how to use different period, pulse width, and delay settings for each of the first three timer periods after the timer starts.

1. Program the first set of `TIMER_TMR[n]_PER`, `TIMER_TMR[n]_WID`, and `TIMER_TMR[n]_DLY` register values.
2. Enable the timer using the `TIMER_RUN` register.
3. Immediately program the second set of `TIMER_TMR[n]_PER`, `TIMER_TMR[n]_WID`, and `TIMER_TMR[n]_DLY` register values, as needed.
4. Wait for the first timer interrupt request.
5. Program the third set of `TIMER_TMR[n]_PER`, `TIMER_TMR[n]_WID`, and `TIMER_TMR[n]_DLY` register values.

Each new setting is then programmed when the preceding timer interrupt request is received.

Configuring, Enabling, and Disabling One or More Timers

1. Configure the relevant timers for the operating mode and other properties using the TIMER_TMR[n]_CFG register.
2. Write a 1 to the representative TIMER_RUN.TMR[nn] bit. Or use the TIMER_RUN_SET register to avoid disturbing the settings of other timers that are not going through configuration.

   The timer is enabled and operating.
3. To stop one or more timers, first program the TIMER_STOP_CFG register to determine whether to stop immediately or gracefully upon receiving a stop command.

   ADDITIONAL INFORMATION: PWMOUT modes are the only modes where a timer can be configured for graceful termination.
4. Write a 0 to the representative TIMER_RUN.TMR[nn] bits to stop the timer according to their TIMER_STOP_CFG settings. Alternately, write a 1 to the appropriate TIMER_RUN_CLR.TMR[nn] bits to avoid disturbing the settings of other timers that are not terminating.

   The timers stop.

Configuring Timer Data and Status Interrupts

1. Configure the TIMER_TMR[n]_CFG.IRQMODE bit field with the desired interrupt properties.
2. Unmask the interrupt source.
3. Set the TIMER_TMR[n]_CFG.IRQMODE field but leave the interrupt masked at the system level to poll the TIMER_DATA_ILAT.TMR[nn] bit of the timer without generating an interrupt.
4. Use the TIMER_STAT_IMSK register to generate interrupt requests by overflow or error conditions (incorrect programming values). The timer uses the TIMER_STAT_ILAT.TMR[nn] bits to report interrupt errors, when the timer status interrupt source is unmasked.
5. To poll the TIMER_STAT_ILAT.TMR[nn] bit of the timer without generating an interrupt, unmask the corresponding bit in the TIMER_STAT_IMSK register, but leave the interrupt masked at the system level.

Configuring the Timer as a Trigger Receiver

The timer can be configured to either start or stop or toggle between these two states on the input trigger pulse depending on the configuration of the TIMER_TMR[n]_CFG.TGLTRIG and TIMER_TMR[n]_CFG.SLAVETRIG bits.

- If TIMER_TMR[n]_CFG.TGLTRIG bit =0 and TIMER_TMR[n]_CFG.SLAVETRIG bit =1 then the trigger pulse starts timer, if it is stopped.

- If TIMER_TMR[n]_CFG.TGLTRIG bit =0 and TIMER_TMR[n]_CFG.SLAVETRIG bit =0 then the trigger pulse stops timer, if it is running.
- When TIMER_TMR[n]_CFG.TGLTRIG bit =0, the trigger pulse has no effect when the timer is already in the requested state.

If TIMER_TMR[n]_CFG.TGLTRIG bit is 1, the trigger pulse starts the timer if it is stopped, or stops the timer if it is running. The TIMER_TMR[n]_CFG.SLAVETRIG bit has no effect on trigger mechanism. In continuous PWMOUT mode, the timer stops gracefully or abruptly depending on the stop mechanism programmed in the TIMER_STOP_CFG_CLR register. In other modes, the timer stops immediately.

Ordered Trigger Toggle Mode

The timer can be configured to either start or stop the timer on the input trigger pulse depending on the configuration of the TIMER_TMR[n]_CFG.TGLTRIG and TIMER_TMR[n]_CFG.ORDTGLTRIG bits.

- If TIMER_TMR[n]_CFG.TGLTRIG bit is 1 and TIMER_TMR[n]_CFG.ORDTGLTRIG bit is 0, then the input trigger pulse on trigger receiver 0 or trigger receiver 1 starts the timer if it is stopped, or stops the timer if it is running.
- If TIMER_TMR[n]_CFG.TGLTRIG bit is 1 and TIMER_TMR[n]_CFG.ORDTGLTRIG bit is 1, then the input trigger pulse on trigger receiver 0 starts timer if it is stopped. If the timer is running, it stops when the input trigger pulse on trigger receiver 1 is detected.

  Trigger receiver 0 cannot toggle the timer from the run to halt state. Trigger receiver 1 cannot toggle the timer from the halt to run state.

NOTE: The timer state is not toggled by writes to the TIMER_RUN, TIMER_RUN_SET, and TIMER_RUN_CLR registers in this mode.

Using the Timer Broadcast Feature

The broadcast feature provides a means to update period, width, and delay registers simultaneously across more than one timer.

1. Enable the appropriate broadcast bits (TIMER_TMR[n]_CFG.BPEREN, TIMER_TMR[n]_CFG.BWIDEN are TIMER_TMR[n]_CFG.BDLYEN) for the timers involved in the broadcast. The use of these bits depends on which broadcast registers the timer uses (TIMER_BCAST_PER, TIMER_BCAST_WID, or TIMER_BCAST_DLY).
2. Program the TIMER_BCAST_PER register (for example), to broadcast the period setting across the multiple timers enabled.

   The enabled timers load their TIMER_TMR[n]_PER registers with the value specified in the TIMER_BCAST_PER register.
3. Repeat Step 2 as needed for the TIMER_BCAST_WID and TIMER_BCAST_DLY register settings.

Timer Illegal States

The following sections use these definitions:

- Startup. The first clock period during which the timer counter is running after the timer is started by writing the TIMER_RUN register.
- Rollover. The time when the current count in TIMER_TMR[n]_CNT matches the value in TIMER_TMR[n]_PER and the counter is reloaded with the value 1.
- Overflow. The timer counter was incremented instead of doing a rollover when it was holding the maximum count value of 0xFFFF FFFF. The counter does not have a large enough range to express the next greater value and so it erroneously loads a new value of 0x0000 0000.
- Unchanged. No new error.

When the TIMER_ERR_TYPE register is designated unchanged, it displays the previously reported error code orb# 00 when there has been no error since this timer was enabled.

When the TIMER_STAT_ILAT register is unchanged, it reads 0 when there has been no error or overflow since this timer was enabled. Or, it reads 0 if software has performed a W1C to clear any previous error. If software has not acknowledged a previous error, the TIMER_STAT_ILAT register reads 1. Software can read the TIMER_STAT_ILAT register to check for errors. If a particular bit of a timer is set in this register, software can then read the TIMER_ERR_TYPE register for more information. Once detected, software can W1C the appropriate TIMER_STAT_ILAT bit to acknowledge the error.

Read the following tables as:

- In mode __ at event __,
- if TIMER_TMR[n]_PER is __ and TIMER_TMR[n]_WID is __ and TIMER_TMR[n]_DLY is __,
- then TIMER_ERR_TYPE is __ and TIMER_STAT_ILAT is __.

Startup error conditions do not prevent the timer from starting. Similarly, overflow and rollover error conditions do not stop the timer. Illegal cases can cause unwanted behavior of the TIMER_TMR[nn] pins.

NOTE: For PININT mode, the timer does not use error functionality.

Continuous PWMOUT Mode

Table 26-10: Startup Event

TIMER_TMR[n]_PER	TIMER_TMR[n]_DLY	TIMER_TMR[n]_WID	TIMER_TMR[n]_WID + TIMER_TMR[n]_DLY	TIMER_ERR_TYPE	TIMER_STAT_ILAT (if enabled)
≤ 1	Anything other than period [*1]	Anything	Anything	b#10	Set

Table 26-10: Startup Event (Continued)

TIMER_TMR[n]_PER	TIMER_TMR[n]_DLY	TIMER_TMR[n]_WID	TIMER_TMR[n]_WID + TIMER_TMR[n]_DLY	TIMER_ERR_TYPE	TIMER_STAT_ILAT (if enabled)
≥ 2	Anything including 0, excluding TMR_PER value	Anything including 0	≤ PERIOD	Unchanged	Unchanged
	Anything including 0	Anything including 0	> PERIOD	Unchanged *2(Detected at rollover)	Unchanged (Detected at rollover)
	Anything	Anything	> 2^{32} – 1	b#11	Set
	=Period	=0	=Period	No error	Unchanged (Detected at rollover)

*1 If delay = period, the #10 error is rolled to a #11 error.

*2 This case is not detected at startup, but when the timer counts to the complete period.

Table 26-11: Rollover Event

TIMER_TMR[n]_PER	TIMER_TMR[n]_DLY	TIMER_TMR[n]_WID	TIMER_TMR[n]_WID + TIMER_TMR[n]_DLY	TIMER_ERR_TYPE	TIMER_STAT_ILAT (if enabled)
≥ 1	Anything	Anything	Anything	b#10[timer running at SCLK0] b#11 [timer running at ALT_CLKx]	Set

ADSP-SC59x TIMER Register Descriptions

General-Purpose Timer Block (TIMER) contains the following registers.

Table 26-22: ADSP-SC59x TIMER Register List

Name	Description
TIMER_BCAST_DLY	Broadcast Delay Register
TIMER_BCAST_PER	Broadcast Period Register
TIMER_BCAST_WID	Broadcast Width Register
TIMER_DATA_ILAT	Data Interrupt Latch Register
TIMER_DATA_IMSK	Data Interrupt Mask Register
TIMER_ERR_TYPE	Error Type Status Register
TIMER_RUN	Run Register
TIMER_RUN_CLR	Run Clear Register
TIMER_RUN_SET	Run Set Register
TIMER_STAT_ILAT	Status Interrupt Latch Register
TIMER_STAT_IMSK	Status Interrupt Mask Register
TIMER_STOP_CFG	Stop Configuration Register
TIMER_STOP_CFG_CLR	Stop Configuration Clear Register
TIMER_STOP_CFG_SET	Stop Configuration Set Register
TIMER_TMR[n]_CFG	Timer n Configuration Register

Table 26-22: ADSP-SC59x TIMER Register List (Continued)

Name	Description
TIMER_TMR[n]_CNT	Timer n Counter Register
TIMER_TMR[n]_DLY	Timer n Delay Register
TIMER_TMR[n]_PER	Timer n Period Register
TIMER_TMR[n]_WID	Timer n Width Register
TIMER_TRG_IE	Trigger Receiver Enable Register
TIMER_TRG_MSK	Trigger Generator Mask Register

Broadcast Delay Register

For timers with TIMER_TMR[n]_CFG.BDLYEN enabled, a write to the TIMER_BCAST_DLY register concurrently updates the delay (TIMER_TMR[n]_DLY) registers of only those timers. A read of the TIMER_BCAST_DLY register returns 0x00000000, and no bus error is generated. To read back a written value, read that TMR's TIMER_TMR[n]_DLY register.

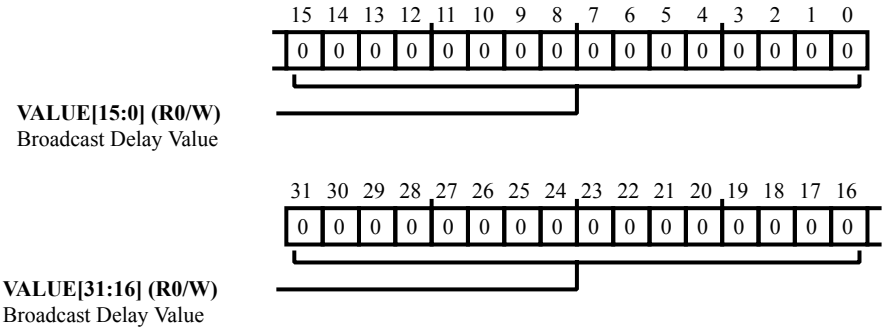

Figure 26-11: TIMER_BCAST_DLY Register Diagram

Table 26-23: TIMER_BCAST_DLY Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R0/W)	VALUE	Broadcast Delay Value. A write to the TIMER_BCAST_DLY.VALUE bit field concurrently updates the delay (TIMER_TMR[n]_DLY) registers of only those timers. A read of the TIMER_BCAST_DLY.VALUE bit field returns 0x0000 0000, and no bus error is generated.

Broadcast Period Register

For timers with TIMER_TMR[n]_CFG.BPEREN enabled, a write to the TIMER_BCAST_PER register concurrently updates the period (TIMER_TMR[n]_PER) registers of only those timers. A read of TIMER_BCAST_PER returns 0x00000000, and no bus error is generated. To read back a written value, read that TMR's TIMER_TMR[n]_PER register.

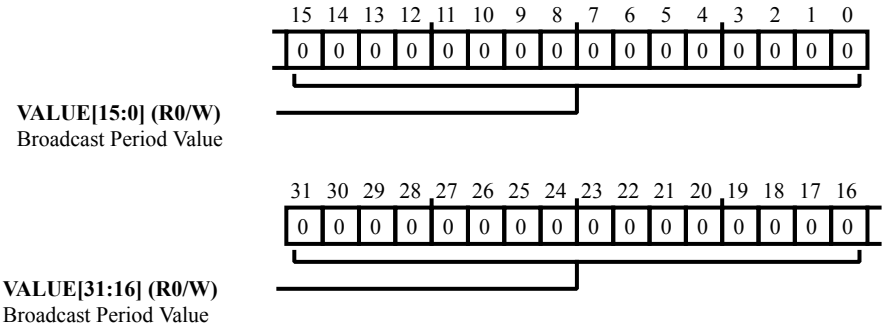

Figure 26-12: TIMER_BCAST_PER Register Diagram

Table 26-24: TIMER_BCAST_PER Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R0/W)	VALUE	Broadcast Period Value. A write to the TIMER_BCAST_PER.VALUE bit field concurrently updates the period (TIMER_TMR[n]_PER) registers of only those timers. A read of the TIMER_BCAST_PER.VALUE bit fields returns 0x0000 0000, and no bus error is generated.

Broadcast Width Register

For timers with TIMER_TMR[n]_CFG.BWIDEN enabled, a write to the TIMER_BCAST_WID register concurrently updates the width (TIMER_TMR[n]_WID) registers of only those timers. A read of the TIMER_BCAST_WID register returns 0x00000000, and no bus error is generated. To read back a written value, read that TMR's TIMER_TMR[n]_WID register.

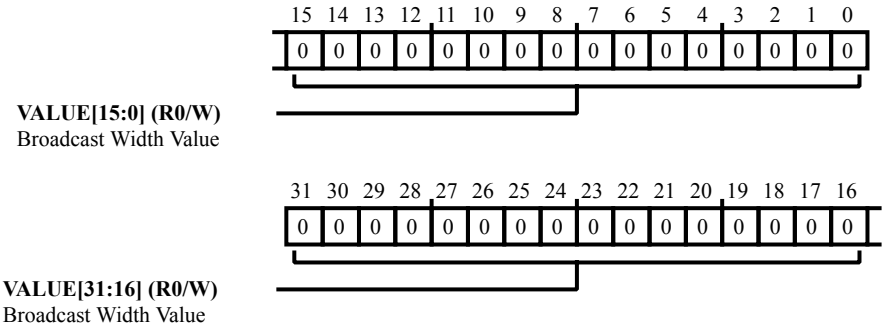

Figure 26-13: TIMER_BCAST_WID Register Diagram

Table 26-25: TIMER_BCAST_WID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R0/W)	VALUE	Broadcast Width Value. A write to the TIMER_BCAST_WID.VALUE bit field concurrently updates the width (TIMER_TMR[n]_WID) registers of only those timers. A read of the TIMER_BCAST_WID.VALUE bit field returns 0x0000 0000, and no bus error is generated.

Data Interrupt Latch Register

The TIMER_DATA_ILAT holds the latched interrupt status for interrupt requests that have been unmasked (enabled) by the TIMER_DATA_IMSK register and generated according to the conditions selected by the TIMER_TMR[n]_CFG.IRQMODE bits. If a bit in TIMER_DATA_ILAT is already set and the corresponding interrupt is masked in TIMER_DATA_IMSK, the latch holds its old value, leaving the interrupt request asserted until it is reset by software with a W1C operation.

Note that interrupt service routines (ISRs) should clear the appropriate bits in TIMER_DATA_ILAT before returning from the ISR, to ensure that the interrupt is not re-issued. To make sure that no timer event is missed, the latch should be reset at the very beginning of the ISR when in EXTCLK mode.

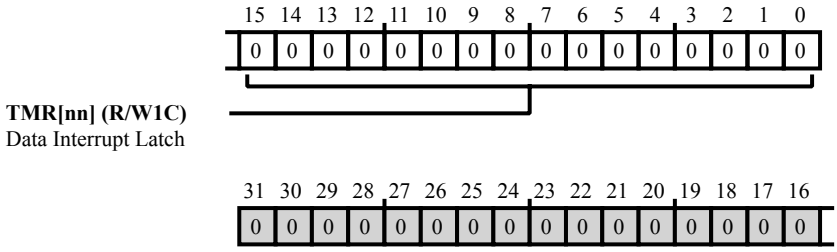

Figure 26-14: TIMER_DATA_ILAT Register Diagram

Table 26-26: TIMER_DATA_ILAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W1C)	TMR[nn]	Data Interrupt Latch. For all TIMER_DATA_ILAT.TMR[nn] bits, status of =0 indicates no interrupt is latched, and status of =1 indicates a latched interrupt (indicating an unmasked interrupt request from a timer with a condition matching the one selected with corresponding TIMER_TMR[n]_CFG.IRQMODE bit has occurred).

Data Interrupt Mask Register

Each timer may generate a unique processor data interrupt request signal. The TIMER_DATA_IMSK register contains an interrupt mask for these requests, masking (disabling) or unmasking (enabling) the interrupts as programmed. The reset value of the TIMER_DATA_IMSK register is 0xFFFF, masking these interrupts after reset.

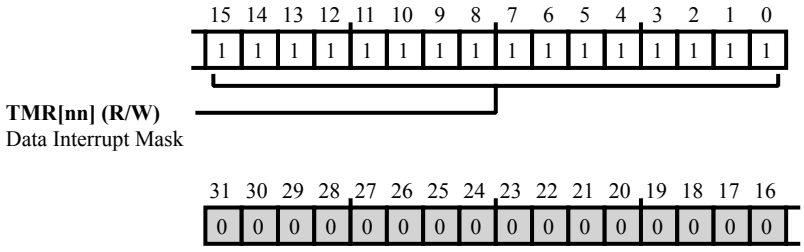

Figure 26-15: TIMER_DATA_IMSK Register Diagram

Table 26-27: TIMER_DATA_IMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	TMR[nn]	Data Interrupt Mask. For all TIMER_DATA_IMSK.TMR[nn] bits, write =0 unmasks (enables) the corresponding data interrupt request, and write =1 masks (disables) the corresponding data interrupt request.

Error Type Status Register

The TIMER_ERR_TYPE register contains error type status bits for each timer. These bits indicate the type of error (if any) in a running timer. This register is read-only. These status bits are cleared at reset and when a particular timer is enabled.

Each time an error request interrupt is latched in the TIMER_STAT_ILAT register, the corresponding TERRx bits in the TIMER_ERR_TYPE register are loaded with a code that identifies the type of error that was detected. This status value is held until the next error or until a particular timer is restarted. No bus error is generated if a write is performed on the TIMER_ERR_TYPE register.

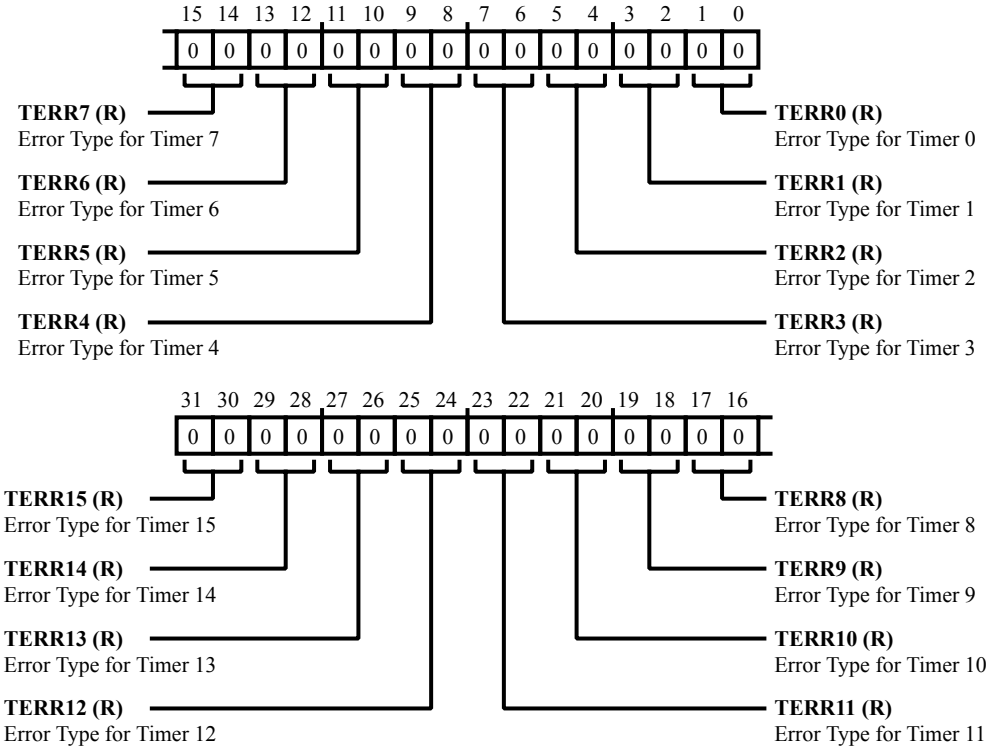

Figure 26-16: TIMER_ERR_TYPE Register Diagram

Run Register

The TIMER_RUN allows all timers to be enabled simultaneously, permitting them to run synchronously. For each timer, there is a single start/stop control bit. Writing a 1 to this bit starts the corresponding timer; writing a 0 stops the timer with mechanism specified in the timer stop configuration TIMER_STOP_CFG register.

The start/stop control bits can be set/reset individually or in any combination. While starting or stopping one particular timer directly with this register, software must perform a read-modify write, so the bits corresponding to other timers remain unchanged. To avoid this need, software can use the TIMER_RUN_CLR register.

Reading the TIMER_RUN register shows the start status for the corresponding timer. A 1 indicates that the timer is running.

If a timer is in run state (corresponding run bit is =1), a software write of 1 in this bit does not have any effect on the timer state. The write does not result in restarting the timer.

Note that the TIMER_RUN register is not used in PININT mode. PININT mode starts as soon as the TIMER_TMR[n]_CFG.TMODE bits are set to 111.

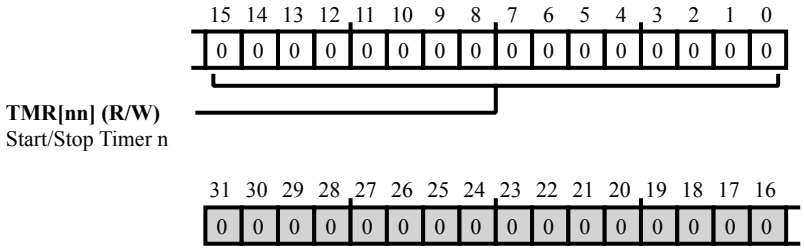

Figure 26-17: TIMER_RUN Register Diagram

Table 26-29: TIMER_RUN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	TMR[nn]	Start/Stop Timer n. For all TIMER_RUN.TMR[nn] bits, write =0 for stop, and write =1 for start. Read =1 when timer is running.

Run Clear Register

The TIMER_RUN_CLR register is an alias register, providing a mechanism to clear a specific start/stop bit in the TIMER_RUN register without affecting other bits in TIMER_RUN. To stop a particular timer, software must write a 1 into the corresponding TIMER_RUN_CLR bit. Writing a 0 has no effect. Because TIMER_RUN_CLR is a write-only register, the result of any write to this register must be checked by reading the TIMER_RUN register. A read of the TIMER_RUN_CLR returns 0x0000.

Note that the stopping mechanism of a timer may be abrupt or graceful (after completion of current waveform period) depending on the selection in the TIMER_STOP_CFG register.

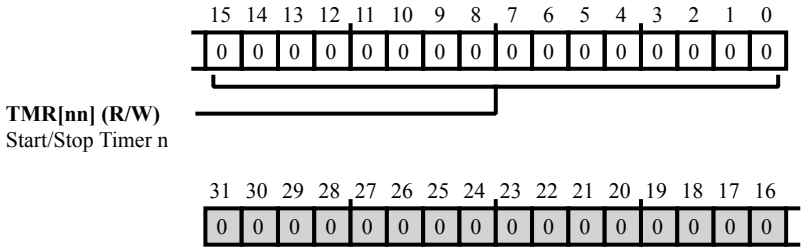

Figure 26-18: TIMER_RUN_CLR Register Diagram

Table 26-30: TIMER_RUN_CLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R0/W1C)	TMR[nn]	RUN Clear Alias. For all TIMER_RUN_CLR.TMR[nn] bits, write =0 has no effect, and write =1 for stop (clearing the corresponding in start/stop bit in the TIMER_RUN register). Using TIMER_RUN_CLR to clear start/stop bits permits stopping specific timers without influencing run status of other timers.

Run Set Register

The TIMER_RUN_SET register is an alias register, providing a mechanism to set a specific start/stop bit in the TIMER_RUN register without affecting other bits in TIMER_RUN. To start a particular timer, software must write a 1 into the corresponding TIMER_RUN_SET bit. Writing a zero has no effect. For an example, to start timer 3 without affecting any other timer, write 0x0008 into TIMER_RUN_SET. Because TIMER_RUN_SET is a write-only register, the result of any write to this register must be checked by reading the TIMER_RUN register. A read of the TIMER_RUN_SET returns 0x0000.

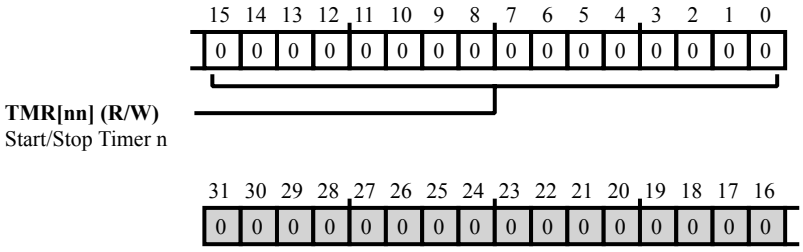

Figure 26-19: TIMER_RUN_SET Register Diagram

Table 26-31: TIMER_RUN_SET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R0/W1S)	TMR[nn]	RUN Set Alias. For all TIMER_RUN_SET.TMR[nn] bits, write =0 has no effect, and write =1 for start (setting the corresponding start/stop bit in the TIMER_RUN register). Using TIMER_RUN_SET to set start/stop bits permits starting specific timers without influencing the run status of other timers.

Status Interrupt Latch Register

The TIMER_STAT_ILAT holds the latched interrupt status for error interrupt requests, indicating a timer overflow condition or indicating that prohibited programming has occurred for a timer. These interrupt status bits are sticky and are W1C. The bits in the TIMER_STAT_ILAT register provide information regarding each timer interrupt request source.

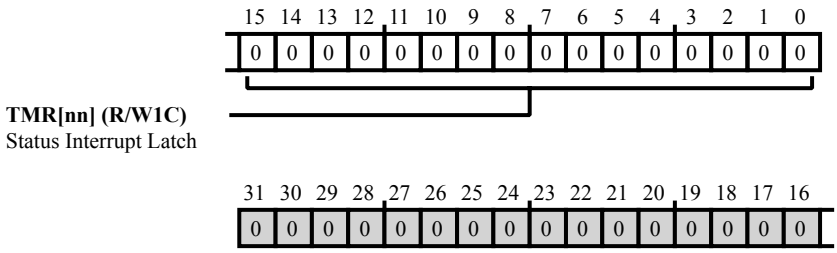

Figure 26-20: TIMER_STAT_ILAT Register Diagram

Table 26-32: TIMER_STAT_ILAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W1C)	TMR[nn]	Status Interrupt Latch. For all TIMER_STAT_ILAT.TMR[nn] bits, status of 0 indicates no error interrupt request is latched, and status of 1 indicates a timer counter overflow or programming error interrupt request is latched.

Status Interrupt Mask Register

While each timer may generate a status interrupt request, these requests are OR'ed to generate a single status interrupt signal to the system event controller. The TIMER_STAT_IMSK register contains an interrupt mask for these requests, masking (disabling) or unmasking (enabling) the interrupts as programmed. The reset value of the TIMER_STAT_IMSK register is 0xFFFF, masking these interrupts after reset.

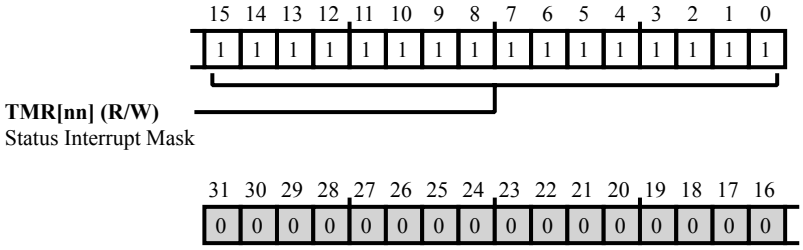

Figure 26-21: TIMER_STAT_IMSK Register Diagram

Table 26-33: TIMER_STAT_IMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	TMR[nn]	Status Interrupt Mask. For all TIMER_STAT_IMSK.TMR[nn] bits, write =0 unmasks (enables) the corresponding status interrupt request, and write =1 masks (disables) the corresponding status interrupt request.

Stop Configuration Register

The TIMER_STOP_CFG register selects the stop mode for each timer. Timers may be stopped abruptly (immediate halt - all modes) or gracefully in PWMOUT modes (single pulse and continuous). The halt is achieved through either a write =0 to the corresponding bit in TIMER_RUN or a write =1 to the corresponding bit in TIMER_RUN_CLR. A read of TIMER_STOP_CFG returns the last value written.

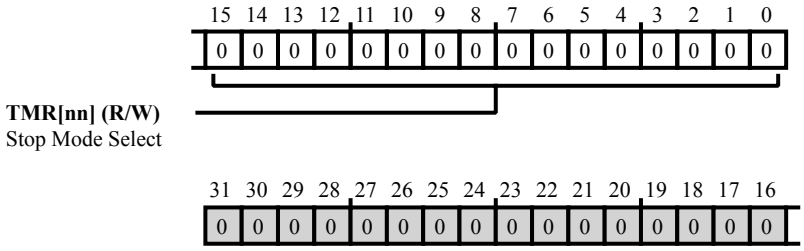

Figure 26-22: TIMER_STOP_CFG Register Diagram

Table 26-34: TIMER_STOP_CFG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	TMR[nn]	Stop Mode Select. For all TIMER_STOP_CFG.TMR[nn] bits, write =0 for graceful termination (PWMOUT modes only), and write =1 for abrupt (immediate halt) on stop.

Stop Configuration Clear Register

This is an alias register, providing a mechanism to clear a specific bit in the TIMER_STOP_CFG register without affecting other bits in TIMER_STOP_CFG. To clear a bit in TIMER_STOP_CFG, software must write a 1 to the corresponding bit of TIMER_STOP_CFG_CLR register. Writing a zero has no effect. Because the TIMER_STOP_CFG_CLR register is a write-only register, the result of any write to this register must be checked by reading the TIMER_STOP_CFG register. A read of the TIMER_STOP_CFG_CLR register returns 0x0000.

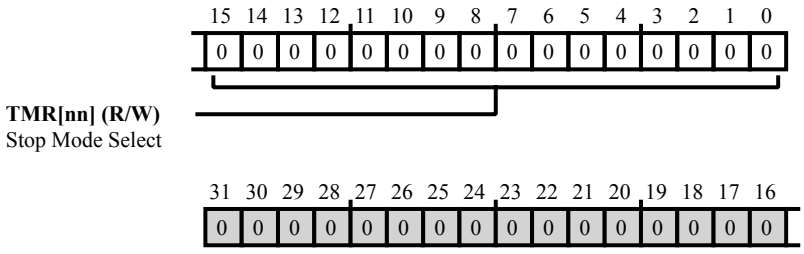

Figure 26-23: TIMER_STOP_CFG_CLR Register Diagram

Table 26-35: TIMER_STOP_CFG_CLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R0/W1C)	TMR[nn]	STOP_CFG Clear Alias. For all TIMER_STOP_CFG_CLR.TMR[nn] bits, write =0 has no effect, and write =1 for graceful stop in PWMOUT modes (clearing the corresponding stop mode select bit in the TIMER_STOP_CFG register). Using TIMER_STOP_CFG_CLR to clear stop mode bits permits configuring specific timers without influencing the stop mode configuration of other timers.

Stop Configuration Set Register

This is an alias register, providing a mechanism to set a specific bit in the TIMER_STOP_CFG register without affecting other bits in TIMER_STOP_CFG. To set a bit in the TIMER_STOP_CFG register, software must write a 1 to the corresponding bit of the TIMER_STOP_CFG_SET register. Writing a zero has no effect. Because the TIMER_STOP_CFG_SET register is a write-only register, the result of any write to this register must be checked by reading the TIMER_STOP_CFG register. A read of the TIMER_STOP_CFG_SET register returns 0x0000.

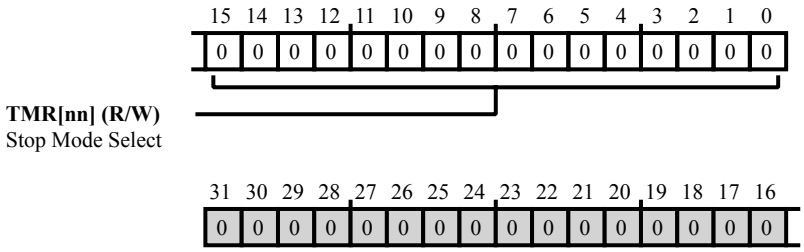

Figure 26-24: TIMER_STOP_CFG_SET Register Diagram

Table 26-36: TIMER_STOP_CFG_SET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R0/W1S)	TMR[nn]	STOP_CFG Set Alias. For all TIMER_STOP_CFG_SET.TMR[nn] bits, write =0 has no effect, and write =1 for abrupt stop (setting the corresponding stop mode select bit in the TIMER_STOP_CFG register). Using TIMER_STOP_CFG_SET to set stop mode bits permits configuring specific timers without influencing the stop mode configuration of other timers.

Timer n Configuration Register

Each timer has a TIMER_TMR[n]_CFG register that specifies its operating mode. Only write to a TIMER_TMR[n]_CFG register when the corresponding timer is not running.

After disabling a timer operating in PWMOUT mode, verify that the timer has stopped running by checking the start/stop status of the timer in the TIMER_RUN register before writing to the timer's TIMER_TMR[n]_CFG register.

Note that a timer's TIMER_TMR[n]_CFG register may be read at any time.

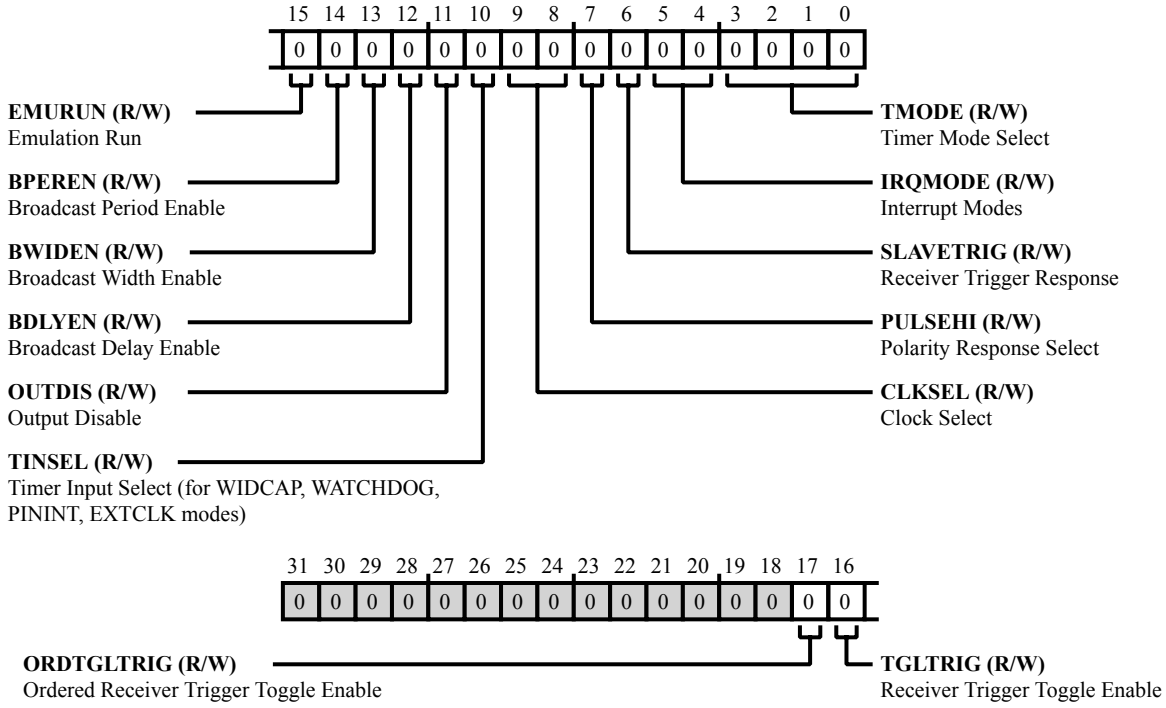

Figure 26-25: TIMER_TMR[n]_CFG Register Diagram

Table 26-37: TIMER_TMR[n]_CFG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/W)	ORDTGLTRIG	Ordered Receiver Trigger Toggle Enable. The TIMER_TMR[n]_CFG.ORDTGLTRIG bit controls ordered receive trigger toggle mode. The timer(receiver) state is not toggled by writes to the TIMER_RUN, TIMER_RUN_SET and TIMER_RUN_CLR registers when this bit is enabled.	
		0	No effect
		1	Trigger pulse on trigger receiver 0 starts the timer if it is in the halt state. Trigger pulse in trigger receiver 1 stops the timer if it is running.
16 (R/W)	TGLTRIG	Receiver Trigger Toggle Enable. The TIMER_TMR[n]_CFG.TGLTRIG bit stops the timer if it is running and starts the timer if it is halted (in the stop state). If the TIMER_TMR[n]_CFG.TGLTRIG bit is set, then the setting of the TIMER_TMR[n]_CFG.SLAVETRIG bit is ignored.	
		0	Receiver trigger response depends on SLAVETRIG bit
		1	Receiver trigger toggles timer state
15 (R/W)	EMURUN	Emulation Run. The TIMER_TMR[n]_CFG.EMURUN bit causes the timer to run (count) during emulation.	
		0	Stop Timer During Emulation
		1	Run Timer During Emulation
14 (R/W)	BPEREN	Broadcast Period Enable. The TIMER_TMR[n]_CFG.BPEREN bit enables updates to the TIMER_TMR[n]_PER register simultaneously across more than one timer.	
		0	Disable Broadcast to PER Register
		1	Enable Broadcast to PER Register
13 (R/W)	BWIDEN	Broadcast Width Enable. The TIMER_TMR[n]_CFG.BWIDEN bit enables updates to the TIMER_TMR[n]_WID register simultaneously across more than one timer.	
		0	Disable Broadcast to WID Register
		1	Enable Broadcast to WID Register

Table 26-37: TIMER_TMR[n]_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W)	BDLYEN	Broadcast Delay Enable. The `TIMER_TMR[n]_CFG.BDLYEN` bit enables updates to the `TIMER_TMR[n]_DLY` register simultaneously across more than one timer.	
		0	Disable Broadcast to DLY Register
		1	Enable Broadcast to DLY Register
11 (R/W)	OUTDIS	Output Disable. The `TIMER_TMR[n]_CFG.OUTDIS` bit enables or disables the timer pin output buffer.	
		0	Enable TMR Pin Output Buffer
		1	Disable TMR Pin Output Buffer
10 (R/W)	TINSEL	Timer Input Select (for WIDCAP, WATCHDOG, PININT, EXTCLK modes).	
		0	Use TMR Pin Input
		1	Use TMR Alternate Capture Input
9:8 (R/W)	CLKSEL	Clock Select. The `TIMER_TMR[n]_CFG.CLKSEL` bit field selects the TIMER clock to use.	
		0	Use SCLK0
		1	Use TMR_ALT_CLK0 as TMR Clock
		3	Use TMR_ALT_CLK1 as TMR Clock
7 (R/W)	PULSEHI	Polarity Response Select. The `TIMER_TMR[n]_CFG.PULSEHI` bit defines specific behaviors of the timer based on the operating mode. For more information, see the specific operating mode in the Programming Concepts section.	
		0	Negative Response or Pulse. A Negative Edge Response or Negative Action Pulse on the TMR pin.
		1	Positive Response or Pulse. A Positive Edge Response or Positive Action Pulse on the TMR pin.
6 (R/W)	SLAVETRIG	Receiver Trigger Response. The `TIMER_TMR[n]_CFG.SLAVETRIG` bit controls the trigger response. The trigger pulse has no effect (to stop or start the timer) if the timer is already in the requested state.	
		0	Pulse Stops Timer if it is Running
		1	Pulse Starts Timer if it is Stopped

Table 26-37: TIMER_TMR[n]_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5:4 (R/W)	IRQMODE	Interrupt Modes. The TIMER_TMR[n]_CFG.IRQMODE bit field selects the interrupt request mode. Note that any mismatched combination of the TIMER_TMR[n]_CFG.IRQMODE and the TIMER_TMR[n]_CFG.TMODE bits results in no interrupt being generated. In WIDCAP modes, the position of the interrupt is controlled with the TIMER_TMR[n]_CFG.TMODE bit, and the TIMER_TMR[n]_CFG.IRQMODE bit is ignored. Whenever an interrupt is generated, a trigger generator pulse is also occurs, when enabled in the TIMER_TRG_MSK register.	
		0	Active Edge Mode. The timer generates an interrupt at every active edge. The active edge polarity depends on the state of the TIMER_TMR[n]_CFG.PULSEHI bit. Valid for PININT mode only.
		1	Delay Expired Mode. The timer generates an interrupt when the TIMER_TMR[n]_CNT value reaches the value in the TIMER_TMR[n]_DLY register. This mode is valid for all PWMOUT modes.
		2	Width Plus Delay Expired Mode. The timer generates an interrupt when the TIMER_TMR[n]_CNT value reaches the value in the TIMER_TMR[n]_WID register plus the value in the TIMER_TMR[n]_DLY register. (PWMOUT modes only) The timer generates an interrupt if the deasserting edge is within the specified window. (WATCHDOG modes only)
		3	Period Expired Mode. The timer generates an interrupt when the TIMER_TMR[n]_CNT value reaches the value in the TIMER_TMR[n]_PER register. (Continuous PWMOUT and EXTCLK modes only) The timer generates an interrupt if the deasserting edge is outside the specified window.(WATCHDOG modes only)
3:0 (R/W)	TMODE	Timer Mode Select. The TIMER_TMR[n]_CFG.TMODE bit field selects the operating mode of each timer.	
		0-7	Idle Mode

Timer n Counter Register

The TIMER_TMR[n]_CNT register holds the current timer count. After enabling, the count is re-initialized to either 0x0 or 0x1, depending on the configuration and mode. The TIMER_TMR[n]_CNT register is read-only and may be read at any time (whether the timer is running or stopped). Reading the TIMER_TMR[n]_CNT register returns an atomic 32-bit value.

Depending on the timer operation mode, the counter increment can be clocked by a number of sources, including SCLK0, the TMR or alternate capture input pins, ACLK[n]. The counter retains its value after the timer is disabled.

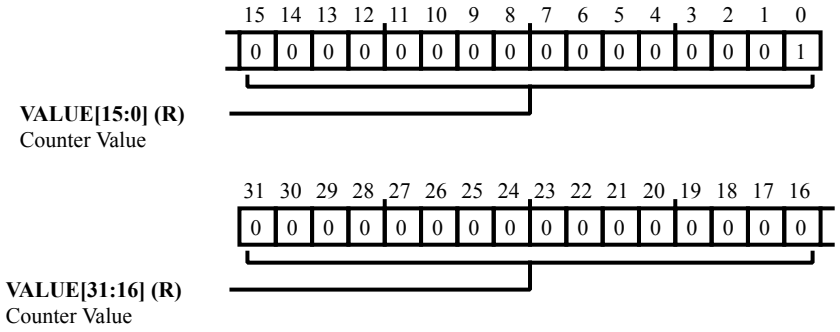

Figure 26-26: TIMER_TMR[n]_CNT Register Diagram

Table 26-38: TIMER_TMR[n]_CNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Counter Value. The TIMER_TMR[n]_CNT.VALUE bit field holds the current timer count.

Timer n Delay Register

The TIMER_TMR[n]_DLY register holds the delay value for the corresponding timer. This register's use is based on the selected timer mode.

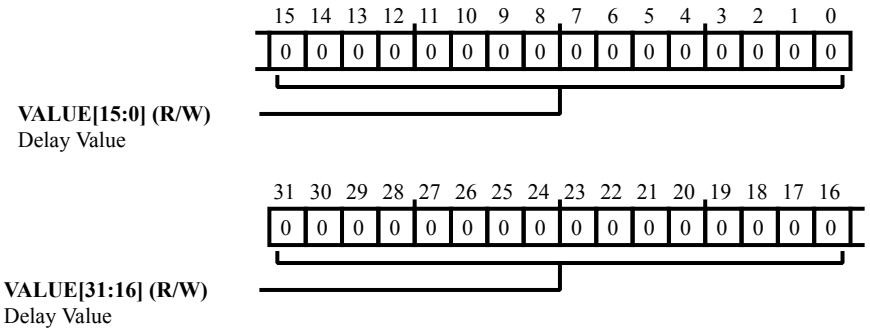

Figure 26-27: TIMER_TMR[n]_DLY Register Diagram

Table 26-39: TIMER_TMR[n]_DLY Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Delay Value. The TIMER_TMR[n]_DLY.VALUE bit field holds the delay value for the corresponding timer.

Timer n Period Register

The TIMER_TMR[n]_PER register holds the period value for the corresponding timer. This register's use is based on the selected timer mode.

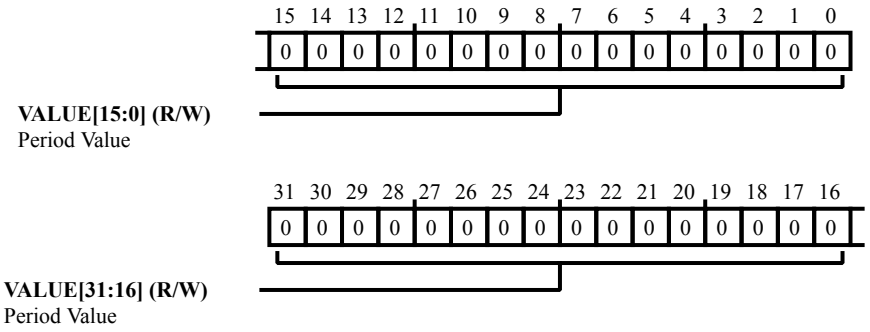

Figure 26-28: TIMER_TMR[n]_PER Register Diagram

Table 26-40: TIMER_TMR[n]_PER Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Period Value. The TIMER_TMR[n]_PER.VALUE bit field holds the period value for the corresponding timer.

Timer n Width Register

The TIMER_TMR[n]_WID register holds the width value for the corresponding timer. This register's use is based on the selected timer mode.

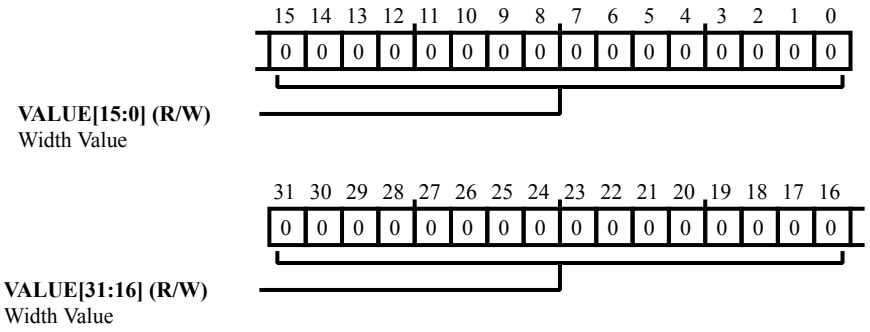

Figure 26-29: TIMER_TMR[n]_WID Register Diagram

Table 26-41: TIMER_TMR[n]_WID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Width Value. The TIMER_TMR[n]_WID.VALUE bit field holds the width value for the corresponding timer.

Trigger Receiver Enable Register

As a trigger receiver, each timer can generate a unique data trigger pulse signal. The `TIMER_TRG_IE` contains trigger input enable bits for these signals, disabling or enabling the triggers as programmed. The reset value of the `TIMER_TRG_IE` register is 0xFFFF, masking these triggers after reset.

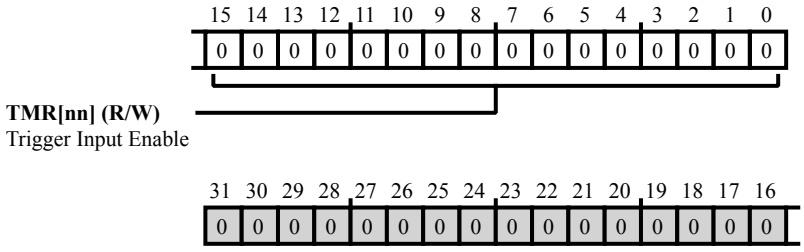

Figure 26-30: TIMER_TRG_IE Register Diagram

Table 26-42: TIMER_TRG_IE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	TMR[nn]	Trigger Input Enable. For all `TIMER_TRG_IE.TMR[nn]` bits, write =0 disables the corresponding trigger input, and write =1 enables the corresponding trigger input.

Trigger Generator Mask Register

As a trigger generator, each timer can generate a unique data trigger pulse signal. The TIMER_TRG_MSK register contains a trigger mask for these outputs, masking (disabling) or unmasking (enabling) the triggers as programmed. The reset value of the TIMER_TRG_MSK register is 0xFFFF, masking these triggers after reset.

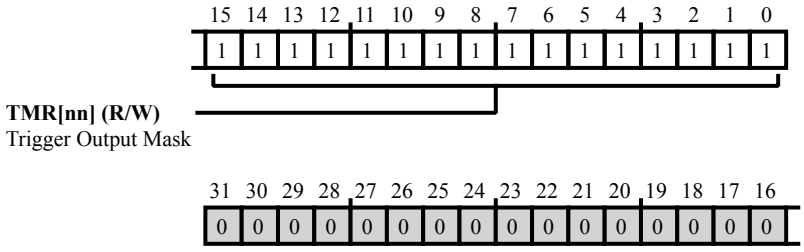

Figure 26-31: TIMER_TRG_MSK Register Diagram

Table 26-43: TIMER_TRG_MSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	TMR[nn]	Trigger Output Mask. For all TIMER_TRG_MSK.TMR[nn] bits, write =0 unmasks (enables) the corresponding data trigger output, and write =1 masks (disables) the corresponding data trigger output.

27 General-Purpose Counter (CNT)

The GP counter converts pulses from incremental position encoders into data that is representative of the actual position of the pulse. This conversion is done by integrating (counting) pulses on one or two inputs. Since integration provides relative position, some devices also feature a zero-position input (zero marker). The GP counter can use the zero position input feature to establish a reference point for verifying that the acquired position does not drift over time. In addition, the GP counter can use the incremental position information to determine speed, if the time intervals are measured.

The GP counter provides flexible ways to establish position information. When used with the GP timer block, the GP counter can allow for the acquisition of coherent position or time stamp information that enables speed calculation.

GP Counter Features

The GP counter includes the following features:

- 32-bit up or down counter
- Quadrature encode mode (Gray code)
- Binary encoder mode
- Alternative frequency-direction mode
- Timed direction and up or down counting modes
- Zero marker or push-button support
- Capture event timing in association with GP Timer
- Boundary comparison and boundary setting features

GP Counter Functional Description

The ***GP Counter Block Diagram*** shows a block diagram of the GP counter. The `CNT_UD` and `CNT_DG` pins accept various forms of incremental inputs. The 32-bit counter processes the inputs. The GP counter uses the `CNT_ZM` pin to sense the pressing of a push button.

NOTE: When enabled, the GP counter requires 3 SCLK0 cycles of initialization before recognizing valid toggles on its input pins.

The three input pins can be filtered (debounced) before the GP counter evaluates them.

The GP counter features a flexible boundary comparison. In all of the operating modes, the counter can be compared to an upper and lower limit. It takes various actions when reaching these limits.

The GP counter has a flexible input selection. Apart from accepting inputs from the CNT0_UD and CNT0_DG and PORT pins, the counter can be configured to accept trigger inputs by setting PADS_PCFG0.CNT0UDSEL and PADS_PCFG0.CNT0DGSEL bits. Refer to the PADS_PCFG0 register description in General-Purpose Ports (PORT) chapter for details.

The module can optionally generate an interrupt request to the system through its IRQ line. On many processors, a GP timer module can use an output to generate time stamps on certain events.

ADSP-SC59x CNT Register List

The GP Counter (CNT) provides support for manually controlled rotary controllers, such as the volume wheel on a radio device. This unit also supports industrial encoders.

The CNT converts pulses from incremental position encoders into data that is representative of the actual position. To complete this task, the CNT integrates (counts) pulses on one or two inputs. Because integration provides relative position, a zero position input (zero marker) is usually provided that establishes a reference point, verifying that the acquired position does not drift over time. The incremental position information may also be used to determine speed, if the relevant time intervals are measured. The CNT provides flexible ways to establish position information. When used in conjunction with the General-purpose Timer (TIMER), the CNT allows acquisition of coherent position/time stamp information, enabling speed calculation.

A set of registers govern CNT operations. For more information on CNT functionality, see the CNT register descriptions.

Table 27-1: ADSP-SC59x CNT Register List

Name	Description

GP Counter Operating Modes

The GP counter has the following modes of operation.

1. Quadrature Encoder
2. Binary Encoder
3. Up/Down Counter
4. Direction Counter
5. Timed Direction

With the exception of the timed direction mode, the GP counter can operate with the GP timer block to capture additional timing information (time stamps) associated with events detected by this block.

Quadrature Encoder Mode

In this mode, the CNT_UD and CNT_DG inputs expect a quadrature-encoded signal that is interpreted as a two-bit Gray code. The order of transitions of the CNT_UD and CNT_DG inputs determines whether the counter increments or decrements. The CNT_CNTR register contains the number of transitions that have occurred as shown in the ***Quadrature Events and Counting Mechanism*** table. Optionally, an interrupt is generated when both inputs

change within one SCLK0 cycle. Gray coding prohibits such transitions. Therefore, the CNT_CNTR register remains unchanged, and an error condition is signaled.

Table 27-5: Quadrature Events and Counting Mechanism

CNT_COUNTER Register Value	-4	-3	-2	-1	0	+1	+2	+3	+4
CDG, CUD Inputs	00	01	11	10	00	01	11	10	00

It is possible to reverse the count direction of the Gray-coded signal by enabling the polarity inverter of either the CNT_UD pin or the CNT_DG pin. Inverting both pins does not alter the behavior. The GP counter can enable this feature with the CNT_CFG.CDGINV and CNT_CFG.CUDINV bits.

As an example, the CNT_DG and CNT_UD inputs are 00 and the next transition is to 01. These inputs normally change the counter in increments as shown in the table. If the CNT_UD polarity is inverted, this condition generates a received input of 01 followed by 00. The results is a decrement of the counter, altering the behavior of the connected hardware.

Binary Encoder Mode

This mode is almost identical to quadrature encoder mode, with the exception that the CNT_UD: CNT_DG inputs expect a binary-encoded signal. The order of transitions of the CNT_UD and CNT_DG inputs determines whether the counter increments or decrements. The CNT_CNTR register contains the number of transitions that have occurred as shown in the ***Binary Events and Counting Mechanism*** table. Optionally, an interrupt is generated when the detected code steps by more than 1 (in binary arithmetic) within one SCLK0 cycle. Such transitions are erroneous. Therefore, the CNT_CNTR register remains unchanged, and an error condition is signaled.

Table 27-6: Binary Events and Counting Mechanism

CNT_COUNTER Register Value	-4	-3	-2	-1	0	+1	+2	+3	+4
CDG:CUD Inputs	00	01	10	11	00	01	10	11	00

Reversing the CNT_UD and CNT_DG pin polarity has a different effect in binary encoder mode than for the quadrature encoder mode. Inverting the polarity of the CNT_UD pin only or inverting both the CNT_UD and CNT_DG pins, results in reversing the count direction.

Up/Down Counter Mode

In this mode, the counter increments or decrements at every active edge of the input pins. The GP counter uses the CNT_CFG.CUDINV bit to select an active edge and has the following results.

- If the GP counter module detects an active edge at the CNT_UD input, the counter increments.
- If the GP counter module detects an active edge at the CNT_DG input, the counter decrements.
- If simultaneous edges occur on the CNT_DG and CNT_UD pins, the counter remains unchanged, and both up-count and down-count events are signaled in the CNT_STAT register.

Direction Counter Mode

In this mode, the counter is incremented or decremented at every active edge of the CNT_DG input pin. The state of the CNT_UD input determines whether the counter increments or decrements. The GP counter uses the CNT_CFG.CUDINV bit to select the polarity.

If the GP counter detects an active edge at the CNT_DG input, the counter value changes by one in the selected direction.

Timed Direction Mode

In this mode, the counter is incremented or decremented at each SCLK0 cycle. The state of the CNT_UD input determines whether the counter increments or decrements. The GP counter uses the CNT_CFG.CUDINV bit to select the polarity. The CNT_DG pin can be used to gate the clock. The GP counter uses the CNT_CFG.CDGINV bit to select the polarity.

GP Counter Programming Model

The following sections provide information for programming the interface.

GP Counter General Programming Flow

The following are general guidelines for configuring and enabling the GP counter.

1. Initialize (but do not enable) the GP counter for the desired mode and settings through the CNT_CFG register.
2. Usually, events of interest are processed using interrupts rather than by polling status bits. In this case, clear all status bits and activate the interrupt generation requests with the CNT_IMSK register.
3. Configure interrupts at the system level to insure desired interrupt signaling to the system.
4. If timing information is required, set up the relevant GP Timer in width capture mode.
5. Finally, enable interrupt requests and the GP Counter itself using the CNT_IMSK and CNT_CFG registers, respectively.

GP Counter Mode Configuration

The GP counter can use the CNT_ZM input pin to sense the zero marker output of a rotary device or to detect the pressing of a push button. There are four programming schemes, which are functional in all counter modes:

- Push-button mode
- Zero-marker-zeros-counter mode
- Zero-marker-error mode
- Zero-once mode

Configuring GP Counter Push-Button Operation

Use the following procedure to configure push-button operation:

1. Set CNT_IMSK.CZM to enable (unmask) the zero marker interrupt.
2. Select the active edge polarity through the CNT_CFG.CZMINV bit.
3. Proceed with any other desired configuration steps and enable the peripheral.

An active edge at the CNT_ZM input sets the CNT_IMSK.CZM bit.

Configuring Zero-Marker-Zeros-Counter Mode

The following provides information on configuring zero-marker-zeros-counter mode for the GP counter.

1. Set CNT_IMSK.CZMZ to enable CNT_CNTR. The zero marker interrupt zeroes the counter.
2. Set CNT_CFG.ZMZC to enable ZMZC mode.
3. Select the active edge polarity through the CNT_CFG.CZMINV bit.
4. Proceed with any other desired configuration steps and enable the peripheral.

This configuration causes an active level at the CNT_ZM pin to clear the CNT_CNTR register and keep it cleared until the CNT_ZM pin is deactivated. In addition, the CNT_STAT.CZMZ bit is set.

Configuring Zero-Marker-Error Mode

The GP counter uses this mode to detect discrepancies between counter-value and the zero marker output of certain rotary encoder devices.

1. Set the CNT_STAT.CZME bit to enable this mode.
2. Select the active edge of the CNT_ZM pin through the CNT_CFG.CZMINV bit.
3. Proceed with any other desired configuration steps and enable the peripheral.

When the GP counter detects an active edge at the CNT_ZM input pin, it compares the four LSBs of the CNT_CNTR register to zero. If they are not zero, the GP counter uses CNT_STAT.CZME bit to signal a mismatch.

Configuring Zero-Once Mode

The GP counter uses this mode to perform an initial reset of the counter-value when it detects an active zero marker. After that, the zero marker is ignored (the counter is no longer reset).

1. Set the CNT_CMD.W1ZMONCE bit to enable this mode.
2. Select the active edge of the CNT_ZM pin through the CNT_CFG.CZMINV bit.
3. Ensure that at least one of the following bits is enabled: CNT_IMSK.CZM, CNT_IMSK.CZME, CNT_IMSK.CZMZ.

4. Proceed with any other desired configuration steps and enable the peripheral.

The CNT_CNTR register and the CNT_CMD.W1ZMONCE bit are cleared on the next active edge of the CNT_ZM pin. Now the CNT_CMD.W1ZMONCE bit can be read to check whether the event has already occurred.

Configuring Boundary Auto-Extend Mode

In this mode, hardware modifies the boundary registers (CNT_MIN and CNT_MAX) whenever the CNT_CNTR value reaches either of them. The GP counter uses this mode to monitor the widest angle a thumb wheel even if the software did not generate interrupts.

1. Initialize CNT_CNTR with the desired value.
2. Set both CNT_MIN and CNT_MAX to this same value.
3. Configure the CNT_CFG.BNDMODE field for auto extend mode.
4. Proceed with any other desired configuration steps and enable the peripheral.

The CNT_MAX register is loaded with the current CNT_CNTR value when the latter increments beyond the CNT_MAX value. Similarly, the CNT_MIN register is loaded with the CNT_CNTR value when the latter decrements below the CNT_MIN value. The CNT_STAT.MAXC and CNT_STAT.MINC status bits are set when the CNT_CNTR value matches the respective boundary register value.

Configuring Boundary Capture Mode

In this mode, the CNT_CNTR value is latched into the CNT_MIN register at one detected edge of the CNT_ZM input pin and latched into the CNT_MAX boundary register at the opposite edge.

1. To capture the CNT_ZM pin rising edge into CNT_MIN and the falling edge into CNT_MAX, program CNT_CFG.CZMINV for active high polarity. Conversely, to capture the CNT_ZM pin falling edge into CNT_MIN and the rising edge into CNT_MAX, program CNT_CFG.CZMINV for active low polarity.
2. Program the CNT_IMSK.MAXC and CNT_IMSK.MINC interrupt mask bits according to interrupt generation requirements.
3. Configure the CNT_CFG.BNDMODE field for boundary capture mode.
4. Proceed with any other desired configuration steps and enable the peripheral.

The CNT_STAT.MAXC and CNT_STAT.MINC status bits report the capture event, depending on how interrupt masks are configured.

Configuring Boundary Compare and Boundary Zero Modes

In these modes, the two boundary registers (CNT_MAX and CNT_MIN) are compared to the value in the CNT_CNTR register.

1. Program CNT_MAX and CNT_MIN registers with appropriate upper and lower range values.

2. Program the CNT_IMSK.MAXC and CNT_IMSK.MINC interrupt mask bits according to interrupt generation requirements.
3. Configure the CNT_CFG.BNDMODE field for boundary compare mode.
4. Proceed with any other desired configuration steps and enable the peripheral.

If after incrementing, CNT_CNTR = CNT_MAX, then the CNT_STAT.MAXC bit is set. Similarly if after decrementing, CNT_CNTR = CNT_MIN, then the CNT_STAT.MINC bit is set.

Additionally, for boundary zero mode, the counter-value in CNT_CNTR is set to zero. The CNT_STAT.MAXC and CNT_STAT.MINC bits are not set when software updates the CNT_MAX or CNT_MIN registers.

Configuring GP Counter Push-Button Operation

Use the following procedure to configure push-button operation:

1. Set CNT_IMSK.CZM to enable (unmask) the zero marker interrupt.
2. Select the active edge polarity through the CNT_CFG.CZMINV bit.
3. Proceed with any other desired configuration steps and enable the peripheral.

An active edge at the CNT_ZM input sets the CNT_IMSK.CZM bit.

GP Counter Programming Concepts

Using the features, operating modes, and event control for the GP counter to their greatest potential requires an understanding of some GP counter-related concepts. Some key aspects to consider are input noise filtering and capturing timing information.

CNT Input Noise Filtering

In all modes, the three input pins can be filtered to present clean signals to the GP counter logic. The GP counter uses the CNT_CFG.DEBEN bit to enable or disable this filtering. The ***Programmable Noise Filtering*** figure shows the filtering operation for the CNT_UD pin.

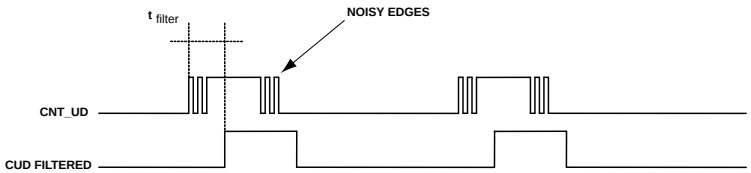

Figure 27-1: Programmable Noise Filtering

The CNT module implements the filtering mechanism using counters for each GP counter pin, where each counter is initialized from the CNT_DEBNCE.DPRESCALE field. When a transition is detected on a pin, the corresponding counter starts counting up to the programmed number of SCLK0 cycles. The state of the pin is latched after time t_{filter} and passed on to the GP counter logic.

The following formula determines the time t_{filter}, given SCLK0 and the CNT_DEBNCE.DPRESCALE value, where lower values of CNT_DEBNCE.DPRESCALE result in shorter debounce delays:

$t_{filter} = 128 \times (2^{DPRESCALE} \times SCLK0)$

Capturing Counter Interval and CNT_CNTR Read Timing

When the count speed is low, it is often useful to capture the time elapsed since the last count event. Program the TIMER_TMR[n]_CFG register of the associated GP timer in a width capture mode with the following bit settings.

- TIMER_TMR[n]_CFG.PULSEHI = 0
- TIMER_TMR[n]_CFG.TMODE = b#1011
- TIMER_TMR[n]_CFG.TINSEL = 1

The ***Capture Intervals*** figure shows and the following list describes the operation of the GP counter and the GP timer in this mode.

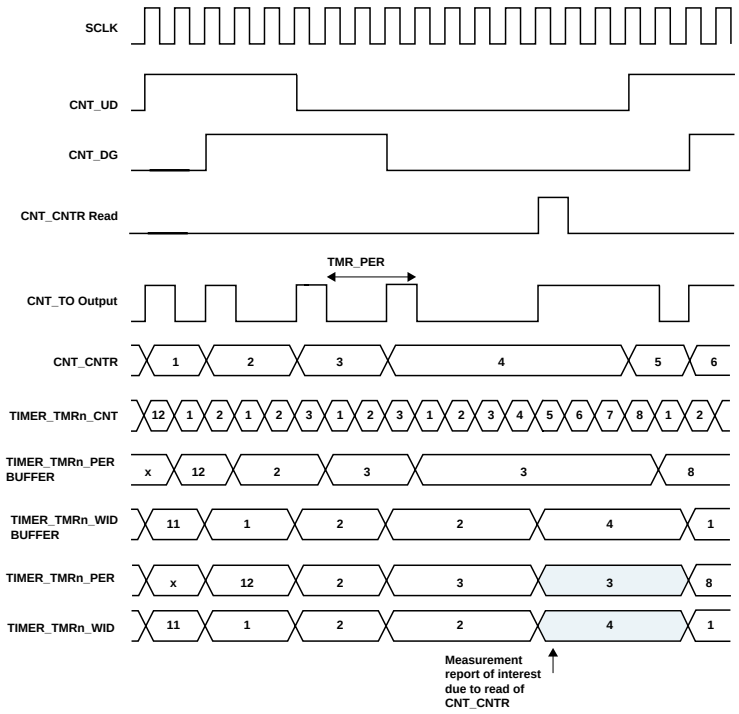

Figure 27-2: Capture Intervals

NOTE: SCLK in the ***Capture Intervals*** figure is SCLK0.

1. The CNT_TO signal generates a pulse every time a count event occurs. In addition, when the processor reads the CNT_CNTR register, the CNT_TO signal presents a pulse which is extended (high) until the next count event.
2. The GP timer updates its TIMER_TMR[n]_PER register with the period (measured from falling edge to falling edge, because TIMER_TMR[n]_CFG.PULSEHI = 0) of the CNT_TO signal.

3. The TIMER_TMR[n]_WID register is updated with the pulse width (the portion where CNT_TO is low, again because TIMER_TMR[n]_CFG.PULSEHI = 0).
4. Both registers are updated at every rising edge of the CNT_TO signal (because TIMER_TMR[n]_CFG.TMODE= b#011).

The TIMER_TMR[n]_PER register contains the period between the last two count events. The TIMER_TMR[n]_WID register contains the time since the last count event and the read of the CNT_CNTR register, both measured in SCLK0 cycles.

Read the CNT_CNTR register to latch the two time measurements, providing a coherent triplet of information to calculate speed and position.

NOTE: Speed restrictions apply to the use of the CNT_TO signal. Therefore, programs must not operate at count event rates that are high. For instance, if CNT_CNTR is incremented or decremented every SCLK0 cycle (timed direction mode), the CNT_TO signal is not valid.

Capturing Time Interval Between Successive Counter Events

When the required timing information is the interval between successive count events, program the associated timer in a width capture mode. Set the TIMER_TMR[n]_CFG bit of TIMER_TMR[n]_CFG.PULSEHI = 1, TIMER_TMR[n]_CFG.TMODE = b#1010 and TIMER_TMR[n]_CFG.TINSEL = 1. Typically, this information is sufficient if the speed of GP counter events does not to reach low values.

The ***Period Register Timing*** figure shows the operation of the GP counter and the GP timer in this mode.

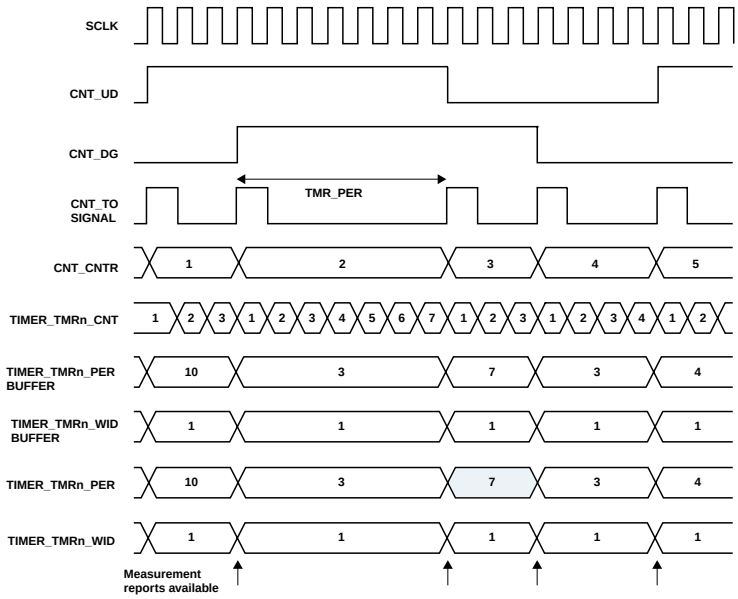

Figure 27-3: Period Register Timing

NOTE: SCLK in the ***Period Register Timing*** figure is SCLK0.

The CNT_TO signal generates a pulse every time a count event occurs. The GP timer updates its TIMER_TMR[n]_PER register with the period (measured from rising edge to rising edge) of the CNT_TO signal. The TIMER_TMR[n]_PER register is updated at every rising edge of the CNT_TO signal and contains the number of SCLK0 cycles that have elapsed since the previous rising edge.

Incidentally, the TIMER_TMR[n]_WID register is also updated at the same time, but is of no interest in this mode of operation. If no reads of the CNT_CNTR register occur between counter events, the TIMER_TMR[n]_WID register only contains the width of the CNT_TO pulse. If a read of CNT_CNTR has occurred between events, the TIMER_TMR[n]_WID register contains the time between the read of CNT_CNTR and the next event.

This mode can also be used with TIMER_TMR[n]_CFG.PULSEHI = 0. In this case, the period of CNT_TO is measured between falling edges. It results in the same values as in the previous case, only the latching occurs one SCLK0 cycle later.

GP Counter Event Control

Eleven events can be signaled to the processor using status information and optional interrupt requests. The GP counter uses the respective bits in the CNT_IMSK register to enable the interrupt requests. It uses dedicated bits in the CNT_STAT register to report events. When an interrupt request from the GP counter is serviced, the application software is responsible for correct interpretation of the events. It is recommended to logically AND the content of the CNT_IMSK and CNT_STAT registers to identify pending interrupt requests.

Perform a write-one-to-clear (W1C) operation to the CNT_STAT register to clear the interrupt requests. Hardware does not clear the status bits automatically unless the counter module is disabled.

The following sections describe the events associated with the GP counter.

Illegal Gray and Binary Code Events

When illegal transitions occur in quadrature encoder or binary encoder modes, the CNT_STAT.IC bit is set. If enabled by the CNT_STAT.IC bit, the counter module generates an interrupt request. Set the CNT_STAT.IC bit only in the quadrature encoder or binary encoder modes.

Up/Down Count Events

The GP counter uses the CNT_STAT.UC bit to indicate whether the counter has been incremented. Similarly, the CNT_STAT.DC bit reports decrements. The two events are independent. For instance, if the counter increments by one and then decrements by two, both bits remain set, even though the resulting counter-value shows a decrement by one.

In up/down counter mode, hardware can detect simultaneous active edges on the CNT_UD and CNT_DG inputs. In that case, the CNT_CNTR remains unchanged, but both the CNT_STAT.UC and CNT_STAT.DC bits are set. Interrupt requests for these events can be enabled through the CNT_IMSK.UC and CNT_IMSK.DC bits. Use this feature carefully when the counter is clocked at high rates. This suggestion is especially critical when the counter operates in DIR_TMR mode, as interrupts are generated every SCLK0 cycle.

These events can also be used for more push buttons, when GP counter features are unnecessary. When up/down counter mode is enabled, the GP counter can use these count events to report interrupts from push buttons that connect to the CNT_UD and CNT_DG inputs.

Zero-Count Events

The CNT_STAT.CZERO status bit indicates that the CNT_CNTR has reached a value equal to 0x0000 0000 after an increment or decrement. This bit is not set when the counter value is set to zero by a write to CNT_CNTR or by setting the CNT_CMD.W1LCNTZERO bit. If enabled by the CNT_IMSK.CZERO bit, the GP counter module generates an interrupt request.

Overflow Events

There are two status bits that indicate whether the signed counter-register has overflowed from a positive to a negative value or conversely. The CNT_STAT.COV31 bit reports that the 32-bit CNT_CNTR register has either incremented from 0x7FFF FFFF to 0x8000 0000, or decremented from 0x8000 0000 to 0x7FFF FFFF.

If enabled by the CNT_IMSK.COV31 bit, an interrupt request is generated. Similarly, in applications where only the lower 16 bits of the counter are of interest, the CNT_STAT.COV15 status bit reports counter transitions from 0xXXXX 7FFF to 0xXXXX 8000, or from 0xXXXX 8000 to 0xXXXX 7FFF. If enabled by the CNT_IMSK.COV15 bit, an interrupt request is generated.

Boundary Match Events

The CNT_STAT.MINC and CNT_STAT.MAXC status bits report boundary events as described in Configuring Boundary Capture Mode. These bits are not set if the software updates the CNT_CNTR, CNT_MAX, or CNT_MIN registers or writes to the CNT_CMD register. The CNT_IMSK.MINC and CNT_IMSK.MAXC bits enable interrupt request generation on boundary events.

Zero Marker Events

The CNT_STAT.CZM, CNT_STAT.CZME, and CNT_STAT.CZMZ bits are associated with zero marker events, as described in Configuring GP Counter Push-Button Operation. Each of these events can optionally generate an interrupt request, when enabled by the corresponding CNT_IMSK.CZM, CNT_IMSK.CZME and CNT_IMSK.CZMZ bits.

ADSP-SC59x CNT Register Descriptions

General-Purpose Counter (CNT) contains the following registers.

Table 27-7: ADSP-SC59x CNT Register List

Name	Description
CNT_CFG	Configuration Register
CNT_CMD	Command Register

Table 27-7: ADSP-SC59x CNT Register List (Continued)

Name	Description
CNT_CNTR	Counter Register
CNT_DEBNCE	Debounce Register
CNT_IMSK	Interrupt Mask Register
CNT_MAX	Maximum Count Register
CNT_MIN	Minimum Count Register
CNT_STAT	Status Register

Configuration Register

The CNT_CFG register configures counter modes, configures input pins, and enables the CNT.

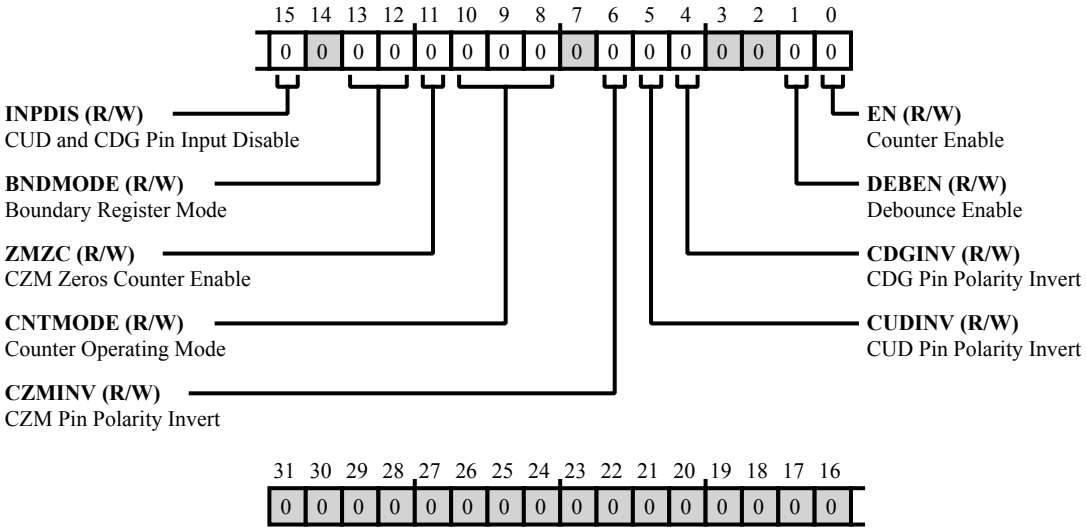

Figure 27-4: CNT_CFG Register Diagram

Table 27-8: CNT_CFG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	INPDIS	CUD and CDG Pin Input Disable. The CNT_CFG.INPDIS disables or enables the CNT_UD input pin and the CNT_DG pin.	
		0	Enable
		1	Pin Input Disable
13:12 (R/W)	BNDMODE	Boundary Register Mode. The CNT_CFG.BNDMODE bit field selects the mode for the CNT_MIN and CNT_MAX boundary registers.	
		0	BND_COMP. Boundary Compare Mode
		1	BND_ZERO. Boundary Zero Mode
		2	BND_CAPT. Boundary Capture Mode
		3	BND_AEXT. Boundary Auto-extend Mode

Table 27-8: CNT_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W)	ZMZC	CZM Zeros Counter Enable. The CNT_CFG.ZMZC bit enables or disables level sensitive - active CNT_ZM pin operation to zero the CNT_CNTR register.	
		0	Disable
		1	Enable
10:8 (R/W)	CNTMODE	Counter Operating Mode. The CNT_CFG.CNTMODE bit field selects the operating mode for the CNT_UD input pin and the CNT_DG pin.	
		0	QUAD_ENC. Quadrature Encoder Mode
		1	BIN_ENC. Binary Encoder Mode
		2	UD_CNT. Rotary Counter Mode
		4	DIR_CNT. Direction Counter Mode
		5	DIR_TMR. Direction Timer Mode
6 (R/W)	CZMINV	CZM Pin Polarity Invert. The CNT_CFG.CZMINV bit selects the polarity for the CNT_ZM pin. This polarity must be configured before the counter is enabled. It must not change on-the-fly while the counter is enabled.	
		0	Active High, Rising Edge
		1	Active Low, Falling Edge
5 (R/W)	CUDINV	CUD Pin Polarity Invert. The CNT_CFG.CUDINV bit selects the polarity for the CNT_UD pin. This polarity must be configured before the counter is enabled. It must not change on-the-fly while the counter is enabled.	
		0	Active High, Rising Edge
		1	Active Low, Falling Edge
4 (R/W)	CDGINV	CDG Pin Polarity Invert. The CNT_CFG.CDGINV bit selects the polarity for the CNT_DG pin. This polarity must be configured before the counter is enabled. It must not change on-the-fly while the counter is enabled.	
		0	Active High, Rising Edge
		1	Active Low, Falling Edge

Table 27-8: CNT_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W)	DEBEN	Debounce Enable. The `CNT_CFG.DEBEN` bit enables or disables CNT input debounce filtering operation selected with the `CNT_DEBNCE` register.	
		0	Disable
		1	Enable
0 (R/W)	EN	Counter Enable. The `CNT_CFG.EN` bit enables or disables CNT operation.	
		0	Counter Disable
		1	Counter Enable

Command Register

The CNT_CMD register configures the CNT, enabling operations such as zeroing a counter register and copying or swapping boundary registers. These actions are taken by setting the appropriate bit.

Read operations from this register do not return meaningful values, with the exception of the CNT_CMD.W1ZMONCE bit, where a set bit indicates that the bit has been set by software before, but a zero marker event has not yet been detected on the CNT_ZM pin yet. For more information, see the CNT functional description.

The CNT_CNTR, CNT_MIN, and CNT_MAX registers can be initialized to zero by setting the CNT_CMD.W1LCNTZERO, CNT_CMD.W1LMINZERO, and CNT_CMD.W1LMAXZERO bits. In addition to clearing registers, the CNT_CMD register permits modifying the CNT_MIN and CNT_MAX boundary registers in a number of ways. The current counter value in the CNT_CNTR register can be captured and loaded into either of the two boundary registers to create new boundary limits. This operation is performed by setting the CNT_CMD.W1LMAXCNT and CNT_CMD.W1LMINCNT bits. Alternatively, the counter can be loaded from CNT_MAX or CNT_MIN using the CNT_CMD.W1LCNTMAX and CNT_CMD.W1LCNTMIN bits. It is also possible to transfer the current CNT_MAX value into CNT_MIN (or conversely) through the CNT_CMD.W1LMINMAX and CNT_CMD.W1LMAXMIN bits.

Another counter operation is the ability to only have the zero marker clear the CNT_CNTR register once. For more information, see the CNT functional description.

It is possible for multiple actions to be performed simultaneously by setting multiple bits in the CNT_CMD register. However, there are restrictions. The bits associated with each command have been grouped together such that all bits that involve a write to the CNT_CNTR, CNT_MAX, or CNT_MIN registers are located within bits 4-bit groups of the CNT_CMD register.

Note that a maximum of three commands can be issued at any one time, excluding the CNT_CMD.W1ZMONCE command. Also, note that CNT_CMD.W1LCNTMIN, CNT_CMD.W1LCNTMAX, and CNT_CMD.W1LCNTZERO bits have to be used exclusively. Never set more than one of them at the same time.

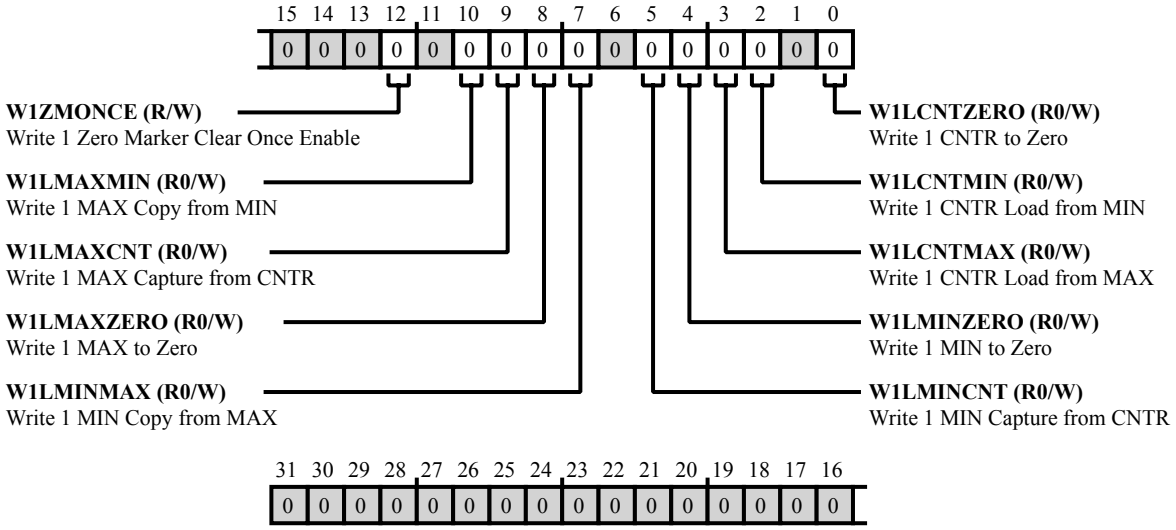

Figure 27-5: CNT_CMD Register Diagram

Table 27-9: CNT_CMD Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
12 (R/W)	W1ZMONCE	Write 1 Zero Marker Clear Once Enable. The CNT_CMD.W1ZMONCE enables a single zero marker clear of the CNT_CNTR register. Reading a 1 in this bit indicates that the bit has been set by software before, but no zero marker event has been detected on the CNT_ZM pin yet.
10 (R0/W)	W1LMAXMIN	Write 1 MAX Copy from MIN. The CNT_CMD.W1LMAXMIN bit transfers the current CNT_MIN register value into CNT_MAX register.
9 (R0/W)	W1LMAXCNT	Write 1 MAX Capture from CNTR. The CNT_CMD.W1LMAXCNT bit loads the current value in the CNT_CNTR register into the CNT_MAX register to create a new boundary limit.
8 (R0/W)	W1LMAXZERO	Write 1 MAX to Zero. Writing a 1 to the CNT_CMD.W1LMAXZERO bit clears the CNT_MAX register.
7 (R0/W)	W1LMINMAX	Write 1 MIN Copy from MAX. The CNT_CMD.W1LMINMAX bit transfers the current CNT_MAX register value into CNT_MIN register.
5 (R0/W)	W1LMINCNT	Write 1 MIN Capture from CNTR. The CNT_CMD.W1LMINCNT bit loads the current value in the CNT_CNTR register into the CNT_MIN register to create a new boundary limit.
4 (R0/W)	W1LMINZERO	Write 1 MIN to Zero. Writing a 1 to the CNT_CMD.W1LMINZERO bit clears the CNT_MIN register.

Table 27-9: CNT_CMD Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
3 (R0/W)	W1LCNTMAX	Write 1 CNTR Load from MAX. The CNT_CMD.W1LCNTMAX bit loads the current value in the CNT_MAX register into the CNT_CNTR register to create a new boundary limit.
2 (R0/W)	W1LCNTMIN	Write 1 CNTR Load from MIN. The CNT_CMD.W1LCNTMIN bit loads the current value in the CNT_MIN register into the CNT_CNTR register to create a new boundary limit.
0 (R0/W)	W1LCNTZERO	Write 1 CNTR to Zero. Writing a 1 to the CNT_CMD.W1LCNTZERO bit clears the CNT_CNTR register.

Counter Register

The CNT_CNTR register holds the 32-bit, two's-complement count value. It can be read and written at any time. Hardware ensures that reads and write are atomic, by providing respective shadow registers. This register can be accessed with either 32-bit or 16-bit operations. This allows use of the CNT as a 16-bit counter if sufficient for the application.

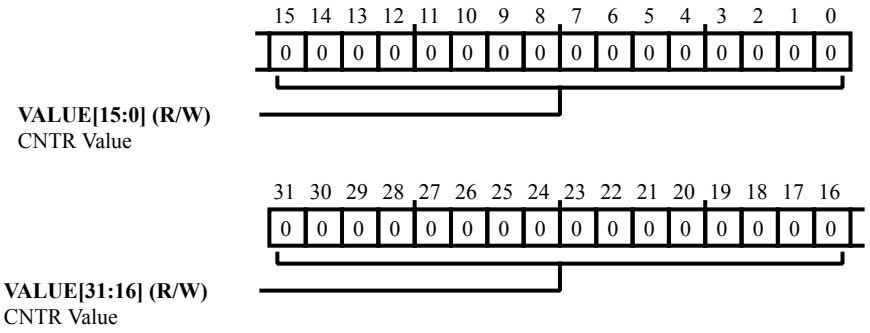

Figure 27-6: CNT_CNTR Register Diagram

Table 27-10: CNT_CNTR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	CNTR Value. The CNT_CNTR.VALUE bit field holds the 32-bit, two's-complement count value.

Debounce Register

The CNT_DEBNCE register selects the noise filtering characteristic of the three input pins according to the formula:

t_{filter} = 128 x ($2^{DPRESCALE}$/ SCLK0)

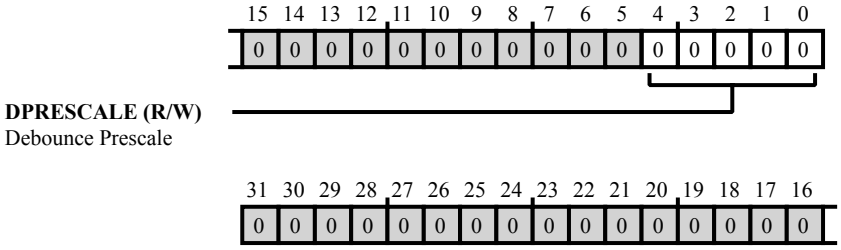

Figure 27-7: CNT_DEBNCE Register Diagram

Table 27-11: CNT_DEBNCE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
4:0 (R/W)	DPRESCALE	Debounce Prescale. The CNT_DEBNCE.DPRESCALE selects the desired number of input filtering cycles (and resulting input debounce time) in multiples of SCLK0.	
		0	1x Cycles = 128 SCLK0 Cycles
		1	2x Cycles
		2	4x Cycles
		3	8x Cycles
		4	16x Cycles
		5	32x Cycles
		6	64x Cycles
		7	128x Cycles

Bit No. (Access)	Bit Name	Description/Enumeration	
		17	131072x Cycles
		18	Reserved from This Value. The values 10010 - 11111 are reserved.
		31	Reserved Until This Value

Interrupt Mask Register

The CNT_IMSK register supports enabling (unmasking) interrupt request generation from each of the CNT events.

All bits in CNT_IMSK either disable/mask an interrupt request (if bit cleared) or enable/unmask an interrupt request (if bit set).

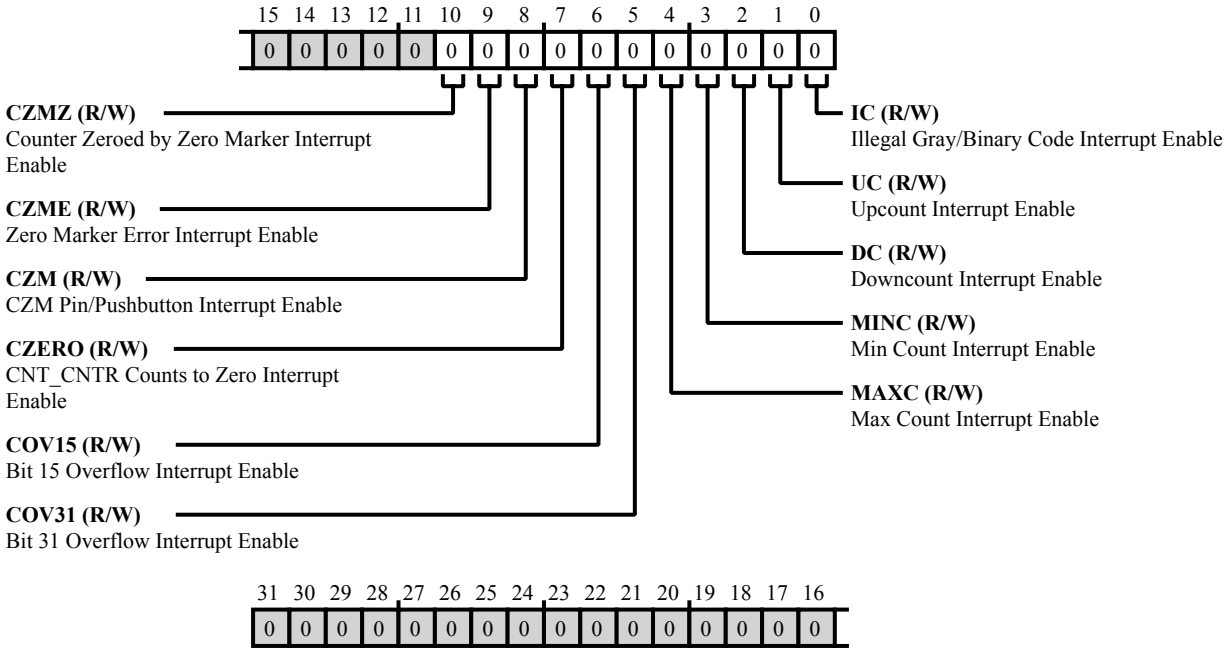

Figure 27-8: CNT_IMSK Register Diagram

Table 27-12: CNT_IMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
10 (R/W)	CZMZ	Counter Zeroed by Zero Marker Interrupt Enable. The CNT_IMSK.CZMZ bit enables (unmasks) the counter zeroed by zero marker interrupt request.	
		0	Mask Interrupt
		1	Unmask Interrupt
9 (R/W)	CZME	Zero Marker Error Interrupt Enable. The CNT_IMSK.CZME bit enables (unmasks) the zero marker error interrupt request.	
		0	Mask Interrupt
		1	Unmask Interrupt

Table 27-12: CNT_IMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W)	CZM	CZM Pin/Pushbutton Interrupt Enable. The CNT_IMSK.CZM bit enables (unmasks) the CZM pin/pushbutton interrupt request.	
		0	Mask Interrupt
		1	Unmask Interrupt
7 (R/W)	CZERO	CNT_CNTR Counts to Zero Interrupt Enable. The CNT_IMSK.CZERO bit enables (unmasks) the counts to zero interrupt request.	
		0	Mask Interrupt
		1	Unmask Interrupt
6 (R/W)	COV15	Bit 15 Overflow Interrupt Enable. The CNT_IMSK.COV15 bit enables (unmasks) the bit 15 overflow interrupt request.	
		0	Mask Interrupt
		1	Unmask Interrupt
5 (R/W)	COV31	Bit 31 Overflow Interrupt Enable. The CNT_IMSK.COV31 bit enables (unmasks) the bit 31 overflow interrupt request.	
		0	Mask Interrupt
		1	Unmask Interrupt
4 (R/W)	MAXC	Max Count Interrupt Enable. The CNT_IMSK.MAXC bit enables (unmasks) the max count interrupt request.	
		0	Mask Interrupt
		1	Unmask Interrupt
3 (R/W)	MINC	Min Count Interrupt Enable. The CNT_IMSK.MINC bit enables (unmasks) the min count interrupt request.	
		0	Mask Interrupt
		1	Unmask Interrupt
2 (R/W)	DC	Downcount Interrupt Enable. The CNT_IMSK.DC bit enables (unmasks) the down count interrupt request.	
		0	Mask Interrupt
		1	Unmask Interrupt

Table 27-12: CNT_IMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W)	UC	Upcount Interrupt Enable. The `CNT_IMSK.UC` bit enables (unmasks) the up count interrupt request.	
		0	Mask Interrupt
		1	Unmask Interrupt
0 (R/W)	IC	Illegal Gray/Binary Code Interrupt Enable. The `CNT_IMSK.IC` bit enables (unmasks) the illegal Gray/Binary Code interrupt request and should only be used in these modes.	
		0	Mask Interrupt
		1	Unmask Interrupt

Maximum Count Register

The CNT_MAX register holds the 32-bit, two's-complement, higher boundary value. It can be read and written at any time. Hardware ensures that reads and write are atomic, by providing respective shadow registers. This register can be accessed with either 32-bit or 16-bit operations. This allows for using the CNT as a 16-bit counter if sufficient for the application.

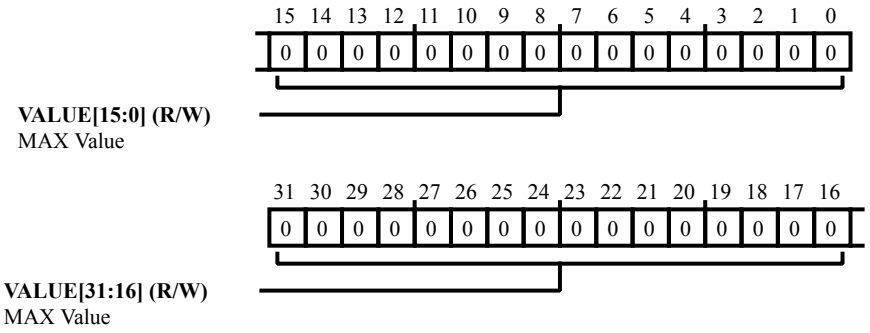

Figure 27-9: CNT_MAX Register Diagram

Table 27-13: CNT_MAX Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	MAX Value. The CNT_MAX.VALUE bit field holds the 32-bit, two's-complement, higher boundary value.

Minimum Count Register

The CNT_MIN register holds the 32-bit, two's-complement, lower boundary value. It can be read and written at any time. Hardware ensures that reads and write are atomic, by providing respective shadow registers. This register can be accessed with either 32-bit or 16-bit operations. This allows for using the CNT as a 16-bit counter if sufficient for the application.

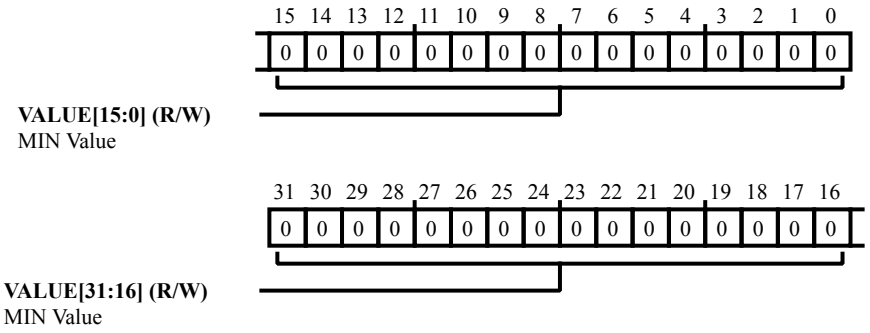

Figure 27-10: CNT_MIN Register Diagram

Table 27-14: CNT_MIN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	MIN Value. The CNT_MIN.VALUE bit field holds the 32-bit, two's-complement, lower boundary value.

Status Register

The CNT_STAT register provides status information for each of the CNT events as configured in the CNT_IMSK register. When a CNT event is detected, the corresponding bit in this register is set. It remains set until either software writes a 1 to the bit (write-1-to-clear) or the CNT is disabled.

All bits in the CNT_STAT register indicate either no interrupt request pending (if bit cleared) or an interrupt request pending (if bit set).

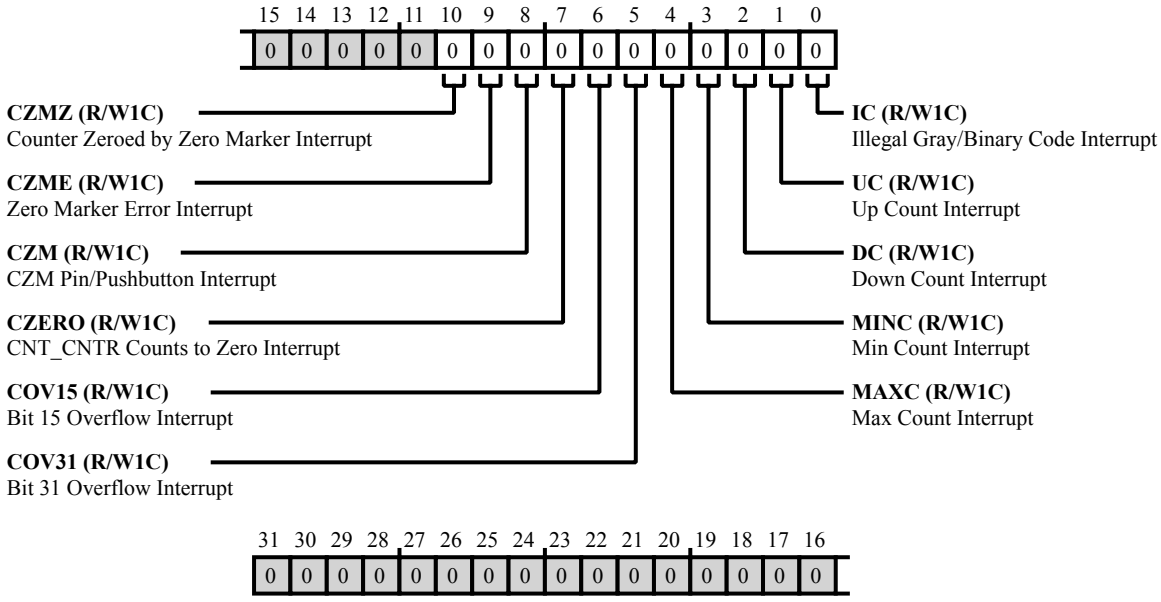

Figure 27-11: CNT_STAT Register Diagram

Table 27-15: CNT_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
10 (R/W1C)	CZMZ	Counter Zeroed by Zero Marker Interrupt. The CNT_STAT.CZMZ bit indicates a zero marker error. If the CNT_CFG.ZMZC bit =1, this interrupt request is generated when the CZMII latch reports a significant edge on the CZM input. Once cleared by software the CNT_STAT.CZM bit is not set again when the CZM input remains active without pulsing.	
		0	No Error
		1	Error Occurred

Table 27-15: CNT_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W1C)	CZME	Zero Marker Error Interrupt. The CNT_STAT.CZME bit behaves similarly to the CNT_STAT.CZM bit, with the exception that CNT_STAT.CZME is not set on the CZM edge when the lower four bits of the CNT_CNTR are not zero. In many applications this indicates an error condition, as the zero marker might be out of sync with the counter.	
		0	No Error
		1	Error Occurred
8 (R/W1C)	CZM	CZM Pin/Pushbutton Interrupt. The CNT_STAT.CZM bit indicates a CZM pin/pushbutton error. This interrupt request is generated when a significant edge is seen on the CZM pin, regardless what mode the counter is operating in. This is often used to sense push buttons (especially with the debouncing circuit enabled).	
		0	No Error
		1	Error Occurred
7 (R/W1C)	CZERO	CNT_CNTR Counts to Zero Interrupt. The CNT_STAT.CZERO bit indicates a counts to zero error. This error is generated when the CNT_CNTR register has incremented or decremented toward 0x0000.0000. The latch is not set when software writes to the CNT_CNTR register directly or when the counter is zeroed by writes to the CNT_CMD register.	
		0	No Error
		1	Error Occurred
6 (R/W1C)	COV15	Bit 15 Overflow Interrupt. The CNT_STAT.COV15 bit indicates a bit 15 overflow error. This error is generated when the 16-bit twos-complement CNT_CNTR register has incremented from 0xxxxx.7FFF to 0xxxxx.8000 or decremented from 0xxxxx.8000 to 0xxxxx.7FFF.	
		0	No Error
		1	Error Occurred
5 (R/W1C)	COV31	Bit 31 Overflow Interrupt. The CNT_STAT.COV31 bit indicates a bit 31 overflow error. This error is generated when the 32-bit twos-complement CNT_CNTR register has incremented from 0x7FFF.FFFF to 0x8000.0000 or decremented from 0x8000.0000 to 0x7FFF.FFFF.	
		0	No Error
		1	Error Occurred

Table 27-15: CNT_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/W1C)	MAXC	Max Count Interrupt. The CNT_STAT.MAXC bit indicates a max count error. This interrupt is used in boundary compare (BND_COMP) mode. If after incrementing the CNT_CNTR register equals CNT_MAX, the CNT_STAT.MAXC bit is set.	
		0	No Error
		1	Error Occurred
3 (R/W1C)	MINC	Min Count Interrupt. The CNT_STAT.MINC bit indicates a minimum count error. This interrupt is used in boundary compare (BND_COMP) mode. If, after decrementing, the CNT_CNTR register equals CNT_MIN, the CNT_STAT.MINC bit is set.	
		0	No Error
		1	Error Occurred
2 (R/W1C)	DC	Down Count Interrupt. The CNT_STAT.DC bit indicates a down count error. This interrupt is generated when the CNT_CNTR register decrements.	
		0	No Error
		1	Error Occurred
1 (R/W1C)	UC	Up Count Interrupt. The CNT_STAT.UC bit indicates an up count interrupt. This interrupt is generated when the CNT_CNTR register increments.	
0 (R/W1C)	IC	Illegal Gray/Binary Code Interrupt. The CNT_STAT.IC bit indicates a illegal Gray/Binary Code interrupt and should only be used in these modes. In normal operation those codes can increment or decrement the CNT_CNTR register by one at a time. If the sensed inputs instruct the counter to increment or decrement by two, the CNT_STAT.IC bit is set. Hardware sets the CNT_STAT.IC bit in QUAD_ENC and BIN_ENC encoder modes only.	
		0	No Error
		1	Error Occurred

28 Media Local Bus (MLB)

Media Local Bus (MediaLB®) is an on-PCB or inter-chip communication bus, which allows an application to access the MOST network data. Media Local Bus supports all the MOST network data transport methods including synchronous stream data, asynchronous packet data, control message data and isochronous data. The MLB topology supports communication among the MLB controller and MLB devices, where the MLB controller is the interface between the MLB devices and the MOST network.

The MLB module serves as an interface between the MediaLB and the processor, implementing the requirements of the physical layer and the link layer outlined in the MediaLB specification. It supports up to 64 logical channels with up to 468 bytes of data per MediaLB frame. Transmit and receive data can be transferred between MediaLB and on-chip memory with DMA block transfers.

The MLB supports the MOST25, MOST50 and MOST150 standards and this document assumes familiarity with these standards. For more information, refer to the Media Local Bus specification version 4.2.

- Copyright 1998-2016 Microchip Technology Inc. All rights reserved. Portions of this chapter are included with permission from Microchip Technology, Inc.

Features

The objective of MLB is to map all the MOST Network data types (transport methods) into a single low-cost, scalable, and standardized hardware interface between a MediaLB controller and at least one other MediaLB Device. The adoption of MediaLB simplifies the hardware interface, reduces the pin count, and facilitates the design of modular reusable hardware. From a software development perspective, the use of MediaLB relieves the system developer from the complexity of the MOST network, which simplifies software development and enables the design of reusable software for different applications. This simplified, standardized interface shortens time to market and makes software maintenance effortless.

- Compliant to Media Local Bus specification version 4.2
- Support MOST25, MOST50, MOST150 standards
- Support 3-pin and 6-pin mode
    - 6-pin mode supports a data rate of 2048 × FS
    - 3-pin mode support various data rates of 256 × FS, 512 × FS, 1024 × FS

- Support 64 logic channels
- Dedicated PLL for clock recovery and phase alignment
- Dedicated pins for 6-pin mode (LVDS)
- Shared pins for 3-pin mode
- Dedicated internal RAM for data buffering and channel table
- Recovered clock (after division) available out on a shared pin for DAI

NOTE: Only one MLB interface (3-pin mode or 6-pin mode) is active at any given time.

MLB Definitions

The following are standard MLB and MOST terms that are used in this chapter.

AGU

Address Generation Units. To access a particular HBI channel the HC must first configure one of two HBI address generation units. AGUs can be configured by writing the HBI command registers, HCMD0 and HCMD1.

CAT

Channel Allocation Table. The Channel Allocation Table (CAT) is comprised of 16 CTR entries. Each 16-bit CAT entry represents a logical connection to or from a transmit/receive device (for example MediaLB or HBI channel).

CDT

Channel Descriptor Table.

FCE

Flow Control Enable bit. The FCE bit is used by MediaLB isochronous Rx channels only.

HBI

Host Bus Interface. The HBI block provides 16-bit parallel completer access to all MOST channels and data types for the external Host Controller (HC). The HBI supports up to 64 independent channels.

HC

Host Controller (external).

HCMDx

HBI Command registers.

HSTSx

HBI status registers.

MFE

Multi-Frame per sub-buffer enable bit. The MFE bit is used by MediaLB synchronous channels only.

PML

Packet Message Length.

Clocking

The MLB controller provides an external clock pin—the media local bus clock. The MLB controller generates the clock. It is synchronized to the MOST network and provides the timing for the entire MLB interface at FS = 48 kHz.

Functional Description

The ***MediaLB Block Diagram*** figure shows the MLB high-level architecture. The MLB core serves as an interface between the MediaLB and the processor, implementing the requirements of the physical layer and the link layer outlined in the MediaLB specification. The MLB core has the following responsibilities.

- Transmit commands and data when functioning as the transmitting device associated with a *Channel Address*
- Receive data and transmit Rx status responses when functioning as the receiving device associated *Channel Address*
- MLB lock detection
- System channel command handling

The MediaLB device can function as either a MediaLB 3-pin interface (single-ended) or MediaLB 6-pin interface (differential) but only one interface can be active at a time. The MediaLB interfaces are capable of exchanging data at speeds up to 1024 × Fs in 3-pin mode or 2048 × Fs in 6-pin mode.

A set of physical channels for exchanging data over the MediaLB bus is supported. These physical channels (4 bytes in length, or a quadlet) can be grouped into logical channels, where each logical channel is referenced using a channel address and represents a uni-directional datapath between a specific MediaLB device transmitting the data and the MediaLB device(s) receiving the data. The MediaLB 6-pin interface provides support for up to 468 bytes of data per frame. The logical channels, configured by system software, can be any combination of channel types (synchronous, asynchronous, isochronous, or control) and direction (transmit or receive).

ADSP-SC59x MLB Register List

The MediaLB Device Interface Macro 2 (MediaLB DIM 2), also referred to as OS62420, implements the required functionality of a Media Local Bus (MediaLB) device. This logic serves as an interface between the inter-chip MediaLB bus and a customer IC, implementing the physical- and link-layer requirements outlined in the MediaLB Specification.

189	MLB0_STAT	MLB0 Status		

MediaLB Protocol

The MediaLB topology supports communication among all MediaLB devices, including the MediaLB controller. The bus interface consists of a uni-directional line for clock (MLBC), a bidirectional line for signal information (MLBS), and a bidirectional line for data transfer (MLBD). The MediaLB topology supports one controller connected to one or more devices, where the controller is the interface between the MediaLB devices and the MOST network.

The MediaLB controller includes MediaLB device functionality, and also generates the MediaLB clock (MLBC) that is synchronized to the MOST Network. This generated clock provides the timing for the entire MediaLB interface. The MLBS line is a multiplexed signal which carries channel addresses generated by the MediaLB controller, as well as command and RxStatus bytes from MediaLB devices. The MLBD line is driven by the transmitting MediaLB device and is received by all other MediaLB devices, including the MediaLB controller. The MLBD line carries the actual data (synchronous, asynchronous, control, or isochronous).

Once per MOST network frame, the MLB controller generates a unique frame sync pattern on the MLB_SIG line. The end of the frame sync pattern defines the byte boundary and the channel boundary for the MLB_SIG and MLB_DAT lines of all MLB devices.

The MLB controller manages the arbitration for all the channels on the MLB and grants bandwidth for all the MLB devices. An MLB *physical channel* is defined as four bytes wide, or a quadlet. Physical channels can be grouped into multiple quadlets (which do not have to be consecutive) to form an MLB *logical channel*, which is defined by a unique channel address.

As shown in ***MLB Data Structure***, the MLB controller initiates communication by sending out a channel address on the MLB_SIG line for each physical channel. The channel address indicates which MLB device is transmitting and which MLB devices are receiving in the following physical channel. Therefore, four bytes after the controller outputs the channel address on the MLB_SIG line, the transmitting device outputs a command byte command on the MLB_SIG line and outputs the respective data on the MLB_DAT line, concurrently. The MLB command byte contains the type of data currently being transmitted (for example synchronous, asynchronous or control).

The MLB device receiving the channel data outputs a status byte, RxStatus, on the MLB_SIG line immediately after the transmitting device outputs the command byte. The status response can indicate that the receiving device is busy and cannot receive the data at present, or the device is ready to receive the data. Since synchronous stream data is sent in a broadcast fashion, receiving devices cannot return a busy status and should not drive RxStatus onto the MLB_SIG line.

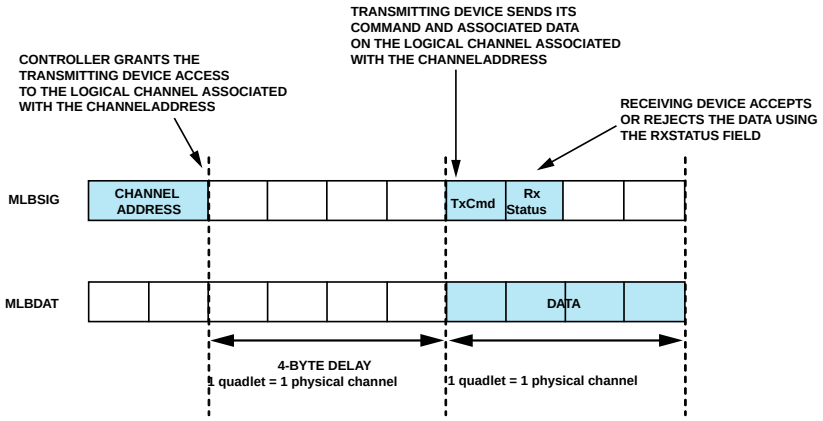

Figure 28-1: MLB Data Structure

MLB Architectural Concepts

The following sections provide information about the MLB architecture.

MediaLB Block Diagram

The ***MediaLB Block Diagram*** shows the various blocks within the interface its connections to the processor.

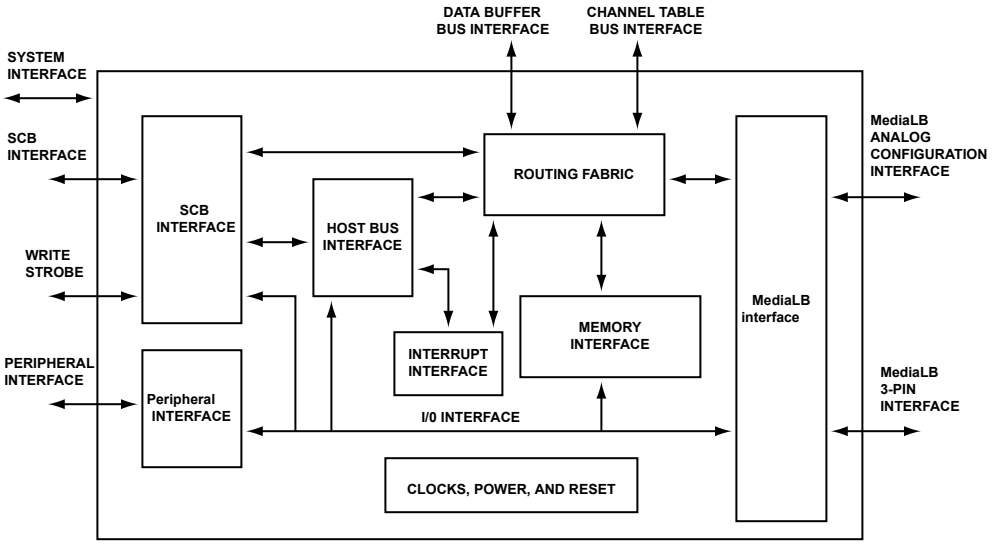

Figure 28-2: MediaLB Block Diagram

MediaLB Interface

The Media Local Bus (MediaLB) block supports both a MediaLB 3-pin interface and MediaLB 6-pin interface; however, only one MediaLB interface can be active at any given time. Both MediaLB interfaces provide real-time access to all network data types - synchronous, asynchronous, control, and isochronous data.

- MediaLB 3-pin interface–supports the MediaLB protocol for single-ended 3-pin mode, with a maximum data rate of 1024 FS (49.152 MHz at FS = 48 kHz).
- MediaLB 6-pin interface–supports the MediaLB protocol for high-speed differential 6-pin mode, with a maximum data rate of 2048 FS (98.304 MHz at FS = 48 kHz).

MediaLB Channel Address to Logical Channel Mapping

The MediaLB channel addresses are mapped to the logical channels as shown in the ***MediaLB Channel Address to Logical Channel Mapping*** table.

Table 28-3: MediaLB Channel Address to Logical Channel Mapping

Channel Address	Logical Address
0x0002	1
0x0004	2
0x0006	3
...	...
0x007C	62
0x007E	63
0x01FE	0 (Logical channel 0 is the system channel and is reserved)

Routing Fabric

The Routing Fabric (RF) block manages the flow of data between the MediaLB port and the HBI port. It manages accessing the Channel Table RAM (CTR) and Data Buffer RAM (DBR), which are explained in the following subsections. The routing fabric uses channel descriptors (stored in the CTR) to manage access to dynamic buffers in the DBR.

Data Buffer RAM

The Data Buffer RAM (DBR) is an 8-bit x 16k entriy buffer, single-port synchronous SRAM, and provides dynamic circular buffering between the transmit and receive devices. The size and location of each data buffer is defined by software in the Channel Descriptor Table (CDT), which is in the Channel Table RAM (CTR), described in following sections.

Channel Table RAM

The Channel Table RAM (CTR) is a 128-bit x 144-entry table that allows system software to dynamically configure channel routing and allocate data buffers in the DBR. The CTR is logically divided into three tables:

- Channel Descriptor Tables
- AHB Descriptor Table (ADT)
- Channel Allocation Table

Address Mapping

The ***CTR Address Mapping*** table shows the address mapping for the CTR.

Table 28-4: CTR Address Mapping

Label	Address	Bits [127:96]	Bits [95:64]	Bits [63:32]	Bits [31:0]
Channel Descriptor Table (CDT)					
CDT	0x00	CDT0[127:0], CL = 0

*1 A fixed relationship exists between ADT entries and HBI CAT entries. When using HBI channel 0 (CAT64), program ADT0. When using HBI channel 1 (CAT65), program ADT1, and so on.

Channel Allocation Table

The ***Channel Allocation Table (CAT)*** table is comprised of 16 CTR entries (addresses 0x80 0x8F) as shown in the ***CTR Entry Map*** table. Each 16-bit CAT entry represents a logical connection to or from a transmit or receive device. (for example, MediaLB channel). All entries are indexed according to a fixed physical address assigned to every RX/TX channel as shown in the ***CAT Entry Formats*** table. The value stored in a CAT entry includes a 6-bit connection label, which provides a pointer to the CDT. To complete a logical channel and form a routing connection, system software must assign the same connection label to both the RX and TX channels.

Table 28-5: CAT Entry Map

Peripheral	TX Channels	RX Channels	CAT Start Index	CAT End Index	Entries
MediaLB	0 to 64	64 TX Channels	0	63	64
HBI	0 to 64	64 TX Channels	64	127	64

The format of a full CAT entry is shown in the ***CAT Entry Formats*** table, with field descriptions described in the ***CAT Field Definitions*** table. All reserved bits of a CAT entry field should be written as zero.

Table 28-6: CAT Entry Formats

Channel Type	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 28-7: CAT Field Definitions

Field	Description
CL[5:0]	Connection Label (offset into CDT)
CT[2:0]	Channel Type (others) 111 = Reserved 110 = Reserved 101 = Reserved 100 = Reserved 011 = Isochronous 010 = Asynchronous 001 = Control 000 = Synchronous
CE	Channel Enable. 0 = Disabled, 1 = Enabled
RNW	Read Not Write. 0 = Write, 1 = Read
MT	Mute Enable. 0 = Disabled When set for synchronous channels, the MT bit forces RX channels to write zeros into the channel data buffer, and TX channels to output zeros on the physical interface. When set for asynchronous and control channels, the MT bit causes DMA to halt at a packet boundary. Not valid for isochronous channels.
FCE	Flow Control Enable. 0 = Disabled, 1 = Enabled The FCE bit is used by MediaLB isochronous RX channels only.
MFE	Multi-Frame per sub-buffer enable. 0 = Disabled, 1 = Enabled The MFE bit is used by MediaLB synchronous channels only.
rsvd	Reserved. Software writes a 0 to all reserved bits when the entry is initialized. These bits are read-only after initialization.

Channel Set Up

Data direction is in reference to the DBR. The data direction of CAT entries corresponding to the same channel is reversed for the HBI CAT and the MediaLB CAT.

- For a Tx channel (from the HC to the MediaLB interface):
  - HBI CAT entry: RNW = 0 (write)
  - MediaLB CAT entry: RNW = 1 (read)
- Conversely, for an Rx channel (data from MediaLB to HC):

- HBI CAT entry: RNW = 1 (read)
- MediaLB CAT entry: RNW = 0 (write)

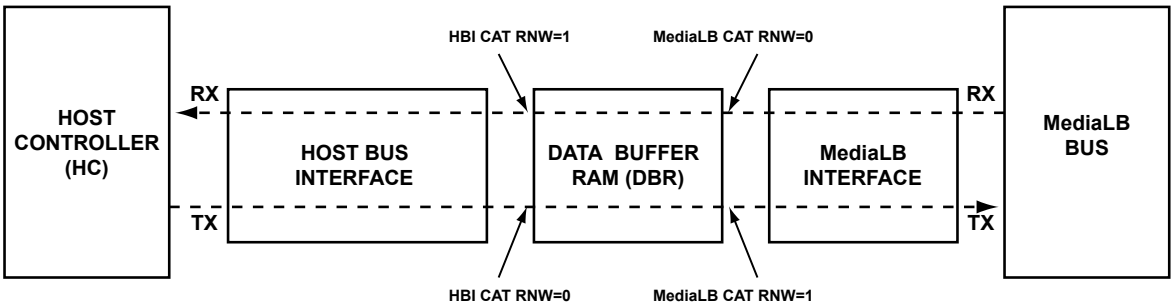

Figure 28-3: DBR Directional Relationship

Channel Descriptor Tables

The Channel Descriptor Table (CDT) is comprised of 64 CTR entries (addresses 0x00 - 0x3F), as shown in the Table 28-4 CTR Address Mapping table. Each 128-bit CDT entry (also referred to as a channel descriptor) is referenced by a connection label and contains information about a data buffer in the DBR (for example buffer size, address pointers). The format of each CDT entry is dependent on the channel type (synchronous, isochronous, asynchronous, or control).

NOTE: All reserved channel descriptor bits must be written to 0 by software when initialized.

Synchronous Channel Descriptors

The format and field definitions for a synchronous CDT entry are shown in the ***Synchronous CDT Entry Format*** and ***Synchronous CDT Entry Field Definitions*** tables.

Table 28-8: Synchronous CDT Entry Format

AHB Descriptor Table (ADT)

The AHB block manages data exchange between local channel data buffers within MLB module and the system memory buffer. To support system memory buffering, a ping-pong memory structure is implemented on a per channel basis using 128-bit descriptors for AHB Descriptor Table (ADT) entries. The Table 28-4 CTR Address Mapping table provides a complete address map of the CTR, including the location of the ADT.

Each logical channel is assigned a separate 128-bit descriptor, defining the data buffers in the system memory used by the DMA interface for that channel. The descriptors are stored at fixed addresses in the CTR as described in previous section. The ***ADT Field Definitions*** table provides an overview of field definitions for ADT entries.

Table 28-14: ADT Field Definitions

Field	No. of Bits	Description	Access
CE	1	Channel Enable. 0 = Disabled	RW, U
LE	1	Endianness Select. 0 = Big Endian, 1 = Little Endian	RW
PG	1	Page pointer. Software initializes to 0, hardware writes thereafter. 0 = Ping buffer, 1 = Pong buffer	RW, U
RDY1	1	Buffer Ready bit for ping buffer page. 0 = Not ready, 1 = Ready	RW
RDY2	1	Buffer Ready bit for pong buffer page. 0 = Not ready, 1 = Ready	RW
DNE1	1	Buffer Done bit for ping buffer page. 0 = Not done, 1 = Done	R, U, c0
DNE2	1	Buffer Done bit for pong buffer page. 0 = Not done, 1 = Done	R, U, c0
ERR1	1	Error Response detected for ping buffer page. 0 = No error, 1 = Error	R, U, c0
ERR2	1	Error Response detected for pong buffer page. 0 = No error, 1 = Error	R, U, c0
PS1	1	Packet Start bit for ping buffer page. 0 = No packet start, 1 = Packet start Reserved for synchronous and isochronous channels.	RW, U both TX and RX
PS2	1	Packet Start bit for pong buffer page. 0 = No packet start, 1 = Packet start Reserved for synchronous and isochronous channels.	RW, U both TX and RX
MEP1	1	Most Ethernet Packet indicator for ping buffer page. 0 = Not MEP, 1 = MEP. MEP1 only valid for the first page of a segmented buffer. Reserved for control synchronous and isochronous channels.	Rsvd for TX, R, U, c0 for RX
MEP2	1	Most Ethernet Packet indicator for pong buffer page. 0 = Not MEP, 1 = MEP. MEP2 only valid for the first page of a segmented buffer. Reserved for control synchronous and isochronous channels.	Rsvd for TX, R, U, c0 for RX
BD1	11 to 13	Buffer Depth for ping buffer page. 11 or 12 bits for asynchronous and control channels. 13 bits for synchronous and isochronous channels.	RW
BD2	11 to 13	Buffer Depth for pong buffer page. 11 or 12 bits for asynchronous and control channels. 13 bits for synchronous and isochronous channels.	RW
BA1	32	Buffer Base Address for ping buffer page	RW
BA2	32	Buffer Base Address for pong buffer page.	RW
Reserved	varies	Reserved. Software writes a 0 to all these bits when the entry is initialized. Reserved bits are RO after initialization.	RW, U

The ***Ping-Pong System Memory Structure*** figure shows that this system memory structure is similar for all channel types and shows the relationship between the BAn, BDn, and PG descriptor fields.

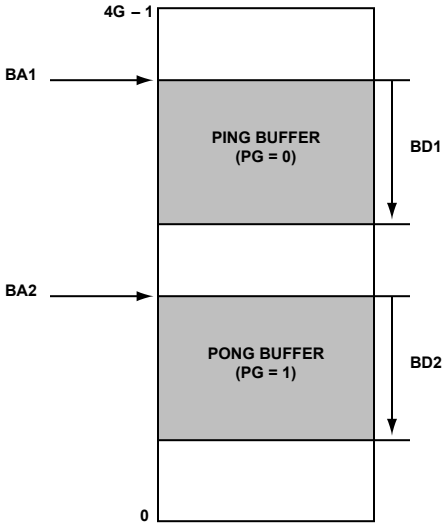

Figure 28-4: Ping-Pong System Memory Structure

Each ADT entry (also referred to as a *Channel Descriptor)* holds a 32-bit BAn field which defines the start of each ping or pong buffer within system memory. The BDn field is used to indicate the size for the respective ping or pong page. The maximum size is 2k entries for asynchronous and control channels and 8k entries for isochronous and synchronous channels.

Synchronous Channel Descriptors

The synchronous buffering scheme allows each ping or pong buffer to contain a single frame or a multiple number of frames. For this reason, the synchronous buffer depth (BDn) must be defined in terms of an integer number (n), frames per sub-buffer (m) and bytes per frame (bpf) of data (for example BDn = n m bpf 1). The ***Synchronous ADT Entry Format*** table shows the format for a synchronous ADT entry. The field definitions are defined in the ***ADT Field Definitions*** table. Each synchronous channel buffer can be up to 8k-bytes deep.

Table 28-15: Synchronous ADT Entry Format

Bit Offset	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	CE	LE	PG	Reserved												
16	Reserved															
32	RDY1	DNE1	ERR1	BD1[12:0]												
48	RDY2	DNE2	ERR2	BD2[12:0]												
64	BA1[15:0]															
80	BA1[31:16]															
96	BA2[15:0]															
112	BA2[31:16]															

Isochronous Channel Descriptors

The isochronous buffering scheme allows each ping or pong buffer to contain a single block or a multiple number of blocks. For this reason, the isochronous buffer depth (BDn) must be defined in terms of an integer number (n) and block size (BS) (for example BDn = n (BS + 1) 1).

The ***Isochronous ADT Entry Format*** table shows the format for an isochronous ADT entry. The field definitions are defined in the ***ADT Field Definitions*** table. Each isochronous channel buffer can be up to 8k-bytes deep.

Table 28-16: Isochronous ADT Entry Format

Bit Offset	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	CE	LE	PG	Reserved												
16	Reserved															
32	RDY1	DNE1	ERR1	BD1[12:0]												
48	RDY2	DNE2	ERR2	BD2[12:0]												
64	BA1[15:0]															
80	BA1[31:16]															
96	BA2[15:0]															
112	BA2[31:16]															

Asynchronous and Control Channel Descriptors

Every asynchronous and control packet adheres to the Port Message Protocol (PMP), which designates the first two bytes of each packet as the packet length (PML). Each packet must be no more than 2048-bytes (PML 2048).

Software must set the buffer ready bit (RDYn) for each buffer as it programs the DMA. As hardware processes each buffer, it sets the done bit (DNEn) and generates an interrupt to inform HC. When hardware finishes processing a buffer, it can begin processing another buffer if RDYn is set. The application is responsible for setting up and configuring the channel buffer descriptor prior to every DMA access on the channel.

Two packet buffering modes are supported by hardware for programming the DMA, single-packet mode (`MLB_ACTL.MPB` =0) and multiple-packet mode (`MLB_ACTL.MPB` =1). The MPB is written prior to enabling the channel DMA.

Single Packet Mode. The single-packet mode asynchronous and control buffering scheme supports a maximum of one packet per buffer (for example, ping or pong). Both non-segmented and segmented data packets are allowed while using single-packet mode. Non-segmented packets are exchanged when only one buffer (for example, ping or pong) is needed for packet transfer. Segmented packets are exchanged when a single packet is too long for one buffer and the packet must span multiple buffers.

The ***Single-Packet Asynchronous and Control Entry Format*** table shows the format for single-packet mode asynchronous and control ADT entries. The field definitions are defined in the ***ADT Field Definitions*** table.

Table 28-17: Single-Packet Asynchronous and Control Entry Format

Bit Offset	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	CE	LE	PG	Reserved												
16	Reserved															
32	RDY1	DNE1	ERR1	PS1	MEP1	BD1[10:0]										
48	RDY2	DNE2	ERR2	PS2	MEP2	BD2[10:0]										
64	BA1[15:0]															
80	BA1[31:16]															
96	BA2[15:0]															
112	BA2[31:16]															

Multiple Packet Mode. The multiple-packet mode asynchronous and control buffering scheme supports more than one packet per system memory buffer, as shown in the ***Asynchronous/Control CDT Entry Format*** table. Multiple-packet mode reduces the interrupt rate for packet channels at the cost of increasing buffering and latency.

For TX packet channels in multiple-packet mode, software sets the packet start bit (PSn) for every buffer. Setting PSn informs hardware that the first two bytes of the buffer contains the port message length (PML) of the first packet. After the first packet, hardware keeps track of where packets start and end within the current buffer. Software should not write to PSn while the buffer is active (RDYn = 1 and DNEn = 0). For TX packet channels, the buffer is done (DNEn = 1) when the last byte of the last packet in the buffer is read from system memory. Software should set the buffer depth to contain the exact number of complete packets for that buffer. Segmented buffers are not supported for TX packet channels in multiple-packet mode.

NOTE: The PS1 and PS2 bits are only valid for TX channels. Set PS1 and PS2 = 1 at the start of the buffer.

Table 28-18: Multiple-Packet Asynchronous and Control Entry Format

Bit Offset	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	CE	LE	PG	Reserved												
16	Reserved															
32	RDY1	DNE1	ERR1	PS1	BD1[11:0]											
48	RDY2	DNE2	ERR2	PS2	BD2[11:0]											
64	BA1[15:0]															
80	BA1[31:16]															
96	BA2[15:0]															
112	BA2[31:16]															

Interrupt Interface Block

The interrupt interface raises an interrupt when specific changes to HBI channel descriptors occur, including:

- For asynchronous and control read/write channels:
  - a packet is available to read in the channel buffer, or
  - sufficient empty space is available in the channel buffer to accept a requested packet write
- For isochronous read/write channels:
  - the number of valid bytes in the channel buffer exceeds the block size, or
  - the number of empty bytes in the channel buffer exceeds the block size

Operating Modes

The following sections describe the operating modes of the MLB interface. The channel type selection enables the logical channels to operate in synchronous, asynchronous, isochronous, or control channels.

NOTE: The logical channels can be any combination of channel type (for example synchronous, asynchronous, or control) and direction (transmit or receive).

Isochronous Data Exchange

An isochronous HBI channel is initially opened and synchronized with HCMD0.CMD[2:0]= 010. For isochronous channels, no further synchronization is required from the HBI perspective; however, an optional resynchronization command is available for HC flexibility. Setting HCMD0.CMD[2:0]= 011 reinitializes the address pointer within the data buffer, ensuring that subsequent data exchange with the channel is aligned at an isochronous packet boundary. When the HC must close an isochronous channel before it has read or written an entire data packet, setting HCMD0.CMD[2:0]= 000 reopens the channel without synchronizing the address pointer in the buffer. This action allows reading and writing to continue where the HC previously stopped.

For isochronous data transmission, the ***Exchanging Isochronous Data on an HBI Channel*** figure shows the flow control.

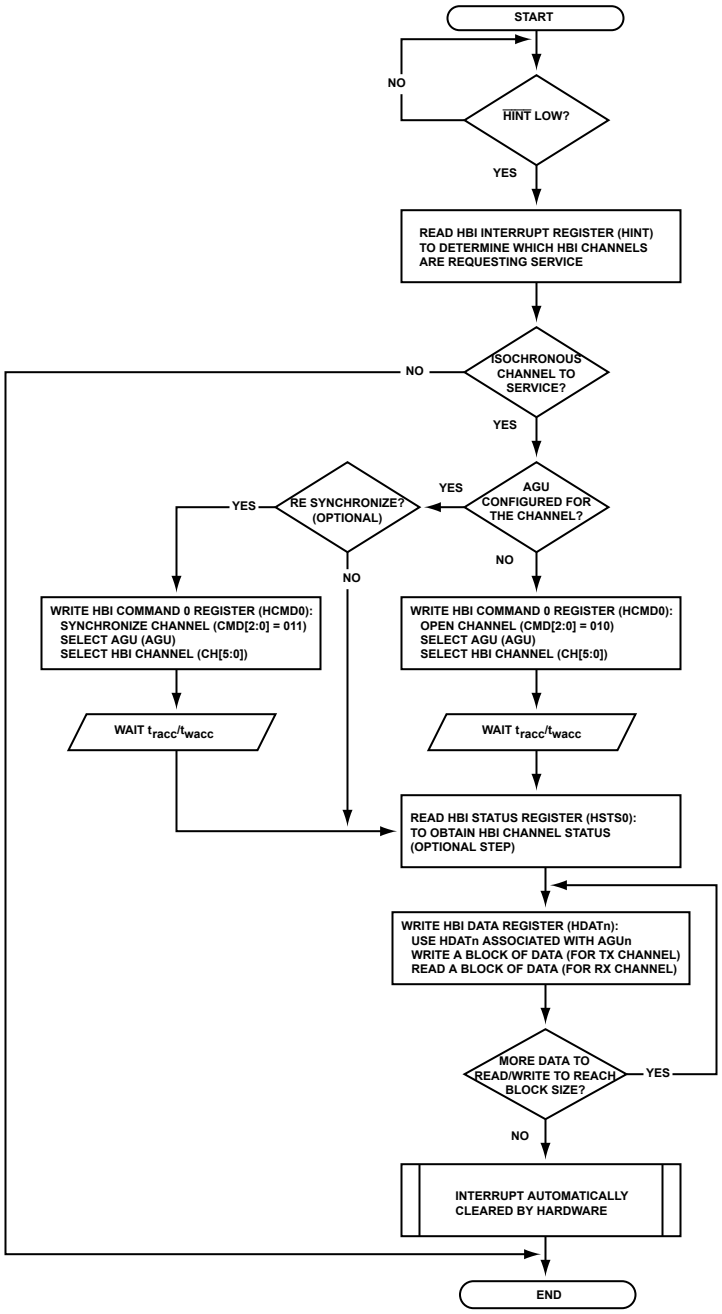

Figure 28-5: Exchanging Isochronous Data on an HBI Channel

Asynchronous and Control Data Exchange

An asynchronous or control HBI channel is initially opened using HCMD0.CMD[2:0]= 010. Occasionally, the HC may need to close a packet channel before it has completed writing or reading the current packet of data (for example, the HC needs to use this AGU to service another HBI channel). In this case, the HC can reopen the previous channel with HCMD0.CMD[2:0]= 000. This situation allows the HC to continue writing or reading a packet from

the point it left off. In this situation, the PML is already known, and the packet length is not reread or rewritten by the HC.

During the reading of a packet, if the HC sets HCMD0.CMD[2:0]= 010 for the channel before the last byte of the packet is read, an internal hardware pointer is reset to the beginning of the packet buffer. This situation requires that the HC reread the PML (from HSTS1) and reread the packet data (from HDATn) from the beginning. In the same manner, if the HC resets HCMD0.CMD[2:0]= 010 for the channel before the last byte of a packet is written, an internal hardware pointer is reset to the beginning of the packet buffer. This situation requires that the HC rewrite the PML (to HCMD1) and rewrite the packet data (to HDATn) from the beginning. Any previous packet data in the buffer is overwritten.

Frame synchronization is not supported for asynchronous channels.

Synchronous Data Exchange

The MLB core provides two modes of operation; standard and multi-frame per sub-buffer which provide flexibility for implementing synchronous channels. Channels configured for standard mode require less buffer space but have higher interrupt rates and more stringent latency requirements. Channels setup for each multi-frame per sub-buffer mode requires more buffer space, but has lower interrupt rates and less stringent latency requirements.

To set up a channel in multi-frame per sub-buffer mode:

1. Program the `MLB_CTL0.FCNT` bit field to select the number of frames per sub-buffer.
2. Program the CAT to enable multi-frame sub-buffering (MFE= 1) for each channel.
3. Set the buffer depth in the CDT: BD= 4 × m × bpf 1 where: m = frames per sub-buffer, bpf = bytes per frame.
4. Repeat for additional synchronous channels

A sample synchronous data buffer is shown in the ***Synchronous Data Buffer Structure*** figure. Each data buffer contains four sub-buffers and each sub-buffer contains space for 1 to 64 frames of data, determined by the `MLB_CTL0.FCNT` bits.

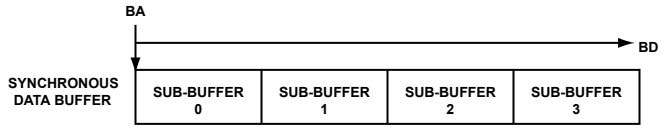

Figure 28-6: Synchronous Data Buffer Structure

Data Transfer

Two modes of operation are supported for transferring channel data between the MLB and internal memory. DMA allows the multi-channel DMA engine to manage data transfers without core intervention. Core driven mode (I/O mode) allows software to manage the transfer of data between MLB and internal memory.

NOTE: All hardware channels must use the same data transfer method. Mixed mode operation where hardware channels operate in both I/O mode and DMA mode is not supported.

DMA

The processor supports DMA mode which uses only INCR8, INCR4 and SINGLE beat bursts. Program the `MLB_ACTL.DMAMODE` = 1 to use DMA mode.

Programming Model

This section provides general guidelines for programming the MediaLB interface.

Channel Initialization

The software flow required to initialize a channel must be performed to ensure proper operation.

Configure the Hardware

1. Initialize the CTR and registers.
    a. Set all the CTR (CAT, CDT, and ADT) bits to 0.
    b. Set all bits of all registers to 0.
2. Configure the MediaLB interface.
    a. Select 3-pin or 6-pin MediaLB operation: `MLB_CTL0.PEN` =0 (3-pin), `MLB_CTL0.PEN` =1 (6-pin).
    b. Select MediaLB clock speed via `MLB_CTL0.CLK`.
    c. Set MediaLB enable via `MLB_CTL0.EN`.
3. Configure the HBI interface.
    a. Set `MLB_HCMR0` and `MLB_HCMR1` = 0xFFFFFFFF to activate all channels.
    b. Set the HBI enable bit: `MLB_HCTL.EN` =1.

Program the CAT and the CDT

1. Initialize all bits of the CAT to 0.
2. Select a logical channel: N = 1 – 63.
3. Program the CDT for channel N.
    a. Set the 14-bit base address (BA)
    b. Set the 12-bit or 13-bit buffer depth (BD): BD = buffer depth in bytes 1

- For synchronous channels: (BD + 1) = 4 frames per sub-buffer (m) bytes-per-frame (bpf)
- For isochronous channels: (BD + 1) mod (BS + 1) = 0

- For asynchronous channels: (BD + 1) max packet length (1024 for a MOST Data Packet (MDP)
- 1536 for a MOST Ethernet Packet (MEP)
- For control channels: (BD + 1) max packet length (64)

4. Program the CAT for the inbound DMA.
    a. For TX channels (to MediaLB) HBI is the inbound DMA
    b. For RX channels (from MediaLB) MediaLB is the inbound DMA
    c. Set the channel direction: RNW = 0
    d. Set the channel type: CT[2:0] = 010 (asynchronous), 001 (control), 011 (isochronous), or 000 (synchronous)
    e. Set the connection label: CL[5:0] = N
    f. If CT[2:0] = 000 (synchronous), set the mute bit (MT = 1)
    g. Set the channel enable: CE = 1
    h. Set all other bits of the CAT to 0
5. Program the CAT for the outbound DMA.
    a. For TX channels (to MediaLB) HBI is the outbound DMA
    b. For RX channels (from MediaLB) MediaLB is the outbound DMA
    c. Set the channel direction: RNW = 1
    d. Set the channel type: CT[2:0] = 010 (asynchronous), 001 (control), 011 (isochronous), or 000 (synchronous)
    e. Set the channel label: CL[5:0] = N
    f. If CT[2:0] = 000 (synchronous), set the mute bit (MT = 1)
    g. Set the channel enable: CE = 1
    h. Set all other bits of the CAT to 0
6. Repeat steps 2 through 5 to initialize all logical channels.

Program the ADT

1. Initialize all bits of the ADT to 0
2. Select a logical channel: N = 1 – 63
3. Program the AMBA AHB block ping page for channel N
    a. Set the 32-bit base address (BA1)

b. Set the 11-bit buffer depth (BD1): BD1 = buffer depth in bytes – 1
   - For synchronous channels: (BD1 + 1) = n frames per sub-buffer (m) bytes-per-frame (bpf)
   - For isochronous channels: (BD1 + 1) mod (BS + 1) = 0
   - For asynchronous channels: 5 (BD1 + 1) 4096 (max packet length)
   - For control channels: 5 (BD1 + 1) 4096 (max packet length)

c. For asynchronous and control Tx channels set the packet start bit (PS1) when the page contains the start of the packet

d. Clear the page done bit (DNE1)

e. Clear the error bit (ERR1)

f. Set the page ready bit (RDY1)

4. Program the AMBA AHB block pong page for channel N
   a. Set the 32-bit base address (BA2)
   b. Set the 11-bit buffer depth (BD2): BD2 = buffer depth in bytes – 1
      - For synchronous channels: (BD2 + 1) = n frames per sub-buffer (m) bytes-per-frame (bpf)
      - For isochronous channels: (BD2 + 1) mod (BS + 1) = 0
      - For asynchronous channels: 5 (BD2 + 1) 4096 (max packet length)
      - For control channels: 5 (BD2 + 1) 4096 (max packet length)
   c. For asynchronous and control TX channels set the packet start bit (PS2) when the page contains the start of the packet
   d. Clear the page done bit (DNE2)
   e. Clear the error bit (ERR2)
   f. Set the page ready bit (RDY2)
5. Select Big Endian (LE = 0) or Little Endian (LE = 1)
6. Select the active page: PG = 0 (ping), PG = 1 (pong)
7. Set the channel enable (CE) bit for all active logical channels
8. Repeat steps 2 through 7 for all active logical channels.

Service

After initialization, each channel will require periodic servicing. Use the procedures in the following sections to service DMA and MLB interrupts and to poll for MLB system commands.

Servicing the DMA Channel Interrupts

1. Program the MLB_ACMR0/MLB_ACMR1 registers to enable interrupts from all active DMA channels.
2. Select the status clear method. MLB_ACTL.SCE =0 (hardware clears on read), MLB_ACTL.SCE = 1 (software writes a 1 to clear).
3. Select 1 or 2 interrupt signals. Configure the MLB_ACTL.SMX bit =0 (one interrupt for channels 0 through 31 and another interrupt for channels 32 through 63 on). Configure the MLB_ACTL.SMX bit =1 (single interrupt for all channels).
4. Wait for an interrupt.
5. Read the MLB_ACSR0/MLB_ACSR1 registers to determine which channel or channels are causing the interrupt.
6. If the MLB_ACTL.SCE bit =1, write the results of step 5 back to the MLB_ACSR0 and MLB_ACSR1 registers to clear the interrupt.
7. Select a logical channel (N = 0 – 63) with an interrupt to service.
8. Read the ADT entry for channel N to:
    a. Determine the active page (ping or pong) via the PG bit
    b. Determine which page(s) are done via the DNEn bits
    c. Determine which channels encountered an AHB error via the ERRn bit
    d. Determine which asynchronous and control Rx channel pages contain a packet start via the PSn bit (extract the PML)
9. Repeat steps 6 through 8 for all channels with pending interrupts
10. Repeat steps 4 through 9 while there are active channels.

Servicing the MediaLB Status Interrupts

1. Select the MediaLB channel status register (MLB_MS0/MLB_MS1) to be cleared by software, writing a 0 to the appropriate bits.
2. Program the MLB_MIEN register to enable protocol error interrupts for all active MediaLB channels. (MLB_MIEN.CTXPE =1, MLB_MIEN.CRXPE =1, MLB_MIEN.ATXPE =1, MLB_MIEN.ARXPE =1, MLB_MIEN.SYNCPE =1, and MLB_MIEN.ISOCPE =1).
3. Wait for an interrupt on the MLB_INT0/MLB_INT1 signal.
4. Read the MLB_MS0/MLB_MS1 registers to determine which channel(s) are causing the interrupt.
5. Read the RSTS/WSTS of the appropriate CDT(s) to determine the interrupt type.

6. Clear the RSTS/WSTS errors to ensure that the status of channel operations is reflected in the register:

Option	Description
For synchronous RX channels	WSTS[3] = 0
For synchronous TX channels	RSTS[3] = 0
For isochronous RX channels	WSTS[2:1] = 00
For isochronous TX channels	RSTS[2:1] = 00
For asynchronous and control RX channels	WSTS[4] = 0 and WSTS[2] = 0
For asynchronous and control TX channels	RSTS[4] = 0 and RSTS[2] = 0

Polling for MediaLB System Commands

The MediaLB System status (`MLB_MSS`) register is used to detect a system command received from the MediaLB controller. The processor's peripheral automatically sends the appropriate system response to the MediaLB controller. The procedure for the application is:

1. The application periodically polls the `MLB_MSS` register.
2. Clear by writing a 0 to the appropriate bit in the `MLB_MSS` register after the application finishes the service.
3. If `MLB_MSS.SWSYSCMD` = 1, read the `MLB_MSD` register to receive the system data sent from MediaLB controller.

ADSP-SC59x MLB Register Descriptions

MediaLB Device Interface Macro 2 (MLB) contains the following registers.

Table 28-19: ADSP-SC59x MLB Register List

Name	Description
`MLB_ACMR0`	Peripheral Channel Mask 0 Register
`MLB_ACMR1`	Peripheral Channel Mask 1 Register
`MLB_ACSR0`	Peripheral Channel Status 0 Register
`MLB_ACSR1`	Peripheral Channel Status 1 Register
`MLB_ACTL`	Bus Control Register
`MLB_CTL0`	MediaLB Control 0 Register
`MLB_CTL1`	Control 1 Register
`MLB_GCTL`	MLB Global Control Register
`MLB_HCBR0`	HBI Channel Busy 0 Register
`MLB_HCBR1`	HBI Channel Busy 1 Register

Table 28-19: ADSP-SC59x MLB Register List (Continued)

Name	Description
MLB_HCER0	HBI Channel Error 0 Register
MLB_HCER1	HBI Channel Error 1 Register
MLB_HCMR0	HBI Channel Mask 0 Register
MLB_HCMR1	HBI Channel Mask 1 Register
MLB_HCTL	HBI Control Register
MLB_MADR	Memory Interface Address Register
MLB_MCTL	Memory Interface Control Register
MLB_MDAT0	Memory Interface Control Data 0 Register
MLB_MDAT1	Memory Interface Control Data 1 Register
MLB_MDAT2	Memory Interface Control Data 2 Register
MLB_MDAT3	Memory Interface Control Data 3 Register
MLB_MDWE0	Memory Interface Control Data Write Enable 0 Register
MLB_MDWE1	Memory Interface Control Data Write Enable 1 Register
MLB_MDWE2	Memory Interface Control Data Write Enable 2 Register
MLB_MDWE3	Memory Interface Control Data Write Enable 3 Register
MLB_MIEN	Interrupt Enable Register
MLB_MS0	Channel Status 0 Register
MLB_MS1	Channel Status 1 Register
MLB_MSD	System Data Register
MLB_MSS	System Status Register
MLB_PCTL0	MediaLB 6-pin Control 0 Register

Peripheral Channel Mask 0 Register

The MLB_ACMR0 register allows control over which channel(s) generate interrupts on MLB_INT[1:0]. All of the bits in this register default to 0 (masked) so the HC must initially write to the MLB_ACMR0 register to enable interrupts. Each bit of this register is read/write accessible.

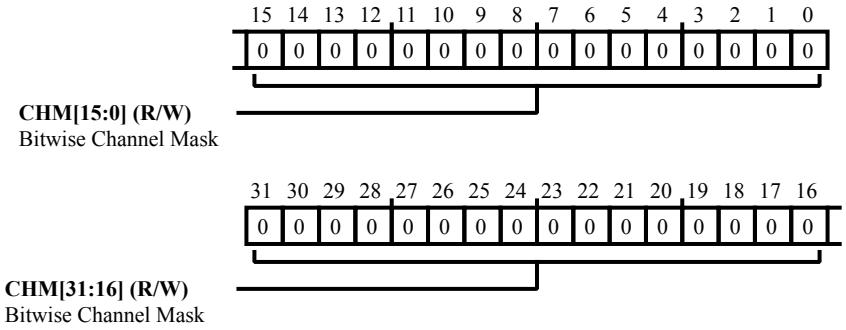

Figure 28-7: MLB_ACMR0 Register Diagram

Table 28-20: MLB_ACMR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:0 (R/W)	CHM	Bitwise Channel Mask. The MLB_ACMR0.CHM bit field masks or unmasks channels 31-0.	
		0	Mask interrupt for Channel 31:0 (bitwise; all channels shown)
		4294967295	Unmask interrupt for Channel 31:0 (bitwise; all channels shown)

Peripheral Channel Mask 1 Register

The MLB_ACMR1 register allows control over which channel(s) generate interrupts on MLB_INT[1:0]. All of the bits in this register default to 0 (masked) so the HC must initially write to the MLB_ACMR1 register to enable interrupts. Each bit of this register is read/write accessible.

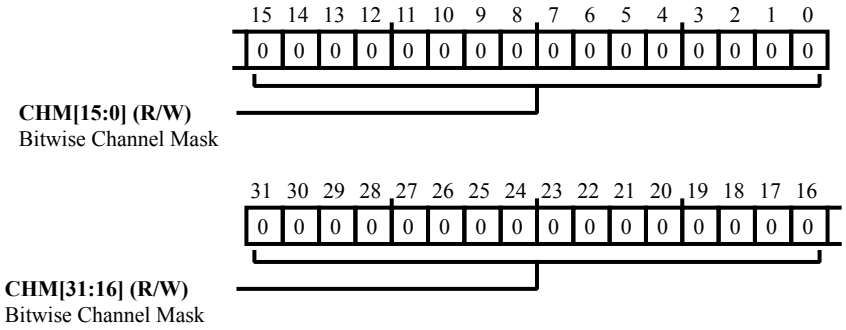

Figure 28-8: MLB_ACMR1 Register Diagram

Table 28-21: MLB_ACMR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:0 (R/W)	CHM	Bitwise Channel Mask. The MLB_ACMR1.CHM bit field masks or unmasks channels 63-32.	
		0	Mask interrupt for Channel 63:32 (bitwise; all channels shown)
		4294967295	Unmask interrupt for Channel 63:32 (bitwise; all channels shown)

Peripheral Channel Status 0 Register

The MLB_ACSR0 register contains interrupt bits for each of the 64 physical channels. When a bit in this register is set, it indicates that the corresponding physical channel has an interrupt pending.

A peripheral interrupt is triggered when either DNEn or ERRn is set within the Bus Channel Descriptor. The HC is notified of the channel interrupt via MLB_INT[1:0]. When an interrupt occurs in ACCUSER (for channels 31 to 0) MLB_INT[0] is set. When an interrupt occurs in MLB_ACSR1 (for channels 63 to 32) MLB_INT[1] is set.

Interrupts in the MLB_ACSR0 and MLB_ACSR1 registers can be optionally multiplexed onto a single interrupt signal, MLB_INT[0], if the MLB_ACTL.SMX bit = 1.

If the MLB_ACTL.SCE bit =0, hardware automatically clears the interrupt bit(s) after the HC reads the peripheral channel status registers. Alternatively, if the MLB_ACTL.SCE bit =1, software must write a 1 to the appropriate bit(s) of the peripheral channel status registers to clear the interrupt(s).

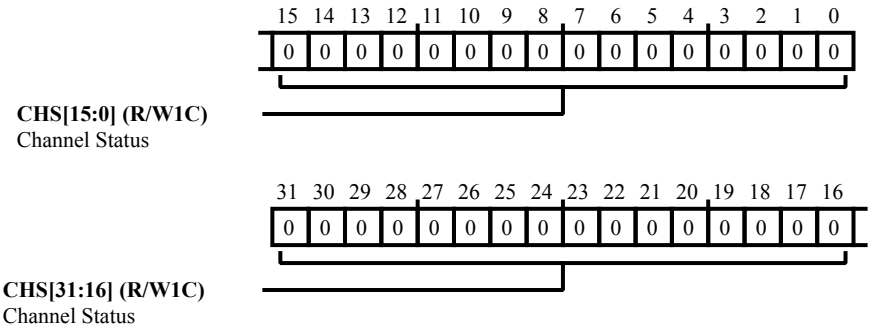

Figure 28-9: MLB_ACSR0 Register Diagram

Table 28-22: MLB_ACSR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:0 (R/W1C)	CHS	Channel Status. The MLB_ACSR0.CHS bit field indicates channel status for channels 31-0.	
		0	No interrupt on Channel 31:0 (bitwise; all channels shown)
		4294967295	Interrupt on Channel 31:0 (bitwise; all channels shown)

Peripheral Channel Status 1 Register

The MLB_ACSR1 register contains interrupt bits for each of the 64 physical channels. When a bit in this register is set, it indicates that the corresponding physical channel has an interrupt pending.

A peripheral interrupt is triggered when either DNEn or ERRn is set within the Bus Channel Descriptor. The HC is notified of the channel interrupt via MLB_INT[1:0]. When an interrupt occurs in ACCUSER (for channels 31 to 0) MLB_INT[0] is set. When an interrupt occurs in MLB_ACSR1 (for channels 63 to 32) MLB_INT[1] is set.

Interrupts in the MLB_ACSR1 and MLB_ACSR0 registers can be optionally multiplexed onto a single interrupt signal, MLB_INT[0], if the MLB_ACTL.SMX bit = 1.

If the MLB_ACTL.SCE bit =0, hardware automatically clears the interrupt bit(s) after the HC reads the peripheral channel status registers. Alternatively, if the MLB_ACTL.SCE bit =1, software must write a 1 to the appropriate bit(s) of peripheral channel status registers to clear the interrupt(s).

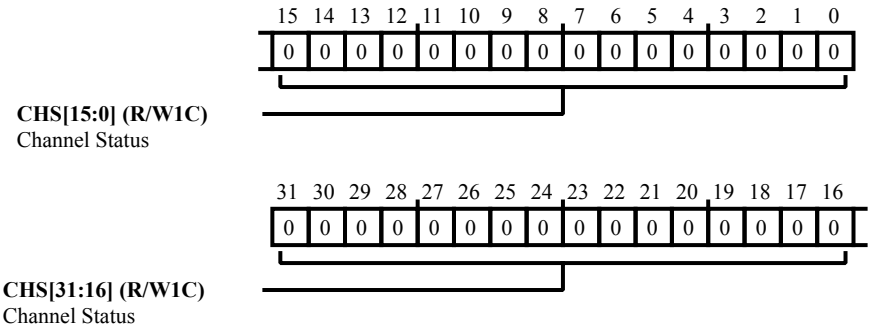

Figure 28-10: MLB_ACSR1 Register Diagram

Table 28-23: MLB_ACSR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:0 (R/W1C)	CHS	Channel Status. The MLB_ACSR1.CHS bit field indicates channel status for channels 63-32.	
		0	No interrupt on Channel 63:32 (bitwise; all channels shown)
		4294967295	Interrupt on Channel 63:32 (bitwise; all channels shown)

Bus Control Register

The MLB_ACTL register is written by the HC to configure the block for channel interrupts. This register contains bits to select the packet buffering mode and the DMA mode. This register also contains bits that are used to multiplex channel interrupts onto a single interrupt signal and to select the method of clearing channel interrupts.

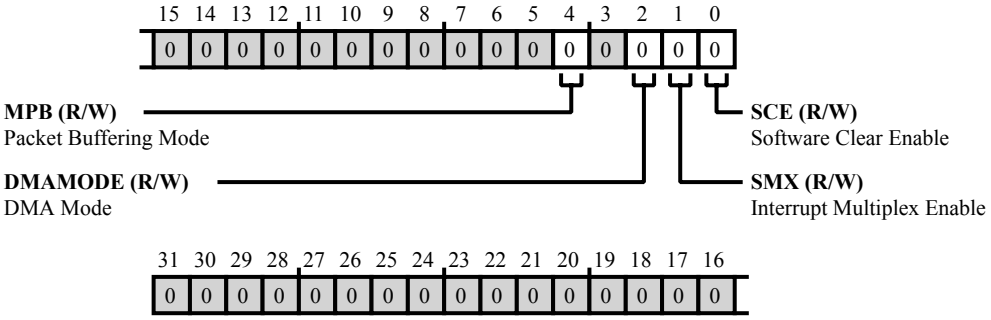

Figure 28-11: MLB_ACTL Register Diagram

Table 28-24: MLB_ACTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/W)	MPB	Packet Buffering Mode. The MLB_ACTL.MPB bit selects whether the buffering mode is single-packet or multiple-packet.	
		0	single-packet mode
		1	multiple-packet mode
2 (R/W)	DMAMODE	DMA Mode. The MLB_ACTL.DMAMODE bit selects between DMA mode 1 and 0. DMA Mode 0 uses incrementing bursts of an unspecified length. This allows the block to perform single beat transfers as well as an incrementing (INCR) burst of unspecified length up to the maximum specified burst length (8 beats). DMA Mode 1 uses only INCR8, INCR4, and SINGLE beat bursts. The hburst[2:0] signal encodes the burst transfer used for a DMA operation.	
		0	DMA Mode 0
		1	DMA Mode 1

Table 28-24: MLB_ACTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W)	SMX	Interrupt Multiplex Enable. The `MLB_ACTL.SMX` bit selects whether ACSR0 generates an interrupt on MLB_INT[0] and ACSR1 generates an interrupt on MLB_INT[1] or ACSR0 and ACSR1 generate an interrupt on MLB_INT[0] only.	
		0	ACSR0 generates an interrupt on MLB_INT[0]; ACSR1 generates an interrupt on MLB_INT[1]
		1	ACSR0 and ACSR1 generate an interrupts on MLB_INT[0] only
0 (R/W)	SCE	Software Clear Enable. The `MLB_ACTL.SCE` bit selects whether hardware clears the interrupt after a ACSRn register read or software clears the interrupt.	
		0	Hardware clears interrupt after a ACSRn register read
		1	Software clears interrupt

MediaLB Control 0 Register

The MLB_CTL0 register contains bit that enable the module and provide module status. Note that the maximum speed for ML6-pin mode is 2048 x FS.

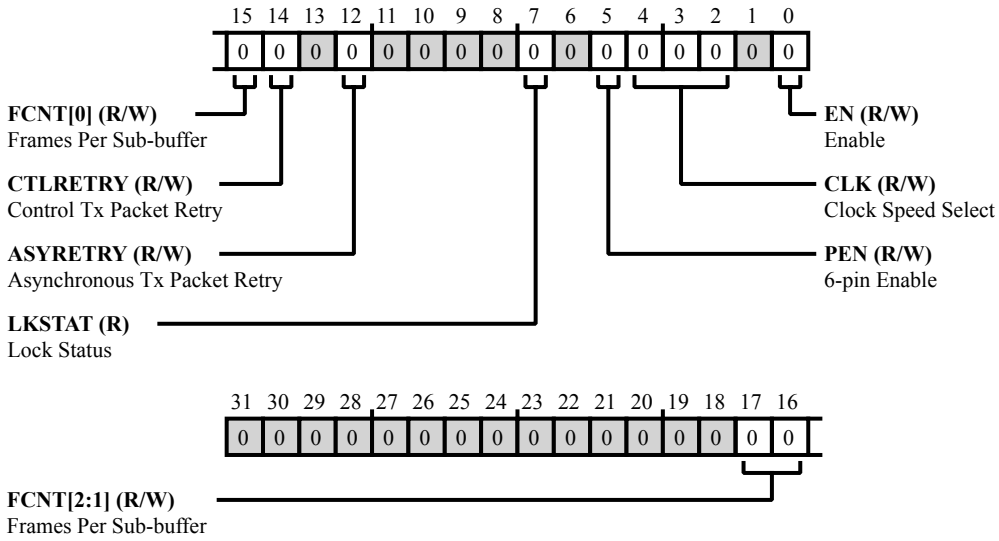

Figure 28-12: MLB_CTL0 Register Diagram

Table 28-25: MLB_CTL0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
17:15 (R/W)	FCNT	Frames Per Sub-buffer. The MLB_CTL0.FCNT bit field configures the frames per sub-buffer on synchronous channels.	
		0	1 Frame per sub-buffer (Operation is the same as Standard mode)
		1	2 frames per sub-buffer
		2	4 frames per sub-buffer
		3	8 frames per sub-buffer
		4	16 frames per sub-buffer
		5	32 frames per sub-buffer
		6	64 frames per sub-buffer
14 (R/W)	CTLRETRY	Control Tx Packet Retry. When the MLB_CTL0.CTLRETRY bit is set, a control packet that is flagged with a Break or Protocol error by the receiver is retransmitted. When cleared, a control packet that is flagged with a Break or Protocol error by the receiver is skipped.	

Table 28-25: MLB_CTL0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W)	ASYRETRY	Asynchronous Tx Packet Retry. When the MLB_CTL0.ASYRETRY bit is set, an asynchronous packet that is flagged with a Break or Protocol error by the receiver is retransmitted. When cleared, an asynchronous packet that is flagged with a Break or ProtocolError by the receiver is skipped.	
7 (R/NW)	LKSTAT	Lock Status. When the MLB_CTL0.LKSTAT bit is set (=0), the MediaLB block is synchronized to the incoming MediaLB frame with the following conditions. • If MLB_CTL1.LOCK =0 (unlocked), MLB_CTL1.LOCK is set after a FRAMESYNC is detected at the same position for three consecutive frames. • If MLB_CTL1.LOCK =1 (locked), MLB_CTL1.LOCK is cleared after not receiving a FRAMESYNC at the expected time for two consecutive frames. In this case FRAMESYNC patterns occurring at locations other than the expected one are ignored.	
5 (R/W)	PEN	6-pin Enable. The MLB_CTL0.PEN bit configures the MLB for 6-pin or 3-pin mode.	
		0	3-pin interface enabled
		1	6-pin interface enabled
4:2 (R/W)	CLK	Clock Speed Select. The MLB_CTL0.CLK bit field sets the clock speed.	
		0	256 x Fs (MLB_CTL.PEN = 0)
		1	512 x Fs (MLB_CTL.PEN = 0)
		2	1024 x Fs (MLB_CTL.PEN = 0)
		3	2048 x Fs (MLB_CTL.PEN = 1)
		4	Reserved
		5	Reserved
		6	Reserved
		7	Reserved
0 (R/W)	EN	Enable. When the MLB_CTL0.EN bit is set (=1), MediaLB clock, signal, and data are received and transmitted on the appropriate MediaLB pins.	

Control 1 Register

The MLB_CTL1 register contains bits that provide lock status and control system commands.

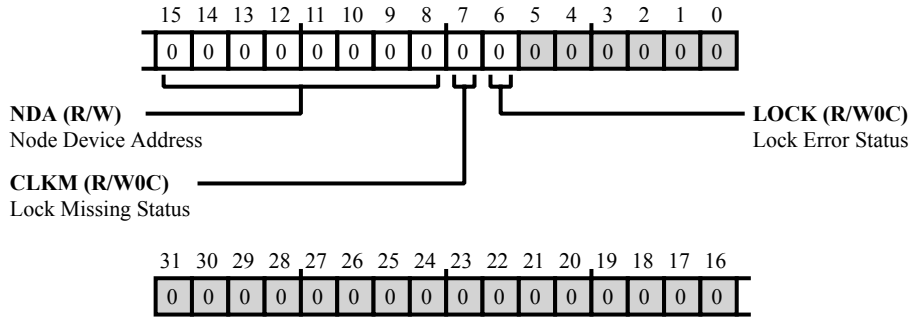

Figure 28-13: MLB_CTL1 Register Diagram

Table 28-26: MLB_CTL1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:8 (R/W)	NDA	Node Device Address. The MLB_CTL1.NDA bit field is used for system commands directed to individual MediaLB nodes.
7 (R/W0C)	CLKM	Lock Missing Status. The MLB_CTL1.CLKM bit is set when the MediaLB clock is not toggling at the pin. This bit is cleared by software.
6 (R/W0C)	LOCK	Lock Error Status. The MLB_CTL1.LOCK bit is set when the MediaLB is unlocked. This bit is cleared by software.

MLB Global Control Register

The MLB_GCTL register contains bits that manage the MLB clock.

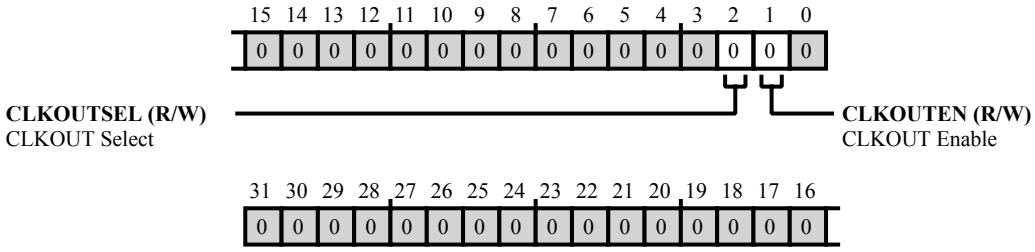

Figure 28-14: MLB_GCTL Register Diagram

Table 28-27: MLB_GCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W)	CLKOUTSEL	CLKOUT Select. The MLB_GCTL.CLKOUTSEL bit selects either the MLB 3 pin clock or the 6 pin clock as MLBCLKOUT.	
		0	MLB 3 pin clock is selected for MLBCLKOUT
		1	MLB 6 pin clock is selected for MLBCLKOUT
1 (R/W)	CLKOUTEN	CLKOUT Enable.	

HBI Channel Busy 0 Register

The HC can determine which channel(s) are busy by reading the MLB_HCBR0 register. An HBI channel is busy if:

- it is currently loaded into one of the two AGUs
- the channel is enabled, CE = 1 from the Channel Allocation Table
- the DMA is active

When an HBI channel is busy, hardware may write back its local copy of the channel descriptor at any time. System software should not write a CDT descriptor for a channel that is busy. Only two HBI channels can be busy at any given time. Each bit of this register is read-only.

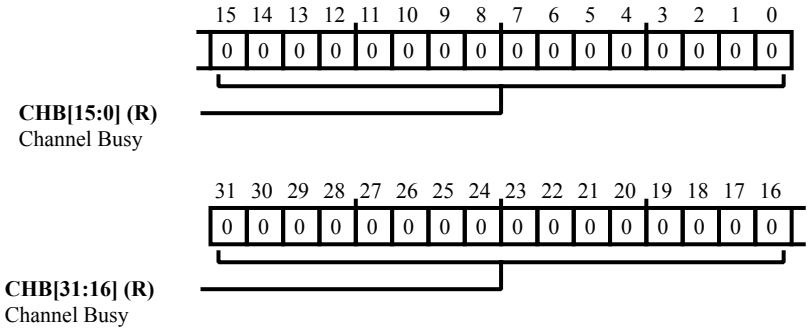

Figure 28-15: MLB_HCBR0 Register Diagram

Table 28-28: MLB_HCBR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CHB	Channel Busy. The MLB_HCBR0.CHB bit field contains the bitwise channel busy bit for channels 31:0. When a bit is cleared (=0) the channel is idle. When a bit is set (=1) the channel is busy.

HBI Channel Busy 1 Register

The HC can determine which channel(s) are busy by reading the MLB_HCBR1 register. An HBI channel is busy if:

- it is currently loaded into one of the two AGUs
- the channel is enabled, CE = 1 from the Channel Allocation Table
- the DMA is active

When an HBI channel is busy, hardware may write back its local copy of the channel descriptor at any time. System software should not write a CDT descriptor for a channel that is busy. Only two HBI channels can be busy at any given time. Each bit of this register is read-only.

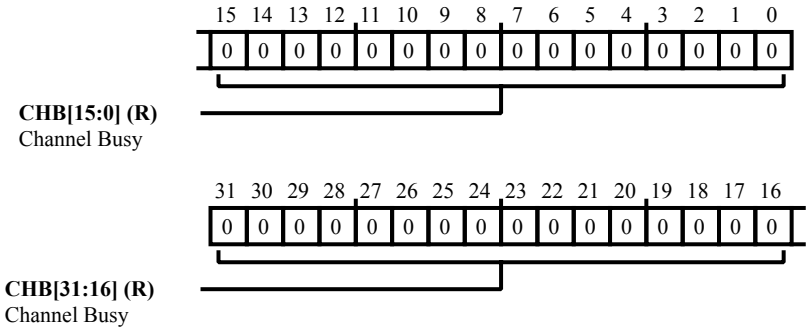

Figure 28-16: MLB_HCBR1 Register Diagram

Table 28-29: MLB_HCBR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CHB	Channel Busy. The MLB_HCBR1.CHB bit field contains the bitwise channel busy bit for channels 63:32. When a bit is cleared (=0) the channel is idle. When a bit is set (=1) the channel is busy.

HBI Channel Error 0 Register

The MLB_HCER0 register indicates which channels (channels 31:0) have encountered fatal errors.

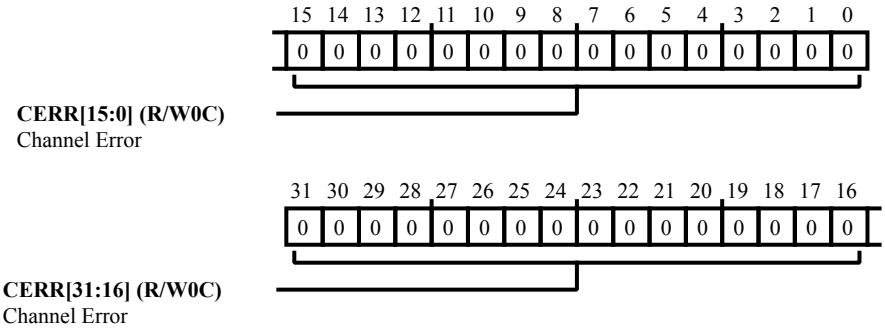

Figure 28-17: MLB_HCER0 Register Diagram

Table 28-30: MLB_HCER0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W0C)	CERR	Channel Error. The MLB_HCER0.CERR bit field reports bitwise errors for channels 31:0.

HBI Channel Error 1 Register

The MLB_HCER1 register indicates which channel(s) have encountered fatal errors.

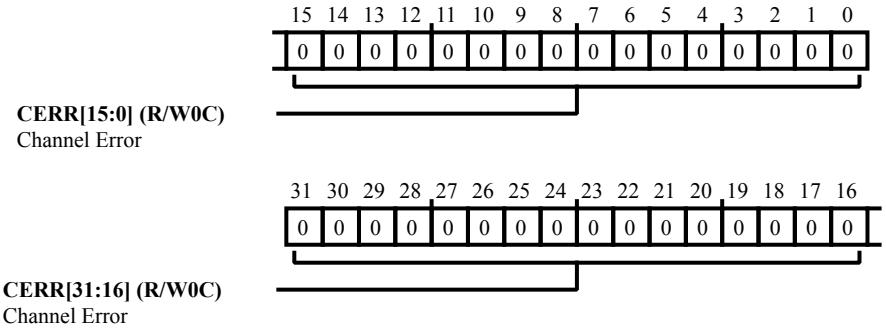

Figure 28-18: MLB_HCER1 Register Diagram

Table 28-31: MLB_HCER1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W0C)	CERR	Channel Error. The MLB_HCER1.CERR bite field reports bitwise errors for channels 63:32.

HBI Channel Mask 0 Register

The MLB_HCMR0 register controls which channels (for channels 31:0) are able to generate an HBI interrupt.

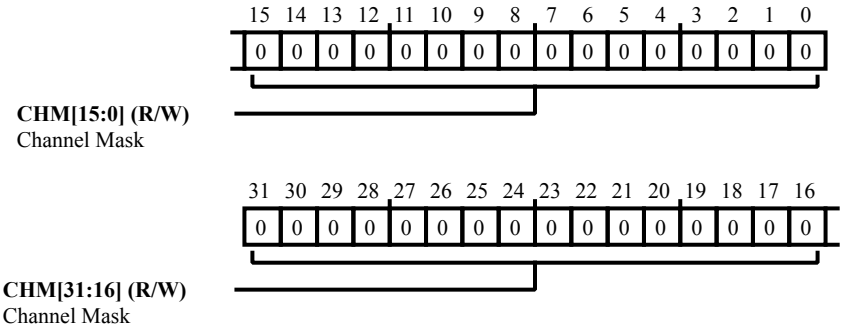

Figure 28-19: MLB_HCMR0 Register Diagram

Table 28-32: MLB_HCMR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	CHM	Channel Mask. The MLB_HCMR0.CHM bit field contains the bitwise channel mask bit for channels 31:0. When a bit is cleared (=0) the channel is masked. When set (=1) the channel is unmasked.

HBI Channel Mask 1 Register

The MLB_HCMR1 register controls which channels (for channels 63:32) are able to generate an HBI interrupt.

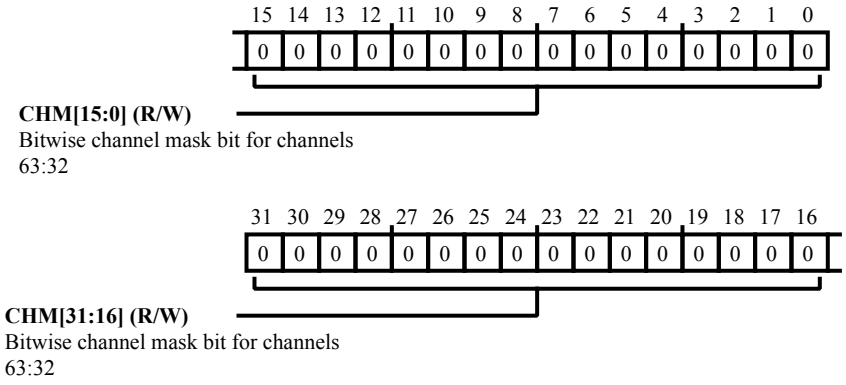

Figure 28-20: MLB_HCMR1 Register Diagram

Table 28-33: MLB_HCMR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	CHM	Bitwise channel mask bit for channels 63:32. The MLB_HCMR1.CHM bit field contains the bitwise channel mask bit for channels 63:32. When a bit is cleared (=0) the channel is masked. When set (=1) the channel is unmasked.

HBI Control Register

The MLB_HCTL register controls and monitors general operation of the HBI block through the Address Generation Units) by reading and writing the register through the I/O interface. Each bit of this register is read/write.

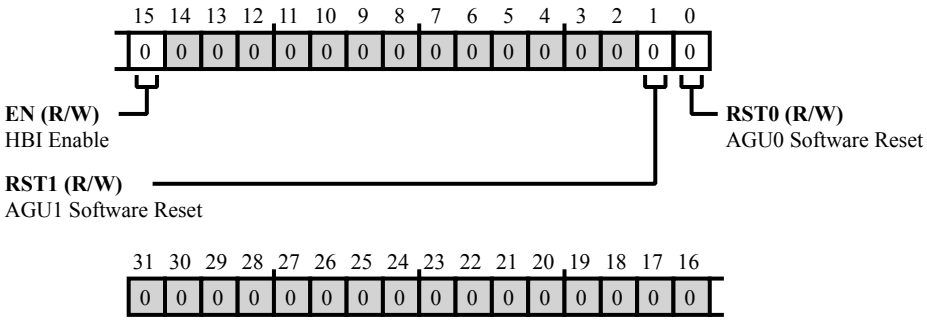

Figure 28-21: MLB_HCTL Register Diagram

Table 28-34: MLB_HCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W)	EN	HBI Enable. Setting the MLB_HCTL.EN bit enables the HBI.
1 (R/W)	RST1	AGU1 Software Reset. Setting the MLB_HCTL.RST1 bit resets AGU1.
0 (R/W)	RST0	AGU0 Software Reset. Setting the MLB_HCTL.RST0 bit resets AGU0.

Memory Interface Address Register

The MLB_MADR register contains bit fields that contain the Channel Table RAM (CTR) or Data Buffer RAM (DBR) addresses. It also contains bits that set target location and read-not-write parameters.

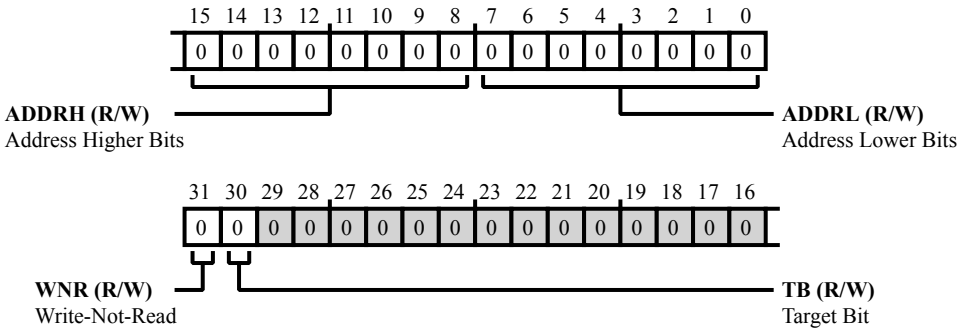

Figure 28-22: MLB_MADR Register Diagram

Table 28-35: MLB_MADR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	WNR	Write-Not-Read. The MLB_MADR.WNR bit selects Write-Not-Read.	
		0	Read
		1	Write
30 (R/W)	TB	Target Bit. The MLB_MADR.TB bit sets the target location.	
		0	Channel Table RAM (CTR)
		1	Data Buffer RAM (DBR)
15:8 (R/W)	ADDRH	Address Higher Bits. The MLB_MADR.ADDRH bit field contains the DBR address of the 8-bit entry (bits [13:8]).	
7:0 (R/W)	ADDRL	Address Lower Bits. The MLB_MADR.ADDRL bit field contains the CTR address of the 128-bit entry or the DBR address of the 8-bit entry (bits [7:0]).	

Memory Interface Control Register

The MLB_MCTL register contains a bit that indicates that the data transfer is complete.

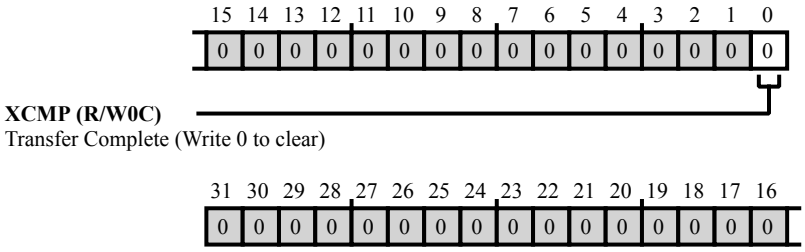

Figure 28-23: MLB_MCTL Register Diagram

Table 28-36: MLB_MCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
0 (R/W0C)	XCMP	Transfer Complete (Write 0 to clear). The MLB_MCTL.XCMP bit indicates that the data transfer is complete.

Memory Interface Control Data 0 Register

The MLB_MDAT0 register contains Channel Table RAM (CTR) data (bits [31:0] of 128-bit entry) or Data Buffer RAM (DBR) data (bits [7:0] of 8-bit entry).

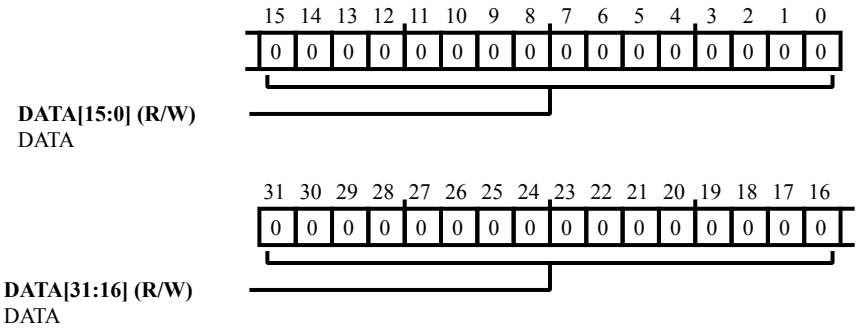

Figure 28-24: MLB_MDAT0 Register Diagram

Table 28-37: MLB_MDAT0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	DATA	DATA. The MLB_MDAT0.DATA bit field contains CTR data or DBR data.

Memory Interface Control Data 1 Register

The MLB_MDAT1 register contains Channel Table RAM (CTR) data (bits [63:32] of 128-bit entry).

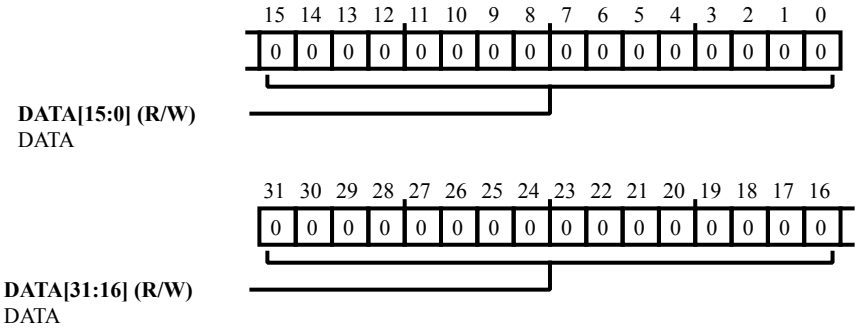

Figure 28-25: MLB_MDAT1 Register Diagram

Table 28-38: MLB_MDAT1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	DATA	DATA. The MLB_MDAT1.DATA bit field contains CTR data.

Memory Interface Control Data 2 Register

The MLB_MDAT2 register contains Channel Table RAM (CTR) data (bits [95:64] of 128-bit entry).

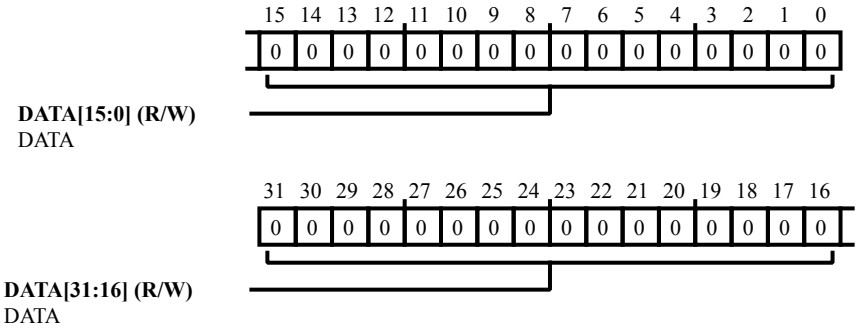

Figure 28-26: MLB_MDAT2 Register Diagram

Table 28-39: MLB_MDAT2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	DATA	DATA. The MLB_MDAT2.DATA bit field contains CTR data.

Memory Interface Control Data 3 Register

The MLB_MDAT3 register contains Channel Table RAM (CTR) data (bits [127:96] of 128-bit entry).

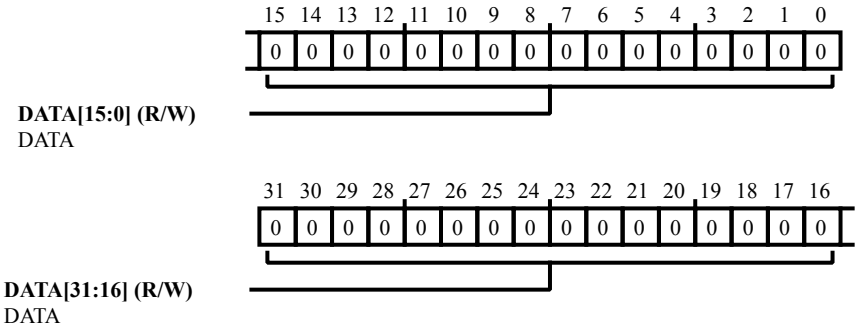

Figure 28-27: MLB_MDAT3 Register Diagram

Table 28-40: MLB_MDAT3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	DATA	DATA. The MLB_MDAT3.DATA bit field contains CTR data.

Memory Interface Control Data Write Enable 0 Register

The MLB_MDWE0 register contains the bitwise write enable for Channel Table RAM (CTR) data bits [31:0]. When cleared (=0) the bit is disabled, when set (=1) the bit is enabled.

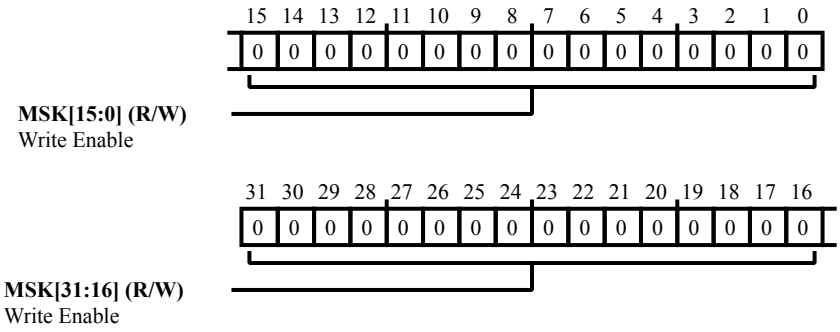

Figure 28-28: MLB_MDWE0 Register Diagram

Table 28-41: MLB_MDWE0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	MSK	Write Enable. The MLB_MDWE0.MSK bit field contains the bitwise write enable for CTR data.

Memory Interface Control Data Write Enable 1 Register

The MLB_MDWE1 register contains the bitwise write enable for Channel Table RAM (CTR) data bits [63:32]. When cleared (=0), the bit is disabled. When set (=1), the bit is enabled.

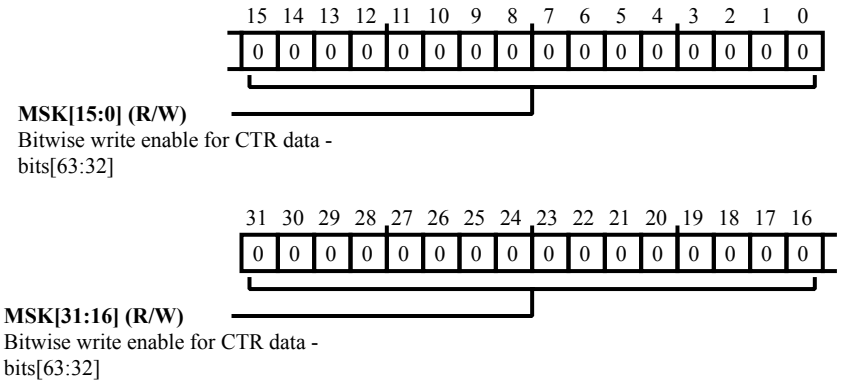

Figure 28-29: MLB_MDWE1 Register Diagram

Interrupt Enable Register

The MLB_MIEN register is used to enable various interrupt conditions.

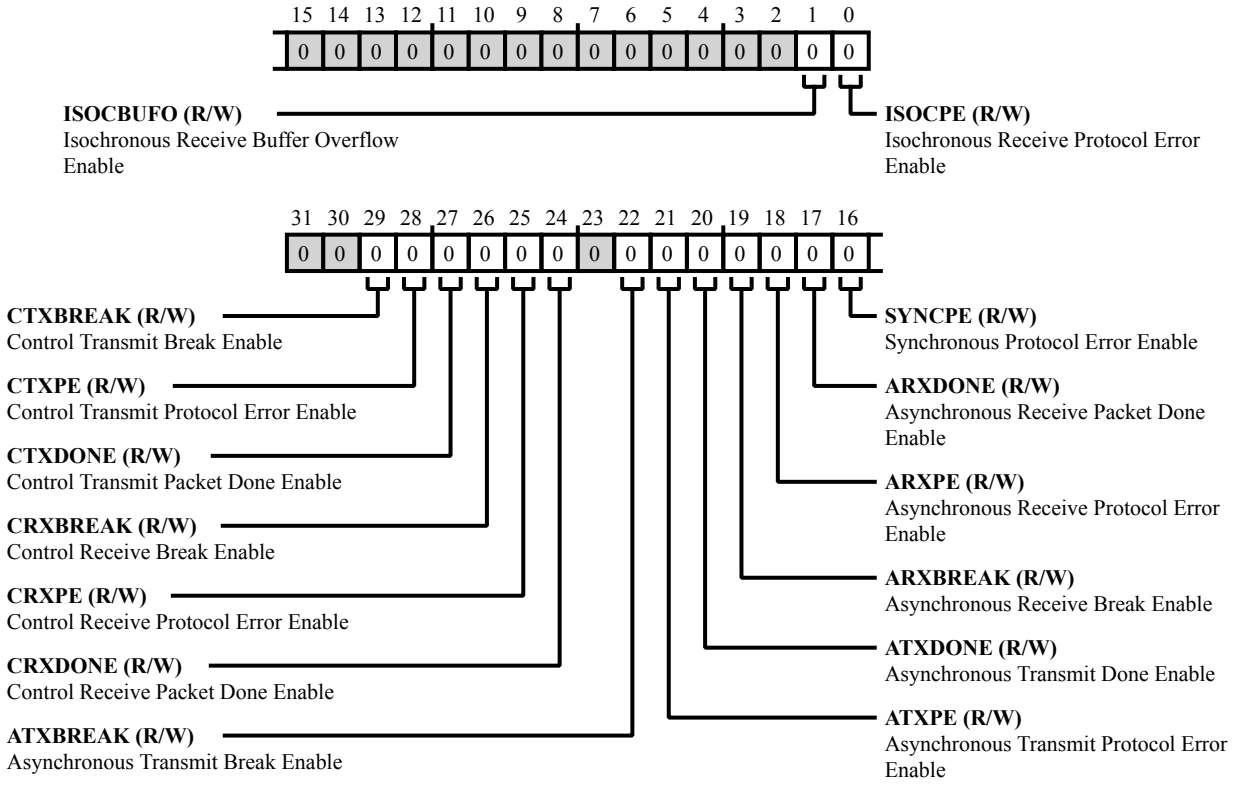

Figure 28-32: MLB_MIEN Register Diagram

Table 28-45: MLB_MIEN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29 (R/W)	CTXBREAK	Control Transmit Break Enable. When the MLB_MIEN.CTXBREAK bit is set, a ReceiverBreak response received from the receiver on a control Tx channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set.
28 (R/W)	CTXPE	Control Transmit Protocol Error Enable. When the MLB_MIEN.CTXPE bit is set, a ProtocolError generated by the receiver on a control Tx channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set.
27 (R/W)	CTXDONE	Control Transmit Packet Done Enable. When the MLB_MIEN.CTXDONE bit is set, a packet transmitted with no errors on a control Tx channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set.

Table 28-45: MLB_MIEN Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
26 (R/W)	CRXBREAK	Control Receive Break Enable. When the MLB_MIEN.CRXBREAK bit is set, a ControlBreak command received from the transmitter on a control Rx channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set.
25 (R/W)	CRXPE	Control Receive Protocol Error Enable. When the MLB_MIEN.CRXPE bit is set, a ProtocolError detected on a control Rx channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set.
24 (R/W)	CRXDONE	Control Receive Packet Done Enable. When the MLB_MIEN.CRXDONE bit is set, a packet received with no errors on a control Rx channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set.
22 (R/W)	ATXBREAK	Asynchronous Transmit Break Enable. When the MLB_MIEN.ATXBREAK bit is set, a ReceiverBreak response received from the receiver on an asynchronous Tx channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set.
21 (R/W)	ATXPE	Asynchronous Transmit Protocol Error Enable. When the MLB_MIEN.ATXPE bit is set, a ProtocolError generated by the receiver on an asynchronous Tx channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set.
20 (R/W)	ATXDONE	Asynchronous Transmit Done Enable. When the MLB_MIEN.ATXDONE bit is set, a packet transmitted with no errors on an asynchronous Tx channel channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set.
19 (R/W)	ARXBREAK	Asynchronous Receive Break Enable. When the MLB_MIEN.ARXBREAK bit is set, a AsyncBreak command received from the transmitter on an asynchronous Rx channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set.
18 (R/W)	ARXPE	Asynchronous Receive Protocol Error Enable. When the MLB_MIEN.ARXPE bit is set, a protocol error detected on an asynchronous Rx channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set.
17 (R/W)	ARXDONE	Asynchronous Receive Packet Done Enable. When the MLB_MIEN.ARXDONE bit is set, a packet received with no errors on an asynchronous Rx channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set.

Table 28-45: MLB_MIEN Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
16 (R/W)	SYNCPE	Synchronous Protocol Error Enable. When the MLB_MIEN.SYNCPE bit is set, a protocol error detected on a synchronous Rx channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set. This occurs only when isochronous flow control is disabled.
1 (R/W)	ISOCBUFO	Isochronous Receive Buffer Overflow Enable. When the MLB_MIEN.ISOCBUFO bit is set, a buffer overflow on an isochronous Rx channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set. This occurs only when isochronous flow control is disabled.
0 (R/W)	ISOCPE	Isochronous Receive Protocol Error Enable. When the MLB_MIEN.ISOCPE bit is set, a protocol error detected on an isochronous Rx channel causes the appropriate channel bit in the MLB_MS0 or MLB_MS1 registers to be set.

Channel Status 0 Register

The MLB_MS0 register indicates the channel status for MediaLB channels 31 to 0. Channel status bits are set by hardware and cleared by software. Status is only set if the appropriate bits in the MLB_MIEN register are set.

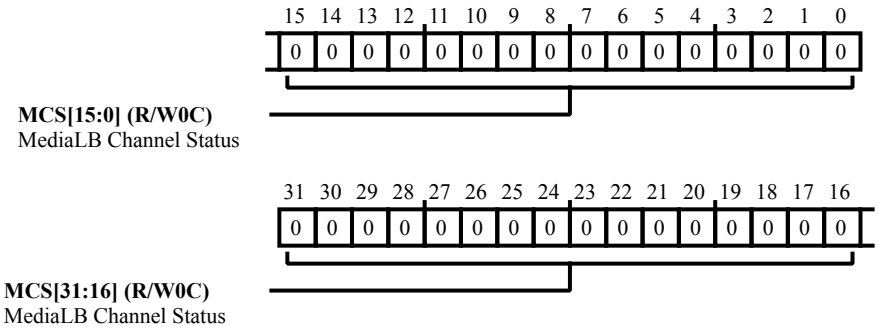

Figure 28-33: MLB_MS0 Register Diagram

Table 28-46: MLB_MS0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W0C)	MCS	MediaLB Channel Status. The MLB_MS0.MCS bit field indicates the MediaLB channel status for channels 31 to 0.

Channel Status 1 Register

The MLB_MS1 register indicates the channel status for MediaLB channels 32 to 63. Channel status bits are set by hardware and cleared by software. Status is only set if the appropriate bits in the MLB_MIEN register are set.

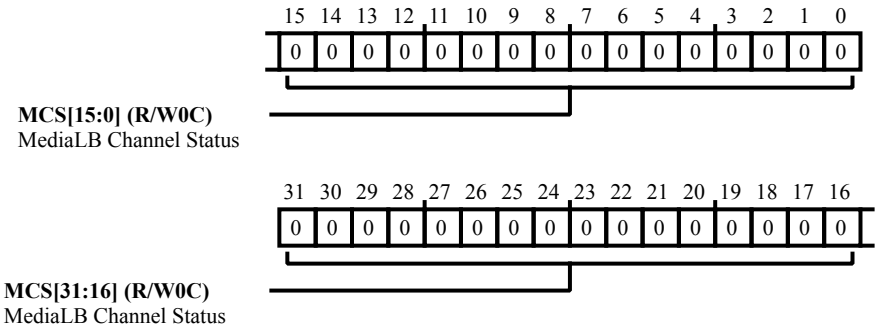

Figure 28-34: MLB_MS1 Register Diagram

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W0C)	MCS	MediaLB Channel Status. The MLB_MS1.MCS bit field indicates the MediaLB channel status for channels 63 to 32.

System Data Register

The MLB_MSD register allows system software to receive control information from the MLB controller. The MLB_MSD register is updated once per frame by the hardware during the MLB system channel.

The MLB_MSD register is loaded with the data from the MLBDAT_IN signal during the system channel quadlet. System software must read this register before the start of the next MLB frame to prevent the current data from being lost.

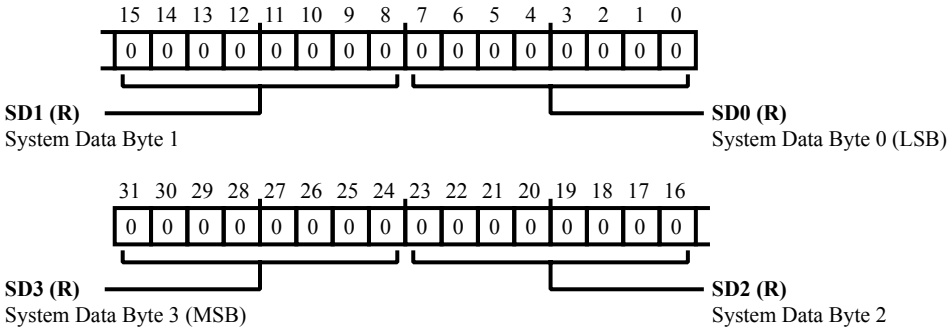

Figure 28-35: MLB_MSD Register Diagram

Table 28-48: MLB_MSD Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/NW)	SD3	System Data Byte 3 (MSB). The MLB_MSD.SD3 bits are updated with MediaLB Data [31:24] when a MediaLB software system command is received in the system quadlet. If the MLB_MSS.SWSYSCMD bit is already set, then SD3 is not updated.
23:16 (R/NW)	SD2	System Data Byte 2. The MLB_MSD.SD2 bits are updated with MediaLB Data [23:16] when a MediaLB software system command is received in the system quadlet. If the MLB_MSS.SWSYSCMD bit is already set, then SD2 is not updated.
15:8 (R/NW)	SD1	System Data Byte 1. The MLB_MSD.SD1 bits are updated with MediaLB Data [15:8] when a MediaLB software system command is received in the system quadlet. If the MLB_MSS.SWSYSCMD bit is already set, then SD1 is not updated.
7:0 (R/NW)	SD0	System Data Byte 0 (LSB). The MLB_MSD.SD0 bits are updated with MediaLB Data [7:0] when a MediaLB software system command is received in the system quadlet. If the MLB_MSS.SWSYSCMD bit is already set, then SD0 is not updated.

System Status Register

The MLB_MSS register allows system software to monitor and control the status of the MLB network. The register is updated once per frame by hardware during the MLB system channel. The bits of this register are not valid until the processor is locked to the MLB interface (except for the bits associated with MLB lock and unlock, SDMU and SDML). System software must service events before the start of the next MLB frame to prevent the current frame status from being lost.

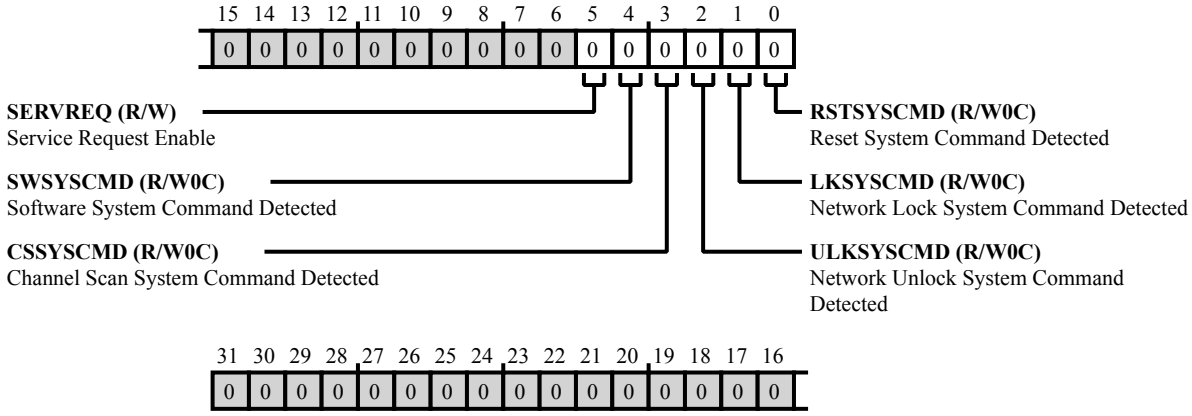

Figure 28-36: MLB_MSS Register Diagram

Table 28-49: MLB_MSS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
5 (R/W)	SERVREQ	Service Request Enable. When the MLB_MSS.SERVREQ bit set, the MediaLB block responds with a device present, request service system response if a matching channel scan system command is detected. When cleared, the MediaLB block responds with a device present system response.
4 (R/W0C)	SWSYSCMD	Software System Command Detected. The MLB_MSS.SWSYSCMD bit indicates that a software system command was detected (in the system quadlet). The MLB_MSS.SWSYSCMD bit is set by hardware, cleared by software. Data is stored in the MLB_MSD register for this command.
3 (R/W0C)	CSSYSCMD	Channel Scan System Command Detected. The MLB_MSS.CSSYSCMD bit indicates that a channel scan system command was detected (in the system quadlet). The MLB_MSS.CSSYSCMD bit is set by hardware, cleared by software. If the node address specified in the data quadlet matches the value in the MLB_CTL1.NDA bit field, the device responds either device present or device present, request service system response in the next system quadlet.

Table 28-49: MLB_MSS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
2 (R/W0C)	ULKSYSCMD	Network Unlock System Command Detected. The `MLB_MSS.ULKSYSCMD` bit indicates a network unlock system command was detected (in the system quadlet). The `MLB_MSS.ULKSYSCMD` bit is by hardware, cleared by software.
1 (R/W0C)	LKSYSCMD	Network Lock System Command Detected. The `MLB_MSS.LKSYSCMD` bit indicates a network lock system command was detected (in the system quadlet). The `MLB_MSS.LKSYSCMD` bit is set by hardware and cleared by software.
0 (R/W0C)	RSTSYSCMD	Reset System Command Detected. The `MLB_MSS.RSTSYSCMD` bit indicates a reset system command was detected (in the system quadlet). The `MLB_MSS.RSTSYSCMD` bit is set by hardware, cleared by software.

1 (R/W)	CMRES	MediaLB 6-pin common mode resistor enable. This signal is no longer used.

29 Two-Wire Interface (TWI)

The processor has a two-wire interface (TWI), that provides a simple exchange method of control data between multiple devices. The TWI module is compatible with the widely used I^2C bus standard. Additionally, the TWI module is fully compatible with serial camera control bus (SCCB) functionality for easier control of various CMOS camera sensor devices.

The TWI module offers the capabilities of simultaneous requester and completer operation and support for both 7-bit addressing and multimedia data arbitration. The TWI interface uses two pins for transferring clock (`TWI_SCL`) and data (`TWI_SDA`) and supports the protocol at speeds up to 400K bits/s. The TWI interface pins are compatible with 3.3V logic levels.

To preserve processor bandwidth, the TWI module can be set up with transfer-initiated interrupts to only service FIFO buffer data reads and writes. Protocol-related interrupts are optional. The TWI externally moves 8-bit data while maintaining compliance with the I^2C bus protocol.

NOTE: All TWI instances operate in the SCLK0 domain.

TWI Features

The TWI is fully compatible with the widely used I^2C bus standard.

The TWI controller includes the following features.

- Simultaneous requester and completer operation on multiple device systems
- Support for multi-controller bus arbitration
- 7-bit addressing
- 100K bits/second and 400K bits/second data rates
- General call address support
- Controller clock synchronization and support for clock low extension
- Separate multiple-byte receive and transmit FIFOs
- Low interrupt rate

- Individual override control of data and clock lines in the event of bus lock-up
- Input filter for spike suppression
- Serial camera control bus support as specified in the *OmniVision Serial Camera Control Bus (SCCB) Functional Specification*
- Programmable drive/tolerance of TWI pins. Refer to the PADS_PCFG0 register description in General-Purpose Ports (PORT) chapter for details.

TWI Functional Description

The TWI interface is a shift register that serially transmits and receives data bits. It moves data 1 bit at a time at the SCL rate, to and from other TWI devices. The SCL signal synchronizes the shifting and sampling of the data on the serial data pin.

ADSP-SC59x TWI Register List

The Two-Wire Interface controller TWI allows a device to interface to an inter-IC bus as specified by the Philips I^2C Bus Specification version 2.1, dated January 2000. A set of registers governs TWI operations. For more information on TWI functionality, see the TWI register descriptions.

Table 29-1: ADSP-SC59x TWI Register List

Name	Description
TWI_CLKDIV	SCL Clock Divider Register
TWI_CTL	Control Register
TWI_FIFOCTL	FIFO Control Register
TWI_FIFOSTAT	FIFO Status Register
TWI_IMSK	Interrupt Mask Register
TWI_ISTAT	Interrupt Status Register
TWI_MSTRADDR	Controller Mode Address Register
TWI_MSTRCTL	Controller Mode Registers
TWI_MSTRSTAT	Controller Mode Status Register
TWI_RXDATA16	Rx Data Double-Byte Register
TWI_RXDATA8	Rx Data Single-Byte Register
TWI_SLVADDR	Target Mode Address Register
TWI_SLVCTL	Target Mode Control Register
TWI_SLVSTAT	Target Mode Status Register
TWI_TXDATA16	Tx Data Double-Byte Register
TWI_TXDATA8	Tx Data Single-Byte Register

TWI Block Diagram

The *TWI Block Diagram* figure shows the basic blocks of the TWI interface.

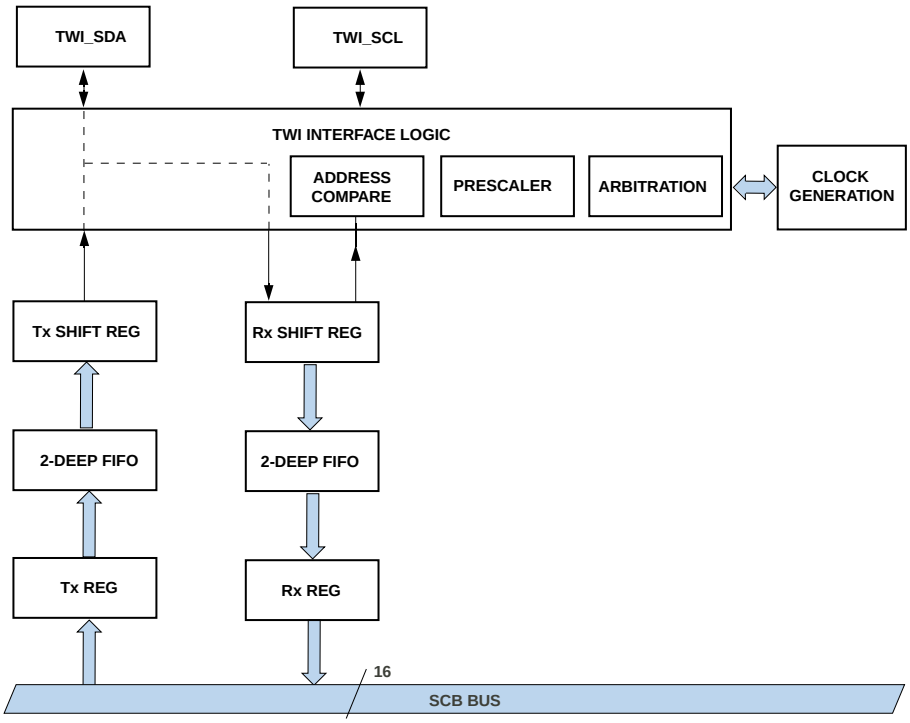

Figure 29-1: TWI Block Diagram

External Interface

The `TWI_SDA` (serial data) and `TWI_SCL` (serial clock) signals are open drain and require pull-up resistors. These bidirectional signals externally interface the TWI controller to the I^2C bus, and no other external connections or logic are necessary.

Serial Clock Signal (SCL)

The serial clock signal (TWI_SCL) is an input in completer mode. In requester mode, the TWI controller must set this signal to the desired frequency.

The TWI controller supports the standard mode of operation (up to 100 kHz) or fast mode (up to 400 kHz). The TWI control register (TWI_CTL) sets the TWI_CTL.PRESCALE value which sets the relationship between the system clock (SCLK0) and the internally timed events of the TWI controller. The internal time reference is derived from SCLK0 using a prescaled value. The prescale value is the number of SCLK0 periods used in the generation of one internal time reference. Set the value of prescale to create an internal time reference with a period of 10 MHz. It is represented as a 7-bit binary value as follows.

PRESCALE = f_{SCLK0}/10MHz

NOTE: It is not always possible to achieve 10-MHz accuracy. In such cases, it is safe to round up the PRESCALE value to the next highest integer. For example, if SCLK0 is 100 MHz, the PRESCALE value is calculated as 100 MHz/10 MHz = 10. A prescale value of 14 in this case ensures that all timing requirements are met.

During requester mode operation, the TWI module uses the TWI_CLKDIV register values to create the minimum TWI_CLKDIV.CLKHI and TWI_CLKDIV.CLKLO durations of the TWI_SCL signal. The TWI_CLKDIV.CLKHI field specifies the minimum number of 10-MHz time reference periods the TWI_SCL waits before a new clock low period begins, assuming a single requester. (The 10-MHz time reference periods are represented as an 8-bit binary value). The TWI uses the TWI_CLKDIV.CLKLO field to specify the minimum number of internal time reference periods (represented as an 8-bit binary value); the TWI_SCL signal is held low.

Serial clock frequencies can vary from 400 kHz to less than 20 kHz. The resolution of the clock generated is 1/10 MHz or 100 ns. The following equation describes the frequency.

CLKDIV = TWI_SCL period/10 MHz time reference.

For example, for an TWI_SCL of 400 kHz (period = 1/400 kHz = 2500 ns) and an internal time reference of 10 MHz (period = 100 ns), the following equation applies:

CLKDIV =2500 ns/100 ns = 25

Therefore, a TWI_SCL signal with a 30% duty cycle has TWI_CLKDIV.CLKLO=17 and TWI_CLKDIV.CLKHI=8. Adding TWI_CLKDIV.CLKLO and TWI_CLKDIV.CLKHI equals CLKDIV.

NOTE: The TWI_CLKDIV.CLKHI and TWI_CLKDIV.CLKLO fields are not intended to guarantee a certain frequency. Rather, they guarantee a certain minimum high and low duration for the TWI_SCL signal. Slew rate controls falling edges. The *RC* time constant governs the rising edges. The pull-up resistor and the TWI_SCL capacitance form the time constant. See the “Register Descriptions” section for more details.

Serial Data Signal (SDA)

The TWI transmits and receives serial data, depending on the direction of the transfer, on the bidirectional serial data signal (SDA).

Internal Interface

The peripheral bus interface supports the transfer of 16-bit wide data. The processor uses the interface in the support of register and FIFO buffer reads and writes. The TWI internal interface is comprised of the blocks described as follows.

Register block. Contains all control and status bits and reflects what can be written or read as outlined by the programming model. Each function block updates their corresponding status bits.

FIFO buffer. Configured as a 1-byte-wide, 2-deep transmit FIFO buffer and a 1-byte-wide, 2-deep receive FIFO buffer.

Transmit shift register. Serially shifts its data out externally off chip. The output can be controlled for generation of acknowledgments, or it can be manually overwritten.

Receive shift register. Receives its data serially from off chip. The receive shift register is 1 byte wide and data received can either be transferred to the FIFO buffer or used in an address comparison.

Address compare block. Supports address comparison in the event the TWI controller module is accessed as a completer.

Prescaler block. Must be programmed to generate a 10-MHz time reference relative to the system clock. The block uses this time base for filtering of data and timing events specified by the electrical data sheet (See the Philips specification). The block uses the time base to generate the `TWI_SCL` clock as well.

Clock generation module. Generates an external `TWI_SCL` clock when in requester mode. It includes the logic necessary for synchronization in a multi-requester clock configuration and clock stretching when configured in completer mode.

NOTE: The TWI does not support DMA based operation.

TWI Architectural Concepts

The TWI controller follows the transfer protocol of the Philips I^2C Bus specification version 2.1 dated January 2000.

NOTE: The TWI unit does not support DMA-based operation.

TWI Protocol

The ***Data Transfer*** figure shows a simple complete transfer.

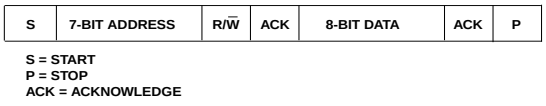

Figure 29-2: Data Transfer

The TWI controller register contents maps to a basic transfer. The ***Data Transfer with Bit Illustration*** figure details the same transfer from the ***Data Transfer*** figure noting the corresponding TWI controller bit names. In this

illustration, the TWI controller successfully transmits 1 byte of data. The completer has acknowledged both address and data.

Figure 29-3: Data Transfer with Bit Illustration

Clock Generation and Synchronization

The TWI controller implementation only issues a clock during requester mode operation and only at the time a transfer initiates. If arbitration for the bus is lost, the serial clock output immediately three-states. If multiple clocks attempt to drive the serial clock line, the TWI controller synchronizes its clock with the other remaining clocks. The ***Clock Synchronization*** figure shows this functionality.

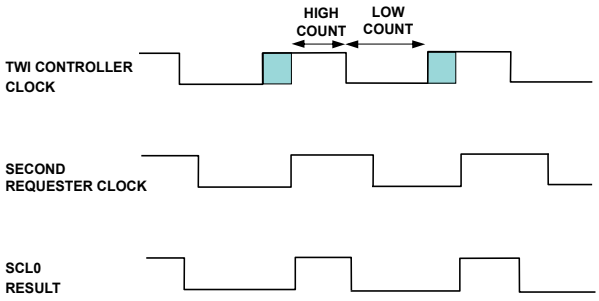

Figure 29-4: Clock Synchronization

The TWI controller serial clock (`TWI_SCL`) output follows these rules:

- Once the clock high (`TWI_CLKDIV.CLKHI`) count is complete, the serial clock output is driven low and the clock low (`TWI_CLKDIV.CLKLO`) count begins.
- Once the clock low count is complete, the serial clock line is three-stated. This state allows the external pull-up resistor to pull the `TWI_SCL` signal high. The clock synchronization logic enters a delay mode (shaded area) until the `TWI_SCL` signal is detected at logic 1 level. Now, the clock high count begins.

Bus Arbitration

The TWI controller initiates a requester mode transmission only when the bus is idle. Whenthe bus is idle and two requesters initiate a transfer, arbitration for the bus begins. The ***Bus Arbitration*** figure shows the arbitration.

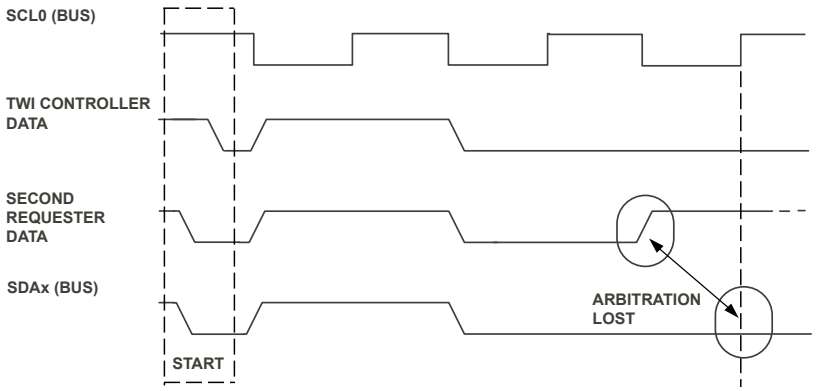

Figure 29-5: Bus Arbitration

The TWI controller monitors the serial data bus (SDA) while the `TWI_SCL` signal is high. If the `TWI_SDA` signal is determined to be an active logic 0 level while the data of the TWI controller is a logic 1 level, the TWI controller has lost arbitration. It stops generating the clock and data signals. Arbitration is not only performed at the serial clock edges, but also during the entire time the `TWI_SCL` signal is high.

Start and Stop Conditions

Start and stop conditions involve serial data transitions while the serial clock is a logic 1 level. The TWI controller generates and recognizes these transitions. Typically, start and stop conditions occur at the beginning and at the conclusion of a transmission, except repeated start combined transfers. The ***Start and Stop Conditions*** figure shows the transitions.

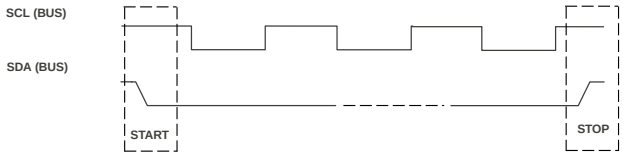

Figure 29-6: Start and Stop Conditions

The TWI special case start and stop conditions of the TWI controller include the following.

- Controller addressed as a completer-receiver. If the requester asserts a stop condition during the data phase of a transfer, the TWI controller concludes the transfer (`TWI_ISTAT.SCOMP`).
- Controller addressed as a completer-transmitter. If the requester asserts a stop condition during the data phase of a transfer, the TWI controller concludes the transfer (`TWI_ISTAT.SCOMP`) and indicates a completer transfer error (`TWI_ISTAT.SERR`).
- Controller as a requester-transmitter or requester-receiver. If the stop bit (`TWI_MSTRCTL.STOP`) is set during an active requester transfer, the TWI controller issues a stop condition as soon as possible avoiding any error conditions. The TWI controller operates as if data transfer count had been reached.

General Call Support

The TWI controller always decodes and acknowledges a general call address if:

- The TWI controller is enabled as a target
- General call is enabled

The TWI_SLVCTL.GEN bit configures general call addressing (0x00) only when the TWI controller is a target-receiver.

If the data associated with the transfer is (NAK) not acknowledged, the TWI_SLVCTL.NAK bit can be set. If the TWI controller issues a general call as a requester-transmitter, set the appropriate address (TWI_MSTRADDR register) and transfer direction (TWI_MSTRCTL.DIR bit) and load the transmit FIFO data.

NOTE: The byte following the general call address usually defines the completer's response to the call. The interpretation of the command in the second byte is based on the value of its LSB. For a TWI completer device, the bytes received after the general call address are considered data.

Fast Mode

Fast mode uses the same mechanics as the standard mode of operation. Fast mode affects electrical specifications and timing. When fast mode is enabled, (FAST) timing is modified to meet the following electrical requirements.

- Serial data rise times before arbitration evaluation (t_r)
- Stop condition set-up time from serial clock to serial data (t_{SUSTO})
- Bus free time between a stop and start condition (t_{BUF})

TWI Operating Modes

The TWI has two modes of operation: repeated start and clock stretching. The following sections describe the operating modes.

Repeated Start

A repeated start condition is the absence of a stop condition between two transfers. The two transfers can be of any direction type. Examples include a transmit followed by a receive, or a receive followed by a transmit. The following sections guide the programmer in developing a service routine.

Transmit Receive Repeated Start

The ***Repeated Start Followed by Data Receive*** figure shows a repeated start followed by a data receive sequence. The shading in the figure indicates that the completer has control of the bus.

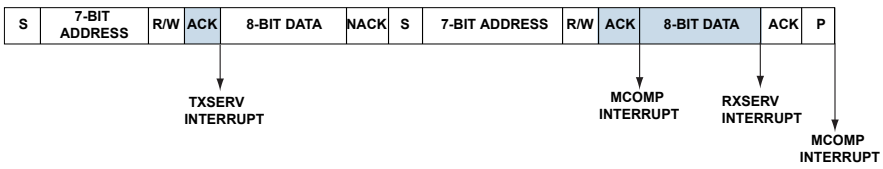

Figure 29-7: Repeated Start Followed by Data Receive

The tasks performed at each interrupt are:

- Transmit FIFO service (TWI_ISTAT.TXSERV) interrupt request. This interrupt is generated due to a FIFO access. Since this byte is the last of this transfer, the TWI uses the TWI_FIFOSTAT register to indicate that the transmit FIFO is empty. When read, TWI_MSTRCTL.DCNT bit field=0. Set the TWI_MSTRCTL.RSTART bit to indicate a repeated start and set the TWI_MSTRCTL.DIR bit if the following transfer is a data receive.
- Requester transfer complete (TWI_ISTAT.MCOMP) interrupt. This interrupt request is generated when all data transfers (TWI_MSTRCTL.DCNT bit field=0). If no errors occur, a start condition initiates. Clear the TWI_MSTRCTL.RSTART bit and program the TWI_MSTRCTL.DCNT bits with the desired number of bytes to receive.
- Receive FIFO service (TWI_ISTAT.RXSERV) interrupt. This interrupt request is generated due to the arrival of a byte in the receive FIFO. Simple data handling is the only requirement.
- Requester transfer complete (TWI_ISTAT.MCOMP) interrupt. This interrupt request is generated when the transfer completes.

Receive Transmit Repeated Start

The ***Repeated Start Data Receive Followed by Data Transmit*** figure illustrates a repeated start data receive followed by a data transmit sequence. The shading in the figure indicates that the completer has control of the bus.

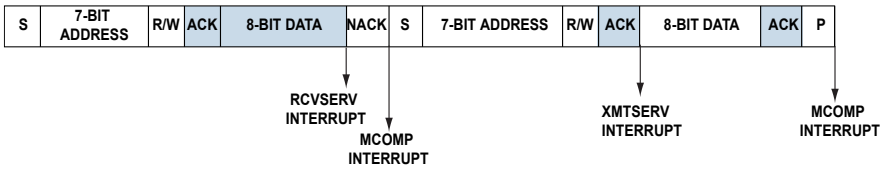

Figure 29-8: Repeated Start Data Receive Followed by Data Transmit

The tasks performed at each interrupt are:

- Receive FIFO service (TWI_ISTAT.RXSERV) interrupt. This interrupt request is generated due to the arrival of a data byte in the receive FIFO. Set the TWI_MSTRCTL.RSTART bit to indicate a repeated start and clear the TWI_MSTRCTL.DIR bit if the following transfer is a data transmit.
- Requester transfer complete (TWI_ISTAT.MCOMP) interrupt. This interrupt request has occurred due to the completion of the data receive transfer. If no errors occur, a start condition initiates. Clear the TWI_MSTRCTL.RSTART bit and program the TWI_MSTRCTL.DCNT bits with the desired number of bytes to transmit.
- Transmit FIFO service (TWI_ISTAT.TXSERV) interrupt. This interrupt request is generated due to a FIFO access. Simple data handling is the only requirement.
- Requester transfer complete (TWI_ISTAT.MCOMP) interrupt. This interrupt request is generated when the transfer completes.

NOTE: There is no timing constraint to meet the conditions—program the bits as required. Refer to Clock Stretching During Repeated Start section for more on how the controller stretches the clock during repeated start transfers.

Clock Stretching

Clock stretching is an added function of the TWI controller in requester mode operation. This behavior uses self-induced stretching of the I ^{2}C clock while waiting to service interrupts. Hardware initiates stretching automatically. No programming is necessary. The TWI controller as a requester supports three modes of clock stretching:

- Clock Stretching During FIFO Underflow
- Clock Stretching During FIFO Overflow
- Clock Stretching During Repeated Start

Clock Stretching During FIFO Underflow

During a requester mode transmit, an interrupt request occurs the instant the transmit FIFO becomes empty. The most recent byte begins transmission. If the `TWI_ISTAT.TXSERV` interrupt request is not serviced, the concluding acknowledge phase of the transfer stretches.

Stretching of the clock continues until new data bytes are written to the transmit FIFO (`TWI_TXDATA8` or `TWI_TXDATA16` registers). No other action is required to release the clock and continue the transmission. This behavior continues until the transmission completes (`TWI_MSTRCTL.DCNT`=0). The transmission concludes (`TWI_ISTAT.MCOMP`). The ***Clock Stretching during FIFO Underflow*** figure and table show the stretching.

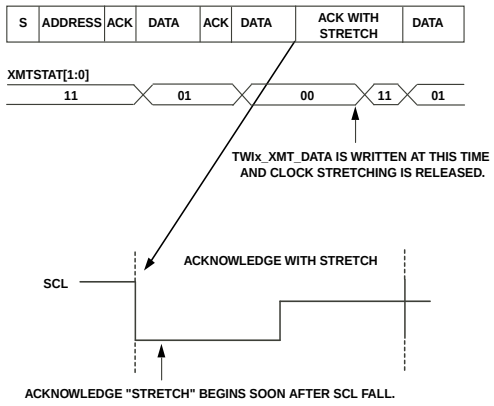

Figure 29-9: Clock Stretching during FIFO Underflow

TWI Controller	Processor
Interrupt: XMTSERV – Transmit FIFO buffer is empty	Acknowledge: Clear the interrupt request source bits. Write to the transmit FIFO buffer
...	...
Interrupt: MCOMP – requester transmit complete (DCNT= 0x00)	Acknowledge: Clear the interrupt request source bits

Clock Stretching During FIFO Overflow

During a requester mode receive operation, an interrupt occurs at the instant the receive FIFO becomes full. It is during the acknowledge phase of this received byte that clock stretching begins. The TWI module makes no attempt to initiate the reception of another byte. Stretching of the clock continues until the data bytes previously received are read from the receive FIFO buffer (`TWI_RXDATA8` or `TWI_RXDATA16` registers). No other action is required to release the clock and continue the reception of data. This behavior continues until the reception is complete (`TWI_MSTRCTL.DCNT=0`). Reception concludes (`TWI_ISTAT.MCOMP`). The ***Clock Stretching During FIFO Overflow*** figure and table show the clock stretching.

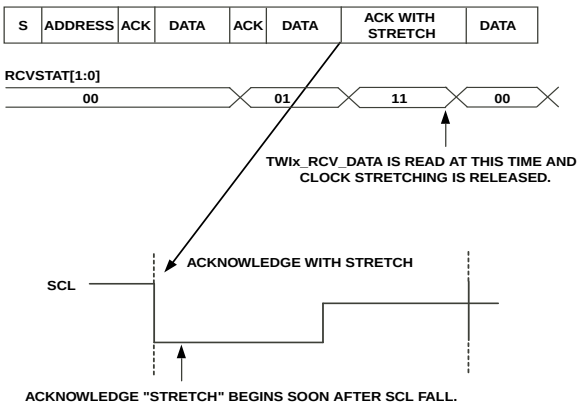

Figure 29-10: Clock Stretching During FIFO Overflow

TWI Controller	Processor
Interrupt: RCVSERV – Receive FIFO buffer is full	Acknowledge: Clear the interrupt request source bits. Read the receive FIFO buffer
...	...
Acknowledge: Clear the interrupt source bits	Interrupt: MCOMP – requester receive complete

Clock Stretching During Repeated Start

The repeated start feature in I^2C protocol requires a transition between two subsequent transfers. With the use of clock stretching, the task of managing transitions becomes simpler and common to all transfer types.

Once an initial TWI requester transfer completes (transmit or receive), the clock initiates a stretch during the repeated start phase between transfers. Concurrent with this event, the initial transfer generates a `TWI_ISTAT.MCOMP` interrupt to signify the initial transfer has completed (`TWI_MSTRCTL.DCNT=0`). This initial transfer is handled without any special bit setting sequences or timing.

The clock stretching logic described applies here. With no system-related timing constraints, the subsequent transfer (receive or transmit) is set up and activated. This sequence can repeat as many times as required to string a series of repeated start transfers together. The ***Clock Stretching during Repeated Start Condition*** figure and table show the clock stretching.

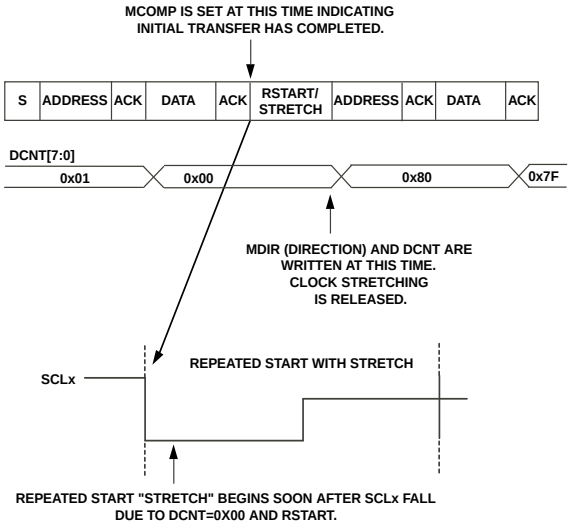

Figure 29-11: Clock Stretching during Repeated Start Condition

TWI Controller	Processor
Interrupt: MCOMP – Initial transmit has completed and DCNT = 0x00. Note: transfer in progress, RSTART previously set.	Acknowledge: Clear the interrupt request source bits. Write to TWIx_MASTER_CTL, setting MDIR (receive), clearing RSTART, and setting new DCNT value (nonzero).
Interrupt: RCVSERV – Receive FIFO is full	Acknowledge: Clear the interrupt request source bits. Read the receive FIFO buffer
...	...
Interrupt: MCOMP – requester receive complete	Acknowledge: Clear the interrupt request source bits

TWI Programming Model

The topics in this section provide information on the basic programming steps required to set up and run the two wire interface.

General Setup

General setup refers to register writes that are required for both completer mode and requester mode operations.

Perform general setup before setting either the requester or completer enable bits.

1. Program the `TWI_CTL.EN` bit to enable the TWI controller and set the prescale value (`TWI_CTL.PRESCALE` bit).
2. Program the prescale value to the binary representation of f_{SCLK0}/10 MHz. Round up all values to the next whole number.
3. Set the `TWI_CTL.EN` bit to enable the controller.

Once the TWI controller is enabled, a bus busy condition can be detected. This condition clears after t_{BUF} has expired, assuming no additional bus activity has been detected.

Completer Mode

When enabled, completer mode operation supports both receive and transmit data transfers.

It is not possible to enable only one data transfer direction and not acknowledge (NAK) the other. The following setup reflects this functionality.

1. Program the TWI_SLVADDR register. The TWI uses the appropriate 7 bits in determining a match during the address phase of the transfer.
2. Program the TWI_TXDATA8.VALUE or TWI_TXDATA16 registers. These values are the initial data values for transmission when the completer is addressed, and transmission is needed. This step is optional. If no data is written when the completer is addressed and transmission is needed, the serial clock (TWI_SCL) stretches. An interrupt is generated until data is written to the transmit FIFO.
3. Program the TWI_IMSK register. There are enable-bits associated with the desired interrupt sources. For example, programming the value 0x000F results in an interrupt request output to the processor, when the TWI module detects a valid address match. An interrupt request also occurs when a valid completer transfer completes or has an error, or a subsequent transfer has begun, and the previous transfer has not been serviced.
4. Program the TWI_SLVCTL register. This step prepares and enables completer mode operation. For example, programming the value 0x0005 enables completer mode operation and requires 7-bit addressing. It indicates that data in the transmit FIFO buffer is for completer mode transmission.

The ***Completer Mode Interaction*** table and ***TWI Completer Mode Program Flow*** diagram represent the interaction between the TWI controller and the processor using this example.

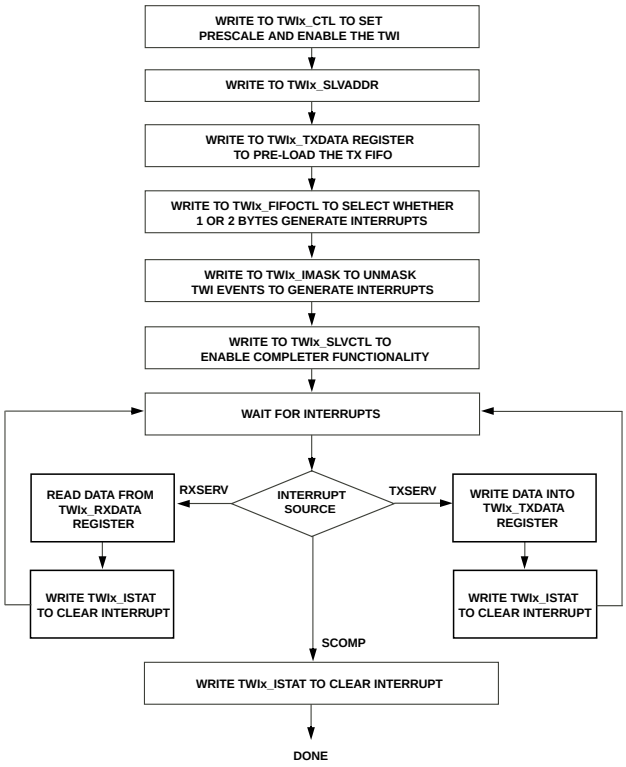

Figure 29-12: TWI Completer Mode Program Flow

Table 29-3: Completer Mode Interaction

TWI Controller	Processor
Interrupt: SINIT – completer transfer in progress.	Acknowledge: Clear the interrupt source bits.
Interrupt: RCVSERV – Receive buffer is full.	Acknowledge: Clear the interrupt source bits. Read TWIx_FIFO_STAT. Read the receive FIFO buffer.
...	...
Interrupt: SCOMP – completer transfer complete.	Acknowledge: Clear the interrupt source bits. Read the receive FIFO buffer.

Requester Mode Program Flow

The ***Requester Mode Program Flow*** figure shows the program for the TWI in requester mode.

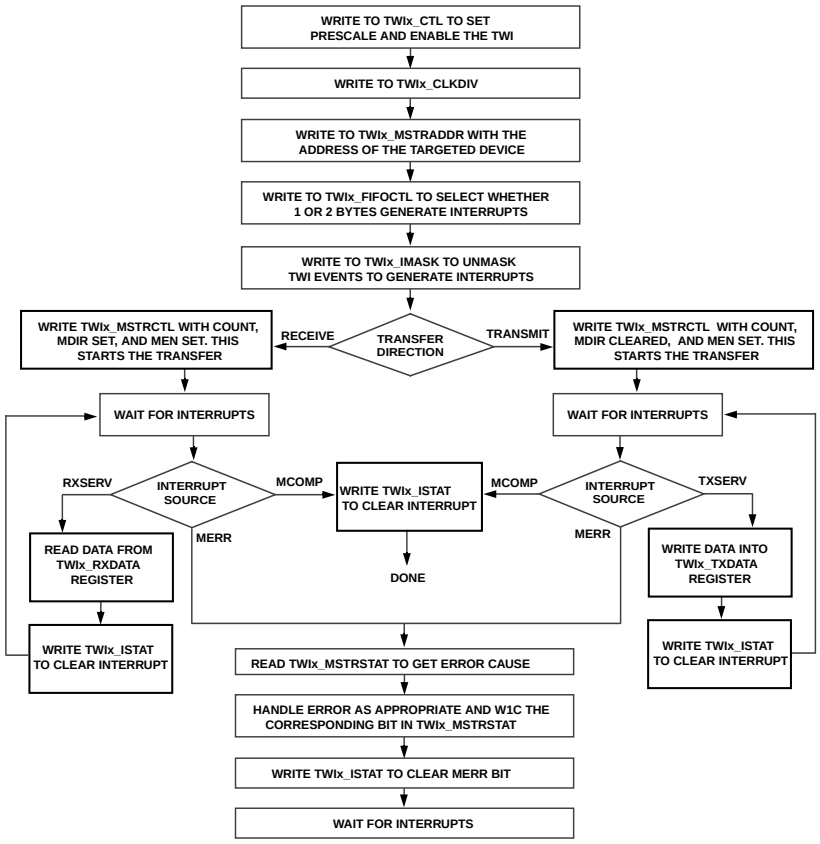

Figure 29-13: Requester Mode Program Flow

Requester Mode Clock Setup

Requester mode operation is set up and executed on a per-transfer basis.

An example of programming steps for a receive and for a transmit is given separately in following sections. The programming step for clock setup listed here is common to both transfer types.

1. Program the `TWI_CLKDIV` register to define the minimum high and minimum low duration for the clock.

The `TWI_CLKDIV.CLKHI` and `TWI_CLKDIV.CLKLO` fields do not guarantee a certain frequency. Rather, they guarantee a certain minimum high and low duration for `TWI_SCL`. The slew rate controls falling edges. The RC time constant formed by the pull-up resistor and the SCL capacitance govern rising edges. See the “Register Descriptions” section for more details.

Requester Mode Transmit

Follow these programming steps for a single requester mode transmission:

1. Program the `TWI_MSTRADDR` register. This step defines the address transmitted during the address phase of the transfer.

2. Program the TWI_TXDATA8 or TWI_TXDATA16 register. This step configures the initial data transmitted. It is an error to complete the address phase of the transfer and not have data available in the transmit FIFO buffer.
3. Program the TWI_FIFOCTL register. The programming indicates if the transmit FIFO buffer interrupt requests occur with each byte transmitted (8-bits) or with every 2 bytes transmitted (16-bits).
4. Program the TWI_IMSK register. This step enables the bits associated with the desired interrupt request sources. For example, programming the value 0x0030 results in an interrupt output to the processor when the requester transfer completes, and the requester transfer has an error.
5. Program the TWI_MSTRCTL register. This step prepares and enables requester mode operation. For example, programming the value 0x0201: enables requester mode operation, generates a 7-bit address, sets the direction to requester-transmit, uses standard mode timing, and transmits 8 data bytes before generating a stop condition.

The ***Requester Mode Transmit Setup Interaction*** table represents the interaction between the TWI controller and the processor using this example.

Table 29-4: Requester Mode Transmit Setup Interaction

TWI Controller	Processor
Interrupt: XMTSERV – Transmit buffer is empty	Acknowledge: Clear the interrupt request source bits and write to the transmit FIFO buffer
...	...
Interrupt: MCOMP – requester transfer complete	Acknowledge: Clear the interrupt request source bits

Requester Mode Receive

Follow these programming steps for a single requester mode receive.

1. Program the TWI_MSTRADDR register. This step defines the address transmitted during the address phase of the transfer.
2. Program the TWI_FIFOCTL register. This step indicates if the receive FIFO buffer interrupt requests occur with each byte received (8-bits) or with every 2 bytes received (16-bits).
3. Program the TWI_IMSK register. This step configures the enable bits associated with the desired interrupt sources. For example, programming the value 0x0030 results in an interrupt request output to the processor when the requester transfer completes, and the requester transfer has an error.
4. Program the TWI_MSTRCTL register. This step prepares and enables requester mode operation. For example, programming the value 0x0205: enables requester mode operation, generates a 7-bit address, sets the direction to requester-receive, uses standard mode timing, and receives 8 data bytes before generating a stop condition.

The ***Requester Mode Receive Setup Interaction*** table shows the interaction between the TWI controller and the processor using this example.

Table 29-5: Requester Mode Receive Setup Interaction

TWI Requester	Processor
Interrupt: RCVSERV – receive buffer is full	Acknowledge: Clear the interrupt request source bits. Read the receive FIFO buffer.
...	...
Interrupt: MCOMP – requester transfer complete	Acknowledge: Clear the interrupt request source bits and read the receive FIFO buffer

NOTE: After the `TWI_MSTRCTL.DCNT` bit decrements to zero, the TWI controller device sends a NAK to indicate to the completer transmitter to release the bus. This operation allows the requester to send the stop signal to terminate the transfer.

ADSP-SC59x TWI Register Descriptions

Two-Wire Interface (TWI) contains the following registers.

Table 29-6: ADSP-SC59x TWI Register List

Name	Description
`TWI_CLKDIV`	SCL Clock Divider Register
`TWI_CTL`	Control Register
`TWI_FIFOCTL`	FIFO Control Register
`TWI_FIFOSTAT`	FIFO Status Register
`TWI_IMSK`	Interrupt Mask Register
`TWI_ISTAT`	Interrupt Status Register
`TWI_MSTRADDR`	Controller Mode Address Register
`TWI_MSTRCTL`	Controller Mode Registers
`TWI_MSTRSTAT`	Controller Mode Status Register
`TWI_RXDATA16`	Rx Data Double-Byte Register
`TWI_RXDATA8`	Rx Data Single-Byte Register
`TWI_SLVADDR`	Target Mode Address Register
`TWI_SLVCTL`	Target Mode Control Register
`TWI_SLVSTAT`	Target Mode Status Register
`TWI_TXDATA16`	Tx Data Double-Byte Register
`TWI_TXDATA8`	Tx Data Single-Byte Register

SCL Clock Divider Register

During controller mode operation, the TWI_CLKDIV holds values, which the TWI uses to create the high and low durations of the serial clock (SCL). The clock signal SCL is an output in controller mode and an input in target mode. The values in the TWI_CLKDIV.CLKLO and TWI_CLKDIV.CLKHI fields add up to the CLKDIV value the following equation.

CLKDIV = TWI SCL period / 10 MHz time reference

Serial clock frequencies can vary from 400 KHz to less than 20 KHz. The resolution of the clock generated is 1/10 MHz or 100 ns. For example, for an SCL of 400 KHz (period = 1/400 KHz = 2500 ns) and an internal time reference of 10 MHz (period = 100 ns):

CLKDIV = 2500 ns / 100 ns = 25

For an SCL with a 30% duty cycle, use TWI_CLKDIV.CLKLO = 17 and TWI_CLKDIV.CLKHI = 8.

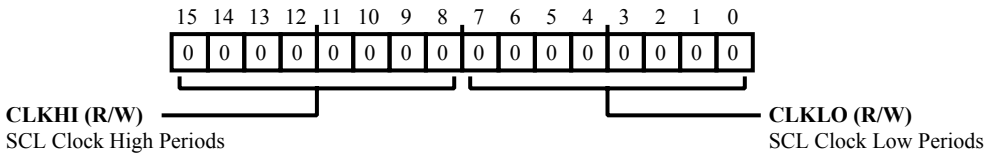

Figure 29-14: TWI_CLKDIV Register Diagram

Table 29-7: TWI_CLKDIV Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:8 (R/W)	CLKHI	SCL Clock High Periods. The TWI_CLKDIV.CLKHI specifies the number of 10 MHz time reference periods the serial clock (SCL) waits before a new clock low period begins, assuming a single requester.
7:0 (R/W)	CLKLO	SCL Clock Low Periods. The TWI_CLKDIV.CLKLO specifies the number of internal time reference periods the serial clock (SCL) is held low.

Control Register

The TWI_CTL enables the TWI, establishes a relationship between the system clock (SCLK0) and the TWI controller's internally timed events, and enables SCCB compatibility.

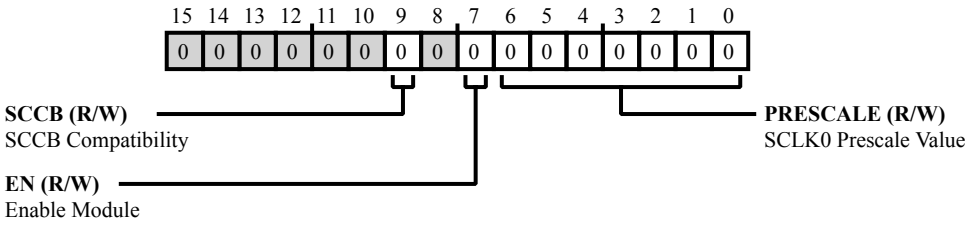

Figure 29-15: TWI_CTL Register Diagram

Table 29-8: TWI_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W)	SCCB	SCCB Compatibility. The TWI_CTL.SCCB enables SCCB compatible operation for the TWI. SCCB compatibility is an optional feature and should not be used in an I^2C bus system. When this feature is enabled, all completer asserted acknowledgement bits are ignored by this requester. This feature is valid only during transfers where the TWI is requesting an SCCB bus. Completer mode transfers should be avoided when this feature is enabled because the TWI controller always generates an acknowledge in completer mode.	
		0	Disable SCCB compatibility. When disabled, requester transfers are not SCCB compatible.
		1	Enable SCCB compatibility. When enabled, requester transfers are SCCB compatible. All completer-asserted acknowledgment bits are ignored by this requester.
7 (R/W)	EN	Enable Module. The TWI_CTL.EN enables TWI controller operation for either requester and/or completer mode of operation. It is recommended that this bit be set at the time TWI_CTL.PRESCALE is initialized and remain set. This method guarantees accurate operation of bus busy detection logic.	
		0	Disable
		1	Enable

Table 29-8: TWI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
6:0 (R/W)	PRESCALE	SCLK0 Prescale Value. The `TWI_CTL.PRESCALE` holds the pre-scaled value for the TWI internal time reference. This reference is derived from SCLK0 according to the formula: `TWI_CTL.PRESCALE` = f_{SCLK0}/10MHz The `TWI_CTL.PRESCALE` specifies the number of system clock (SCLK0) periods used in the generation of one internal time reference. The value of `TWI_CTL.PRESCALE` must be set to create an internal time reference with a period of 10 MHz. It is represented as a 7-bit binary value.

FIFO Control Register

The TWI_FIFOCTL control bits affect only the FIFO and are not tied in any way with controller or target mode operation.

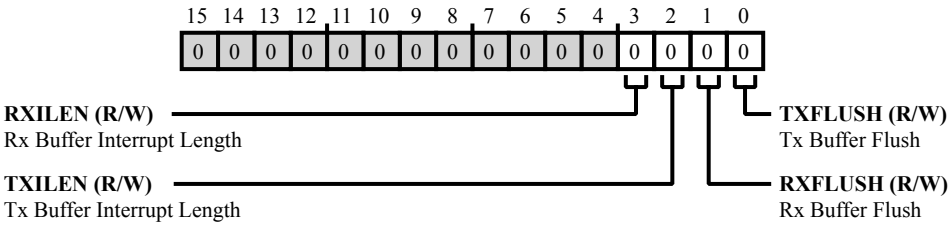

Figure 29-16: TWI_FIFOCTL Register Diagram

Table 29-9: TWI_FIFOCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	RXILEN	Rx Buffer Interrupt Length. The TWI_FIFOCTL.RXILEN determines the rate at which receive buffer interrupts are to be generated. Interrupts may be generated with each byte received or after two bytes are received. Interrupt status is available in TWI_FIFOSTAT.RXSTAT.	
		0	RXSERVI on 1 or 2 Bytes in FIFO
		1	RXSERVI on 2 Bytes in FIFO
2 (R/W)	TXILEN	Tx Buffer Interrupt Length. The TWI_FIFOCTL.TXILEN determines the rate at which transmit buffer interrupts are to be generated. Interrupts may be generated with each byte transmitted or after two bytes are transmitted. Interrupt status is available in TWI_FIFOSTAT.TXSTAT.	
		0	TXSERVI on 1 Byte of FIFO Empty
		1	TXSERVI on 2 Bytes of FIFO Empty
1 (R/W)	RXFLUSH	Rx Buffer Flush. The TWI_FIFOCTL.RXFLUSH directs the TWI to flush the contents of the receive buffer and update TWI_FIFOSTAT.RXSTAT to indicate the buffer is empty. This state is held until this bit is cleared. During an active receive, the receive buffer in this state responds to the receive logic as if it is full.	
		0	Normal Operation of Rx Buffer
		1	Flush Rx Buffer

Table 29-9: TWI_FIFOCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	TXFLUSH	Tx Buffer Flush. The `TWI_FIFOCTL.TXFLUSH` directs the TWI to flush the contents of the transmit buffer and update `TWI_FIFOSTAT.TXSTAT` to indicate the buffer is empty. This state is held until this bit is cleared. During an active transmit, the transmit buffer in this state responds to the transmit logic as if it is empty.	
		0	Normal Operation of Tx Buffer
		1	Flush Tx Buffer

FIFO Status Register

The TWI_FIFOSTAT fields indicate the state of the FIFO buffers' receive and transmit contents. The FIFO buffers do not discriminate between controller data and target data. By using the status and control bits provided, the FIFO can be managed to allow simultaneous controller and target operation.

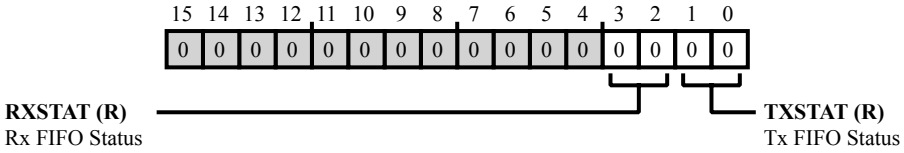

Figure 29-17: TWI_FIFOSTAT Register Diagram

Table 29-10: TWI_FIFOSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
3:2 (R/NW)	RXSTAT	Rx FIFO Status. The read-only TWI_FIFOSTAT.RXSTAT indicates the number of valid data bytes in the receive FIFO buffer. The status is updated with each FIFO buffer read using the peripheral data bus or write access by the receive shift register. Simultaneous accesses are allowed.	
		0	Empty. The FIFO is empty.
		1	Contains 1 Byte. The FIFO contains one byte of data. A single byte peripheral read of the FIFO is allowed.
		2	Reserved
		3	Full. The FIFO is full and contains two bytes of data. Either a single or double byte peripheral read of the FIFO is allowed.
1:0 (R/NW)	TXSTAT	Tx FIFO Status. The read-only TWI_FIFOSTAT.TXSTAT field indicates the number of valid data bytes in the FIFO buffer. The status is updated with each FIFO buffer write using the peripheral data bus or read access by the transmit shift register. Simultaneous accesses are allowed.	
		0	Empty. The FIFO is empty. Either a single or double byte peripheral write of the FIFO is allowed.
		1	Contains 1 Byte. The FIFO contains one byte of data. A single byte peripheral write of the FIFO is allowed.
		2	Reserved
		3	Full. The FIFO is full and contains two bytes of data.

Interrupt Mask Register

The TWI_IMSK enables interrupt sources to assert the interrupt output. Each mask bit corresponds with one interrupt request source bit in TWI_ISTAT. Reading and writing TWI_IMSK does not affect the contents of the TWI_ISTAT.

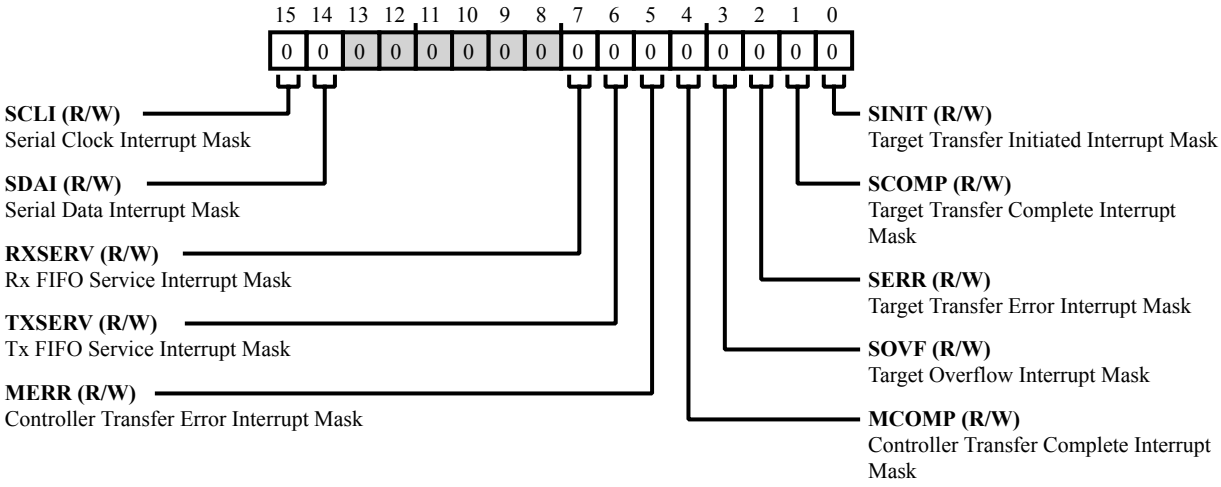

Figure 29-18: TWI_IMSK Register Diagram

Table 29-11: TWI_IMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	SCLI	Serial Clock Interrupt Mask.	
		0	Mask (Disable) Interrupt
		1	Unmask (Enable) Interrupt
14 (R/W)	SDAI	Serial Data Interrupt Mask.	
		0	Mask (Disable) Interrupt
		1	Unmask (Enable) Interrupt
7 (R/W)	RXSERV	Rx FIFO Service Interrupt Mask.	
		0	Mask (Disable) Interrupt
		1	Unmask (Enable) Interrupt
6 (R/W)	TXSERV	Tx FIFO Service Interrupt Mask.	
		0	Mask (Disable) Interrupt
		1	Unmask (Enable) Interrupt

Table 29-11: TWI_IMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (R/W)	MERR	Controller Transfer Error Interrupt Mask.	
		0	Mask (Disable) Interrupt
		1	Unmask (Enable) Interrupt
4 (R/W)	MCOMP	Controller Transfer Complete Interrupt Mask.	
		0	Mask (Disable) Interrupt
		1	Unmask (Enable) Interrupt
3 (R/W)	SOVF	Target Overflow Interrupt Mask.	
		0	Mask (Disable) Interrupt
		1	Unmask (Enable) Interrupt
2 (R/W)	SERR	Target Transfer Error Interrupt Mask.	
		0	Mask (Disable) Interrupt
		1	Unmask (Enable) Interrupt
1 (R/W)	SCOMP	Target Transfer Complete Interrupt Mask.	
		0	Mask (Disable) Interrupt
		1	Unmask (Enable) Interrupt
0 (R/W)	SINIT	Target Transfer Initiated Interrupt Mask.	
		0	Mask (Disable) Interrupt
		1	Unmask (Enable) Interrupt

Interrupt Status Register

The TWI_ISTAT contains information about functional areas requiring servicing. Many of the bits serve as an indicator to further read and service various status registers. After servicing the interrupt source associated with a bit, the user must clear that interrupt source bit by writing a 1 to it.

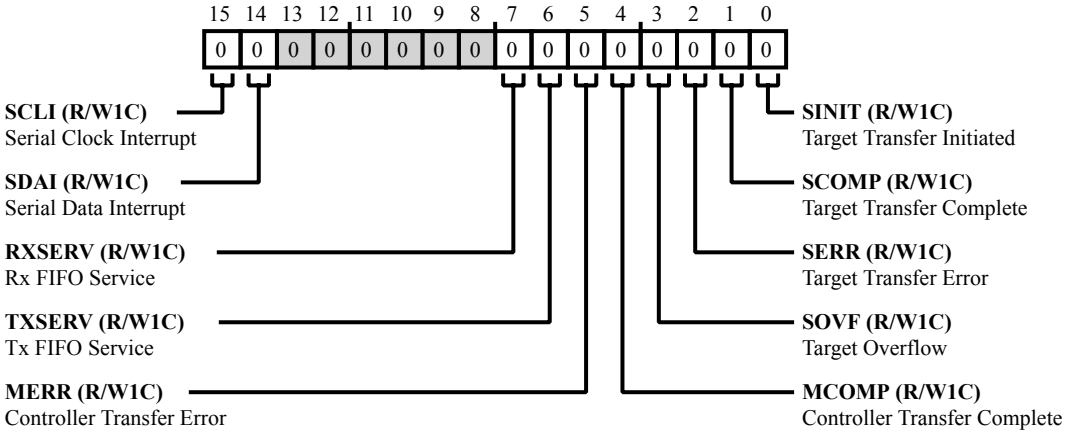

Figure 29-19: TWI_ISTAT Register Diagram

Table 29-12: TWI_ISTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W1C)	SCLI	Serial Clock Interrupt. If the TWI is enabled (TWI_CTL.EN), SCLI is set on a high-to-low transition of the serial clock pin (SCLx). Normally, this bit is not required for I^2C bus transfers. It will be initially set on an I^2C transfer and does not require clearing.	
		0	No Interrupt. No transition was detected on the SCLx pin.
		1	Interrupt Detected. A high-to-low transition was detected on the SCLx pin. This bit is W1C.
14 (R/W1C)	SDAI	Serial Data Interrupt. If the TWI is enabled (TWI_CTL.EN), SDAI is set on a high-to-low transition of the serial data pin (SDAx). Normally, this bit is not required for I^2C bus transfers. It will be initially set on an I^2C transfer and does not require clearing.	
		0	No Interrupt. No transition was detected on the SDAx pin.
		1	Interrupt Detected. A high-to-low transition was detected on the SDAx pin. This bit is W1C.

Table 29-12: TWI_ISTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W1C)	RXSERV	Rx FIFO Service. If TWI_FIFOCTL.RXILEN =0, the TWI_ISTAT.RXSERV is set each time the TWI_FIFOSTAT.RXSTAT field is updated to either 01 or 11. If TWI_FIFOCTL.RXILEN =1, the TWI_ISTAT.RXSERV is set each time TWI_FIFOSTAT.RXSTAT is updated to 11.	
		0	No Interrupt. The FIFO does not require servicing, or the TWI_FIFOSTAT.RXSTAT field has not changed since this bit was last cleared.
		1	Interrupt Detected. The receive FIFO buffer has one or two 8-bit words of data available to be read.
6 (R/W1C)	TXSERV	Tx FIFO Service. If TWI_FIFOCTL.TXILEN =0, the TWI_ISTAT.TXSERV is set each time the TWI_FIFOSTAT.TXSTAT field is updated to either 01 or 00. If TWI_FIFOCTL.TXILEN =1, the TWI_ISTAT.TXSERV is set each time TWI_FIFOSTAT.TXSTAT is updated to 00.	
		0	No Interrupt. FIFO does not require servicing, or the TWI_FIFOSTAT.TXSTAT field has not changed since this bit was last cleared.
		1	Interrupt Detected. The transmit FIFO buffer has one or two 8-bit locations available to be written.
5 (R/W1C)	MERR	Controller Transfer Error. The TWI_ISTAT.MERR indicates that a requester error has occurred. The conditions surrounding the error are indicated by the requester status register (TWI_MSTRSTAT).	
		0	No Interrupt
		1	Interrupt Detected
4 (R/W1C)	MCOMP	Controller Transfer Complete. The TWI_ISTAT.MCOMP indicates that the initiated requester transfer has completed. In the absence of a repeat start, the bus has been released.	
		0	No Interrupt
		1	Interrupt Detected

Table 29-12: TWI_ISTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W1C)	SOVF	Target Overflow. The `TWI_ISTAT.SOVF` indicates that the `TWI_ISTAT.SCOMP` bit was set at the time a subsequent transfer has acknowledged an address phase. The transfer continues, however, it may be difficult to delineate data of one transfer from another.	
		0	No Interrupt
		1	Interrupt Detected
2 (R/W1C)	SERR	Target Transfer Error. The `TWI_ISTAT.SERR` indicates that a completer error has occurred. A restart or stop condition has occurred during the data receive phase of a transfer.	
		0	No Interrupt
		1	Interrupt Detected
1 (R/W1C)	SCOMP	Target Transfer Complete. The `TWI_ISTAT.SCOMP` indicates that the transfer is complete and either a stop, or a restart was detected.	
		0	No Interrupt
		1	Interrupt Detected
0 (R/W1C)	SINIT	Target Transfer Initiated. The `TWI_ISTAT.SINIT` indicates whether or not a completer transfer is in progress.	
		0	No Interrupt. A transfer is not in progress, or an address match has not occurred since the last time this bit was cleared.
		1	Interrupt Detected. The completer has detected an address match, and a transfer has been initiated.

Controller Mode Address Register

During the addressing phase of a transfer, the TWI controller, with its controller enabled, transmits the contents of TWI_MSTRADDR. When programming this register, omit the read/write bit. That is, only the upper 7 bits that make up the target address should be written to this register. For example, if the target address is b#1010000X, where X is the read/write bit, the TWI_MSTRADDR is programmed with b#1010000, which corresponds to 0x50. When sending out the address on the bus, the TWI controller appends the read/write bit as appropriate based on the state of the TWI_MSTRCTL.DIR bit.

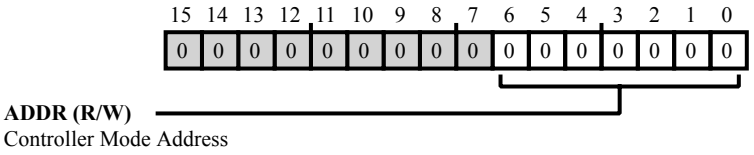

Figure 29-20: TWI_MSTRADDR Register Diagram

Table 29-13: TWI_MSTRADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
6:0 (R/W)	ADDR	Controller Mode Address.

Controller Mode Registers

The TWI_MSTRCTL controls the logic associated with controller mode operation. Bits in this register do not affect target mode operation and should not be modified to control target mode functionality.

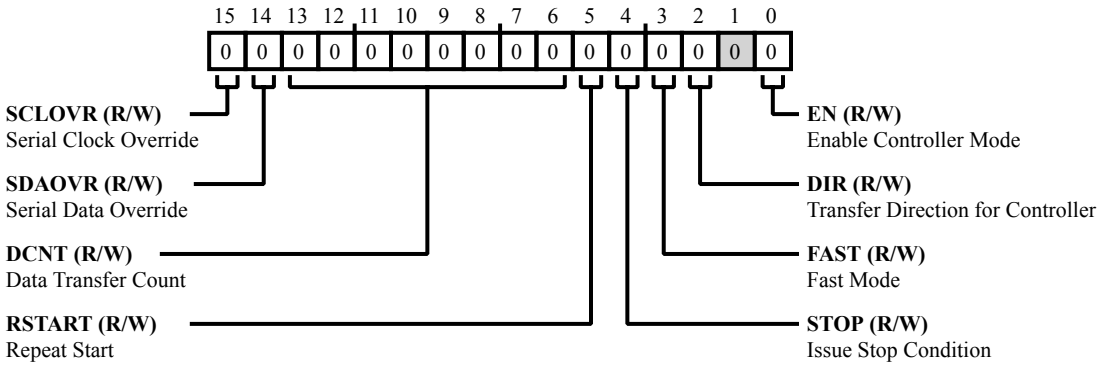

Figure 29-21: TWI_MSTRCTL Register Diagram

Table 29-14: TWI_MSTRCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	SCLOVR	Serial Clock Override. The TWI_MSTRCTL.SCLOVR provides direct control of the serial clock line when required. Normal requester and completer mode operation should not require override operation. When TWI_MSTRCTL.SCLOVR is set, the TWI overrides normal serial clock output, driving it to an active 0 level and overriding all other logic. This state is held until this bit is cleared. When TWI_MSTRCTL.SCLOVR is cleared, the TWI permits normal serial clock operation under the control of requester mode clock generation and completer mode clock stretching logic.	
		0	Permit Normal SCL Operation
		1	Override Normal SCL Operation
14 (R/W)	SDAOVR	Serial Data Override. The TWI_MSTRCTL.SDAOVR provides direct control of the serial data line when required. Normal requester and completer mode operation should not require override operation. When TWI_MSTRCTL.SDAOVR is set, the TWI overrides normal serial data operation under the control of the transmit shift register and acknowledge logic, driving serial data output to an active 0 level and overriding all other logic. This state is held until this bit is cleared. When TWI_MSTRCTL.SDAOVR is cleared, the TWI permits normal serial data operation.	
		0	Permit Normal SDA Operation
		1	Override Normal SDA Operation

Table 29-14: TWI_MSTRCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
13:6 (R/W)	DCNT	Data Transfer Count. The TWI_MSTRCTL.DCNT indicates the number of data bytes to transfer. As each data word is transferred, the TWI decrements this counter. When TWI_MSTRCTL.DCNT decrements to 0, a stop condition is generated. Setting TWI_MSTRCTL.DCNT to 0xFF disables the counter. In this transfer mode, data continues to be transferred until it is concluded by setting the TWI_MSTRCTL.STOP bit. In the event a requester transmit is aborted due to a completer data NAK, the value of TWI_MSTRCTL.DCNT equals the number of bytes not sent. The byte which was NAK'ed by the completer is counted as a sent byte.	
5 (R/W)	RSTART	Repeat Start. The TWI_MSTRCTL.RSTART enables the TWI to issue a repeat start condition at the conclusion of the current transfer (TWI_MSTRCTL.DCNT =0) and begin the next transfer. The current transfer concludes with updates to the appropriate status and interrupt bits. If errors occurred during the previous transfer, a repeat start does not occur. In the absence of any errors, requester enable (TWI_MSTRCTL.EN) does not self clear on a repeat start.	
		0	Disable Repeat Start
		1	Enable Repeat Start
4 (R/W)	STOP	Issue Stop Condition. The TWI_MSTRCTL.STOP directs the TWI to issue a stop condition. The transfer concludes as soon as possible avoiding any error conditions (as if data transfer count had been reached). At that time, the TWI_IMSK is updated along with any associated status bits.	
		0	Permit Normal Operation
		1	Issue Stop
3 (R/W)	FAST	Fast Mode. The TWI_MSTRCTL.FAST selects whether the TWI operates in fast mode or standard mode. In fast mode, the TWI uses timing specifications for transfers at up to 400K bits/s. In standard mode, the TWI uses timing specifications for transfers at up to 100K bits/s.	
		0	Select Standard Mode
		1	Select Fast Mode
2 (R/W)	DIR	Transfer Direction for Controller. The TWI_MSTRCTL.DIR selects the transfer direction for the TWI as requester initiated receive or transmit.	
		0	Requester Transmit
		1	Requester Receive

Table 29-14: TWI_MSTRCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	EN	Enable Controller Mode. The `TWI_MSTRCTL.EN` enables requester mode functionality. A start condition is generated if the bus is idle. This bit self clears at the completion of a transfer (after `TWI_MSTRCTL.DCNT` decrements to zero), including transfers terminated due to errors. If disabled (=0) during operation, the transfer is aborted, and all logic associated with requester mode transfers are reset. Serial data and serial clock (SDA, SCL) are no longer driven. Write-1-to-clear status bits are not affected.	
		0	Disable
		1	Enable

Controller Mode Status Register

The TWI_MSTRSTAT holds information during controller mode transfers and at their conclusion. Generally, controller mode status bits are not directly associated with the generation of interrupt requests, but these bits offer information on the current transfer. Target mode operation does not affect controller mode status bits.

Note that while TWI_MSTRSTAT.SCLSEN is set (this condition could be due to having no pull-up resistor on TWI_SCL or another agent is driving TWI_SCL low), the acknowledge bits (TWI_MSTRSTAT.ANAK and TWI_MSTRSTAT.DNAK) do not update. This result occurs because the acknowledge conditions are sampled during the high phase of TWI_SCL.

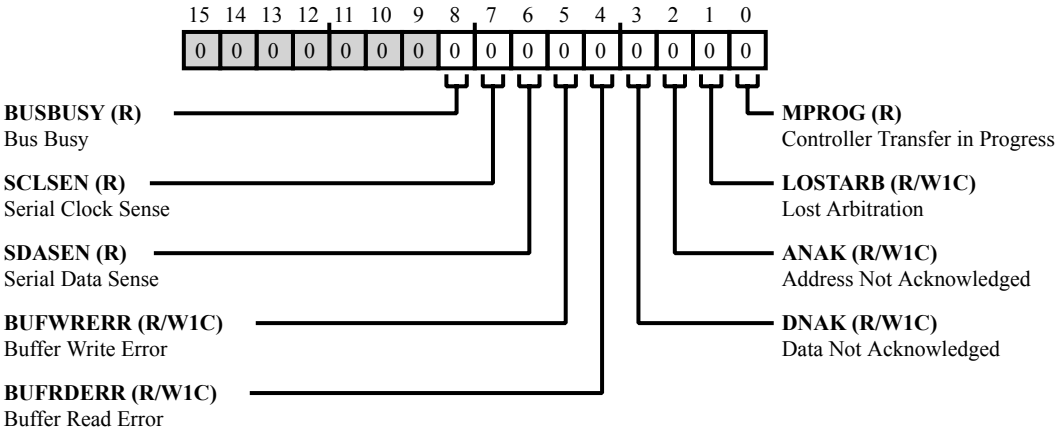

Figure 29-22: TWI_MSTRSTAT Register Diagram

Table 29-15: TWI_MSTRSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/NW)	BUSBUSY	Bus Busy. The TWI_MSTRSTAT.BUSBUSY indicates whether the bus is currently busy or free. This indication is not limited to only this device but is for all devices. On a start condition, the setting of the register value is delayed due to the input filtering. On a stop condition the clearing of the register value occurs after t_{BUF}.	
		0	Bus Free. The bus is free. The clock and data bus signals have been inactive for the appropriate bus free time.
		1	Bus Busy. The bus is busy. Clock or data activity has been detected.

Table 29-15: TWI_MSTRSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/NW)	SCLSEN	Serial Clock Sense. The `TWI_MSTRSTAT.SCLSEN` indicates the active or inactive state of the serial clock. Use this status bit when direct sensing of the serial clock line is required. The register value is delayed due to the input filter (nominally 50 ns). Normal requester and completer mode operation should not require this feature.	
		0	SCL Inactive "One". An inactive "one" is being sensed on the serial clock.
		1	SCL Active "Zero". An active "zero" is being sensed on the serial clock. The source of the active driver is not known and can be internal or external.
6 (R/NW)	SDASEN	Serial Data Sense. The `TWI_MSTRSTAT.SDASEN` indicates the active or inactive status of the serial data. Use this status bit when direct sensing of the serial data line is required. The register value is delayed due to the input filter (nominally 50 ns). Normal requester and completer mode operation should not require this feature.	
		0	SDA Inactive "One". An inactive "one" is currently being sensed on the serial data line.
		1	SDA Active "Zero". An active "zero" is currently being sensed on the serial data line. The source of the active driver is not known and can be internal or external.
5 (R/W1C)	BUFWRERR	Buffer Write Error. The `TWI_MSTRSTAT.BUFWRERR` indicates whether the current requester transfer was aborted due to a receive buffer write error. The receive buffer and receive shift register were both full at the same time. This bit is W1C.	
		0	No Status
		1	Buffer Write Error
4 (R/W1C)	BUFRDERR	Buffer Read Error. The `TWI_MSTRSTAT.BUFRDERR` indicates whether the current requester transfer was aborted due to a transmit buffer read error. The error occurs if the buffer is empty when data is required by the transmit shift register. This bit is W1C.	
		0	No Status
		1	Buffer Read Error

Table 29-15: TWI_MSTRSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W1C)	DNAK	Data Not Acknowledged. The `TWI_MSTRSTAT.DNAK` indicates whether the current requester transfer was aborted due to the detection of a NAK during data transmission. This bit is W1C.	
		0	No Status
		1	Data NAK
2 (R/W1C)	ANAK	Address Not Acknowledged. The `TWI_MSTRSTAT.ANAK` indicates whether the current requester transfer was aborted due to the detection of a NAK during the address phase of the transfer. This bit is W1C.	
		0	No Status
		1	Address NAK
1 (R/W1C)	LOSTARB	Lost Arbitration. The `TWI_MSTRSTAT.LOSTARB` indicates whether the current transfer was aborted due to the loss of arbitration with another requester. This bit is W1C.	
		0	No Status
		1	Lost Arbitration
0 (R/NW)	MPROG	Controller Transfer in Progress. The `TWI_MSTRSTAT.MPROG` indicates whether or not a requester transfer is in progress. If clear (`TWI_MSTRSTAT.MPROG` =0), currently no transfer is taking place. This can occur after a transfer is complete or while an enabled requester is waiting for an idle bus.	
		0	No Status
		1	Requester Transfer in Progress

Rx Data Double-Byte Register

The TWI_RXDATA16 holds a 16-bit data value read from the FIFO buffer. To reduce interrupt output rates and peripheral bus access times, a double byte receive data access can be performed. Two data bytes can be read, effectively emptying the receive FIFO buffer with a single access.

The data is read in little endian byte order, where byte 0 is the first byte received and byte 1 is the second byte received. With each access, the receive status (TWI_FIFOSTAT.RXSTAT) field is updated to indicate it is empty. If an access is performed while the FIFO buffer is not full, the read data is unknown and the existing FIFO buffer data and its status remains unchanged.

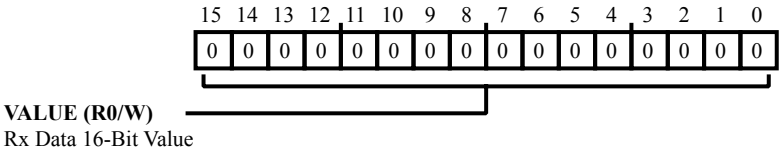

Figure 29-23: TWI_RXDATA16 Register Diagram

Table 29-16: TWI_RXDATA16 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R0/W)	VALUE	Rx Data 16-Bit Value.

Rx Data Single-Byte Register

The TWI_RXDATA8 holds an 8-bit data value read from the FIFO buffer. Receive data is read from the corresponding receive buffer in a first-in first-out order. Although peripheral bus reads are 16 bits, a read access to TWI_RXDATA8 accesses only one transmit data byte from the FIFO buffer. With each access, the receive status (TWI_FIFOSTAT.RXSTAT) field is updated. If an access is performed while the FIFO buffer is empty, the data is unknown and the FIFO buffer status remains indicating it is empty.

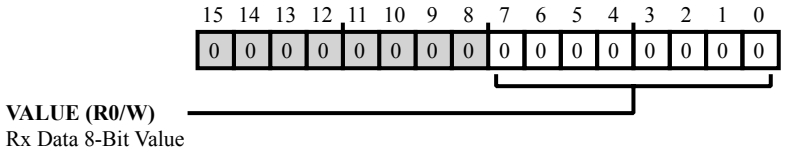

Figure 29-24: TWI_RXDATA8 Register Diagram

Table 29-17: TWI_RXDATA8 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R0/W)	VALUE	Rx Data 8-Bit Value.

Target Mode Address Register

The TWI_SLVADDR holds the target mode address, which is the valid address to which the target-enabled TWI controller responds. The TWI controller compares this value with the received address during the addressing phase of a transfer.

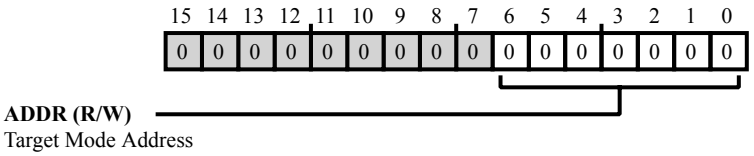

Figure 29-25: TWI_SLVADDR Register Diagram

Table 29-18: TWI_SLVADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
6:0 (R/W)	ADDR	Target Mode Address.

Target Mode Control Register

The TWI_SLVCTL controls the logic associated with target mode operation. Settings in this register do not affect controller mode operation and should not be modified to manage controller mode functionality.

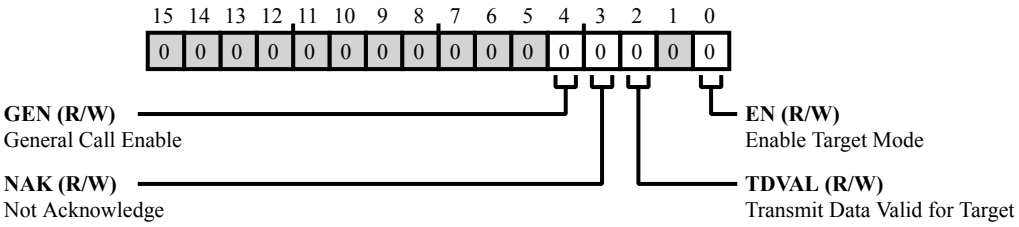

Figure 29-26: TWI_SLVCTL Register Diagram

Table 29-19: TWI_SLVCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/W)	GEN	General Call Enable. The TWI_SLVCTL.GEN enables general call address matching. When enabled, a general call completer receive transfer is accepted. All status and interrupt source bits associated with transfers are updated. Note that general call address detection is available only when completer mode is enabled.	
		0	Disable General Call Matching
		1	Enable General Call Matching
3 (R/W)	NAK	Not Acknowledge. The TWI_SLVCTL.NAK directs the TWI to generate a NAK (if set) or an ACK (if cleared) at the conclusion of data transfer for completer receive. For NAK, the completer is still considered to be addressed at the conclusion of transfer.	
		0	Generate ACK
		1	Generate NAK
2 (R/W)	TDVAL	Transmit Data Valid for Target. The TWI_SLVCTL.TDVAL selects whether the data in the transmit FIFO is available (valid) for completer transmission (TWI_SLVCTL.TDVAL set). If the FIFO data is not available (invalid) for completer transmission (TWI_SLVCTL.TDVAL cleared), the data in the transmit FIFO is for requester mode transmits, and the data is not allowed to be used during a completer transmit; the transmit FIFO is treated as if it is empty.	
		0	Data Invalid for Completer Tx
		1	Data Valid for Completer Tx

Table 29-19: TWI_SLVCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	EN	Enable Target Mode. The `TWI_SLVCTL.EN` enables completer operation. Enabling completer and requester modes of operation concurrently is allowed. If disabled, no attempt is made to identify a valid address. If `TWI_SLVCTL.EN` is cleared during a valid transfer, clock stretching ceases, the serial data line is released, and the current byte is not acknowledged.	
		0	Disable
		1	Enable

Target Mode Status Register

During and at the conclusion of register target mode transfers, the TWI_SLVSTAT holds information on the current transfer. Generally target mode status bits are not associated with the generation of interrupt requests. Controller mode operation does not affect target mode status bits.

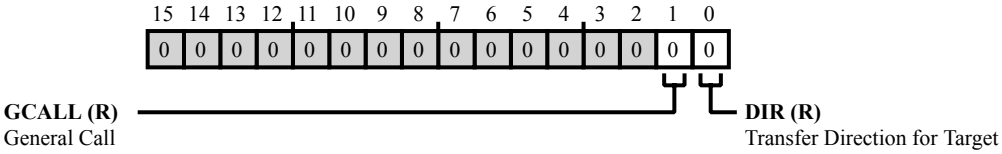

Figure 29-27: TWI_SLVSTAT Register Diagram

Table 29-20: TWI_SLVSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/NW)	GCALL	General Call. The TWI_SLVSTAT.GCALL indicates whether or not--at the time of addressing--the address was determined to be a general call. This bit self clears if completer mode is disabled (TWI_SLVCTL.EN =0).	
		0	Not a General Call Address
		1	General Call Address
0 (R/NW)	DIR	Transfer Direction for Target. The TWI_SLVSTAT.DIR indicates whether--at the time of addressing--the transfer direction was determined to be completer transmit or receive. This bit self clears if completer mode is disabled (TWI_SLVCTL.EN =0).	
		0	Completer Receive
		1	Completer Transmit

Tx Data Double-Byte Register

The TWI_TXDATA16 register holds a 16-bit data value written into the FIFO buffer. To reduce interrupt latency output rates and peripheral bus access times, a double byte transfer data access can be done. Two data bytes can be written, effectively filling the transmit FIFO buffer with a single access.

The data is written in little endian byte order, where byte 0 is the first byte to be transferred and byte 1 is the second byte to be transferred. With each access, the transmit status (TWI_FIFOSTAT.TXSTAT) field is updated. If an access is performed while the FIFO buffer is not empty, the write is ignored and the existing FIFO buffer data and its status remains unchanged. This register when read back returns zero.

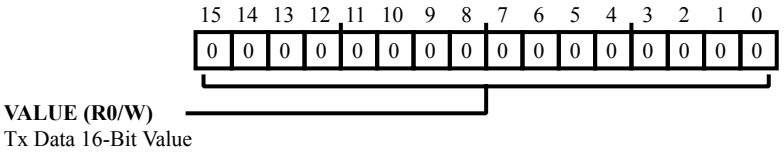

Figure 29-28: TWI_TXDATA16 Register Diagram

Table 29-21: TWI_TXDATA16 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R0/W)	VALUE	Tx Data 16-Bit Value.

Tx Data Single-Byte Register

The TWI_TXDATA8 register holds an 8-bit data value written into the FIFO buffer. Transmit data is entered into the corresponding transmit buffer in a first-in first-out order. For 16-bit peripheral bus writes, a write access to this register adds only one transmit data byte to the FIFO buffer. With each access, the transmit status (TWI_FIFOSTAT.TXSTAT) field is updated. If an access is performed while the FIFO buffer is full, the write is ignored and the existing FIFO buffer data and its status remains unchanged. This register returns zero when read back.

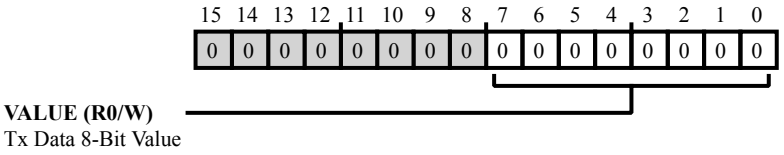

Figure 29-29: TWI_TXDATA8 Register Diagram

Table 29-22: TWI_TXDATA8 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R0/W)	VALUE	Tx Data 8-Bit Value.

30 Ethernet Media Access Controller (EMAC)

The EMAC peripheral in the processor enables network connectivity to applications through an Ethernet interface.

The module is fully compliant to the following standards:

- IEEE 802.3-2015 for Physical Layer Specifications.
- IEEE 1588-2008 for Precision Clock Synchronization Protocol for Networked Measurement and Control Systems.
- IEEE 802.1AS-2011 and 802.1-Qav-2009 for Forwarding and Queuing Enhancements for Time-Sensitive Streams or Audio Video (AV) traffic.
- IEEE 802.1AS-Rev/D4.0 for Timing and Synchronization for Time-Sensitive Applications in Bridged Local Area Networks.
- IEEE 802.3az-2010 for Energy Efficient Ethernet (EEE).
- IEEE 802.1Qbv-2015, 802.1Qbu-2016, and 802.1AS-Rev D5.0 for Time-Sensitive Networking (TSN).
- IEEE 802.1Qaz-2011 and 802.1Qbb-2011 for Data Center Bridging (DCB).
- Reduced Gigabit Media Independent Interface (RGMII), Revision 2.6, HP/Marvell.
- Reduced Media Independent Interface Specification, Revision 1.2, RMII Consortium.

NOTE: Copyright © 2020 Synopsys, Inc.; portions of this chapter are included with permission from Synopsys, Inc.

NOTE: References to MII in this document are applicable to both MII and RMII; references to GMII are applicable to RGMII.

EMAC Features

The EMAC features include the following:

MAC Tx and Rx Features

- 10/100/1000 Mbps data transfer rates with external PHY interfaced through RGMII/RMII/MII

- Support for both full-duplex and half-duplex operations
- CSMA/CD protocol for half-duplex operation
- IEEE 802.3x flow control for full-duplex and using backpressure support for half-duplex

MAC Transmit Features

- Automatic CRC and pad generation controllable on a per-frame basis
- Programmable packet length to support Standard or Jumbo Ethernet packets with up to 16 KB of size
- Programmable Inter-Frame Gap (IFG)
- Source address field insertion or replacement, and VLAN insertion, replacement, and deletion in transmitted frames with per-frame control
- Insertion, replacement, or deletion of up to two VLAN tags
- Option to transmit packets with reduced preamble size in full-duplex mode
- Insert, replace, or delete queue/channel based VLAN tags
- Frame preemption for MAC Tx

MAC Receive Features

- Automatic pad and CRC stripping options
- Preamble and SFD deletion
- Programmable watchdog timeout limit
- Flexible address filtering modes
- Additional packet filtering (VLAN tag based, layer 3, layer 4)
- IEEE 802.1Q VLAN tag detection
- Frame preemption for MAC Rx

MAC Transaction Layer (MTL) Features

- Eight queues each on the transmit and receive path
- Programmable threshold capability for each queue
- Programmable burst length

MTL Transmit Features

- Store-and-forward mechanism or threshold mode (cut-through) for transmission to the MAC

- Programmable queue size in configurations with multiple queues. Each queue size can be programmed in terms of 256 bytes
- Automatic retransmission of collision packets in half-duplex mode
- Discard packets on late collision, excessive collisions, excessive deferral, and underrun conditions with appropriate status
- Option to calculate and insert IPv4 header checksum and TCP, UDP, or ICMP checksum
- Programmable interrupt options for different operational conditions
- Statistics by generating pulses for packets dropped (because of underflow) in the Tx FIFO
- Statistics related to bandwidth consumption by each queue of up to 16 blocks over a 125 us period
- Optional packet-level control for:
    - VLAN tag insertion or replacement
    - Ethernet source address insertion
    - Layer 3/layer 4 checksum insertion control
    - One-step time stamp
    - Time stamp control
    - CRC and pad control
- Following scheduling algorithms in configurations with multiple queues:
    - Weighted Round Robin (WRR)
    - (When Data Center Bridging is enabled) Deficit Weighted Round Robin (DWRR)
    - (When Data Center Bridging is enabled) Weighted Fair Queuing (WFQ)
    - Strict Priority (SP)
    - (When Audio-Video Bridging is enabled) Credit-based Shaper (CBS)
    - (When TSN is enabled), Enhancement to Scheduled Traffic (EST)
    - (When TSN is enabled), Time Based Scheduling (TBS)Option to support dropping of Tx status to improve the transmit throughput

MTL Receive Features

- Programmable Rx queue threshold in threshold (or cut through) mode
- Option to filter all error packets on reception and not forward them to the application in the store-and-forward mode
- Option to forward the undersized good packets

- Statistics by generating pulses for packets dropped (because of overflow) in the Rx FIFO
- Automatic generation of pause packet control or backpressure signal to the MAC based on the Rx queue fill level
- Arbitration among queues when multiple queues are present. The following arbitration schemes are supported:
  - Weighted Round Robin (WRR)
  - Weighted Strict priority (WSP)
  - Strict Priority (SP)
- Option to replicate received multicast packets for transfer by multiple Rx DMA channel
- Option to have a programmable lookup table based flexible parser for filtering and steering the Rx packets
- Address Recognition Protocol (ARP) offload for IPv4 packets

DMA Block Features

- Multichannel transmit and receive engines (eight transmit and eight receive channels)
- Separate DMA channel in the transmit path for each queue in MFL
- Single or multiple DMA channels for any number of queues in MFL receive path
- Dual-buffer (ring) descriptor support
- Comprehensive status reporting for normal operation and transfers with errors
- Individual programmable burst length for Tx DMA and Rx DMA engines
- Programmable interrupt options for different operational conditions
- Per-packet transmit or receive complete interrupt control
- Round-robin or fixed-priority arbitration between the receive and transmit engines
- Fixed-priority, weighted-strict-priority or weighted-round-robin arbitration for data read requests from multiple transmit DMA engines
- Start and stop modes
- Support for TCP Segmentation Offload (TSO) and UDP Fragmentation Offload (UFO) with selectable number of Tx DMA channels
- Routing of received packets to the DMA channels based on the DA or VLAN priority in multichannel DMA configurations
- Option to split the packet header (layer 3 and layer 4) and payload in different buffers
- Time-sensitive conditional packet fetching from system memory by comparing the slot time or IEEE 1588 time information provided in the descriptor (useful for AV applications)

- Programmable control for transmit descriptor posted writes to improve the throughput
- Separate channels or queues for AV data transfer in 100 Mbps and 1000 Mbps modes
- Up to eight queues on the receive paths for AV traffic and seven queues on the transmit path for AV traffic
- IEEE 802.1-Qav specified credit-based shaper (CBS) algorithm for transmit channels
- Single Tx FIFO and Rx FIFO (MFL) for all selected queues
- Programmable slot interval with range from 1µs to 4096 µs and granularity of 1µs

Data Center Bridging Features

- Separate channels or queues for DCB data transfer in 100 Mbps and 1000 Mbps modes
- Up to eight queues on the transmit and receive paths for DCB traffic
- The following Tx queues scheduling mechanisms meet the compliance specification in IEEE 802.1-Qaz Enhanced Transmission Selection (ETS) algorithm:
  - Weighted Round Robin (WRR)
  - Deficit Weighted Round Robin (DWRR)
  - Weighted Fair Queuing (WFQ)
  - Strict Priority (SP)
- Common memory for all selected Tx or Rx queues
- Priority-based Flow Control (PFC) on individual queues configured for DCB
- Programmable control to route received VLAN tagged packets to channels or queues

Time Sensitive Networking Features

- IEEE 802.1Qbv-2015, Enhancements to Scheduling Traffic
- IEEE802.1Qbu/802.3br, Frame preemption and Interspersing Express Traffic

Precision Time Protocol (PTP) Features

- Ethernet frame time stamping as described in IEEE 1588–2002 and IEEE 1588–2008. The transmit or receive status of each frame include 64-bit time stamps
- Hardware assisted time stamping capable of up to 8 ns resolution
- Automatic detection of PTP messages through Ethernet, IPv4, and IPv6 packets
- Four programmable PPS outputs that physically represent PTP system time
- Auxiliary snapshot to time stamp external events - four auxiliary input pins available

- PTP time stamp offload support
- Support for one-step time stamp

Table 30-1: EMAC0/EMAC1 Feature Differences

Feature	EMAC0		EMAC1	
	SC594	SC598	SC594	SC598
Speed	10/100/1000 Mbps		10/100 Mbps	
Line Interface	MII, RMII, RGMII		RMII	
Double VLAN Processing	No	Yes	No	
Queue/Channel-based VLAN Tag Insertion on Tx	No	Yes	No	
Additional MAC Address Registers	1	31	1	
Address Filter Hash Table Size	64 bits	256 bits	64 bits	
Extended RX VLAN Tag-based Filters	0	4	0	4
Layer 3 and Layer 4 Filters	1	8	1	1
Multicast Packet Duplication Support	No	Yes	No	
Number of Tx/Rx Queues and DMA Channels	3	8	1	
Data Center Bridging (DCB)	No	Yes	No	
Audio Video Bridging (AVB)	Yes	Yes	No	
Additional AVB DMA channels	2	7	N/A	
Precision Time Protocol (PTP)	Yes	Yes	No	
PTP - Number of Auxiliary snapshots	4 with 4 deep FIFO	4 with 16 deep FIFO	N/A	
PTP - Timestamp Offloading (Auto Send PTP frames)	No	Yes	N/A	
PTP - One Step Timestamp Feature	No	Yes	N/A	
TSN-EST (Enhancements to Scheduling Traffic) (802.1Qbv)	No	Yes	No	
Frame Preemption Support (802.3br, 802.1Qbu)	No	Yes	No	
Time Based Scheduling (launch time)	No	Yes	No	

Table 30-1: EMAC0/EMAC1 Feature Differences (Continued)

Feature	EMAC0		EMAC1	
	SC594	SC598	SC594	SC598
TCP Segmentation Offloading for TCP/IP Packets	No	Yes	No	
Split Header Feature	No	Yes	No	
IPv4 ARP Offload	No	Yes	No	
Energy Efficient Ethernet (EEE)	Yes	Yes	Yes	No

EMAC Functional Description

This section provides information on the function of Ethernet MAC peripheral.

Hardware for the Media Access Control protocol

This function allows applications to support TCP/IP based network communication. At the system end, the module supports direct connection with the system crossbar bus for memory or MMR transactions. It supports RMII (Reduced Media Independent Interface), RGMII (Reduced Gigabit Media Independent Interface), MII (Media Independent Interface), and SMI (Station Management Interface) for interfacing with the external PHY chip.

Dedicated DMA Controller with independent read/write channels

Performs both data and status transfers between the application and the media independent interfaces. Internal transmit and receive FIFOs are used to buffer and regulate the frames. Dedicated interrupt lines connect the EMAC interrupt sources to the System Event Controller (SEC) for the SHARC core or Generic Interrupt Controller (GIC) for ARM core.

MAC Management Counters (MMC) block

An extended set of registers that collect various statistics compliant with IEEE 802.3 definitions regarding the operation of the interface. The registers are updated for each new transmitted or received frame when the condition to update the counter is met. The EMAC provides a set of such counters, along with extended usage control.

PTP (Precision Time Protocol) engine

Provides hardware assistance for the implementation of the IEEE 1588 version 1 and version 2 standards, which allows time synchronization between systems.

Audio Video (AV) functionality

Enables transmission of time-sensitive traffic over bridged local area networks (LANs). The EMAC provides hardware support for IEEE 802.1-Qav specified credit-based shaper (CBS) algorithm. In addition, slot number function allows scheduling of fetching of data by DMA from system memory.

Data Center Bridging (DCB)

Data center bridging (DCB) is a set of enhancements to the Ethernet local area network communication protocol for use in data center environments, for use with clustering and storage area networks. DCB aims, for selected traffic, to eliminate loss due to queue overflow (sometimes called lossless Ethernet) and to be able to allocate bandwidth on links. DCB enables, to some extent, the treatment of different priorities as if they were different pipes.

Time Sensitive Networking

Time sensitive network (TSN) is a set of standards developed by the IEEE 802.1 work group. The standards define mechanisms for the time-sensitive transmission of data over Ethernet.

ADSP-SC59x EMAC Register List

RGMII, RMII, MII Ethernet Controller (EMAC)

Table 30-2: ADSP-SC59x EMAC Register List

Name	Description
EMAC_DMA[n]_CTL	DMA Channel n Control Register
EMAC_DMA[n]_RXBUF_CUR	DMA Channel n Current Application Receive Buffer Address Register

EMAC Definitions

The following definitions are helpful for using the EMAC.

ARI

Application Receive Interface

ATI

Application Transmit Interface

CPT

Current Presentation Time

DA

Destination Address

DCB

Data Center Bridging

EMAC CORE

CORE layer inside EMAC which performs the actual Ethernet operations, including interface with PHY through the reduced media interface(s).

EMAC DMA

DMA Controller of EMAC

EMAC MTL

MAC Transaction Layer inside EMAC

EMAC SCB

System Crossbar Interface of EMAC

EOP

End of Packet

EST

Enhancement to Scheduled Traffic

ETS

Enhanced Transmission Selection

FPE

Frame Preemption

ICMP

Internet Message Control Protocol

MAC

Media Access Control

MII

Media Independent Interface

MMC

MAC Management Counter

OST

One Step Time Stamp

PTO

PTP Time Stamp Offload

PTP

Precision Time Protocol

LPI

Low Power Interface

MDIO

Management Data Input/Output

RGMII

Reduced Gigabit Media Independent Interface

RMII

Reduced Media Independent Interface

SA

Source Address

SMI

Station Management Interface that controls PHY through MDIO and MDC signals.

SOP

Start Of Packet

TBS

Time Based Scheduling

TPT

Target Presentation Time

TSN

Time Sensitive Networking

VLAN

Virtual LAN

EMAC Block Diagram and Interfaces

The ***EMAC Simplified Block Diagram*** illustrates the overall functional architecture of the Ethernet MAC peripheral. The EMAC module is comprised of four major layers: EMAC SCB, EMAC DMA, EMAC MTL, and EMAC CORE. Each of these layers (sub blocks) is explained in depth in their respective sections in this chapter.

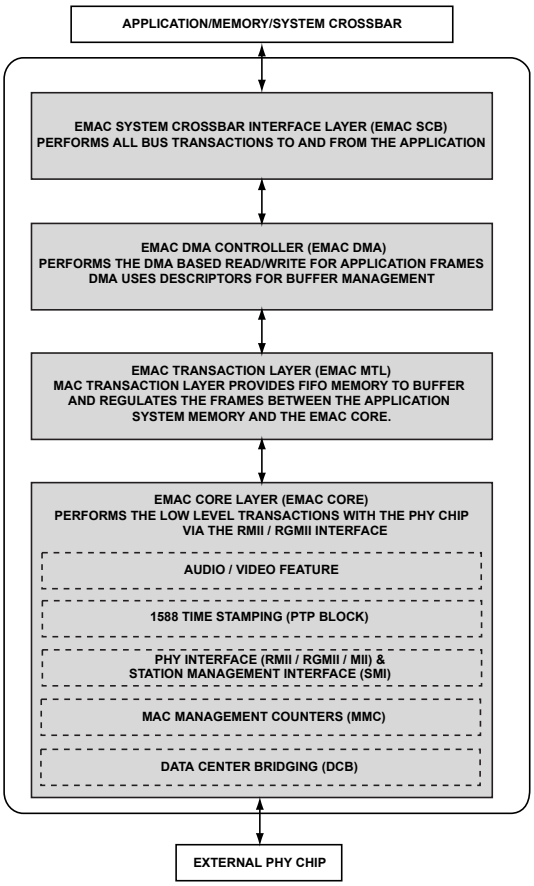

Figure 30-1: EMAC Simplified Block Diagram

A more comprehensive block diagram is shown in the ***EMAC Complete Block Diagram***. It includes most of the important blocks inside the EMAC. The EMAC is connected to processor memory and the system crossbar through

the System Crossbar Bus Interface (SCB) and System Peripheral Bus Interface (SPB). These connections are which are part of the SCB layer. The SPB interface is connected to all modules that require MMR programming.

The DMA controller performs application data transfer frame by frame, through well-defined descriptor structures. A FIFO layer acts as a buffer between the DMA controller and EMAC CORE.

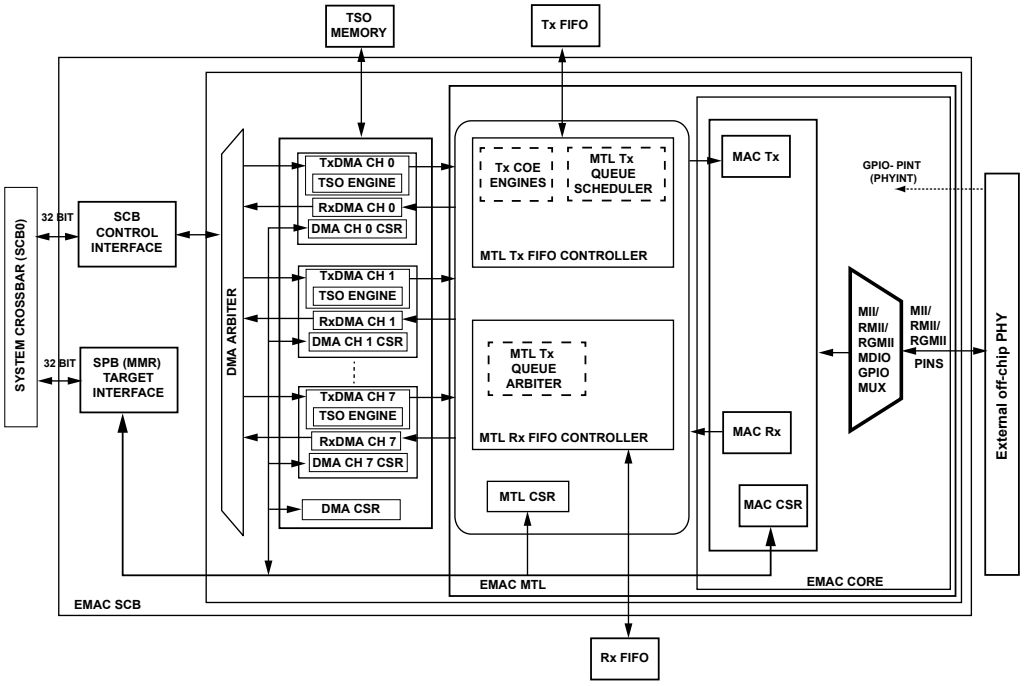

Figure 30-2: EMAC Complete Block Diagram

The *EMAC System Level Block Diagram* shows how the EMAC module interacts with rest of the system inside the processor.

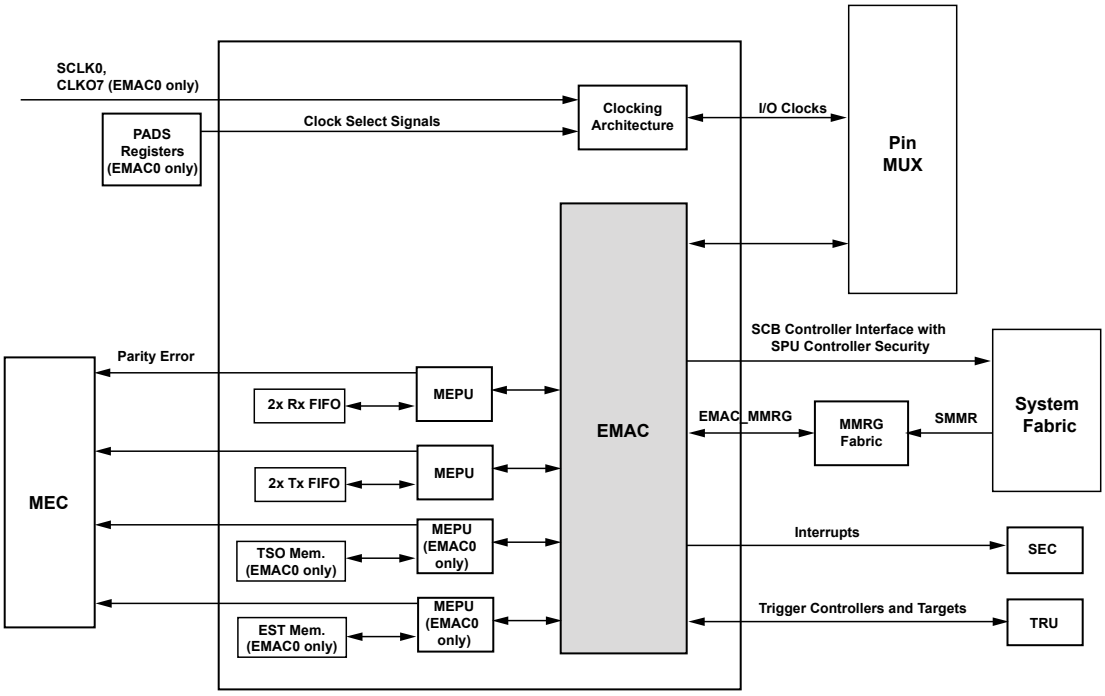

Figure 30-3: EMAC System Level Block Diagram

The *EMAC FIFO/Memory Details* table shows details about various FIFO and memory instances used inside the EMAC module. Each SPRAM/DPRAM stores data along with parity bits generated by MEPU. The parity errors are handled by the Memory Error Controller (MEC) unit.

Table 30-6: EMAC FIFO/Memory Details

EMAC Instance	FIFO/Memory Type	Single (SPRAM)/ Dual Ported (DPRAM)	Runs on	No. of Instances	Size	No. of data bits	No. of parity bits
EMAC0	Rx/Tx FIFOs (Odd/Even)	SPRAM	SCLK0	4	2048x40	35	5
	TSO Memory		SCLK0	1	512x36	32	4
	EST Memory		PTP Clock	1			
EMAC1	Rx FIFO	DPRAM	SCLK0	1	256x40	35	5
	Tx FIFO		SCLK0	1	128x40	35	5

EMAC CORE Sub Blocks

The ***Core Transmit Engine Sub Blocks*** table summarizes the core transmit engine sub blocks and their functions. Refer to the EMAC CORE section for further explanation of each of these sub blocks.

Table 30-7: CORE Transmit Engine Sub Blocks

CORE Transmit Engine Sub Block	Function
Transmit Bus Interface	Interface to the FIFO.
Transmit Packet Controller	Appends Zero-PAD data, if required, for short frames. Appends CRC for frame checksum from the CRC generator.
Transmit Protocol Controller	Generates preamble and SFD, as per 802.3 protocol. Generates jam pattern in half-duplex mode, for collisions. Jabber timeout, for excessively large frames. Flow control for half-duplex mode (back pressure). Generates transmit frame status.
Transmit Scheduler	Maintains the inter-frame gap between two transmitted frames. Follows the truncated binary exponential back-off algorithm for half-duplex mode.
Transmit CRC Generator	Generate CRC for the frame checksum field of the Ethernet frame.
Transmit Flow Control	Receives the pause frame, appends the calculated CRC, and sends the frame to the protocol engine module.
Transmit Checksum Offload Engine	Supports checksum calculation and insertion in the transmit path, for IPV4/TCP/UDP/ICMP packets.
TCP/IP Segmentation Offload (TSO) Engine	Useful in offloading the TCP segmentation functions to the hardware.
UDP/IPv4 Fragment Offload (UFO) Engine	Supports breaking a large UDP packet into smaller multiple packets for transmission.

The ***Core Receive Engine Sub Blocks*** table summarizes the core receive engine sub blocks and their function. Refer to the EMAC CORE section for more information on each of these sub blocks.

Table 30-8: Core Receive Engine Sub Blocks

CORE Receive Engine Sub block	Functionality Overview
Receive Protocol Engine	Strips the incoming preamble and SFD. Checks for correct length or type field. Performs internal loop back, if necessary. Generates receive status. Supports watchdog of received frames. Supports jumbo frames.
Receive CRC Module	Checks for CRC error, by comparing with FCS.

Table 30-8: Core Receive Engine Sub Blocks (Continued)

CORE Receive Engine Sub block	Functionality Overview
Receive Packet Controller Module	Packs incoming 8-bit input stream to 32-bit data internally. Performs frame filtering, for uni-cast, multi-cast, and broadcast frames. Attaches the calculated IP checksum input from checksum offload engine. Updates the receive status to bus interface.
Receive Flow Control Module	Detects the receiving pause frame and pauses the frame transmission for the delay specified within the received pause frame. Works in full duplex mode.
Receive IP Checksum Offload Engine	Calculates IPv4 header checksums and verify against the received IPv4 header checksums. Identifies a TCP, UDP, or ICMP payload in the received IP datagrams.
Receive Bus Interface Unit Module	Interface to the FIFO.
Address Filtering Module	Filters destination and source address based on uni-cast, multi-cast, and broadcast frames. Provides CRC hash filtering.
IPv4 ARP Offload Engine	This feature allows the processing of the IPv4 ARP request packet in the receive path and generating corresponding ARP response packet in the transmit path

EMAC PHY Interface

The EMAC can interface to the PHY through the RMII interface standard. The ***RMII Pins*** table shows the RMII pins available in the EMAC, in terms of their generic names. Refer to the data sheet for exact pin names.

Table 30-9: RMII Pins

Signal No.	Generic Signal Name (IEEE Standards)	RMII Pin Functionality
1.	TXD0	RMII transmit data pin D0 (di-bit lower)
2.	TXD1	RMII transmit data pin D1 (di-bit higher)
3.	RXD0	RMII receive data pin D0 (di-bit lower)
4.	RXD1	RMII receive data pin D1 (di-bit higher)
5.	RMII CLK	RMII common clock (for TX and RX), also called reference clock
6.	TXEN	RMII transmit enable pin (TX valid)
7.	CRS	RMII carrier sense / receive data valid
8.	MDC	Serial management clock driven by EMAC
9.	MDIO	Serial management bidirectional data

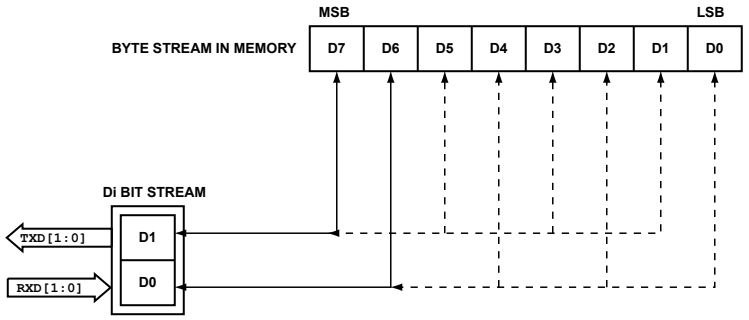

Figure 30-4: RMII Di-bit Data Transfer

RGMII Board Design Recommendations

Use the following guidelines during when performing board design when using the RGMII interface.

MAC to PHY (Transmit)

The Ethernet MAC transmits data to the Ethernet PHY. The Ethernet MAC sends data with tskewT (the timing of TXC at the MAC) that meets the RGMII specification (tskewT = –500 ps to +500 ps skew window for transmitter to drive data). The RGMII specification requires that at the PHY end, tskewR is sampled at 1.0 to 2.6 ns. According to the RGMII standard, clocks must be routed such that an additional trace delay of greater than 1.5 ns and less than 2 ns is added to the associated clock signal.

To meet this standard without adding trace delays, most of the PHYs in the industry already include delay logic that can compensate for this on-board delay. These PHY types can manage a tskewR of ±500 ps (the skew for TXC data sampling seen inside the PHY).

The PHY or the on-board delay must delay the clock signal by 1.5 to 2.0 ns so that tskewR is sampled at 1.0 to 2.6 ns. The ***MAC to PHY Delay Diagram (Transmitting Data)*** figure shows where the delays must occur.

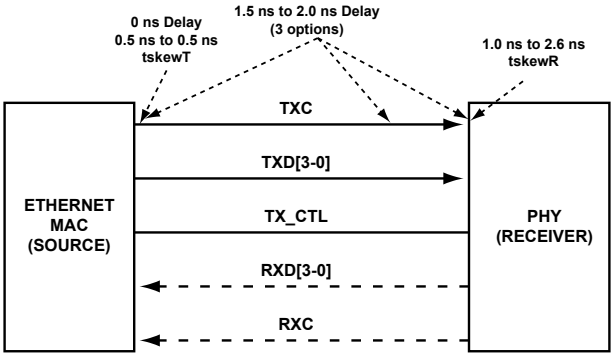

Figure 30-5: MAC to PHY Delay Diagram (Transmitting Data)

PHY to MAC (Receive)

The Ethernet MAC receives data from the Ethernet PHY. Just as in the transmit case, a trace delay of greater than 1.5 ns and less than 2 ns must be added to the associated clock signal, as required by the RGMII specification. Also similar to the transmit case, most of the PHYs in the industry already include delay logic that can compensate for the RXC clock as well.

As shown in the ***MAC to PHY Delay Diagram (Receiving Data)*** figure, a board trace or the PHY can be used to generate the required 1.5–2.0 ns delay to RXC and the 1.0–2.6 ns tskewR.

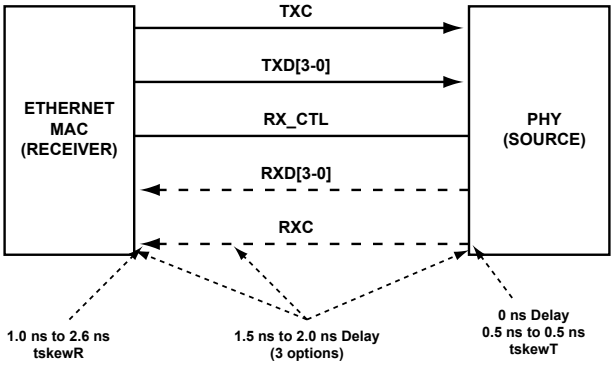

Figure 30-6: MAC to PHY Delay Diagram (Receiving Data)

There following are two options for board design.

- The on-board delay must delay the clock signal by 1.5 to 2.0 ns. In this case, no additional delay must be introduced by the PHY.
- Most of the PHYs in the industry already include a mode that can introduce a delay logic. When this PHY mode is used, then the trace lengths on the board must be matched exactly.

The second option is recommended since it is easier to implement the delay by using the mode in the PHY rather than during the board design. This is the approach followed in the ADI EZ-Kits.

NOTE: Refer to the product specific data sheet for exact processor timing.

For the trace length recommendations for the EMAC signals, see the data sheet.

For the exact requirements as recommended by the RGMII protocol, see the RGMII specification.

Clock Sources

The Ethernet MAC is clocked internally from CLKO7. Check the processor data sheet for the valid frequency range of the appropriate CLKO7 signal for Ethernet operation.

EMAC0 Clock Sources

EMAC0 supports RGMII, RMII and MII interfaces. The external PHY sources a 2.5 MHz or 25 MHz clock (for 10/100 or gigabit Ethernet respectively) to operate the EMAC RXCLK in RGMII mode. The RGMII TXCLK is driven from CLK07 of the CDU (Clock Distribution Unit) and needs to be configured to 125 MHz regardless of the EMAC0 speeds (10/100/1000 Mbit/s). The `EMAC_MAC_CFG.PS` and `EMAC_MAC_CFG.FES` bits are used to divide the clocks down.

The following tables show the clock sources for the RGMII, MII and RMII interfaces.

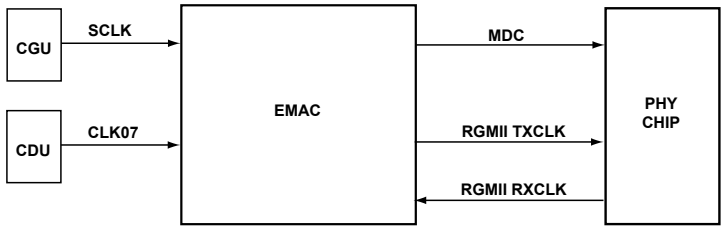

Figure 30-7: EMAC Clock Sources - RGMII PHY Interface

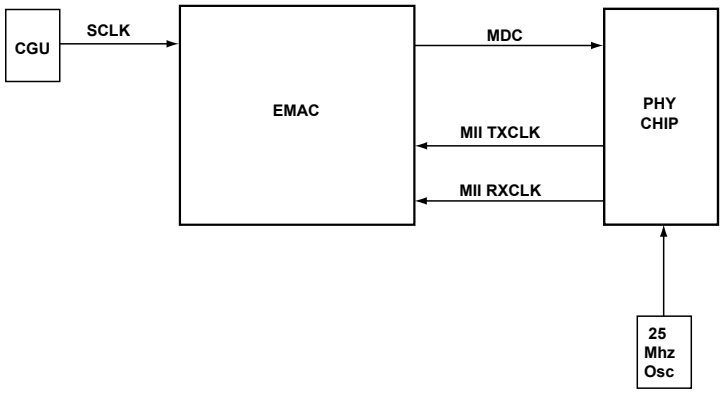

Figure 30-8: EMAC Clock Sources - MII PHY Interface

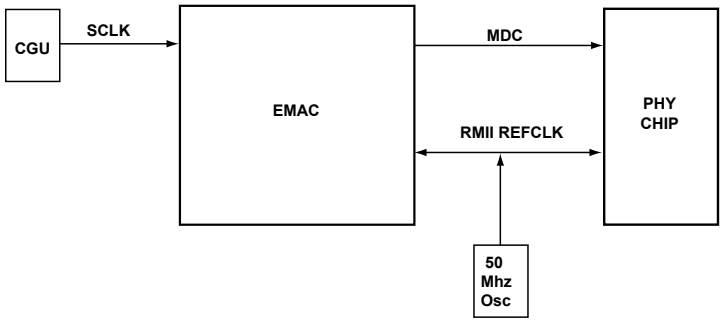

Figure 30-9: EMAC Clock Sources - RMII PHY Interface

EMAC Architectural Concepts

This section explains different architectural concepts relevant to EMAC peripheral, such as EMAC SCB, EMAC DMA, EMAC MTL, EMAC CORE, and others.

EMAC System Crossbar Interface (EMAC SCB)

The EMAC SCB bus interface provides the bus connectivity to support highly effective throughput of data traffic. System bus use is maximized by allowing simultaneous read and write transfers initiated from different DMA channels. The EMAC controller connects directly to the SCB0 crossbar. The following interfaces are available with the design.

- A 32-bit SCB controller interface for reading and writing to and from the application memory.

- A 32-bit SPB target interface for register programming.

Refer to the “System Crossbars (SCB)” chapter for more information on how the crossbar operates. This chapter details only the EMAC-specific information.

Table 30-10: EMAC-SCB Interface Data Transfer Specifications with Crossbar

Specification Term	Comments
1 beat in SCB	SINGLE burst
BLEN4 bursts	4 beats in SCB
BLEN8 bursts	8 beats in SCB
BLEN16 bursts	16 beats in SCB
Bus size	32-bit fixed bus size; equals 1 beat
INCR bursts	Incrementing Bursts
INCR ALIGNED bursts	Incrementing aligned bursts
UNDEF bursts	Undefined burst length
PBL	Programmable Burst Length for DMA

The ***EMAC DMA Read/Write channels with System Crossbar*** figure shows DMA write channel and read channel data paths and their connection to the system crossbar.

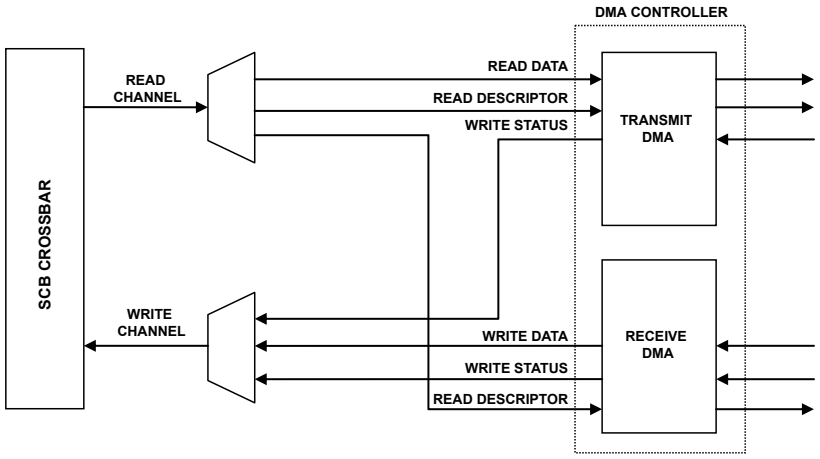

Figure 30-10: EMAC DMA Read/Write channels with System Crossbar

NOTE: Transmit descriptor read and receive descriptor write-back (status update) operations can occur simultaneously. However, transmit descriptor read and write-back operations cannot occur simultaneously. Transmit DMA (or receive DMA) does not initiate the next transfer unless the previous one is complete.

Priority of SCB Requests

The descriptor transfers have higher priority than the data transfers. For example, if there are two bus requests, such as a receive descriptor read and a transmit data read, the receive descriptor read has a higher priority. The next receive data write (after the receive descriptor read) does not depend on the completion of the transmit data-read transfer.

If there are requests for descriptor reads from both DMA channels, they are serviced based on a first-come first-serve. Receive DMA has higher priority if the descriptor-read requests are generated from both the DMA channels in the same clock cycle. Similarly, in the write channel, descriptor writes from DMA have higher priority than the data-write transfers for the receive DMA.

When programs enable the AV or DCB feature, the DMA may contain multiple channels. If the requests are generated from different channels simultaneously in the same clock cycles, the request priority among the channels is: Channel 7 (if present), Channel 6, Channel 5, Channel 4, Channel 3, Channel 2, Channel 1, and Channel 0.

SCB Interface Programming Options

The SCB bus interface supports the following programmable options for the EMAC module. These options are available using the EMAC_DMA_SYSBMODE and EMAC_DMA[n]_CTL registers.

- ***Outstanding transactions.*** The EMAC-SCB supports up to 16 (EMAC0) / 4 (EMAC1) outstanding read/write requests on the SCB bus. Software can control these requests by programming the EMAC_DMA_SYSBMODE.WR_OSR_LMT and EMAC_DMA_SYSBMODE.RD_OSR_LMT bits. Maximum outstanding requests = EMAC_DMA_SYSBMODE.WR_OSR_LMT + 1 or EMAC_DMA_SYSBMODE.RD_OSR_LMT + 1.
- ***Allowed burst sizes.*** The allowed burst sizes are 4 (EMAC_DMA_SYSBMODE.BLEN4), 8 (EMAC_DMA_SYSBMODE.BLEN8), 16 (EMAC_DMA_SYSBMODE.BLEN16) and the SINGLE burst. The EMAC-SCB uses only those burst sizes configured by the program (through the EMAC_DMA_SYSBMODE register) for data transfer through the SCB bus. Data transfers are restricted to the maximum burst size from this list of programmed burst sizes.
- ***Burst splitting and burst selection.*** The EMAC-SCB splits the DMA requests into multiple bursts on the SCB system bus. Splitting is based on DMA count and software controllable burst enable bits (EMAC_DMA_SYSBMODE.FB, BLEN16, BLEN8, BLEN4) as well as burst types (INCR and INCR_ALIGNED). Burst types are also controllable through the software. Burst length select priority is in the sequence: FB, BLEN16, BLEN8, BLEN4
- ***INCR burst type***
  - If the EMAC_DMA_SYSBMODE.FB bit is disabled, the EMAC-SCB always chooses the maximum allowed burst length based on the BLEN16, BLEN8 and BLEN4, bits. When the DMA requests are not multiples of the maximum allowed burst length, the SCB can choose a burst-length of any value less than the maximum enabled. (All lesser burst-length enables are redundant). For example, when length bits are enabled and the DMA requests a burst of 42 beats, the SCB splits it into three bursts of 16, 16 and 10 beats respectively.

- If EMAC_DMA_SYSBMODE.FB is enabled, then the burst length is based on the priority of the enabled bits in the following order: BLEN16, BLEN8 and BLEN4. When the DMA requests a burst transfer, the SCB interface splits the requested bursts into multiple transfers using only the enabled burst lengths. This splitting can occur when the requested burst is not a multiple of the maximum enabled burst. If it cannot choose any of the enabled burst lengths, then it selects the burst length as 1.

For example, the DMA requests a burst transfer of 42 beats, the SCB interface splits it into multiple bursts of size 16, 16, 8, 1 and 1 beats respectively. (In this case, the allowed burst sizes are enabled and the sequence is in decreasing burst sizes).

- ***INCR_ALIGNED burst type.*** When the address-aligned burst-type is enabled (EMAC_DMA_SYSBMODE.AAL), the SCB interface splits the DMA requested bursts. The "INCR Burst Type" section explains burst splitting conditions further. Each burst-size aligns to the least significant bits of the start address. The SCB interface initially generates smaller bursts so that the remaining transfers move with the maximum (enabled) fixed burst lengths.

  For example, in the same setting as explained earlier for the EMAC_DMA_SYSBMODE.FB bit disabled, the DMA requests a burst size of 42 beats at the start address of 0x000003A4 (EMAC_DMA_SYSBMODE.BLEN4, EMAC_DMA_SYSBMODE.BLEN8 and (EMAC_DMA_SYSBMODE.BLEN16 are enabled). The SCB starts the first transfer with size 3 such that the address of the next burst is aligned (0x000003B0) for a burst of 16. Therefore, the sequence of bursts is 3, 16, 16, and 7, respectively.

  When the EMAC_DMA_SYSBMODE.FB bit is enabled, then (having a start address of 0x000003A4 with 42 beats), the sequence of burst transfers is 1, 1, 1, 16, 16, 4, and 3 respectively. The sequence of smaller bursts at the beginning is used to align the address to the next higher enabled burst-lengths programmed in the register.

Burst Reordering and Data Interleaving

The SCB protocol allows reordering of data transfers with different SCB IDs with respect to the sequence of requests. It also allows data interleaving between transfers of different SCB IDs for read channels. In the EMAC, the requests from each internal requester (receive DMA and transmit DMA) are generated with different SCB IDs. Therefore, reordering and data interleaving can be performed as two DMAs operate independently and are allocated different address space on the target memory.

The SCB requester supports reordering and interleaving from the SCB completer on the read channel. Each DMA internally ensures that a read request and a write request is never generated at the same time to the same address (it can occur for only descriptor accesses). The transmit DMA ensures that transmit descriptor reads, transmit data reads, and transmit descriptor write-back requests are generated only after the previous requests are complete. The receive DMA generates only descriptor reads on the read channel with a different ID. Therefore, data reordering and interleaving on the read channel does not cause any problems in the MAC.

Posted Writes

In posted writes, the write channel of SCB requester transfers an OKAY response to the DMA as soon as the last cycle or beat of data is accepted by the SCB interconnect. The SCB requester sends this response without waiting for the response from the target SCB completer on the write response channel.

In non-posted writes, the SCB controller interface transfers the response received from the SCB target channel to the DMA. To transfer the Ethernet data to system memory, the receive DMA always issues posted write requests to the SCB controller interface. This enables pipelining of the data requests without delays.

The SCB controller does not support out-of-order write transfers. However, the receive DMA ensures that the sequence is maintained for descriptor writes, descriptor reads, and data transfers. For writing descriptors (status or time stamp), the DMA always issues the non-posted write requests. This is required because the transfer complete interrupt is generated based on the descriptor writes for which the DMA needs completion response from the memory target. This ensures no race condition between the hardware and the software because the interrupt is generated only after the data and descriptor are written to the target memory.

SCB Bus Transaction Status

The SCB uses the `EMAC_DMA_DBG_STAT0.AXRHSTS` and `EMAC_DMA_DBG_STAT0.AXWHSTS` bits to indicate whether the channel is active or not.

DMA Controller (EMAC DMA)

The DMA has independent transmit and receive engines, and a CSR (control and status register) space. The transmit engine transfers data from the system memory to the FIFO (MTL), whereas the receive engine transfers data from the FIFO (MTL) to the system memory. The DMA engine uses descriptors to efficiently move data from source to destination with minimal processor core intervention. The DMA is designed for packet-oriented data transfers such as packets in Ethernet. The DMA controller can be programmed to interrupt the application for situations such as packet transmit and receive transfer completion, and other normal or error conditions.

The DMA and the application communicate through two internal data structures:

1. Control and status registers (CSR).
2. Descriptor lists and data buffers

The EMAC supports the ring structure for DMA descriptor as shown in the following figure.

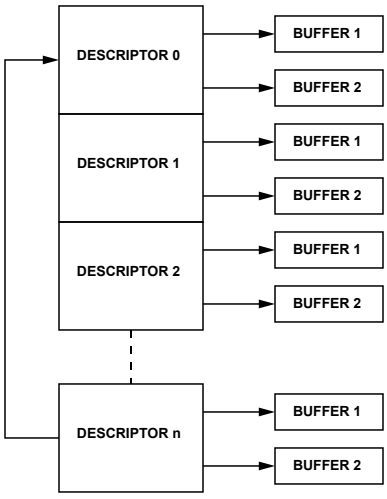

Figure 30-11: Descriptor Ring Structure

In the ring structure, descriptors are separated by the number programmed in the DSL field (32-bit unit) of the EMAC_DMA[n]_CTL registers. The application needs to program the total ring length, that is, the total number of descriptors in ring span in the following registers of a DMA channel:

- Transmit Descriptor Ring Length register (EMAC_DMA[n]_TXDSC_RLEN)
- Receive Descriptor Ring Length register (EMAC_DMA[n]_RXCTL2.RDRL)

The EMAC_DMA[n]_TXDSC_TLPTR or EMAC_DMA[n]_RXDSC_TLPTR register contains the pointer to the descriptor address (N). The base address registers (EMAC_DMA[n]_TXDSC_ADDR and EMAC_DMA[n]_RXDSC_ADDR) and the current descriptor pointer registers (EMAC_DMA[n]_TXDSC_CUR or EMAC_DMA[n]_RXDSC_CUR) determine the address of the current descriptor that the DMA can process. The descriptors up to one location less than the one indicated by the descriptor tail pointer (N – 1) are owned by the DMA. The DMA continues to process the descriptors until the following condition occurs:

```
Current Descriptor Pointer == Descriptor Tail Pointer;
```

The DMA goes into the Suspend mode when this condition occurs. The application must perform a write to the Descriptor Tail pointer register and update the tail pointer so that the following condition is true:

```
Current Descriptor Pointer < Descriptor Tail Pointer;
```

The DMA automatically wraps around the base address when the end of ring is reached, as shown in the *DMA Descriptor Ring* figure.

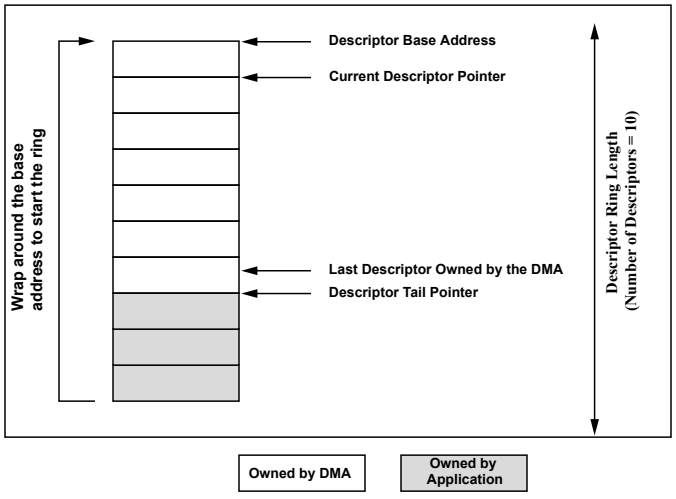

Figure 30-12: DMA Descriptor Ring

For descriptors owned by the application, the OWN bit of DES3 is reset to 0. For descriptors owned by the DMA, the OWN bit is set to 1. If the application has only one descriptor in the beginning, the application sets the last descriptor address (tail pointer) to Descriptor Base Address + 1. The DMA processes the first descriptor and then waits for the application to advance the tail pointer.

The DMA supports up to 8 transmit and 8 receive descriptor lists (or DMA channels). The descriptor lists reside in the physical memory address space of the application. Each descriptor can point to a maximum of two buffers in the

system memory. This enables two buffers to be used, physically addressed, rather than contiguous buffers in memory.

A data buffer resides in the application physical memory space and consists of an entire packet or part of a packet but cannot exceed a single packet. Buffers contain only data. Buffer status is maintained in the descriptor. Data chaining refers to packets that span multiple data buffers. However, a single descriptor cannot span multiple packets. The DMA skips to the data buffer of next packet when EOP (End of Packet) is detected.

For more information on the descriptor, see DMA Descriptors section that describes the descriptor structure and how the DMA accesses the descriptors.

DMA Bursts Using the SCB Interface

The DMA engines attempt to transfer data in maximum size bursts that are programmed using the EMAC_DMA[n]_TXCTL and EMAC_DMA[n]_RXCTL bits. The receive and transmit descriptors are always accessed at the maximum possible burst length to read 16 bytes (limited by PBL or 32). The burst transfers initiated by the DMA can be split into multiple burst transfers as per the SCB protocol requirements and the settings of the EMAC_DMA_SYSBMODE register. The transmit DMA initiates a data transfer only when sufficient space is available in the MTL transmit queue to accommodate either of the following:

- Bytes corresponding to the configured burst (PBL x 4)
- Remaining bytes in the transmit Buffer without EOP
- Number of bytes until EOP

The receive DMA initiates a data transfer in the following conditions:

- Sufficient data is available in MTL receive queue to accommodate the configured burst
- EOP (when it is less than the configured burst length) is detected in the receive queue

The DMA indicates the start address and the number of transfers required to the SCB interface. When the SCB interface is configured for a fixed-length burst, it transfers the data by using the best combination of INCR4, INCR8, or INCR16 and SINGLE transactions. If EOP is reached before the fixed-burst ends on the SCB interface, dummy transfers are performed in-order to complete the fixed-burst. Otherwise, the DMA transfers the data using INCR (undefined length) and SINGLE transactions. When the SCB interface is configured for address-aligned beats, both DMA engines ensure that the first burst transfer initiated by the SCB is less than or equal to the size of the configured PBL. Therefore, all subsequent beats start at an address that is aligned to the configured PBL.

Application Data Buffer Alignment

The transmit and receive data buffers do not have any restrictions on start address alignment. The start address for the buffers aligns to any of the 4 bytes. However, the DMA always initiates write transfers with address aligned to the bus width and dummy data (old data) in the invalid byte lanes. This typically happens during the transfer of the beginning or end of an Ethernet packet. The software driver should discard the dummy bytes based on the start address of the buffer and size of the packet.

Example for Buffer Read

If the transmit buffer address is 0x0002 and 15 bytes must transfer, the DMA reads 5 full words (5 x 32-bit data) from address 0x0000. However, when transferring data to the EMAC transmit FIFO, the extra bytes (the first 2 bytes) are dropped or ignored. Similarly, the last 3 bytes of the last transfer are also ignored. The DMA always transfers a full 32-bit data to the transmit FIFO unless it is the end-of-frame.

Example for Buffer Write

If the receive buffer address is 0x0002 and 15 bytes of a received frame must transfer, the DMA writes 5 full words (5 x 32-bit data) to address 0x0000. However, the first 2 bytes of first transfer and the last 3 bytes of the third transfer have dummy data.

Buffer Size Calculations

The DMA engines do not update the size fields in the transmit and receive descriptors alone. The DMA updates only the status fields (RDES and TDES) of the descriptors. The driver must perform the size calculations.

The transmit DMA transfers the exact number of bytes (indicated by buffer size field of TDES2) towards the MAC. If a descriptor is marked as first (FD bit of TDES3 is set), the DMA marks the first transfer from the buffer as SOP. If a descriptor is marked as last (LD bit of TDES3), the DMA marks the last transfer from that data buffer as EOP to the MTL.

The receive DMA transfers data to a buffer until the buffer is full or the end of packet is received from the MTL. When the FD bit of a descriptor is set, the amount of valid data in a buffer is accurately indicated by the buffer size field (programmed in the `EMAC_DMA[n]_RXCTL` registers) minus the data buffer pointer offset. The offset is zero when the data buffer pointer is aligned to the data bus width (32 bits). If a descriptor is marked as last, the buffer may not be full (as indicated by the buffer size in Bits [14:1] of the `EMAC_DMA[n]_RXCTL` registers). To compute the amount of valid data in this final buffer, the driver must:

- Read the packet length (PL bits of RDES3 [14:0]), and
- Subtract the sum of the buffer sizes of the preceding buffers in this packet

The receive DMA always transfers the start of next packet with a new descriptor.

DMA Transmit Operation

The following sections describe how the transmission process works for direct memory access on the EMAC controller.

Default (Non-OSF) Mode

The following sequence describes the default process for DMA transmit works.

1. The application sets up the transmit descriptor (TDES0–TDES3) and sets the Own bit (TDES3[31]) after setting up the corresponding data buffer(s) with Ethernet packet data.
2. The application advances the descriptor tail pointer offset value of the transmit channel.

3. While in the run state, the DMA runs an arbitration cycle to select the next transmit DMA channel from which the packets requiring transmission should be processed.
4. The DMA fetches the descriptor from the application memory.
5. If the DMA detects one of the following conditions, the transmission from that channel is suspended, the `EMAC_DMA[n]_STAT.TBU` and `EMAC_DMA[n]_STAT.TEB` bits are set, and the transmit engine proceeds to step 11:
   - The descriptor is flagged as owned by the application (TDES3 [31] = 1'b0)
   - The descriptor tail pointer is equal to the current descriptor pointer in ring descriptor list mode
   - An error condition occurs
6. If the acquired descriptor is flagged as owned by DMA (TDES0 [31] = 1#b1), the DMA decodes the transmit data buffer address from the acquired descriptor.
7. The DMA fetches the transmit data from the application memory and transfers the data to the MTL for transmission.
8. If an Ethernet packet is stored over data buffers in multiple descriptors, the DMA closes the intermediate descriptor and fetches the next descriptor. Steps 3 through 7 are repeated until the end of- Ethernet-packet data is transferred to the MTL.
9. When packet transmission is complete, if the IEEE 1588 time stamp feature was enabled for the packet (as indicated in the transmit status), the time stamp value obtained from MTL is written to the transmit descriptor (TDES0 and TDES1) that contains the EOP buffer. The status information is written to this transmit descriptor (TDES3). The application now owns this descriptor because the Own bit is cleared during this step.

   If time stamp feature is not enabled for this packet, the DMA does not alter the contents of TDES0 and TDES1.

   NOTE: By default, the transmit DMA places subsequent request after the current descriptor write request is completed to the descriptor memory. If posted descriptor write is enabled by setting the `EMAC_DMA_MODE.DSPW` bit, the transmit DMA places subsequent request after the current descriptor write request is placed without waiting for its completion, thereby improving the throughput.
10. The transmit interrupt (`EMAC_DMA[n]_STAT.TI`) bits are set after completing transmission of a packet that has interrupt on completion (TDES2[31]) set in its last descriptor. The DMA engine returns to step 3.
11. In the suspend state, the DMA tries to acquire the descriptor again (and thereby return to step 3). A poll demand command is triggered by writing any value to the `EMAC_DMA[n]_TXDSC_TLPTR` registers when it receives a transmit poll demand and the underflow interrupt status bit is cleared. If the application stopped the DMA by clearing transmit interrupt bit, the DMA enters the stop state.

    NOTE: In non-OSF mode, it is not required for the driver/application to extract the packet status and release the descriptor for the packet, even though FD is set to 1. The driver must track the descriptor that has OWN = 0 and LD = 1, as 1; such a descriptor contains the transmission status for the packet.

This indicates that descriptors up to this descriptor can be released for reuse by the driver/application for subsequent packets.

OSF Mode

While in the run state, the transmit process can simultaneously acquire two packets without closing the status descriptor of the first packet (if the EMAC_DMA[n]_TXCTL.OSF bit is set). As the transmit process finishes transferring the first frame, it immediately polls the transmit descriptor list for the second packet. If the second packet is valid, the transmit process transfers this frame before writing the status information of the first packet.

In OSF mode, the run state transmit DMA operates in the following sequence.

1. The DMA operates as described in steps 1–7 of default (non-OSF) mode
2. Without closing the previous last descriptor of the frame, the DMA fetches the next descriptor.
3. If the DMA owns the acquired descriptor, the DMA decodes the transmit buffer address in this descriptor. If the DMA does not own the descriptor, the DMA goes into suspend mode and skips to Step 7.
4. The DMA fetches the transmit packet from the system memory and transfers the packet to the MTL until the EOP data is transferred, closing the intermediate descriptors if this packet is split across multiple descriptors.
5. The DMA waits for the packet transmission status and time stamp of previous packet. When the status is available, the DMA writes the time stamp to TDES0 and TDES1 if such time stamp was captured (as indicated by a status bit). The DMA writes the status, with a cleared Own bit, to the corresponding TDES1, thus closing the descriptor.

   If the time stamp feature is not enabled for the previous packet, the DMA does not alter the contents of TDES0 and TDES1.
6. If enabled, the transmit interrupt is set; the DMA fetches the next descriptor, and then proceeds to Step 3 (when status is normal). If the previous transmission status shows an underflow error, the DMA goes into suspend mode (Step 7).
7. In suspend mode, if a pending status and time stamp are received from the MTL, the DMA:
   - Writes the time stamp (if enabled for the current packet) to TDES0 and TDES1
   - Writes the status to the corresponding TDES1
   - Sets relevant interrupts and returns to Suspend mode

   If no status is pending and the application stopped the DMA by clearing the EMAC_DMA[n]_TXCTL.ST bits, the DMA enters the Stop state.
8. The DMA can exit suspend mode and enter the run state (goes to step 1 or step 2 depending on pending status) only after receiving a transmit poll demand in transmit descriptor tail pointer register of the corresponding channel.

NOTE: The DMA fetches the next descriptor before closing the current descriptor. Therefore, the descriptor ring length must be more than 2. A minimum descriptor length of 4 is recommended.

In OSF mode, all except the last descriptor is closed immediately. The last descriptor is closed after the packet is transmitted on the line. Therefore, to minimize the complexity, the transmission status and only the required control bits are updated in the pending last descriptor of the previous packet.

Transmit Packet Processing

The transmit DMA engine expects that the data buffers contain complete Ethernet packets, excluding the preamble, pad bytes, and FCS fields. The DA, SA, and type/length fields contain valid data. When the transmit descriptor indicates that the MAC must disable CRC or PAD insertion, the buffer must have complete Ethernet packets (excluding preamble), including the CRC bytes.

Packets can be data-chained and can span several buffers. Packets must be delimited by the first descriptor (TDES3[29]) and the last descriptor (TDES3[28]). As transmission starts, the first descriptor must have TDES3[29] set. When this occurs, the packet data is transferred from the application buffer to the MTL transmit queue. Concurrently, iwhen the current packet has the last descriptor (TDES3[28]) clear, the transmit process attempts to acquire the next descriptor. The transmit process expects this descriptor to have TDES3[29] clear. When TDES3[28] is clear, it indicates an intermediary buffer. When TDES3[28] is set, it indicates the last buffer of the packet.

After the last buffer of the packet has been transmitted, the DMA writes back the final status information to the transmit descriptor 3 (TDES3) word of the descriptor that has the last descriptor bit set in transmit descriptor 3 (TDES3[28]). At this time, if interrupt on completion (TDES2[31]) is set, the `EMAC_DMA[n]_STAT.TI` bit is set, the next descriptor is fetched, and the process repeats. The actual packet transmission begins after either of the following:

- The MTL transmit queue has reached a programmable transmit threshold (programmed in the `EMAC_TQ0_OPMODE.TTC` bit field)
- A full packet is contained in the FIFO

Programs can also use the store-and-forward mode (`EMAC_TQ0_OPMODE.TSF` bit is set). In this mode, descriptors are released (OWN bit in TDES0[31] clears) when the DMA finishes transferring the packet.

NOTE: To ensure proper transmission of a packet and the next packet, specify a non-zero buffer size for the transmit descriptor that has the last descriptor (TDES3[28]) set.

Transmit Polling Suspended

Either of the following conditions suspends transmit polling:

- The DMA detects a descriptor owned by the application (TDES3[31] = 0). To resume, the driver must give descriptor ownership to the DMA and then issue a poll demand command by writing the `EMAC_DMA[n]_TXDSC_TLPTR` registers. If the DMA goes into the SUSPEND state because of this condition, the `EMAC_DMA[n]_STAT.NIS` and `EMAC_DMA[n]_STAT.TBU` bits are set.
- A packet transmission is aborted when a transmit error is detected because of underflow.

  The appropriate transmit descriptor 3 (TDES3) bit is set. When this condition occurs, the following bits are set and the information is written to transmit descriptor 0, causing the suspension:

- EMAC_DMA[n]_STAT.AIS
- Transmit Underflow bit of corresponding queue (EMAC_Q0_INT_CTLSTAT.TXUNFIS bits)

In all conditions, the position in the transmit list is retained. The retained position is that of the descriptor following the last descriptor closed by the DMA. The driver must explicitly issue a transmit poll demand command after rectifying the suspension cause.

DMA Transmit Channel Arbitration

An arbiter provides access to multiple DMAs trying to access the Bus Interface Unit (BIU).

When there is a request in the transmit DMA, the DMA arbiter checks the type of the request: packet buffer fetch or descriptor fetch request. The descriptor fetch requests have higher priority than the buffer requests. Therefore, when there is a descriptor fetch request, the DMA arbiter acknowledges the DMA channel that is requesting for a descriptor fetch. If there is no descriptor fetch request, the arbiter looks for packet buffer fetch requests.

The DMA arbiter acknowledges the descriptor fetch request of one DMA channel at a time. Descriptor fetch requests are granted using a fixed priority with the higher channel having higher priority (channel 1 having priority over channel 0, channel 2 having priority over channel 1 and so on). For packet buffer fetches, the DMA arbiter uses the programmed channel weight and priority to decide which channel to acknowledge. The DMA arbiter performs a burst-by-burst arbitration based on one of the following algorithms, which can be selected by programming the EMAC_DMA_MODE.TAA bit field.

- Weighted Strict Priority (WSP). In WSP arbitration mode, the arbiter first processes channel 7 (or the last selected channel) followed by channel 6, channel 5, and so on. If a channel does not have a frame to transmit, the weight of the channel is reassigned to channel 7 (or the last selected channel). If channel 7 has no frames to transmit, the remaining weight is assigned to channel 6 and so on.
- Weighted Round Robin (WRR). In WRR arbitration mode, the arbiter first selects the channel with the highest weight programmed, and then the channel with next highest weight, and so on. If any channel does not have a frame to transmit, the weight of that channel is equally distributed to all channels that have frames to transmit. The weight of the channel is programmed in the EMAC_DMA[n]_TXCTL.TCW (transmit channel weight) bit fields.
- Fixed priority (FP). In fixed priority mode, channel 0 has the lowest priority and the last selected channel has the highest priority. The weight programmed in the TCW bits of a channel is ignored. In WSP or WRR arbitration, the channel weight corresponds to the number of DMA burst transfers for which the DMA arbiter grants the bus to a channel. When a channel completes all the DMA burst transfers, the arbiter grants the bus to the next channel.

In WSP or WRR arbitration, the channel weight corresponds to the number of DMA burst transfers for which the DMA arbiter grants the bus to a channel. When a channel completes all the DMA burst transfers, the arbiter grants the bus to the next channel.

DMA Receive Operation

In the receive path, the DMA reads a packet from the MTL receive queue and writes it to the packet data buffers of the corresponding DMA channel. The ARI data at the start of the frame indicates the channel number to which the current frame must be written. If only one DMA channel is selected, this information is not provided.

The following list shows the reception sequence for the receive DMA engine:

1. The application sets up the receive descriptors (RDES0-RDES3) and the OWN bit (RDES3[31]). The application must set the correct value in the EMAC_DMA[n]_RXDSC_TLPTR register.
2. When the EMAC_DMA[n]_RXCTL.SR bit is set, the DMA enters the run state. The DMA looks for free descriptors based on the EMAC_DMA[n]_RXDSC_ADDR and EMAC_DMA[n]_RXDSC_TLPTR register values. If there are no free descriptors, the DMA channel enters the suspend state and goes to step 11.
3. The DMA fetches the next available descriptor in the ring and decodes the receive data buffer address from the acquired descriptors.
4. If IEEE 1588 time stamping is enabled and the time stamp is available for the previous packet, the DMA writes the time stamp (if available) to the RDES0 and RDES1 registers of the current descriptor and sets the CTXT bit field (RDES3[30]).
5. The DMA processes the incoming packets and places these in the data buffers of acquired descriptor.
6. If the current packet transfer is not complete, the DMA closes the current descriptor as intermediate and goes to step 10.
7. The DMA takes the status of the receive frame from the MTL and writes the status word to current descriptor with the OWN bit cleared and the last descriptor bit set.
8. The DMA writes the frame length to RDES3 and VLAN tag to RDES0. The DMA also writes the MAC control frame opcode, OAM control frame code, and extended status information (if available) to RDES1 of the last descriptor.
9. If the IEEE 1588 time stamp feature is enabled, the DMA stores the time stamp (if available). The DMA writes the context descriptor after the last descriptor for the current packet (in the next available descriptor).
10. If more descriptors are available in the receive DMA descriptor ring, go to step 3; otherwise, go to the suspend state (step 11).
11. The receive DMA exits the suspend state when a receive poll demand is given, and the application advances the receive tail pointer register of a channel.

The engine proceeds to step 2 and refetches the next descriptor.

Receive Descriptor Acquisition

The receive engine always attempts to acquire an extra descriptor in anticipation of an incoming packet. descriptor acquisition is attempted if any of the following conditions is satisfied:

- The EMAC_DMA[n]_RXCTL.SR bit is set immediately after being placed in the run state.

- The EMAC_DMA[n]_RXDSC_TLPTR register value is ahead of the current descriptor acquired by the receive DMA.
- The controller has completed packet reception, but the current receive descriptor is not yet closed.
- A receive poll demand is issued (update of the tail pointer register).

Receive Packet Processing

The sequence for processing a receive packet is as follows:

1. The MAC transfers the received packets to the MTL memory only if the packet passes the address filter. If the packet fails the address filtering, it is dropped in the MAC block (unless the EMAC_MACPKT_FILT.RA bit is set).
2. If the packet size is greater than or equal to the configurable threshold bytes set for the receive queue of the MTL, or when the complete packet is written to the queue in the store-and-forward mode, the MTL block requests the DMA block to begin transferring the packet data to the receive buffer pointed to by the current descriptor.

   Because of collision or premature termination, packets smaller than 64 bytes are removed from the MTL receive queue.
3. When the DMA application interface (SCB or MDC) is ready, it transfers the data and sets the following:
   - If the packet fits in a single descriptor, the DMA sets both last descriptor (RDES3[28]) and first descriptor (RDES3[29]).
   - If the packets fits into more than one descriptor, the DMA sets the first descriptor (RDES3[29]) to delimit the packet.
4. The DMA releases the descriptors by resetting the OWN (RDES3[31]) bit to 1'b0, either because the receive is full or the last segment of the packet is transferred to the receive buffer. The received packet's status is updated in the last descriptor.
5. If the interrupt enabled on completion (RDES3[30]) bit is set in any of the descriptors between the first and last descriptor of the packet and the EMAC_DMA[n]_IEN.RIE bit is set, the DMA sets the EMAC_DMA[n]_STAT.RI bit.

The same process repeats unless the DMA encounters a descriptor flagged as being owned by the application or when there are no more descriptors in the ring. When the DMA finds a descriptor owned by the application and if the EMAC_DMA[n]_IEN.RBUE bits are set, the receive process sets the EMAC_DMA[n]_STAT.RBU bits and then enters the suspend state. The position in the receive list is retained.

DMA Error Response

For any data transfer initiated by a DMA channel, if the completer replies with an error response, the DMA stops all operations and updates the error bits and the EMAC_DMA[n]_STAT.FBE bits. The application can either perform a reset to EMAC or re-initialize the DMA descriptor list and start again. The rest of the DMA channels are not affected by such errors.

DMA Descriptors

The DMA in the EMAC transfers data based on a linked list of descriptors. The descriptor addresses must be aligned to the 32-bit bus width. The application creates the descriptors in the system memory. The EMAC supports the following two types of descriptors.

- Normal Descriptor: Normal descriptors are used for packet data and to provide control information applicable to the packets to be transmitted.
- Context Descriptor: Context descriptors are used to provide control information applicable to the packet to be transmitted. Each normal descriptor contains two buffers and two address pointers. These buffers enable the EMAC to be compatible with various types of memory management schemes.

NOTE: There is no limit for the number of descriptors that can be used for a single packet.

For basic details that describe the descriptor ring structure, see DMA Controller (EMAC DMA).

Transmit Descriptor

The DMA in EMAC requires at least one descriptor for a transmit packet. In addition to two buffers, two byte-count buffers, and two address pointers, the transmit descriptor has control fields which can be used to control the MAC operation on per-transmit packet basis. The transmit normal descriptor has two formats: read format and write-back format.

Transmit Normal Descriptor (Read Format)

The *Transmit Normal Descriptor (Read Format)* figure shows the read format for a transmit normal descriptor. The following tables describe the read format for the transmit normal descriptors: TDES0, TDES1, TDES2, and TDES3.

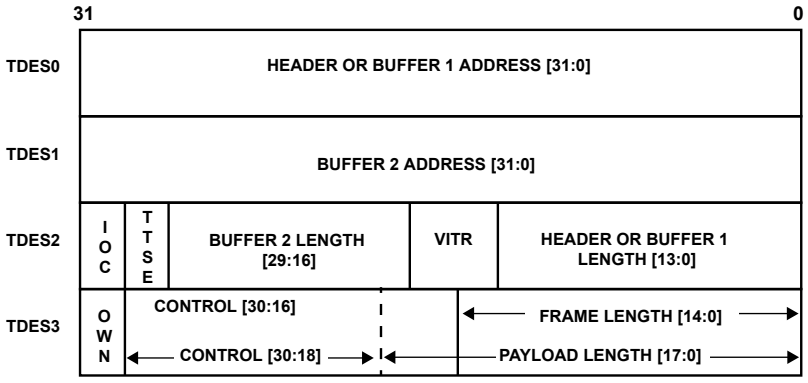

Figure 30-13: Transmit Normal Descriptor (Read Format)

Table 30-11: TDES0 Normal Descriptor (Read Format)

Bit	Name	Description
31–0	BUF1AP	Buffer 1 Address Pointer or TSO Header Address Pointer. These bits indicate the physical address of buffer 1. These bits also indicate the TSO header address pointer when the following bits are set: • TSE bit of TDES3

Table 30-11: TDES0 Normal Descriptor (Read Format) (Continued)

Bit	Name	Description
		• FD bit of TDES3

Table 30-12: TDES1 Normal Descriptor (Read Format)

Bit	Name	Description
31–0	BUF2AP	Buffer 2 or Buffer 1 Address Pointer. These bits indicate the physical address of buffer 2 when a descriptor ring structure is used. There is no limitation for the buffer address alignment.

Table 30-13: TDES2 Normal Descriptor (Read Format)

Bit	Name	Description
31	IOC	Interrupt on Completion. This bit controls the setting of TI and ETI status bits in the EMAC_DMA[n]_STAT register. When ETIC = 1 and TDES2[LD] = 0, this bit sets the ETI bit. When TDES3[LD] = 1, this bit sets the TI status bit.
30	TTSE/TMWD	Transmit Time stamp Enable or External TSO Memory Write Enable. This bit enables the IEEE1588 time stamping for the transmit packet referenced by the descriptor, if the TSE bit is not set. If the TSE bit is set and external TSO memory is enabled, setting this bit disables external TSO memory writing for this packet.
29:16	B2L	Buffer 2 Length. The driver sets this field. When set, this field indicates buffer 2 length.
15:14	VTIR	VLAN Tag Insertion or Replacement. These bits request the MAC to perform VLAN tagging or untagging before transmitting the packets. The application must set the CRC pad control bits appropriately when VLAN tag insertion, Replacement, or Deletion is enabled for the packet. The following list describes the values of these bits: • 00 = Do not add a VLAN tag • 01 = Remove the VLAN tag from the packets before transmission. This option should be used only with the VLAN packets. • 10 = Insert a VLAN tag with the tag value programmed in the MAC_VLAN_Incl register or context descriptor • 11 = Replace the VLAN tag in packets with the tag value programmed in the MAC_VLAN_Incl register or context descriptor. This option should be used only with the VLAN packets. These bits are valid when the enable SA and VLAN insertion on transmit option is selected while configuring the core.
13:0	HL or B1L	Header Length or Buffer 1 Length. For header length only bits [9:0] are taken. The size 13:0 is applicable only when interpreting buffer 1 length. If the TCP segmentation offload feature is enabled through the TSE bit of TDES3, this field is equal to the header length. When the TSE bit is set in TDES3, the header length includes the length in bytes from the Ethernet source address until the end of the TCP header. The maximum header length supported for the TSO feature is 1023 bytes. If the TCP segmentation offload feature is not enabled, this field is equal to buffer 1 length

Table 30-14: TDES3 Normal Descriptor (Read Format)

Bit	Name	Description
31	OWN	Ownership. When set, this bit indicates that the DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit either when it completes the transfer of data given in the associated buffers.
30	CTXT	Context Type. This bit should be set to 1'b0 for normal descriptor.
29	FD	First Descriptor. When set, this bit indicates that the buffer contains the first segment of a packet.
28	LD	Last Descriptor. When this bit is set, it indicates that the buffer contains the last segment of the packet. When this bit is set, the B1L or B2L field should have a non-zero value.
27:26	CPC	Disable CRC. When this bit is set, the EMAC does not append a cyclic redundancy check (CRC) to the end of the transmitted frame. • 00 = CRC and Pad Insertion. The MAC appends the cyclic redundancy check (CRC) at the end of the transmitted packet of length greater than or equal to 60 bytes. The MAC automatically appends padding and CRC to a packet with length less than 60 bytes. • 01 = CRC Insertion (Disable Pad Insertion). The MAC appends the CRC at the end of the transmitted packet but it does not append padding. The application should ensure that the padding bytes are present in the packet being transferred from the transmit buffer, that is, the packet being transferred from the transmit buffer is of length greater than or equal to 60 bytes. • 10 = Disable CRC Insertion. The MAC does not append the CRC at the end of the transmitted packet. The application should ensure that the padding and CRC bytes are present in the packet being transferred from the transmit buffer. • 11 = CRC Replacement. The MAC replaces the last four bytes of the transmitted packet with recalculated CRC bytes. The application should ensure that the padding and CRC bytes are present in the packet being transferred from the transmit buffer. This field is valid only for the first descriptor. Note: When the TSE bit is set, the MAC ignores this field because the CRC and pad insertion is always done for segmentation.

Table 30-14: TDES3 Normal Descriptor (Read Format) (Continued)

Bit	Name	Description
25:23	SAIC	SA Insertion Control. When set, these bits request the MAC to add or replace the source address field in the Ethernet packet with the value given in the MAC address 0 register. The application must set the CRC pad control bits appropriately when SA insertion control is enabled for the packet. Bit 25 specifies the MAC address register (1 or 0) value that is used for source address insertion or replacement. Bits [24:23] encodings are as follows • 00 = Do not include the source address • 01 = Include or insert the source address. For reliable transmission, the application must provide frames without source addresses. • 10 = Replace the source address. For reliable transmission, the application must provide frames without source addresses. • 11 = Reserved These bits are valid when the Enable SA and VLAN Insertion on Tx option is selected while configuring the core and when the First descriptor (FD) bit (TDES3 [29]) is set.
22:19	SLOTNUM or THL	SLOTNUM: Slot Number Control bits in AV mode. These bits indicate the slot interval in which the data should be fetched from the corresponding buffers addressed by TDES0 or TDES1. When the transmit descriptor is fetched, the DMA compares the slot number value in this field with the slot interval maintained in the RSN field in the `EMAC_DMA[n]_SFN_CTLSTAT` register. Fetches the data from the buffers only if a value matches. These bits are valid only for the AV channels. THL: TCP/UDP Header Length. If the TSE bit is set, this field contains the length of the TCP/UDP header. The minimum value of this field must be 5 for TCP header. The value must be equal to 2 for UDP header. This field is valid only for the first descriptor
18	TSE	TCP Segmentation Enable. When this bit is set, the DMA performs the TCP/UDP segmentation or UDP fragmentation for a packet depending on the TSE_MODE[1:0] bit of the `EMAC_DMA[n]_TXCTL` register. This bit is valid only if the FD bit is set.
17:16	CIC/TPL	Checksum Insertion Control or TCP Payload Length. These bits control the checksum calculation and insertion. Bit encodings are as follows: • 00 = Checksum insertion disabled. • 01 = Only IP header checksum calculation and insertion are enabled • 10 = IP header checksum and payload checksum calculation and insertion are enabled, but pseudo-header checksum is not calculated in hardware • 11 = IP header checksum and payload checksum calculation and insertion are enabled, and pseudo-header checksum is calculated in hardware When the TSE bit is set, this field contains the upper bits [17:16] of the TCP payload (or IP payload for UDP fragmentation). This allows the TCP/UDP packet length field to be spanned across TDES3[17:0] to provide 256 KB packet length support. This field is valid only for the first descriptor

Table 30-14: TDES3 Normal Descriptor (Read Format) (Continued)

Bit	Name	Description
15	TPL	Reserved or TCP Payload Length. When the TSE bit is reset, this bit is reserved. When the TSE bit is set, this is bit 15 of the TCP payload length [17:0]. This field is valid only when the enable TCP segmentation offloading for TCP/IP packets option is selected while configuring the core
14:0	FL/TPL	Frame Length or TCP Payload Length. This field is equal to the length of the packet to be transmitted in bytes. When the TSE bit is not set, this field is equal to the total length of the packet to be transmitted: `Ethernet Header Length + TCP /IP Header Length – Preamble Length – SFD Length + Ethernet Payload Length` When the TSE bit is set, this field is equal to the lower 15 bits of the TCP payload length in case of segmentation and IP payload in case of UDP fragmentation. In case of segmentation, this length does not include Ethernet header or TCP/UDP/IP header length. In case of fragmentation, this length does not include Ethernet header and IP header. When DWRR/WFQ algorithm is NOT enabled, value written into this field is not used when TSE = 0.

Transmit Normal Descriptor (Write-Back Format)

The write-back format of the transmit descriptor includes time stamp low, time stamp high, OWN, and status bits.

The write-back format is applicable only for the last descriptor of the corresponding packet. The LD bit (TDES3[28]) is set in the descriptor where the DMA writes back the status and time stamp information for the corresponding transmit packet.

The *Transmit Normal Descriptor (Write-Back Format)* figure illustrates the write-back format of the transmit descriptor.

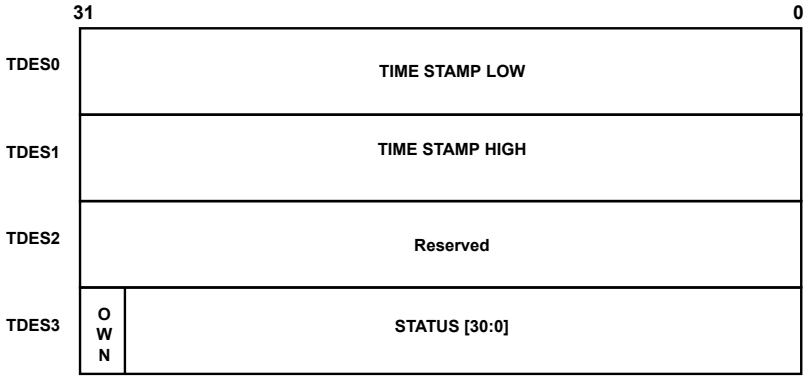

Figure 30-14: Transmit Normal Descriptor (Write-Back Format)

TDES0 Normal Descriptor (Write-Back Format)

As described in the following table, this format is only applicable to the last descriptor of a packet.

Table 30-15: TDES0 Normal Descriptor (Write-Back Format)

Bit	Name	Description
31–0	TTSL	Transmit Packet Time Stamp Low. The DMA updates this field with least significant 32 bits of the time stamp captured for the corresponding transmit packet. The DMA writes the time stamp only if TTSE bit of TDES2 is set in the first descriptor of the packet. This field has the time stamp only if the last segment bit (LS) in the descriptor is set and the time stamp status (TTSS) bit is set.

TDES1 Normal Descriptor (Write-Back Format)

As described in the following table, this format is only applicable to the last descriptor of a packet.

Table 30-16: TDES1 Normal Descriptor (Write-Back Format)

Bit	Name	Description
31–0	TTSH	Transmit Packet Time Stamp High. The DMA updates this field with the most significant 32 bits of the time stamp captured for corresponding transmit packet. The DMA writes the time stamp only if the TTSE bit of TDES2 is set in the first descriptor of the packet. This field has the time stamp only if the last segment bit (LS) in the descriptor is set and time stamp status (TTSS) bit is set.

TDES2 Normal Descriptor (Write-Back Format)

This format is only applicable to the last descriptor of a packet.

Table 30-17: TDES2 Normal Descriptor (Write-Back Format)

Bit	Name
31–0	Reserved

TDES3 Normal Descriptor (Write-Back Format)

This format is applicable only to the last descriptor of a packet.

Table 30-18: TDES3 Normal Descriptor (Write-Back Format)

Bit	Name	Description
31	OWN	Ownership. When this bit is set, it indicates that the EMAC DMA owns the descriptor. The DMA clears this bit when it completes the packet transmission. After the write-back is complete, this bit is set to 0.
30	CTXT	Context Type. This bit should be cleared (=0) for normal descriptor.
29	FD	First Descriptor. When set, this bit indicates that the buffer contains the first segment of a packet.
28	LD	Last Descriptor. This bit is set (=1) for the last descriptor of a packet. The DMA writes the status fields only in the last descriptor of the packet.

Table 30-18: TDES3 Normal Descriptor (Write-Back Format) (Continued)

Bit	Name	Description
27–24	Reserved	
23	DE	Descriptor Error. When this bit is set, it indicates that the descriptor content is incorrect. The DMA sets this bit during write-back while closing the descriptor. Descriptor errors include: • Incorrect sequence from the context descriptor. For example, a location after the first descriptor for a packet. • All 1s • CTXT is set to 1 and the LD or FD bits are set to 1. **NOTE:** When a descriptor error occurs due to all 1s or CTXT, LD, and FD bits set to 1, the transmit DMA closes the transmit descriptor with DE and LD bits set to 1. When the IOC bit in the TDES2 register of the corresponding first descriptor is set to 1, the transmit DMA sets the TI bit in the `EMAC_DMA[n]_STAT` register. **NOTE:** Based on the CTXT, LD, and FD bits of the transmit descriptor, the subsequent descriptor might be considered as the first descriptor (even if the FD bit is not set) and partial packet is sent.
22–18	Reserved	
17	TTSS	Transmit Time Stamp Status. This status bit indicates that a time stamp has been captured for the corresponding transmit packet. When this bit is set, the TDES0 and TDES1 registers have time stamp values that were captured for the transmit packet. This field is valid only when the last segment control bit (TDES3 [28]) in a descriptor is set. This bit is valid only when the IEEE1588 time stamping feature is enabled; otherwise, it is reserved.
16	EUE	ECC Uncorrectable Error Status. Indicates an ECC uncorrectable error in the TSO memory. **NOTE:** An uncorrectable error in transmit FIFO memory is reported when the packet flushed bit (bit 13, FF) = 1. This is because all such packets are flushed by the EMAC module.
15	ES	Error Summary. Indicates the logical OR of the following bits: TDES3[0]: IP Header Error DES3[14]: Jabber Timeout TDES3[13]: Packet Flush TDES3[12]: Payload Checksum Error TDES3[11]: Loss of Carrier TDES3[10]: No Carrier TDES3[9]: Late Collision TDES3[8]: Excessive Collision TDES3[3]: Excessive Deferral TDES3[2]: Underflow Error This bit is also set when the EUE (bit 16) is set.

Table 30-18: TDES3 Normal Descriptor (Write-Back Format) (Continued)

Bit	Name	Description
14	JT	Jabber Timeout. This bit indicates that the MAC transmitter has experienced a jabber timeout. This bit is set only when the JD bit of the EMAC_MAC_CFG register is not set.
13	FF	Packet Flushed. This bit indicates that the DMA or MTL flushed the packet because of a software flush command given by the CPU.
12	PCE	Payload Checksum Error. This bit indicates that the checksum offload engine had a failure and did not insert any checksum into the encapsulated TCP, UDP, or ICMP payload. This failure is caused by: • insufficient bytes in the payload, as indicated by the payload length field of the IP header. • the MTL starts to forward the packet to the MAC transmitter in store-and-forward mode without the checksum being calculated. This error condition only occurs when the transmit FIFO depth is less than the length of the Ethernet packet being transmitted to avoid deadlock. In this case the MTL starts forwarding the packet when the FIFO is full, even in store-and-forward mode. • a bus error is detected during packet transfer. When the full checksum offload engine is not enabled, this bit is reserved.
11	LoC	Loss of Carrier. This bit indicates that a loss of carrier occurred during packet transmission (that is, the gmii_crs_i signal was inactive for one or more transmit clock periods during packet transmission). This is valid only for the packets transmitted without collision and when the MAC operates in the half-duplex mode.
10	NC	No Carrier. This bit indicates that the carrier sense signal form the PHY was not asserted during transmission.
9	LC	Late Collision. This bit indicates that packet transmission was terminated because a collision occurred after the collision window (64 byte times including preamble in MII mode and 512 byte times including preamble and carrier extension in GMII mode). This bit is not valid if underflow error is set.
8	EC	Excessive Collision. This bit indicates that the transmission was terminated after 16 successive collisions while attempting to transmit the current packet. If the DR bit is set in the MAC_Configuration register, this bit is set after first collision and the transmission of the packet is terminated.
7–4	CC	Collision Count. This 4-bit counter value indicates the number of collisions that occurred before the packet was transmitted. The count is not valid when the EC bit is set.
3	ED	Excessive Deferral. This bit indicates that the transmission ended because of excessive deferral of over 24,288 bit times (155,680 bits times in 1000 Mbps mode or jumbo packet enabled mode) if the DC bit is set in the MAC_Configuration register. When TBS is enabled in full duplex mode and this bit is set, it indicates that the frame has been dropped after the expiry time has reached.

Table 30-18: TDES3 Normal Descriptor (Write-Back Format) (Continued)

Bit	Name	Description
2	UF	Underflow Error. This bit indicates that the MAC terminated the packet because the data arrived late from the system memory. The underflow error can occur because of either of the following conditions: • The DMA encountered an empty transmit buffer while transmitting the packet • The application filled the MTL transmit FIFO slower than the MAC transmit rate The transmission process enters the suspended state and sets the underflow bit corresponding to a queue in the EMAC_MTL_ISTAT register.
1	DB	Deferred Bit. This bit indicates that the MAC deferred before transmitting because of presence of carrier. This bit is valid only in the half-duplex mode.
0	IHE	IP Header Error. When this bit is set, it indicates that the checksum offload engine detected an IP header error. This bit is valid only when transmit checksum offload is enabled. Otherwise, it is reserved. If the COE detects an IP header error, it still inserts an IPv4 header checksum if the Ethernet type field indicates an IPv4 payload. In full duplex mode, when EST/Qbv is enabled and this bit is set, it indicates the frame drop status due to frame size error or schedule error.

Transmit Context Descriptor

The context descriptor is used to provide the time stamps for one-step time stamp correction, VLAN tag ID for VLAN insertion feature.

The transmit context descriptor can be provided any time before a packet descriptor. The context is valid for the current packet and subsequent packets. The context descriptor is used to provide the time stamps for one-step time stamp correction and VLAN Tag ID for VLAN insertion feature. Write back is done on a context descriptor only to reset the OWN bit.

NOTE: The VLAN Tag IDs and MSS values, provided by the application in a context descriptor with their corresponding valid bits set, are stored internally by the DMA. When the outer or inner VLAN tag is provided with the valid bit set, the DMA always passes the last valid VLAN tag to the MTL. The application cannot invalidate the valid VLAN tag stored by the DMA. The VLAN tag is inserted or replaced based on the control inputs provided for the packet.

The inner VLAN tag control input is used only for the next packet that immediately follows the context descriptor. The application must provide a context descriptor before the normal descriptor of each packet for which the DMA should use the inner VLAN Tag control input.

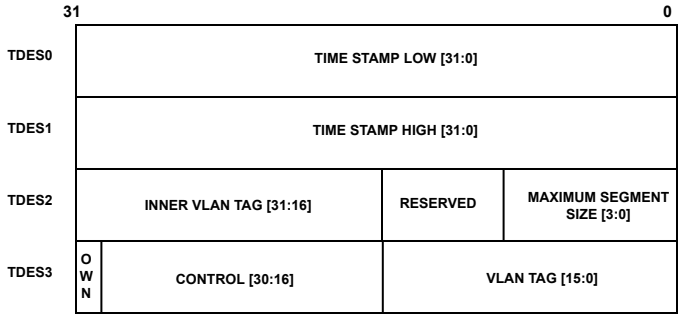

Figure 30-15: Transmit Context Descriptor Format

Table 30-19: TDES0 Context Descriptor

Bit	Name	Description
31–0	TTSL	Transmit Packet Time Stamp Low. For one-step correction, the driver can provide the lower 32 bits of time stamp in this descriptor word. The DMA uses this value as the low word for doing one-step time stamp correction. This field is valid only if the OSTC and TCMSSV bits of TDES3 context descriptor are set.

Table 30-20: TDES1 Context Descriptor

Bit	Name	Description
31–0	TTSH	Transmit Packet Time Stamp High. For one-step correction, the driver can provide the upper 32 bits of time stamp in this descriptor. The DMA uses this value as the high word for doing one-step time stamp correction. This field is valid only if the OSTC and TCMSSV bits of TDES3 context descriptor are set.

Table 30-21: TDES2 Context Descriptor

Bit	Name	Description
31–16	IVT	Inner VLAN Tag. When the IVLTV bit of the TDES3 context descriptor is set and the TCMSSV and OSTC bits of the TDES3 context descriptor are reset, TDES2[31:16] contains the inner VLAN tag that is inserted in the subsequent transmit packets.
15–14	Reserved	
13–0	MSS	Maximum Segment Size. When the enable TCP segmentation offloading for TCP/IP packets option is selected, the driver provides maximum segment size in this field. This segment size is used while segmenting the TCP/IP payload. This field is valid only if the TCMSSV bit of the TDES3 context descriptor is set and the OSTC bit of the TDES3 context descriptor is reset.

Table 30-22: TDES3 Context Descriptor

Bit	Name	Description
31	OWN	Own Bit. When this bit is set, it indicates that the EMAC DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit immediately after the read.
30	CTXT	Context Type. This bit should be cleared (=0) for normal descriptor.

Table 30-22: TDES3 Context Descriptor (Continued)

Bit	Name	Description
29–28	Reserved	
27	OSTC	One-Step Time stamp Correction Enable. When this bit is set, the DMA performs a one-step time stamp correction with reference to the time stamp values provided in TDES0 and TDES1.
26	TCMSSV	One-Step Time stamp Correction Input or MSS Valid. When this bit and the OSTC bit are set, it indicates that the time stamp correction input provided in TDES0 and TDES1 is valid. When the OSTC bit is reset and this bit and the TSE bit of TDES3 are set in subsequent normal descriptor, it indicates that the MSS input in TDES2 is valid.
25–24	Reserved	
23	CDE	Context Descriptor Error. When this bit is set, it indicates that the descriptor content is incorrect. The DMA sets this bit during write-back while closing the context descriptor. Context descriptor errors can be: • Incorrect sequence from the context descriptor. For example, a location before the first descriptor for a packet. • All 1s • CD, LD, and FD bits set to 1. **NOTE:** When the context descriptor error occurs due to all 1s or the CTXT, LD, and FD bits set to 1, the transmit DMA closes the transmit descriptor with the DE and LD bits set to 1. When the IOC bit in TDES2 of the corresponding first descriptor is set to 1, transmit DMA sets the TI bit in the DMA_CH#_Status register. **NOTE:** Based on the CTXT, LD, and FD bits of the transmit descriptor, the subsequent descriptor might be considered as the first descriptor (even if the FD bit is not set) and a partial packet is sent. **NOTE:** This error is categorized as an abnormal event; recovery is only by issuing a software reset (DMA stopping-reconfiguring-restarting recovery mechanism is not supported).
22–20	Reserved	

Table 30-22: TDES3 Context Descriptor (Continued)

Bit	Name	Description
19–18	IVTIR	Inner VLAN Tag Insert or Replace. When these bits are set, the MAC is requested to perform inner VLAN tagging or un-tagging before transmitting the packets. If the packet is modified for VLAN tags, the MAC automatically recalculates and replaces the CRC bytes. The following list describes the values of these bits: • 00 = Do not add the inner VLAN tag. • 01 = Remove the inner VLAN tag from the packets before transmission. This option should be used only with the VLAN frames. • 10 = Insert an inner VLAN tag with the tag value programmed in the MAC_Inner_VLAN_Incl register or context descriptor. • 11 = Replace the inner VLAN tag in packets with the tag value programmed in the MAC_Inner_VLAN_Incl register or context descriptor. This option should be used only with the VLAN frames. These bits are valid when the Enable SA and VLAN Insertion on transmit and Enable Double VLAN Processing options are selected.
17	IVLTV	Inner VLAN Tag Valid. When this bit is set, it indicates that the IVT field of TDES2 is valid.
16	VLTV	VLAN Tag Valid. When this bit is set, it indicates that the VT field of TDES3 is valid.
15–0	VT	VLAN Tag. This field contains the VLAN Tag to be inserted or replaced in the packet. This field is used as VLAN Tag only when the VLTI bit of the MAC_VLAN_Incl register is reset.

Receive Descriptor

The DMA in the EMAC module attempts to read a descriptor only if the tail pointer is different from the base pointer or current pointer. It is recommended to have a descriptor ring with a length that can accommodate at least two complete packets received by the MAC. Otherwise, the performance of the DMA is impacted greatly because of the unavailability of the descriptors. In such situations, the receive FIFO in the MTL becomes full and starts dropping packets.

The following receive descriptors are present:

- Normal descriptors
- Context descriptors

All receive descriptors are prepared by the software and given to the DMA as “Normal” descriptors with the content as shown in Receive Normal Descriptor (Read Format). The DMA reads this descriptor and after transferring a received packet (or part of) to the buffers indicated by the descriptor, the receive DMA closes the descriptor with the corresponding packet status. The format of this status is given in Receive Normal Descriptor (Write-Back Format).

For some packets, the normal descriptor bits are not enough to write the complete status. For such packets, the receive DMA writes the extended status to the next descriptor (without processing or using the buffers/pointers embedded in that descriptor). The format and content of the descriptor write back is described in Receive Context Descriptor.

Receive Normal Descriptor (Read Format)

The read format for a receive normal descriptor is made up of a header or buffer 1 address, reserved field, payload or buffer 2 or next descriptor address, a 30-bit reserved filed, OWN bit, and an interrupt bit.

The *Receive Normal Descriptor Read Format* figure shows the read format for a receive normal descriptor.

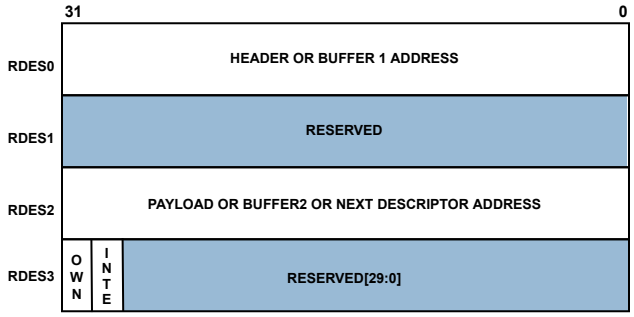

Figure 30-16: Receive Normal Descriptor Read Format

RDES0 Normal Descriptor (Read Format)

The following table explains the read format of the RDES0 normal descriptor.

Table 30-23: Receive Descriptor Fields 0 (RDES0)

Bit	Name	Description
31–0	BUFF1AP	Header or Buffer 1 Address Pointer. These bits indicate the physical address of buffer 1. There are no limit when the SPH bit of the control register of a channel is reset, these bits indicate the physical address of buffer 1. When the SPH bit is set, these bits indicate the physical address of header buffer, where the receive DMA writes the L2/L3/L4 header bytes of the received packet. The application can program a byte-aligned address for this buffer which means that the LS bits of this field can be non-zero. However, while transferring the start of packet, the DMA performs a write operation with RDES0[1:0] as zero. However, the packet data is shifted as per actual offset as given by buffer address pointer. If the address pointer points to a buffer where the middle or last part of the packet is stored, the DMA ignores the offset address and writes to the full location as indicated by the data width.

RDES1 Normal Descriptor (Read Format)

The following table describes the read format of the RDES1 normal descriptor.

Table 30-24: Receive Descriptor Fields 1 (RDES1)

Bit	Name	Description
31–0	Reserved	Reserved

RDES2 Normal Descriptor (Read Format)

The following table describes the read format of the RDES2 normal descriptor.

Table 30-25: Receive Descriptor Fields 2 (RDES2)

Bit	Name	Description
31–0	Reserved or BUF1AP	Buffer 2 Address Pointer. These bits indicate the physical address of buffer 2. When the `EMAC_DMA[n]_CTL.SPH` bit is set, the buffer address pointer must be bus width-aligned, that is, RDES2[3:0, 2:0, or 1:0] = 0 corresponding to 128, 64, or 32 bus width. LSBs are ignored internally. When the `EMAC_DMA[n]_CTL.SPH` bit is reset, there is no limitations on the RDES2 value. However, the receive DMA uses the LS bits of the pointer address only while transferring the start bytes of a packet. If the BUF2AP is giving the address of a buffer in which the middle or last part of a packet is stored, the DMA ignores BUF2AP and writes to the complete location.

RDES3 Normal Descriptor (Read Format)

The following table describes the read format of the RDES3 normal descriptor.

Table 30-26: Receive Descriptor Fields 3 (RDES3)

Bit	Name	Description
31	OWN	Own Bit. When this bit is set, it indicates that the EMAC module owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit when either of the following conditions is true: • The DMA completes the packet reception • The buffers associated with the descriptor are full
30	IOC	Interrupt Enabled on Completion. When this bit is set, an interrupt is issued to the application when the DMA closes this descriptor.
29–26	Reserved	
25	BUF2V	Buffer 2 Address Valid. When this bit is set, it indicates to the DMA that the buffer 2 address specified in RDES2 is valid. The application must set this bit so that the DMA can use the address, to which the buffer 2 address in RDES2 is pointing, to write received packet data.
24	BUF1V	Buffer 1 Address Valid. When set, this indicates to the DMA that the buffer 1 address specified in RDES1 is valid. The application must set this value if the address pointed to by Buffer 1 address in RDES1 can be used by the DMA to write received packet data.
23–16	Reserved	
15–0	Reserved	Reserved

Receive Normal Descriptor (Write-Back Format)

The *Receive Normal Descriptor Write-Back Format* figure illustrates the write-back format for a receive normal descriptor.

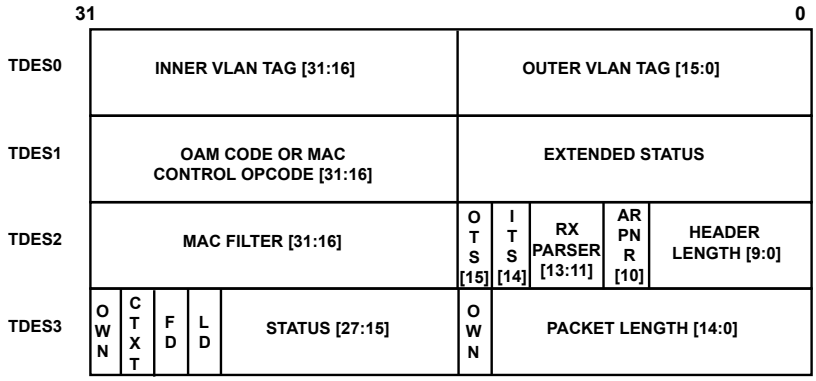

Figure 30-17: Receive Normal Descriptor Write-Back Format

RDES0 Normal Descriptor (Write-Back Format)

The following table describes the write-back format for the RDES0 normal descriptor.

Table 30-27: RDES0 Normal Descriptor (Write-Back Format)

Bit	Name	Description
31–16	IVT	Inner VLAN Tag. This field contains the Inner VLAN tag of the received packet if the RS0V bit of RDES3 is set. This is valid only when double VLAN tag processing and VLAN tag stripping are enabled.
15–0	OVT	Outer VLAN Tag. This field contains the outer VLAN tag of the received packet if the RS0V bit of RDES3 is set.

RDES1 Normal Descriptor (Write-Back Format)

The following table describes the write-back format for the RDES1 normal descriptor.

Table 30-28: RDES1 Normal Descriptor (Write-Back Format)

Bit	Name	Description
31–16	OPC	OAM Subtype Code, or MAC Control Packet opcode. OAM subtype code: If bits [18:16] of RDES3 are set to 3'b111, this field contains the OAM subtype and code fields. MAC Control Packet opcode: The bits [15:8] of RDES3 contains the subtype and bits [7:0] contains the code.
15	TD	Time Stamp Dropped. This bit indicates that the time stamp was captured for this packet but was dropped in the MTL receive FIFO because of overflow. This bit is available only when the time stamp feature is selected. Otherwise, this bit is reserved.
14	TSA	Time Stamp Available. When time stamp is present, this bit indicates that the time stamp value is available in a context descriptor word 2 (RDES2) and word 1(RDES1). This is valid only when the last descriptor bit (RDES3 [28]) is set. The context descriptor is written in the next descriptor just after the last normal descriptor for a packet.

Table 30-28: RDES1 Normal Descriptor (Write-Back Format) (Continued)

Bit	Name	Description
13	PV	PTP Version. This bit indicates that the received PTP message has the IEEE 1588 version 2 format. When this bit is reset, it indicates the IEEE 1588 version 1 format. This bit is available only when time stamp feature is selected. Otherwise, this bit is reserved.
12	PFT	PTP Packet Type. This bit indicates that the PTP message is sent directly over Ethernet. This bit is available only when time stamp feature is selected. Otherwise, this bit is reserved.
11–8	PMT	PTP Message Type. These bits are encoded to give the type of the message received: • 0000 = No PTP message received • 0001 = SYNC (all clock types) • 0010 = Follow_Up (all clock types) • 0011 = Delay_Req (all clock types) • 0100 = Delay_Resp (all clock types) • 0101 = Pdelay_Req (in peer-to-peer transparent clock) • 0110 = Pdelay_Resp (in peer-to-peer transparent clock) • 0111 = Pdelay_Resp_Follow_Up (in peer-to-peer transparent clock) • 1000 = Announce • 1001 = Management • 1010 = Signaling • 1011–1110 = Reserved • 1111 = PTP packet with Reserved message type These bits are available only when the time stamp feature is selected.
7	IPCE	IP Payload Error. When this bit is set, it indicates either of the following: • The 16-bit IP payload checksum (that is, the TCP, UDP, or ICMP checksum) calculated by the MAC does not match the corresponding checksum field in the received segment. • The TCP, UDP, or ICMP segment length does not match the payload length value in the IP Header field. • The TCP, UDP, or ICMP segment length is less than minimum allowed segment length for TCP, UDP, or ICMP. Bit 15 (ES) of RDES3 is not set when this bit is set.
6	IPCB	IP Checksum Bypassed. This bit indicates that the checksum offload engine is bypassed. This bit is available when the enable receive TCP/IP checksum check feature is selected.
5	IPV6	IPv6 Header Present. This bit indicates that an IPV6 header is detected. When the enable split header feature option is selected and the SPH bit of control register of a channel is set, the IPV6 header is available in the header buffer area to which RDES0 is pointing.

Table 30-28: RDES1 Normal Descriptor (Write-Back Format) (Continued)

Bit	Name	Description
4	IPV4	IPV4 Header Present. This bit indicates that an IPV4 header is detected. When the SPH bit of RDES3 is set, the IPV4 header is available in the header buffer area to which RDES0 is pointing.
3	IPHE	IP Header Error. When this bit is set, it indicates either of the following: • The 16-bit IPv4 header checksum calculated by the MAC does not match the received checksum bytes. • The IP datagram version is not consistent with the Ethernet type value. • Ethernet packet does not have the expected number of IP header bytes. This bit is valid when either bit 5 or bit 4 is set. This bit is available when the enable receive TCP/IP checksum check feature is selected.
2–0	PT	Payload Type. These bits indicate the type of payload encapsulated in the IP datagram processed by the Receive Checksum Offload Engine (COE): • 000: Unknown type or IP/AV payload not processed • 001 = UDP • 010 = TCP • 011 = ICMP • 110 = AV Tagged Data Packet • 111 = AV Tagged Control Packet • 101 = AV Untagged Control Packet • 100 = IGMP if IPV4 Header Present bit is set else DCB (LLDP) Control Packet If the COE does not process the payload of an IP datagram because there is an IP header error or fragmented IP, it sets these bits to 000.

RDES2 Normal Descriptor (Write-Back Format)

The following table describes the write-back format for the RDES2 normal descriptor.

Table 30-29: RDES2 Normal Descriptor (Write-Back Format)

Bit	Name	Description
31–29	L3L4FM	Layer 3 and Layer 4 Filter Number Matched. These bits indicate the number of the layer 3 and layer 4 filter that matched the received packet: • 000 = Filter 0 • 001 = Filter 1 • 010 = Filter 2 • 011 = Filter 3 • 100 = Filter 4 • 101 = Filter 5 • 110 = Filter 6 • 111 = Filter 7 This field is valid only when bit 28 or bit 27 is set high. When more than one filter matches, these bits give the number of lowest filter. Note: This status is not available when flexible RX parser is enabled.
28	L4FM	Layer 4 Filter Match. When this bit is set, it indicates that the received packet matches one of the enabled layer 4 port number fields. This status is given only when one of the following conditions is true: • Layer 3 fields are not enabled and all enabled layer 4 fields match • All enabled layer 3 and layer 4 filter fields match When more than one filter matches, this bit gives the layer 4 filter status of filter indicated by bits[31–29]. Note: This status is not available when the flexible receive parser is enabled
27	L3FM	Layer 3 Filter Match. When this bit is set, it indicates that the received packet matches one of the enabled layer 4 port number fields. This status is given only when one of the following conditions is true: • All enabled layer 3 fields match and all enabled layer 4 fields are bypassed • All enabled filter fields match When more than one filter matches, this bit gives the layer 4 filter status of filter indicated by bits[31–29]. Note: This status is not available when the flexible receive parser is enabled
26–19	MADRM	MAC Address Match or Hash Value. When the HF bit is reset, this field contains the MAC address register number that matched the Destination address of the received packet. This field is valid only if the DAF bit is reset. When the HF bit is set, this field contains the hash value computed by the MAC. A packet passes the hash filter when the bit corresponding to the hash value is set in the hash filter register. Note: This status is not available when the flexible receive parser is enabled
18	HF	Hash Filter Status. When this bit is set, it indicates that the packet passed the MAC address hash filter. Bits[26:19] indicate the hash value. Note: This status is not available when the flexible receive parser is enabled.

Table 30-29: RDES2 Normal Descriptor (Write-Back Format) (Continued)

Bit	Name	Description
17	DAF/RXPI	Destination Address Filter Fail. When flexible RX parser is disabled, and this bit is set, it indicates that the packet failed the DA filter in the MAC. When flexible RX parser is enabled, this bit is set to indicate that the packet parsing is incomplete (RXPI) due to ECC error. Note: When this bit is set, ES bit of RDES3 is also set.
16	SAF/RXPD	SA Address Filter Fail. When the flexible receive parser is disabled, and this bit is set, it indicates that the packet failed the SA filter in the MAC. When the flexible receive parser is enabled, this bit is set to indicate that the packet is dropped (RXPD) by the parser. Note: When this bit is set, ES bit of RDES3 is also set.
15	OTS	Outer VLAN Tag Filter Status. This bit is valid for both single and double VLAN tagged frames.
14	ITS	Inner VLAN Tag Filter Status (ITS). This bit is valid only for double VLAN tagged frames, when double VLAN processing is enabled. For more information, see the Filter Status topic.
13–11	RxParser	Rx Parser • 000 = Rx Parser filter passed • 001 = Packet rejected in Rx Parser • 010 = Rx Parser overflow errors • 011 = Incomplete Rx parsing of the packet • 100 = AF = 1, RF = 1, Bypass • 101 = RA = 1 and L2 filter fails (Rx parser bypass) • 110 = Reserved • 111 = Incomplete parsing due to ECC error
10	ARPNR	ARP Reply Not Generated. When this bit is set, it indicates that the MAC did not generate the ARP reply for received ARP request packet. This bit is set when the MAC is busy transmitting ARP reply to earlier ARP request (only one ARP request is processed at a time). This bit is reserved when the Enable IPv4 ARP Offload option is not selected.
9–0	HL	L3/L4 Header Length. This field contains the length of the header of the packet split by the MAC at L3 or L4 header boundary as identified by the MAC receiver. This field is valid only when the first descriptor bit is set (FD = 1). The header data is written to the buffer 1 address of corresponding descriptor. If header length is zero, this field is not valid. It implies that the MAC did not identify and split the header. This field is valid when the enable split header feature option is selected.

RDES3 Normal Descriptor (Write-Back Format)

The following table describes the write-back format for the RDES3 normal descriptor.

Table 30-30: RDES3 Normal Descriptor (Write-Back Format)

Bit	Name	Description
31	OWN	Ownership. When this bit is set, it indicates that the EMAC DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit when either of the following conditions is true: • The DMA completes the packet reception • The buffers associated with the descriptor are full
30	CTXT	Receive Context Descriptor. When this bit is set, it indicates that the current descriptor is a context type descriptor. The DMA writes 1'b0 to this bit for normal receive descriptor. When CTXT and FD bits are used together, {CTXT, FD} • 00 = Intermediate Descriptor • 01 = First Descriptor • 10 = Reserved • 11 = Descriptor Error (due to all 1s) **NOTE:** When a descriptor error occurs, the receive DMA closes the receive descriptor indicating descriptor error. This receive descriptor is skipped and the buffer addresses are not used to write the packet data. Receive DMA sets the CDE field of the `EMAC_DMA[n]_STAT` register but does not the RI field even when IOC field is set, as this is not marked as last receive descriptor for the packet. The subsequent valid receive descriptor is used to write the packet data.
29	FD	First Descriptor. When this bit is set, it indicates that this descriptor contains the first buffer of the packet. If the size of the first buffer is 0, the second buffer contains the beginning of the packet. If the size of the second buffer is also 0, the next descriptor contains the beginning of the packet. See the CTXT bit description for details of using the CTXT bit and FD bit together.
28	LD	Last Descriptor. When this bit is set, it indicates that the buffers to which this descriptor is pointing are the last buffers of the packet.
27	RS2V	Receive Status RDES2 Valid. When this bit is set, it indicates that the status in RDES2 is valid and it is written by the DMA. This bit is valid only when the LD bit of RDES3 is set.
26	RS1V	Receive Status RDES1 Valid. When this bit is set, it indicates that the status in RDES1 is valid and it is written by the DMA. This bit is valid only when the LD bit of RDES3 is set.
25	RS0V	Receive Status RDES0 Valid. When this bit is set, it indicates that the status in RDES0 is valid and it is written by the DMA. This bit is valid only when the LD bit of RDES3 is set.
24	CE	CRC Error. When this bit is set, it indicates that a Cyclic Redundancy Check (CRC) Error occurred on the received packet. This field is valid only when the LD bit of RDES3 is set.
23	GP	Giant Packet. When this bit is set, it indicates that the packet length exceeds the specified maximum Ethernet size of 1518, 1522, or 2000 bytes (9018 or 9022 bytes if jumbo packet enable is set). Note: Giant packet indicates only the packet length. It does not cause any packet truncation.
22	RWT	Receive Watchdog Timeout When this bit is set, it indicates that the Receive Watchdog Timer has expired while receiving the current packet. The current packet is truncated after watchdog timeout.

Table 30-30: RDES3 Normal Descriptor (Write-Back Format) (Continued)

Bit	Name	Description
21	OE	Overflow Error. When this bit is set, it indicates that the received packet is damaged because of buffer overflow in Rx FIFO. Note: This bit is set only when the DMA transfers a partial packet to the application. This happens only when the Rx FIFO is operating in the threshold mode. In the store-and-forward mode, all partial packets are dropped completely in Rx FIFO.
20	RE	Receive Error. When this bit is set, it indicates that the gmii_rxer_i signal is asserted while the gmii_rxdv_i signal is asserted during packet reception. This error also includes carrier extension error in the GMII and half-duplex mode. Error can be of less or no extension, or error (rxd!= 0f) during extension.
19	DE	Dribble Bit Error. When this bit is set, it indicates that the received packet has a non-integer multiple of bytes (odd nibbles). This bit is valid only in the MII Mode.
18–16	LT	Length/Type Field. This field indicates if the packet received is a length packet or a type packet. The encoding of the 3 bits is as follows: • 000 = The packet is a length packet • 001 = The packet is a type packet • 011 = The packet is a ARP Request packet type • 100 = The packet is a type packet with VLAN Tag • 101 = The packet is a type packet with Double VLAN Tag • 110 = The packet is a MAC Control packet type • 111 = The packet is a OAM packet type • 010 = Reserved
15	ES	Error Summary. When this bit is set, it indicates the logical OR of the following bits: • RDES3[24]: CRC Error • RDES3[19]: Dribble Error • RDES3[20]: Receive Error • RDES3[22]: Watchdog Timeout • RDES3[21]: Overflow Error • RDES3[23]: Giant Packet • RDES2[17]: Destination Address Filter Fail, when flexible RX parser is enabled • RDES2[16]: SA Address Filter Fail, when flexible RX parser is enabled This field is valid only when the LD bit of RDES3 is set.
14–0	PL	Packet Length. These bits indicate the byte length of the received packet that was transferred to system memory (including CRC). This field is valid when the LD bit of RDES3 is set and Overflow Error bits are reset. The packet length also includes the two bytes appended to the Ethernet packet when IP checksum calculation is enabled and the received packet is not a MAC control packet. This field is valid when the LD bit of RDES3 is set. When the last descriptor and error summary bits are not set, this field indicates the accumulated number of bytes that have been transferred for the current packet.

Receive Context Descriptor

This descriptor is read-only for the application. Only the DMA can write to this descriptor. The context descriptor provides information about the extended status related to the last received packet. The bit 30 of RDES3 indicates the context type descriptor.

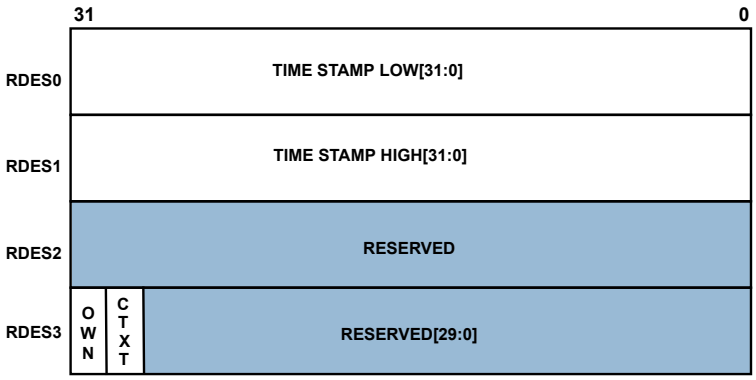

Figure 30-18: Receive Context Descriptor

RDES0 Context Descriptor

The following table describes the format for the RDES0 context descriptor.

Table 30-31: RDES0 Context Descriptor

Bit	Name	Description
31–0	RTSL	Receive Packet Time Stamp Low. The DMA updates this field with least significant 32 bits of the time stamp captured for corresponding receive packet. When this field and the RTSH field of RDES1 show all-one value, the time stamp must be considered as corrupt.

RDES1 Context Descriptor

The following table describes the format for the RDES1 context descriptor.

Table 30-32: RDES1 Context Descriptor

Bit	Name	Description
31–0	RTSH	Receive Packet Time Stamp High. The DMA updates this field with most significant 32 bits of the time stamp captured for corresponding receive packet. When this field and the RTSL field of RDES0 show all-ones value, the time stamp must be considered as corrupt.

RDES2 Context Descriptor

The following table describes the format for the RDES2 context descriptor.

Table 30-33: RDES2 Context Descriptor

Bit	Name	Description
31–0	Reserved	

RDES3 Context Descriptor

The following table describes the format for the RDES3 context descriptor.

Table 30-34: RDES3 Context Descriptor

Bit	Name	Description
31	OWN	Ownership. When this bit is set, it indicates that the DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit when either of the following conditions is true: • The DMA completes the packet reception • The buffers associated with the descriptor are full
30	CTXT	Receive Context Descriptor. When this bit is set, it indicates that the current descriptor is a context descriptor. The DMA writes 10 to this bit for context descriptor. DMA writes 11 to indicate a descriptor error due to all 1s. When CTXT and DE bits are used together, {CTXT, DE} • 00 = Reserved • 01 = Reserved • 10 = Context Descriptor • 11 = Descriptor Error **NOTE:** When a descriptor error occurs, the receive DMA closes the receive descriptor indicating a descriptor error. This receive descriptor is skipped and the buffer addresses are not used to write the packet data. The receive DMA sets the `EMAC_DMA[n]_STAT.CDE` bit but does not set the `EMAC_DMA[n]_STAT.RI` bit field even when IOC is set, as this is not marked as last receive descriptor for the packet. The subsequent valid receive descriptor is used to write the packet data.
29	DE	Descriptor Error. See the CTXT bit description for details of using the DE bit along with the CTXT bit.
28–0	Reserved	

Descriptor Structure for Split Header Support

EMAC supports splitting the incoming receive packet header such that the header and the payload are stored in different buffers (buffer-1 and buffer-2) in the system memory. For more details about splitting header on receive packets, see Header-Payload Split.

The *Descriptors without Split Header Feature* figure shows the descriptor structure without the split header feature.

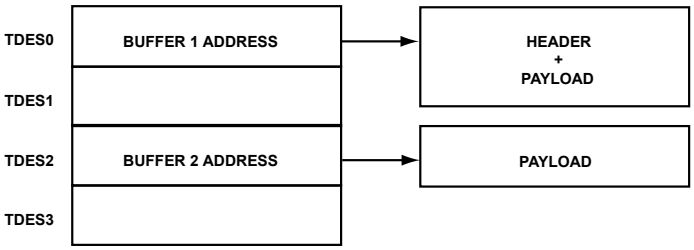

Figure 30-19: Descriptors without Split Header Feature

The *Descriptors with Split Header Feature* figure shows the descriptor structure with the split header feature.

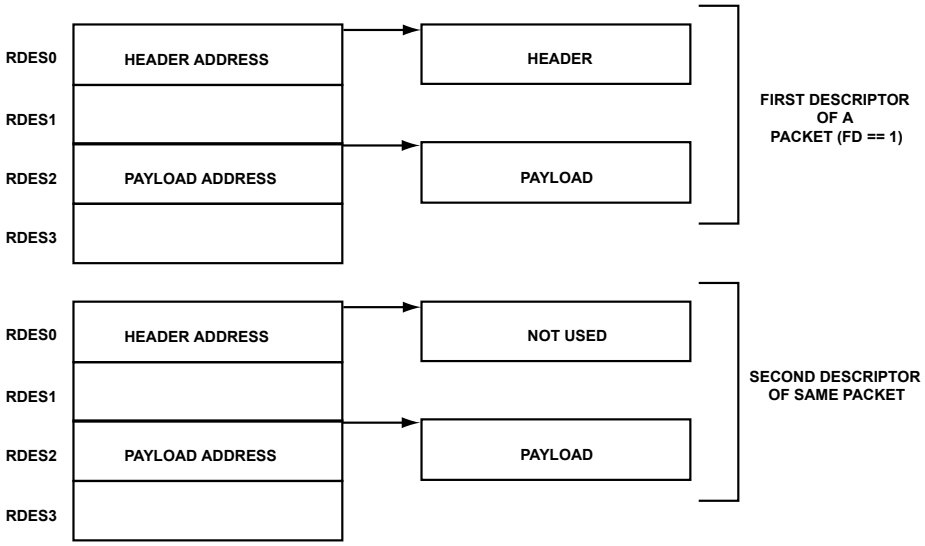

Figure 30-20: Descriptors with Split Header Feature

The DMA writes the header of the received packet by using the header address to which the RDES0 in the first descriptor is pointing (FD bit of RDES3 is set). The DMA writes the payload of the received packet into the buffer address to which the RDES2 is pointing. For subsequent descriptors (FD is set to 0), the address to which RDES0 (Header address) is pointing is not used. The payload is written only to buffers to which the RDES2 (payload address) is pointing.

The `EMAC_MAC_EXT_CFG.HDSMS` bit field indicates the maximum header size allowed for splitting the header data in the received packet based on the value programmed. When the `EMAC_DMA[n]_RXCTL2.ARBS` bit field is programmed to a non-zero value, it indicates the receive buffer size for buffer-1 and the `EMAC_DMA[n]_RXCTL.RBSZ_X_0` and `EMAC_DMA[n]_RXCTL.RBSZ_13_Y` indicates the receive buffer size for buffer-2. The `EMAC_DMA[n]_RXCTL2.ARBS` field can be set to 0, for backward compatibility.

The value in the `EMAC_MAC_EXT_CFG.HDSMS` field should be greater than or equal to the Buffer-1 size indicated by the `EMAC_DMA[n]_RXCTL2.ARBS` field for all the channels.

The following table shows how DMA processes a packet based on the packet type.

Table 30-35: Split Header Support Depending on the Packet Type

Packet Type	Name	Description
TCP or UDP	00 (L3L4 split	The DMA writes the Ethernet header + IP header + TCP or UDP header into the header buffer.
IP (not TCP/UDP)		The DMA writes the Ethernet header + IP header into the header buffer.
Non-IP		The DMA does not split the header and payload
Any packet	01 (L2 split)	The DMA writes the Ethernet header based on split offset (SPLOFST) into the header buffer.
IP	10 (Combination of L2 or L3/L4 split)	L3/L4 split
Non-IP		L2 split
NA	11	Reserved

The IP header includes IPv4 options in case of IPv4 packet and IPv6 extension headers in case of IPv6 frames. The points at which the header is split are shown in the *L3/L4 Header Split Points* figure.

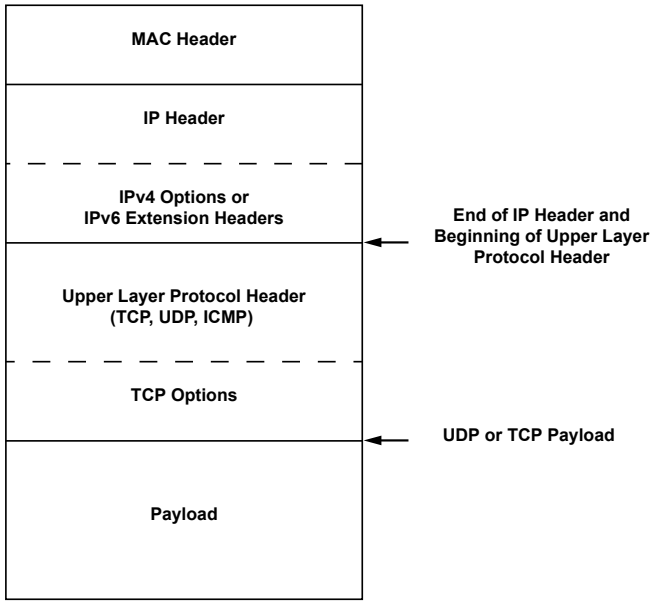

Figure 30-21: L3/L4 Header Split Points

NOTE:
- The VLAN tag stripping must be set for the split function. For instance, the DMA separates the header and payload of an untagged packet only. So, when a tagged packet is received, then program EMAC such that the VLAN tags are deleted/stripped from the received packets.
- L3/L4 split is applicable for IP packets that are either untagged or VLAN stripped. If VLAN tag is retained in the packet forwarded to the DMA, L3-L4 split is not performed. However, if the `EMAC_SPLM_OFST_CFG.SPLM` bit field is set to 2, L2 split is performed for VLAN tagged IP packets.

- For AV packets, to specify an alternative L2 split value, use the EMAC_SPLM_OFST_CFG.SAVE and EMAC_SPLM_OFST_CFG.SAVO bit fields.
- L2 Split is not supported for packets with variable preamble.

The following table shows the header length availability in RDES2.

Table 30-36: Header Length Availability in RDES2

First Descriptor (FD) Value	Last Descriptor (LD) Value	Header Length Availability in RDES2
0	1	Header length not available
1	0	HL[9:0] for all packets
1	1	For IP packets, HL[9:0] For non-IP packets, HL[9:2]

The DMA writes the header length in RDES2 of the first receive descriptor (RDES3[29] FD bit is set) for the packet. The packet length is written in RDES3 of the last receive descriptor (RDES3[28] LD bit set).

The buffer length for the payload is set by the driver through the EMAC_DMA[n]_RXCTL.RBSZ_X_0 and EMAC_DMA[n]_RXCTL.RBSZ_13_Y fields.

The DMA fills receive buffers fully in all except the last descriptor. The header length is taken to be the value based on the bits programmed in the EMAC_MAC_EXT_CFG.HDSMS field.

Enhanced Descriptor for Time-Based Scheduling

The time-based scheduling feature needs Enhanced Descriptors (that are 32 Bytes) to be enabled on all the DMA channels that intend to use the feature (by setting the EMAC_DMA[n]_TXCTL.EDSE bit).

The structure of the 32-byte descriptor for the context and the normal descriptor in read and write formats are described in the following sections.

Enhanced Normal Descriptor - Read

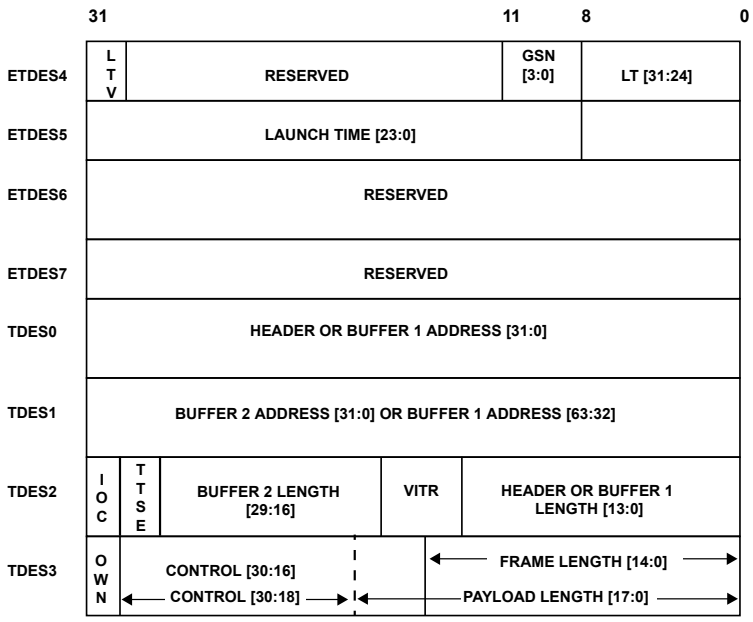

Figure 30-22: Enhanced Normal Descriptor - Read (32-bit Mode)

Table 30-37: Enhanced Normal Descriptor - Read

Bit	Name	Description
31–12	LTV	Launch Time Valid indicates the Launch Time (LT) and GSN fields present in the descriptor are valid. The LTV must be set only if the FD bit of the descriptor is not set.
11–8	GSN	GCL slot number associated with the packet
7–0	LT	Launch Time associated with the packet.

For details of the other fields, see Transmit Normal Descriptor (Read Format).

Enhanced Normal Descriptor - Write

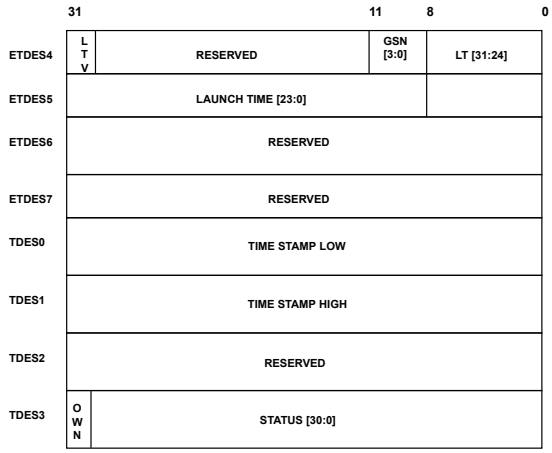

Figure 30-23: Enhanced Normal Descriptor - Write (32-Bit Mode)

For details of LTV, GSN, LT fields, see Enhanced Descriptor for Time-Based Scheduling. For details of the other fields, see Transmit Normal Descriptor (Write-Back Format).

NOTE: In both the write back formats, no modifications can be done to the extended 16 bytes. The rest of the 16 bytes (TDESC0 to TDESC3) are written back as per the previous 16 bytes Descriptor format.

NOTE: Fetch time when enabled overrides the AV slot function

NOTE: When an unaligned new GCL list (with a different CTR) is installed it is recommended not to have traffic during the installation of the new list. Any traffic during the switching of the lists might have unpredictable behavior regarding Fetch, Launch, and Launch expiry as the CTR and BTR values get updated while the frame is being processed.

Enhanced Context Descriptor (Read)

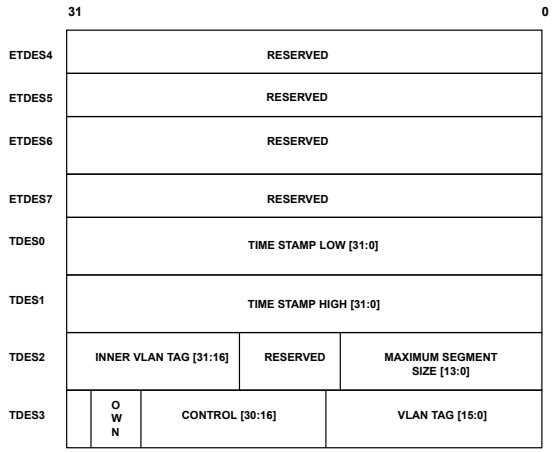

Figure 30-24: Enhanced Context Descriptor - Read

For details of the various fields, see Transmit Context Descriptor.

Enhanced Context Descriptor (Write)

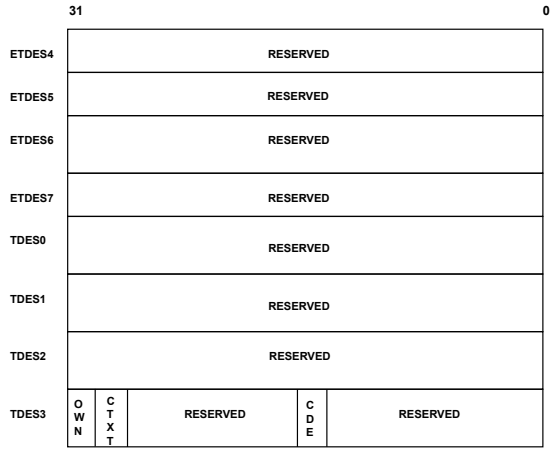

Figure 30-25: Enhanced Context Descriptor (Write)

For details of the various fields, see Receive Context Descriptor.

MAC Transaction Layer (MTL)

The MAC Transaction Layer (MTL) provides the FIFO memory interface to the buffer and regulates the packets between the application system memory and the MAC. It also enables the data to transfer between the application and MAC clock domains. The MTL layer has transmit and receive data paths. The data path for both directions is 32 bits wide and each transmit/receive DMA channel has a dedicated FIFO.

The transmit FIFO size for EMAC0 is 2048 bytes and for EMAC1 is 1024 bytes. The receive FIFO size for EMAC0 is 2048 bytes and for EMAC1 is 512 bytes.

Transmit Path and Operation

The DMA engine controls all transactions for the transmit path with the application. The DMA pushes the Ethernet packets read from the application or system memory into the corresponding queue. The packet is then popped out and transferred to the MAC when the queue threshold is reached (threshold mode) or the complete packet is in the queue (store-and-forward mode). When EOP is transferred, the status of the transmission is taken from the MAC and transferred back to the DMA.

The queue fill level is indicated to DMA (using PBL and watermark) so that it can initiate a data fetch in required bursts from the application or system memory. The DMA indicates the SOP and EOP as packet delimiters through the Application Transmit Interface (ATI). In configurations with multiple queues, the DMA should also indicate the queue number for which the transaction is being addressed.

The following modes of operation trigger reading the data towards the MAC.

1. Threshold mode. When the number of bytes in the FIFO queue crosses the configured threshold level, (or when the end of packet is written before the threshold is crossed), the data is ready to be popped out and

forwarded to the MAC. The threshold level is configured using the EMAC_TQ0_OPMODE.TTC bit field that corresponds to an MTL queue.

2. Store-and-forward mode. In this mode, the MTL pops the packet towards the MAC only when one or more of the following conditions are true:
   - A complete packet is stored in the queue
   - The transmit FIFO becomes almost full
   - The ATI watermark becomes low

   The watermark becomes low when the requested queue does not have space to accommodate the requested burst length on the ATI. Therefore, the MTL, when operating in the store-and-forward mode, allows the packet transmission even if the packet length is bigger than the transmit queue size. The application can flush the complete content of the transmit queue using the EMAC_TQ0_OPMODE.FTQ bit that corresponds to a MTL queue. This bit is self-clearing and initializes the queue pointers to the default state.

   If the EMAC_TQ0_OPMODE.FTQ bit is set during a packet transfer from the MTL to the MAC, the MTL stops further transfer because the queue is empty. Therefore, an underflow event occurs at the MAC transmitter. For information about the initialization and transmit operations for the MTL layer, see the following sections.

Initialization Flow

At reset, the MTL is ready to manage the flow of data to and from the application or DMA, and MAC. For configurations with a single transmit queue, there are no initialization requirements for enabling the MTL. For configurations with multiple transmit queues, the program must initialize the queue size for each of the queues using the EMAC_TQ0_OPMODE.TQS bits that correspond to a transmit queue. The program must also initialize the MAC block. The DMA controllers must be individually enabled through their respective registers.

Transmit DMA Channels and Queues

The number of transmit DMA channels is equal to the transmit queues. This is because the DMA is designed to arbitrate among multiple channels (to fetch the descriptor and packet data from the system memory) in terms of PBLs (Programmable Burst Lengths). However, the transmit queues are packet-based storage memory. Therefore, one to one mapping is required between the DMA channels and transmit queues to maintain the packet-level coherency.

Transmit Operation with Multiple Packets in the Buffer

The transmit FIFO can be configured to accept up to two packets at a time.

Retransmission During Collision

While a packet is being transferred from the MTL to the MAC, a collision event can occur on the MAC line interface in half-duplex mode. The MAC indicates a retry attempt to the MTL by giving the status even before the EOP is transferred from the MTL. The MTL then enables the retransmission by popping out the packet again from the queue.

After more than 96 bytes (or 548 bytes in 1000-Mbps mode) are read out towards the MAC, the queue controller frees up that space and makes it available to the application or the DMA to push in more data. This means that the retransmission is not possible after this threshold is crossed or when the MAC indicates a late-collision event.

Transmit Queue Flush Operation

The MTL allows a transmit Queue to be flushed at any moment using the EMAC_TQ0_OPMODE.FTQ bit. The application can read back the same bit (cleared after flush is complete) to check the status of the flush operation.

Receive Path and Operation

The MTL receive module receives packets from the MAC and pushes them into the receive queue. The status (fill level) of the queue is indicated to the DMA when it crosses the configured receive threshold (EMAC_RQ0_OPMODE.RTC bits of the corresponding MTL queue), or the complete packet is received. The MTL also indicates the fill level of the queue so that the DMA can initiate preconfigured burst transfers towards the SCB interface.

The receive operation occurs as follows:

1. When the MAC receives a packet, it indicates the availability of receive data.
2. The MAC indicates the SOP and EOP delimiters.
3. The MTL accepts the data and pushes it into corresponding receive queue.
4. After the EOP is transferred, the MAC drives the status word which is also pushed into the corresponding receive queue by the MTL.

   NOTE: In Threshold (cut-through) mode, the status words are stored after the packet EOP. In store-and-forward mode, the location for the maximum status words are reserved before writing the SOP and the status is written to reserved locations after writing the EOP.

5. If IEEE 1588 time stamp feature is enabled and the 64-bit time stamp is available along with the packet status, it is pushed into the receive queue as a part of the status word. Therefore, two additional locations are taken per packet to store the time stamp in the receive queue.
6. The MTL takes the data out of the FIFO and sends it to the DMA.
   - Threshold mode (default). In this mode, the MTL reads the data and indicates its availability to the application or DMA when one of the following occurs:
     - Data bytes equal to the threshold amount are written to the receive queue (EMAC_RQ0_OPMODE.RTC bit field value)
     - A full packet of data is received into the queue
   - Receive FIFO Store-and-forward mode. This mode is configured using EMAC_RQ0_OPMODE.RSF bit. The initial receive queue locations are reserved for the status words before writing the SOP. A packet is read out only after it is completely written into the receive queue. In this mode, all error packets are dropped (if configured through the EMAC_RQ0_OPMODE.FEP of a queue) such that only valid packets are read and forwarded to the application.

Multi-Packet Receive Operation

In Threshold mode, the packet status is available immediately after the packet data. In store-and-forward mode, the packet data is available after the packet status. The MTL can store any number of packets into the queue when it is not full. When the MAC receives a packet and the corresponding receive queue is full, the MTL ignores that packet and an overflow event occurs. Additionally, the MTL increments the overflow counter (`EMAC_RQ0_MSPKTOF_CNT.OVFPKTCNT`) of the corresponding queue.

Receive Error Handling

If the MTL receive queue is full before it receives the EOP data from the MAC, the following happens:

- An overflow is declared
- The whole packet (including the status word) is dropped
- The overflow counter in the DMA (`EMAC_RQ0_MSPKTOF_CNT.OVFPKTCNT` bits of corresponding MTL queue) is incremented.

This is true even if the `EMAC_RQ0_OPMODE.FEP` bit of the corresponding MTL queue is set.

If the start address of such a packet has already been transferred to the read controller, the rest of the packet is dropped and a dummy EOP is written to the queue along with the status word with overflow status. The status indicates a partial packet because of overflow. In such packets, the packet length field is invalid. If the MTL receive queue is configured to operate in the store-and-forward mode and the length of the received packet is more than the queue size, overflow occurs, and all such packets are dropped.

The MTL receive control logic can filter error and undersized packets using the `EMAC_RQ0_OPMODE.FEP` and `EMAC_RQ0_OPMODE.FUP` bits of the corresponding MTL queue. If the start address of such a packet has already been transferred to the receive queue read controller, that packet is not filtered. The start address of the packet is transferred to the Read Controller after the packet crosses the receive threshold set by the `EMAC_RQ0_OPMODE.RTC` of the corresponding MTL queue.

EMAC CORE

The EMAC CORE is the lowest block in the EMAC peripheral and it performs all operations with the external world (PHY chip). It has independent transmit and receive modules. The modules interact with the EMAC Transaction Layer (MTL) at one end and interacts with the PHY chip through the RGMII/RMII/MII interface at the other end. Both modules have several sub blocks which are discussed in subsequent sections.

Transmission is initiated when the MTL pushes in data with the start of packet (SOP). The CORE then transmits to the RGMII/RMII/MII. After the end of packet transfers out, the CORE gives the status of the transmission back to the MTL. The MTL forwards the transmission to the application through DMA.

A receive operation initiates when the EMAC detects an SFD on the RGMII/RMII/MII. The CORE strips the preamble and SFD before proceeding to process the frame. The header fields are checked for the filtering and the FCS field used to verify the CRC for the frame. The frame drops in the core when it fails the address filter.

NOTE: The term *CORE* (written in capitals) refers to the internal block of Ethernet peripheral. Do not confuse the term with the *processor core*.

EMAC CORE Transmission Engine

The following modules constitute the transmission function (transmission engine components) of the EMAC:

- Transmit Bus Interface Module (TBU)
- Transmit Packet Controller Module (TPC)
- Transmit Protocol Engine Module (TPE)
- Transmit Scheduler Module (STX)
- Transmit CRC Generator Module (CTX)
- Transmit Flow Control Module (FTX)

Transmit Bus Interface Module (TBU)

This module interfaces the transmit path of the EMAC CORE with the MAC Layer FIFO interface. This module outputs the transmit status to the application at the end of normal transmission or collision.

Transmit Packet Controller Module (TPC)

The Transmit Packet Controller (TPC) module consists of eight registers to hold the data and the last data control received from the TBU.

The register provides a buffer between the application and the Transmit Protocol Engine (TPE) to regulate data flow.

When the number of bytes received from the application are less than 60 (DA+SA+LT+DATA), the state machine that interfaces with TBU automatically appends zeros to the packet being transmitted. This is done to make the data length exactly 46 bytes to meet the minimum data field requirement of IEEE 802.3. The EMAC module can also be programmed to not append any padding.

The cyclic redundancy check (CRC) for the Frame Check Sequence (FCS) field is calculated before transmission to the TPE module. This value is computed by the CTX module. The TPC module receives the computed CRC and appends it to the data being transmitted to the TPE module. When the MAC is programmed to not append the CRC value to the end of Ethernet packets, the TPC module ignores the computed CRC and transmits only the data received from the TBU module to the TPE module. An exception to this rule is that when the MAC is programmed to append pads for packets (DA+SA+LT+DATA) less than 60 bytes sent by the TBU module, the TPC module always appends the CRC at the end of padded packet.

Transmit Protocol Engine Module (TPE)

The Transmit Protocol Engine (TPE) module consists of a Transmit State Machine that controls the operation of Ethernet packet transmission. The Transmit State Machine of this module contains the following features to meet the IEEE 802.3/802.3z specification:

- Generates preamble and SFD
- Generates jam pattern in half-duplex mode after normal collision

- Generates carrier extension in the half-duplex (only in the RGMII) mode when packet is smaller than 512 bytes
- Supports packet bursting in the half-duplex (only in the RGMII) mode
- Jabber timeout
- Flow control for half-duplex mode (back pressure)
- Generates transmit packet status
- Contains time stamp snapshot logic for IEEE 1588 support

When the TPC module requests the TPE module for a new packet transmission, the Transmit State Machine sends out the preamble and SFD, followed by the data received. The preamble is defined as 7 bytes of 10101010 pattern and the SFD is defined as 1 byte of 10101011 pattern.

The collision window is defined as 1 slot time (512-bit times for 10/100 Mbps Ethernet and 4096-bit times for 1,000 Mbps Ethernet). The jam pattern generation is applicable only to half-duplex mode, not to full duplex mode.

In MII/RMII mode, if a collision occurs any time from the beginning of the packet to the end of the CRC field, the Transmit State Machine sends a 32-bit jam pattern of 0x55555555 on MII/RMII to inform all other stations that a collision has occurred. If the collision is seen during the preamble transmission phase, the Transmit state machine completes the transmission of preamble and SFD, and then sends the jam pattern.

In RGMII mode, if a collision occurs any time between the beginning of the packet and the end of the extension field, the Transmit State Machine sends a 32-bit jam pattern of 0x55555555 on RGMII to inform all other stations of the collision. If the collision is seen during the preamble transmission phase, the Transmit State Machine completes the transmission of preamble and SFD, and then sends the jam pattern. If a collision occurs during the extension field, the Transmit State Machine sends a 32-bit jam pattern of 0x1F1F1F1F.

If the collision occurs after the collision window and before the end of the FCS field (or the end of burst if the packet burst mode is enabled), the Transmit State Machine sends a 32-bit jam pattern and sets the late collision bit in the transmit packet status.

In RGMII half-duplex mode (1000 Mbps), the Transmit State Machine ensures that all valid carrier events exceed a slot time of 4,096-bit times. To accomplish this, any transmit packet shorter than 512 bytes from the TFC module is extended using a carrier extension.

When the packet burst mode is enabled, only the first packet of the burst is carrier extended if it is shorter than 512 bytes. The carrier extension is not applicable for MII/RMII half-duplex and RGMII or MII/RMII full-duplex modes. When the packet burst mode is enabled, the Transmit State Machine transmits a burst of packets (when packets are available from the TFC module) without releasing the carrier of the PHY. To accomplish this, the state machine inserts the carrier extension for a minimum IPG period (96-bit times) between the packets. The Transmit State Machine continues to burst packets when additional packets are available from the TPC module and a burst limit of 8192-byte times is not exceeded. When an additional packet is not available at the end of the IPG period in the middle of the burst, the Transmit State Machine releases the carrier RGMII.

Packet bursting is applicable only for the RGMII half-duplex mode. It is not applicable in the MII/RMII and RGMII full-duplex modes. In the RGMII half-duplex mode, the size of the first packet in a packet burst should at least be equal to the slot time. If the first packet (including carrier extension) is less than the slot time, the MAC considers all data bytes, received for the first packet and subsequent packets, which end immediately after the slot time is reached as first packet in the burst. This may result in CRC error. However, if the packet burst ends (both RXDV and RXER go low) before the slot time, the subsequent packet is considered as a new packet. This behavior is according the IEEE 802.3.

The TPE module maintains a jabber timer to stop the transmission of Ethernet packets if the TFC module transfers more than 2,048 (default) bytes. The timeout is changed to 10,240 bytes when the jumbo packet is enabled.

The Transmit State Machine uses the deferral mechanism for flow control (backpressure) in the half-duplex mode. When the application requests to stop receiving packets, the Transmit State Machine sends a JAM pattern of (8'h55) 32 bytes whenever it senses a reception of a packet, provided the transmit flow control is enabled. This results in a collision and the remote station backs off. The application requests the flow control through by setting the `EMAC_Q[i]_TXFLOW_CTL.FCB_BPA` bit of the corresponding MTL queue. If the application requests a packet to transmit, it is scheduled and transmitted even when the backpressure is activated. If the backpressure is kept activated for a long time (and more than 16 consecutive collision events occur), the remote stations abort their transmissions because of excessive collisions.

If IEEE 1588 time stamp is enabled for the transmit packet, this block takes a snapshot of the system time when the SFD is put onto the transmit RGMII or MII/RMII bus. The system time source is either an external input or it is internally generated according to the configuration selected.

Transmit Scheduler Module (STX)

The transmit scheduler is responsible for scheduling the frame transmission on the RGMII or MII/RMII. The two major functions of this module are:

- Maintains the inter-packet gap between two transmitted packets. The STX module maintains an idle period of the configured inter-packet gap (`EMAC_MAC_CFG.IPG`) between any two transmitted packets. If packets from the TPC arrive at the TPE module sooner than the configured IPG time, the TPE module waits for the enable signal from the STX module before starting the transmission on GMII or MII. The STX module starts its IPG counter as soon as the carrier signal of RGMII or MII/RMII goes inactive. At the end of the programmed IPG value, the module issues an enable signal to the TPE module in the full-duplex mode.

  In the half-duplex mode and when IPG is configured for 96-bit times, the STX module follows the rule of deference specified in the IEEE 802.3, Section 4.2.3.2.1. The module resets its IPG counter if a carrier is detected during the first two-thirds (64-bit times for all IPG values) of the IPG interval. If the carrier is detected during the final one-third of the IPG interval, the STX module continues the IPG count and enables the transmitter after the IPG interval.

- Implements the Truncated Binary Exponential Back-off algorithm in half-duplex mode.

Transmit CRC Generator Module (CTX)

The MAC Transmit CRC Generator (CTX) module interfaces with the TFC module to generate the CRC for the FCS field of the Ethernet packet.

The TPC module sends the packet data and any necessary padding to the CTX module through an 8-bit interface.

The CTX module calculates the 32-bit CRC for the FCS field of the Ethernet packet. The encoding is defined by the following generating polynomial:

G (x) = x32 + x26 + x23 + x22 + x16 + x12 + x11 + x10 + x8 + x7 + x5 + x4 + x2 + x + 1

The CTX module gets the byte data of Ethernet packet from the TPC module (DA + SA + LT + DATA + PAD) qualified with a data valid signal. The TPC also indicates to the CTX when to reset the previously calculated CRC and to start the new CRC calculation for the coming packet. The TPC module issues the start command before sending the new packet data for calculation. The calculated CRC is valid on the next clock after the data is received.

In RGMII mode, the data valid signal is valid for every clock, from the first data byte through the last data byte. In MII/RMII mode, this signal is valid every alternate clock.

Transmit Flow Control Module (FTX)

The Transmit Flow Control (FTX) module generates and transmits the pause packets to the TFC module based on the flow control triggers in full-duplex mode. The TFC module receives the pause packet from the FTX module, appends the calculated CRC, and sends the packet to the TPE module.

EMAC Core Reception

The following are the functional blocks (reception engine components) in the receive path of the EMAC core.

- Receive Protocol Engine Module (RPE)
- Receive CRC Module (CRX)
- Receive Packet Controller Module (RPC)
- Receive Flow Control Module (FRX)
- Receive Bus Interface Unit Module (RBU)
- Address Filtering Module (AFM)

Receive Protocol Engine Module (RPE)

The Receive Protocol Engine (RPE) consists of the Receive State Machine which strips the preamble, SFD, and carrier extension of the received Ethernet packet (in half-duplex 1000-Mbps mode). The sequence is as follows:

1. When the RX_DV signal of GMII or MII becomes active, the Receive State Machine of RPE starts looking for the SFD field (byte 0x5D in GMII mode; 0xD nibble in MII mode). The state machine drops received packets until it detects SFD.
2. When SFD is detected, the state machine begins sending the data of Ethernet packet to the RPC module, beginning with the first byte following the SFD (destination address).

3. If the IEEE 1588 time stamp feature is enabled, the RPE takes a snapshot of the system time at which SFD of any packet is detected on GMII or MII. If this packet is not dropped during MAC filtering, the time stamp is passed to the application. In MII mode, the RPE converts the received nibble data into bytes and forwards the valid packet data to the RFC module.
4. The Receive State Machine of the RPE module decodes the length/type field of the receiving Ethernet packet.

   If the length/type field is less than 1,536 and if the MAC is programmed for the Auto CRC/pad stripping (EMAC_MAC_CFG.ACS bit), the state machine sends the data of the packet up to the count specified in the length/type field and starts dropping bytes (including the FCS field). The state machine of the RPE module decodes the length/type field and checks for the length interpretation.

   NOTE: In Audio Video (AV) or Data Center Bridging (DCB) mode when additional receive queues are selected, the packets that are less than or equal to 16 bytes in length after pad stripping, always get dropped inside the MAC receiver. This happens even if the packets have passed the address filter and have no CRC error.

   If the length/type field is greater than or equal to 1,536, the RPE module sends all received Ethernet packet data to the RFC module if the CRC stripping for type packet has not been enabled with the EMAC_MAC_CFG.CST bit. However, if CRC stripping for type packets is enabled and the Receive Checksum Offload Engine is not enabled, the MAC strips and drops the last 4 bytes of all packets of Ether type before forwarding the packets to the application.
5. By default, the MAC is programmed for watchdog timer to be enabled, that is, packets larger than 2,048 (10,240 if Jumbo Packet is enabled) bytes, (DA + SA + LT + DATA + PAD + FCS) are cut off at the RPE module. In addition, a programmable watchdog timer can be used (bit 16 of the EMAC_WDT_TMOUT register) to override the fixed timeout of 2,048 or 10,240 bytes. Programs can disable the watchdog timer using the EMAC_MAC_CFG.WD bit. However, even if the watchdog timer is disabled, a packet greater than 32 KB size is cut off and a watchdog timeout status is given.

At the end of every received packet, the RPE module generates received packet status and sends it to the RPC module. Control, missed packet, and filter fail status are added to the receive status in the RPC module.

Receive CRC Module (CRX)

The receive CRC module checks for any CRC errors in the receiving frame.

This module calculates the 32-bit CRC for the received frame that includes the destination address field through the FCS field (DA+SA+LT+DATA+PAD+FCS). The following generating polynomial defines the encoding.

G (x) = x32 + x26 + x23 + x22 + x16 + x12 + x11 + x10 + x8 + x7 + x5 + x4 + x2 + x + 1

Irrespective of the auto pad or CRC strip, the CRC module receives the entire frame to compute the CRC check for received frame.

Receive Packet Controller Module (RPC)

The MAC Receive Packet Controller (RPC) receives the Ethernet packet data and status from the RPE module.

The RPC module consists of a FIFO of parameterized depth (default set to 4 deep and 33-bits wide) and two state machines for writing and reading the FIFO. The FIFO holds the received Ethernet packet data and byte enables, along with a control bit to indicate the last data. The state machines manage the FIFO and provide a packet buffering for the Ethernet packet being received from the RPE module. The following are main functions of the RPC module:

- Converting Data path — converts 8-bit data to 32-bit data to the RBU module
- Packet filtering
- Attaching the calculated IP checksum input form the IPC
- Updating the receive status and forwarding it to RBU

If the `EMAC_MACPKT_FILT.RA` bit is set, the RPC module initiates the data transfer to the RBU module when 4 bytes of Ethernet data are received from the RPE module. At the end of the data transfer, the RPC module sends out the received packet status that includes the packet filter bits (SA Filterfail and DA Filterfail) and status from the RPC module. These bits are generated based on the filter-fail signals from the AFM module. This status bit indicates to the application whether the received packet has passed the filter controls (both address filter and Packet Filter controls from CSR). The RPC module does not drop any packet on its own in this mode.

If the `EMAC_MACPKT_FILT.RA` bit is reset, the RPC module performs packet filtering based on the destination or source address. If the application does not want to receive any bad packets such as runt, CRC error packets, the application still needs to perform another level of filtering. The RPC module waits to receive the first 14 bytes of received data (type field) from the RPE module. Until then, the module does not initiate any transfers to the RBU module. After receiving the destination or source address bytes, the RPC checks the filter-fail signal from the AFM module for an address match. On detecting filter-fail from AFB, the packet is dropped at the RPC module and not transferred to the application.

On a delayed filter response from the AFM (this can only occur if the AFM logic is changed), the RPC module waits until the FIFO is full, and then proceeds with the packet transfer to the RBU module. However, the RPC module still takes the delayed response from the AFM module and if it is a (DA or SA) filter failure, it drops the rest of the packet and sends the receive status word (with zero packet-length, CRC error and runt error bits set) immediately indicating the filter fail. If there is no response from the AFM until EOP is transmitted, the filter fail status in the receive status word is updated accordingly.

Receive Flow Control Module (FRX)

The Receive Flow Controller (FRX) detects the pause packet being received and pauses the packet transmission for the delay specified within the received pause packet. The FRX module is enabled only in the full-duplex mode.

Receive Bus Interface Unit Module (RBU)

The Receive Bus Interface Unit (RBU) converts the 32-bit data received from the RPC module into a 32-bit protocol on the Application side.

Address Filtering Module (AFM)

The Address Filtering Module (AFM) performs the destination and source address checking function on all received packets and reports the address filtering status to the RPC module.

The address checking is done based on different parameters (EMAC_MACPKT_FILT register) chosen by the application. These parameters are inputs to the AFM module as control signals, and the AFM module reports the status of the address filtering based on the combination of these inputs. The AFM module does not filter the receive packets but reports the status of the address filtering (whether to drop the packet or not) to the RFC module. The AFM module also reports address filter status and whether the received packet is a multicast packet or a broadcast packet.

The AFM module probes the 8-bit receive data path between the RPE module and the RFC module and checks the destination and source address field of each incoming packet. In GMII mode, the module takes 8/14 clocks (from the start of packet) to compare the destination/source address of the packet being received. Similarly, in MII mode, the module takes 14/26 clocks (from the start of packet) to compare the destination or source address of the receiving packet. The AFM module gets the physical (MAC) address of the station and the Multicast Hash table from CSR module for address checking. The CSR module provides the packet filter register parameters to AFM.

Source Address, VLAN, CRC Insertion/Replacement

The following sections provide information on Source Address and VLAN Insertion, Replace, or Delete, Queue/Channel Based VLAN Tag Insertion on Transmission, and CRC Insertion and Replacement.

Double VLAN Processing

The EMAC module supports two VLAN tags, namely inner and outer, for processing double VLANs.

This feature is referred called double VLAN tagging where the MAC can process two VLAN tags. With this feature, the EMAC supports:

- Insertion, replacement, or deletion of up to two VLAN tags in the transmit path.
- Packet filtering and stripping based on any one of the two VLAN tags in the receive path. Stripping and providing up to two VLAN tags in the receive path as a part of the receive status.

Transmit Path

The following table describes the double VLAN features supported by the MAC on the transmit side.

Table 30-38: Double VLAN Processing Features in Transmit Path

Feature	Description
Support for C-VLAN and S-VLAN Tag types	The inner or outer VLAN tag can be of C-VLAN and S-VLAN type. The VLAN type is specified through the EMAC_VLAN_INCL.CSVL bit and the EMAC_INVLAN_INCL.CSVL bit. The EMAC supports processing of any sequence of outer and inner VLAN tags. **NOTE:** The EMAC does not support the C-VLAN S-VLAN sequence. The MAC does not check whether the packet provided by the application has a valid sequence of the VLAN tag types or whether the insertion or replacement operation results in an invalid sequence of VLAN tag type. Therefore, the application must provide a correct sequence of VLAN tag types and program the MAC so that the VLAN tag types in the transmitted packet contains the correct sequence. The application must ensure the following: • The inner tag should not be S-VLAN when the outer C-VLAN tag insertion is enabled. • The outer tag should not be C-VLAN when the inner S-VLAN tag insertion is enabled. • The inner tag cannot be S-VLAN when the outer tag is replaced with C-VLAN. • The outer tag cannot be C-VLAN when the inner tag is replaced with S-VLAN.
VLAN Tag deletion	Programs can enable the VLAN tag deletion for outer or inner tag using the EMAC_VLAN_INCL.VLC and EMAC_INVLAN_INCL.VLC bit fields, respectively. When VLAN deletion is enabled, the MAC deletes the tag present at the corresponding position. When a packet has only one tag, it is considered as the outer tag. If inner tag deletion is enabled and the packet has only one tag, the MAC does not delete the tag.
VLAN Tag Insertion or Replacement	Programs can enable the VLAN tag insertion or replacement for outer or inner tag using the EMAC_VLAN_INCL.VLC EMAC and EMAC_INVLAN_INCL.VLC bit fields, respectively. When VLAN tag insertion or replacement is enabled, the EMAC_VLAN_INCL.VLTI bit and the EMAC_INVLAN_INCL.VLTI bit are used to determine whether the VLAN tag is taken from the register or the control word.

Receive Path

The following table describes the features supported by the MAC on the receive side and the corresponding bits in the EMAC_VLANTAG_CTL register.

Table 30-39: Double VLAN Processing in Receive Path

Feature	Description
Outer or inner VLAN tag-based filtering	The MAC can filter packets based on the outer or inner VLAN tag through the EMAC_VLANTAG_CTL.ERIVLT bit.
C-VLAN or S-VLAN tag-based filtering	The MAC can filter packets based on the C-VLAN or S-VLAN type based on the EMAC_VLANTAG_CTL.ERSVLM bit.
Outer and Inner VLAN Tag stripping	The MAC can strip the outer and inner VLAN Tags from received frame based on the EMAC_VLANTAG_CTL.EVLS and EMAC_VLANTAG_CTL.EIVLS bits.
16-bit outer and inner VLAN Tag and Type in Rx status	The MAC can provide the 16-bit outer and inner VLAN tag and type in the Rx status based on the EMAC_VLANTAG_CTL.EVLRXS and EMAC_VLANTAG_CTL.EIVLRXS bits, respectively.

Table 30-39: Double VLAN Processing in Receive Path (Continued)

Feature	Description
Disabling or skipping checking of outer VLAN Tag type	The MAC can disable or skip checking of outer VLAN tag type to match C-VLAN or S-VLAN based on the EMAC_VLANTAG_CTL.DOVLTC bit.

Source Address and VLAN Insert, Replace, or Delete

The EMAC supports inserting or replacing the source address based on the information in the MAC address registers. The MAC can also insert, replace, or delete the VLAN fields (VLAN type and VLAN tag) based on the setting of the EMAC_VLAN_INCL.VLTI bit. Programs can enable the SA insert or replace feature for all transmit packets or selective packets. Similarly, programs can enable the VLAN insert, replace, or delete feature for all transmit packets or selective packets.

Programming Source Address Insert or Replace

The software can use the SA insert or replace feature to instruct the MAC to do the following for transmit packets:

- Insert the content of the MAC address registers in the SA field
- Replace the content of the SA field with the content of the MAC address registers

When SA insert is enabled, the application must ensure that the packets sent to the MAC do not have the SA field. The MAC does not check whether the SA field is present in the transmit packet and it inserts the content of MAC address registers in the SA field. Similarly, when SA replace is enabled, the application must ensure that the SA field is present in the packets sent to the MAC. The MAC replaces the six bytes following the destination address field in the transmit packet with the content of the MAC address registers.

The program can enable the SA insert or replace feature for all transmit packets or selective packets:

- Enable SA insert or replace for all packets: program the EMAC_MAC_CFG.SARC bit field
- Enable SA insert or replace for selective packets: program the SA insertion control field (bits [25:23] of TDES3) in the first transmit descriptor of the packet. When bit 25 of TDES3 is set, the SA insertion control field indicates insertion or replacement by the MAC address1 registers. When bit 25 of TDES3 is reset, it indicates insertion or replacement by the MAC address0 registers.

If the MAC address1 registers are not enabled, the MAC address0 registers are used to insert or replace irrespective of the value of the most-significant bit of the SA insertion control field.

Programming VLAN Insert, Replace, or Delete

The software can use the VLAN insert, replace, or delete feature to instruct the MAC to do the following for transmit packets:

- Delete the VLAN type and VLAN tag fields
- Insert or replace the VLAN type and VLAN tag fields using the EMAC_VLAN_INCL.VLTI bit as described in the following table.

Table 30-40: Double VLAN Processing in Receive Path

Condition	Description
EMAC_VLAN_INCL.VLTI bit is set	The MAC inserts or replaces the following: • VLAN type field (C-VLAN or S-VLAN as indicated by the EMAC_VLAN_INCL.CSVL bit • VLAN Tag field content of the VT field of transmit context descriptor of the packet
EMAC_VLAN_INCL.VLTI bit is reset	The MAC inserts or replaces the following: • VLAN Type field (C-VLAN or S-VLAN as indicated by the EMAC_VLAN_INCL.CSVL bit • VLAN tag field with the EMAC_VLAN_INCL.VLT bit field

When VLAN replace or delete is enabled, the MAC checks if the VLAN type field (0x8100 or 0x88a8) is present after the DA and SA fields in the transmit packet. The replace or delete operation does not occur if the VLAN type field is not detected in two bytes following the DA and SA fields. However, when VLAN insertion is enabled, the MAC does not check for the presence of the VLAN type field in the transmit packet and just inserts the VLAN type and VLAN tag fields.

Programs can enable the VLAN insert, replace, or delete feature for all transmit packets or selective packets:

- Enable VLAN insert, replace, or delete for all packets: program the EMAC_VLAN_INCL.VLC and EMAC_VLAN_INCL.VLP bit fields
- Enable VLAN insert, replace, or delete for selective packets: program the VTIR field of the TDES2 normal descriptor

Queue/Channel Based VLAN Tag Insertion on Transmit

The EMAC supports channel/queue based VLAN tag insertion on all transmitted packets. Queue/channel specific VLAN tag registers are accessed using indirect addressing through the EMAC_VLAN_INCL register. VLAN type and tag values can be independently programmed for each queue/channel. See Programming Queue/Channel Based VLAN Inclusion Registers for more details.

CRC Insert and Replace

The software can use the CRC replace feature to instruct the MAC to replace the FCS field in the transmit frame with the CRC computed by the MAC. This feature works on per-frame basis. To enable the CRC replacement feature, program the CRC replacement control field (bit 26 of TDES3) in the first transmit descriptor of the frame.

Packet Filtering

the *Packet Filtering Sequence* figure shows the filtering sequence for receive packets. The sequence shown in the figure is valid when all the filters (L2, VLAN, L3, L4) are active. If any of the layer filters are not enabled, that filter is bypassed, and the subsequent filter is applied. A packet that fails any of the filters is discarded. However, the discarded packet can be forwarded to the host based on the register control. For example, when the EMAC_MACPKT_FILT.RA bit is set to 1, all discarded packets are forwarded to the host but with its packet status indicating the specific filter-failure. If RA=0, the EMAC_MACPKT_FILT.VTFE and

EMAC_MACPKT_FILT.IPFE bits of control whether the packets that fail the VLAN filter and Layer 3-4 filter should be discarded or forwarded to the host.

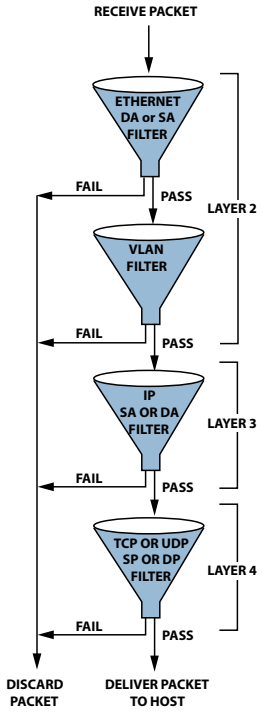

Figure 30-26: Packet Filtering Sequence

Source Address or Destination Address Filtering

The Address Filtering Module of the MAC checks the source address (SA) and destination address (DA) fields of each incoming packet.

Unicast Destination Address Filtering

The MAC supports 32 MAC addresses for unicast perfect filtering. If perfect filtering is selected (the EMAC_MACPKT_FILT.HUC bit is reset), the MAC compares all 48 bits of received unicast address with the programmed MAC address for any match. The default address0 register (EMAC_ADDR0_HI, EMAC_ADDR0_LO) is always enabled.

The address1 through 31 register addresses (both HIGH and LOW) are selected with an individual enable bit. For these addresses, programs can mask each byte during comparison with corresponding received DA byte by setting the corresponding mask byte control bit in the register. This enables group address filtering for the DA.

In hash filtering mode (when the EMAC_MACPKT_FILT.HUC bit is set), the MAC performs imperfect filtering for unicast addresses using a hash table (256 bits for EMAC0 and 64 bits for EMAC1). For hash filtering, the MAC uses the upper 6 bits CRC of the received destination address to index the content of the hash table. A value of 00000 selects bit 0 of the selected register, and a value of 11111 selects bit 63 of the hash table register (registers 7-0). When the corresponding bit (indicated by the 6-bit CRC) is set to 1, the unicast packet is considered to have passed the hash filter; otherwise, the packet is considered to have failed the hash filter.

Multicast Destination Address Filtering

To program the MAC to pass all multicast packets, set the EMAC_MACPKT_FILT.PM bit. If the EMAC_MACPKT_FILT.PM bit is reset, the MAC performs the filtering for multicast addresses based on the EMAC_MACPKT_FILT.HMC bit.

The multicast address is compared with the programmed MAC destination address registers (1–31). Group address filtering is also supported. In hash filtering mode, the MAC performs imperfect filtering using a 64-bit hash table. The MAC uses the upper 6-bits CRC of received multicast address to index the content of the hash table. A value of 000000 selects bit 0 of the selected register and a value of 111111 selects bit 63 of the hash table register. If the corresponding bit is set to 1, the multicast packet is considered to have passed the hash filter. Otherwise, the packet is considered to have failed the hash filter.

Hash or Perfect Address Filtering

To configure the DA filter to pass a packet when its DA matches either the hash filter or the perfect filter, set the EMAC_MACPKT_FILT.HPF bit and the corresponding EMAC_MACPKT_FILT.HUC or EMAC_MACPKT_FILT.HMC bits. This is applicable to both unicast and multicast packets. If the EMAC_MACPKT_FILT.HPF bit is reset, only one of the filters (hash or perfect) is applied to the received packet.

Broadcast Address Filtering

The MAC does not filter any broadcast packets by default. To program the MAC to reject all broadcast packets, set the EMAC_MACPKT_FILT.DBF bit.

Unicast Source Address Filtering

The MAC can perform perfect filtering based on the source address field of received packets. By default, the MAC compares the SA field with the values programmed in the SA registers. Programs can configure the MAC address registers [1–31] to use SA instead of DA for comparison by setting bit 30 of corresponding register.

The MAC also supports group filtering with SA. Programs can filter a group of addresses by masking one or more bytes of the address. The MAC drops the packets that fail the SA filter if the EMAC_MACPKT_FILT.SAF bit is set. Otherwise, the result of the SA filter is given as a status bit in the Receive Status word. When the EMAC_MACPKT_FILT.SAF bit is set, the SA filter and DA filter result is AND'ed to decide whether the packet needs to be forwarded. This means that the packet is dropped if either filter fails. The packet is forwarded to the application only if the packet passes both filters in order.

Inverse Filtering

For DA and SA filtering, programs can invert the filter-match result at the final output by setting the EMAC_MACPKT_FILT.DAIF and EMAC_MACPKT_FILT.SAIF bits. The EMAC_MACPKT_FILT.DAIF bit is applicable for both unicast and multicast DA packets. The result of the unicast or multicast destination address filter is inverted in this mode. Similarly, when the SAIF bit is set, the result of unicast SA filter is reversed.

The following tables summarize the DA and SA filtering based on the type of packets received.

NOTE: When the EMAC_MACPKT_FILT.RA bit is set, all packets are forwarded to the system along with the correct result of the address filtering in the Rx status.

Table 30-41: Destination Address Filtering

Packet Type	PR	HPF	HUC	DAIF	HMC	PM	DBF	DA Filter Operation
Broad-cast	1	X	X	X	X	X	X	Pass
	0	X	X	X	X	X	0	Pass
	0	X	X	X	X	X	1	Fail
Unicast	1	X	X	X	X	X	X	Pass all packets
	0	X	0	0	X	X	X	Pass on Perfect/Group filter match
	0	X	0	1	X	X	X	Fail on Perfect/Group filter match
	0	0	1	0	X	X	X	Pass on Hash filter match
	0	0	1	1	X	X	X	Fail on Hash filter match
	0	1	1	0	X	X	X	Pass on Hash or Perfect/Group filter match
	0	1	1	1	X	X	X	Fail on Hash or Perfect/Group filter match
Multi-cast	1	X	X	X	X	X	X	Pass all packets
	X	X	X	X	X	1	X	Pass all packets
	0	X	X	0	0	0	X	Pass on Perfect/Group filter match and drop Pause packets if `EMAC_MACPKT_FILT.PCF` = 0x
	0	0	X	0	1	0	X	Pass on Hash filter match and drop Pause packets if `EMAC_MACPKT_FILT.PCF` = 0x
	0	1	X	0	1	0	X	Pass on Hash or Perfect/Group filter match and drop Pause packets if `EMAC_MACPKT_FILT.PCF` = 0x
	0	X	X	1	0	0	X	Fail on Perfect/Group filter match and drop Pause packets if `EMAC_MACPKT_FILT.PCF` = 0x
	0	0	X	1	1	0	X	Fail on Hash filter match and drop Pause packets if `EMAC_MACPKT_FILT.PCF` = 0x
	0	1	X	1	1	0	X	Fail on Hash or Perfect/Group filter match and drop Pause packets if `EMAC_MACPKT_FILT.PCF` = 0x

Table 30-42: Source Address Filtering

Packet Type	PR	SAIF	SAF	DA Filter Operation
Unicast	1	X	X	Pass all packets
	0	0	0	Pass status on Perfect or Group filter match but do not drop packets that fail
	0	1	0	Fail status on Perfect or Group filter match but do not drop packet
	0	0	1	Pass on Perfect or Group filter match and drop packets that fail
	0	1	1	Fail on Perfect or Group filter match and drop packets that fail

VLAN Filtering

The following sections provide information on EMAC VLAN filtering.

VLAN Tag Perfect Filtering

In VLAN tag perfect filtering, the MAC compares the VLAN tag of received packet and provides the VLAN packet status to the application. Based on the programmed mode, the MAC compares the lower 12 bits or all 16 bits of received VLAN tag to determine the perfect match.

If VLAN tag perfect filtering is enabled, the MAC forwards the VLAN-tagged packets along with VLAN tag match status and drops the VLAN packets that do not match. Programs can enable the inverse matching for VLAN packets by setting the `EMAC_VLANTAG_CTL.VTIM` bit. In addition, programs can enable processing of S-VLAN tagged packets along with the default C-VLAN tagged packets by setting the `EMAC_VLANTAG_CTL.ESVL` bit. The VLAN packet status bit (bit 10 of RDES0) indicates the VLAN tag match status for the matched packets.

NOTE: The source or destination address (if enabled) has precedence over the VLAN tag filters. This means that a packet that fails the source or destination address filter is dropped irrespective of the VLAN tag filter results. By default, the VLAN tag-based perfect filter is available in all configurations.

VLAN Tag Hash Filtering

The 16-bit VLAN hash table is used for group address filtering based on the VLAN tag. The MAC performs the VLAN hash matching using the `EMAC_VLANTAG_CTL.VTHM` (VLAN tag hash table match enable) bit. The MAC provides VLAN tag hash filtering with a 16-bit hash table.

If the `EMAC_VLANTAG_CTL.VTHM` bit is set, the most significant four bits of CRC-32 of VLAN tag are used to index the content of the `EMAC_VLAN_HASHTBL` register. A value of 1 in the register, corresponding to the index, indicates that the VLAN tag of the packet matched and the packet is forwarded. A value of 0 indicates that VLAN-tagged packet is dropped.

NOTE:
- The 16 or 12 bits of the VLAN tag are considered for CRC-32 computation based on the `EMAC_VLANTAG_CTL.ETV` bit.
- When the bit is reset, most significant four bits of CRC-32 of VLAN tag are inverted and used to index the content of `EMAC_VLANTAG_CTL` register.
- When the bit is set, most significant four bits of CRC-32 of VLAN tag are directly used to index the content of the `EMAC_VLANTAG_CTL` register.

If the VLAN tag of a packet matches the perfect or hash filter, the packet is dropped. If the VLAN perfect and VLAN hash match are enabled, a packet is considered as matched if either the VLAN hash or the VLAN perfect filter matches. When inverse matching is set, a packet is forwarded only when both perfect and hash filters indicate mismatch.

The *VLAN Match Status* table shows the different possibilities for VLAN matching and the final VLAN match status. When the `EMAC_MACPKT_FILT.RA` bit is set, all packets are received, and the VLAN match status is indicated in the VF bit of RDES2 normal descriptor (write-back format). When the RA bit is not set and the

EMAC_MACPKT_FILT.VTFE bit is set, the packet is dropped if the final VLAN match status is fail. In the following table, X signifies that entry can have any value.

When VLAN VID is programmed to 0 in the EMAC_VLANTAG_DAT.VID bit field, all VLAN-tagged packets are considered as perfect matched but the status of the VLAN hash match depends on the EMAC_VLANTAG_CTL.VTHM and EMAC_VLANTAG_CTL.VTIM bits.

Table 30-43: VLAN Match Status

VID	VLAN Perfect Filter Match Result	VTHM Bit	VLAN Hash Filter Match Result	VTIM Bit	Final VLAN Match Status
VID = 0	Pass	0	X	X	Pass
	Pass	1	X	0	Pass
	Pass	1	Fail	1	Pass
	Pass	1	Pass	1	Fail
VID! = 0	Pass	X	X	0	Pass
	Fail	0	X	0	Fail
	Fail	1	Fail	0	Fail
	Fail	1	Pass	0	Pass
	Fail	0	X	1	Pass
	Pass	X	X	1	Fail
	Fail	1	Pass	1	Fail
	Fail	1	Fail	1	Pass

Extended Receive VLAN Filtering and Routing

The MAC receiver can classify the received packets based on a VLAN tag and steer them to a specific Rx DMA channel. The MAC compares the received frame's VLAN tag with all the enabled and relevant filters and provides a filtering result. If any of the perfect filters give a pass result and if the respective filter's DMA channel number is enabled, the frame is routed to that DMA channel.

In addition to filtering, routing can also be done. For more details about routing, see Extended VLAN Based DMA Selection in Dynamic Mapping.

Comparison Modes

For each VLAN tag filter, the application has the following comparison options:

- It can program the MAC to compare an outer VLAN tag or an inner VLAN tag with the programmed VID.
- It can choose if 12 or 16 bits of the VID field need to be compared.
- Type check can be disabled or enabled for each filter; if enabled, the application can choose if the VID comparison is for SVLAN or CVLAN type frames only. For example, if a filter is enabled for 16-bit comparison,

SVLAN type, and outer VLAN tag, any single or double VLAN tagged frames with outer SVLAN tags are compared with this filter, and a pass or fail result is obtained.

NOTE: The inner VLAN tag comparison is applicable only if double VLAN tag processing is enabled using the `EMAC_VLANTAG_CTL.EDVLP` bit.

Filtering

When extended receive VLAN filtering and routing is enabled, the application can enable both perfect and hash filtering. The overall VLAN filter result is based on the perfect filter result and the hash filter result (if enabled). The filter result is passed to the application as part of the status bits.

Perfect filtering is done using the EMAC_MAC_VLAN_TAG_FILTER[n] registers (these registers are accessed indirectly using the `EMAC_VLANTAG_DAT` and `EMAC_VLANTAG_CTL` registers). For each VLAN tag filter, the MAC compares the relevant VLAN tag ID and gives a result. If any one of the VLAN tag filters gives a match, the frame is considered to have passed the VLAN tag filters. If the frame mismatches all the filters, the frame is considered to have failed the VLAN filter. This behavior is applicable only when the inverse filtering is not enabled in the `EMAC_VLANTAG_CTL` register.

If inverse filtering is enabled and the frame has mismatched all the relevant filters, then it is considered to have passed the VLAN filter. If the frame matches any one of the relevant filters, then it is considered as a fail. If none of the enabled filters can perform a comparison or if none of the filters are enabled, then the frame is bypassed to the application.

The overall filter result and the values programmed in the `EMAC_MACPKT_FILT.VTFE` and `EMAC_MACPKT_FILT.RA` fields determine if the frame must be dropped or forwarded to the application.

- When RA = 1 or VTFE = 0, The MAC forwards the frame, irrespective of the filter result.
- When RA = 0 and VTFE = 1, The MAC forwards the frame only if the VLAN tag filter status is pass. After forwarding a frame to the application, the relevant filter result is indicated through the status bits.

See Programming Extended VLAN Filtering and Routing on Receive.

VLAN Filter Status

The extended receive VLAN filtering and routing feature provides two status bits to indicate the comparison result of the VLAN tags.

By default, the MAC indicates the VLAN filter status through one bit in the status – VF in RDES2. When extended receive VLAN filtering and routing is enabled, two status bits are used to indicate the comparison result of VLAN tags. The outer VLAN tag filter pass and inner VLAN tag filter pass bits are defined in the following positions in various configurations. The status indicated through these bits is updated in RDES2 as follows:

- Bit 15 – Outer VLAN tag filter status
- Bit 14 – Inner VLAN tag filter status

Outer VLAN Tag Filter Status (OTS)

The outer VLAN tag filter pass bit provides the following status:

- In perfect filtering, without inverse filtering enabled, if this bit is set, it indicates that the frame's outer VLAN tag has matched one of the VLAN tag filters.
- When this bit is reset, it indicates that the frame's outer VLAN tag has either failed the relevant outer VLAN tag filters or bypassed them.
- When none of the filters are enabled for outer VLAN tag comparison, then this bit is reset.
- When Inverse filtering is enabled and this bit is set, then the frame's VLAN tag has passed all the relevant VLAN tag filters. If it is reset, then it has failed at least one of or bypassed all the filters programmed for outer VLAN tag comparison.
- This bit is valid for both single and double VLAN tagged frames.

Inner VLAN Tag Filter Status (ITS)

The inner VLAN tag filter pass bit provides the following status:

- In perfect filtering, without inverse filtering enabled, if this bit is set, it indicates that the frame's inner VLAN tag has matched one of the VLAN tag filters.
- When this bit is reset, it indicates that the frame's inner VLAN tag has either failed the relevant inner VLAN tag filters or bypassed them.
- When none of the filters are enabled for inner VLAN tag comparison, then this bit is reset.
- When inverse filtering is enabled and this bit is set, then the frame's VLAN tag has passed all the relevant VLAN tag filters. When it is reset, then it has failed at least one of or bypassed all the filters programmed for inner VLAN tag comparison.
- This bit is valid for only double VLAN tagged frames, when double VLAN processing is enabled.

The application must look at the status bits and the programming to determine if the frame has passed or failed the VLAN filter.

The *OTS and ITS Bit Values with At Least 1 Perfect Filter Enabled* table and *OTS and ITS Bit Values with Only VLAN Hash Filter Enabled* table show the possible filter combinations and the corresponding filter results. These tables explain the scenarios when double VLAN processing and hash VLAN filter are enabled in the design.

In the following tables:

- `EMAC_VLANTAG_CTL.VTIM`: VLAN tag inverse match enable – bit 17.
- HFO: Hash filter enabled for outer VLAN tag comparison – bit 25 (VHTM) in the `EMAC_VLANTAG_CTL` register.
- HFI: hash filter enabled for inner VLAN tag comparison – bit 27 (ERIVLT) in the `EMAC_VLANTAG_CTL` register.

- PFO – Perfect filter comparison enabled for outer VLAN tag – Any of the EMAC_MAC_VLAN_TAG_FILTER registers is enabled (bit 16 is set) and programmed for outer VLAN tag comparison (bit 20 is set to 0).
- PFI – Perfect filter comparison enabled for inner VLAN tag – Any of the EMAC_MAC_VLAN_TAG_FILTER registers is enabled (bit 16 is set) and programmed for inner VLAN tag comparison (bit 20 is set to 1).
- OTS – Outer VLAN tag filter status
- ITS – Inner VLAN tag filter status

The following table shows the possible values of status bits (OTS and ITS) when at least one perfect filter is enabled.

Table 30-44: OTS and ITS Bit Values with At Least 1 Perfect Filter Enabled

VTIM	HFO	HFI	PFO	PFI	OTS	ITS
0	0	0	0	1	0	1/0
0	0	0	1	0	1/0	0
0	0	0	1	1	1/0	1/0
0	1	0	1	1	1/0	1/0
0	1	0	1	0	1/0	0
0	1	0	0	1	1/0	1/0
0	0	1	1	1	1/0	1/0
0	0	1	1	0	1/0	1/0
0	0	1	0	1	0	1/0
1	0	0	0	1	0	1/0
1	0	0	1	0	1/0	0
1	0	0	1	1	1/0	1/0
1	1	0	1	1	1/0	1/0
1	1	0	1	0	1/0	0
1	1	0	0	1	1/0	1/0
1	0	1	1	1	1/0	1/0
1	0	1	1	0	1/0	1/0
1	0	1	0	1	0	1/0

The following table shows the possible values of status bits (OTS and ITS) when none of the perfect filters are enabled and only the VLAN hash filter is enabled.

Table 30-45: OTS and ITS Bit Values with Only VLAN Hash Filter Enabled

VTIM	HFO	HFI	OTS	ITS
0	0	0	0	0

Table 30-45: OTS and ITS Bit Values with Only VLAN Hash Filter Enabled (Continued)

VTIM	HFO	HFI	OTS	ITS
0	1	0	1/0	0
0	0	1	1/0	1/0
1	0	0	1/0	0
1	1	0	1/0	0
1	0	1	1/0	1/0

- When no perfect filters are enabled, any VLAN packet is considered to have bypassed the perfect filter.
- When VLAN hash filter is enabled for one of the tags, the respective status bit depends on the result of the filter. Status bits are set to 0 when VLAN hash filter is not enabled.
- The value 1/0 for the ITS/OTS field indicates that the final result is dependent on the result of the enabled relevant filter.

Example 1: The second row of the above table indicates that at least one perfect filter is enabled for outer VLAN tag comparison and none of the filters are enabled for Inner VLAN tag comparison. Inverse VLAN filtering is not enabled. The bit OTS is given as 1/0. When the received frame passes at the least one of the enabled Outer VLAN Tag filters, then the bit is set to 1. When the frame does not pass any of the enabled Outer VLAN Tag filters, then the bit is set to 0.

Example 2: Last row of the above table indicates that inverse filtering is enabled, Hash filter and at least one perfect filter is enabled for inner VLAN tag comparison, then when the received frame's inner VLAN tag mismatches with both the hash filter and all the enabled perfect filters, then the frame has the ITS bit set to 1. Otherwise, the bit is set to 0. The OTS bit is set to 0 as the comparison is not performed.

VLAN Stripping

Each of the VLAN tags has individual control over stripping. The programming options of always strip, never strip, strip on pass and strip on fail are available. Inner or outer VLAN tag stripping is based on the pass or fail results of the individual tag. If a tag is bypassed by all the relevant filters, stripping is not applicable for the tag.

- If strip on pass is enabled for the outer VLAN tag, stripping is done only if the outer VLAN tag has passed the relevant filters. The outer VLAN tag filter result bit is set.
- If strip on fail is enabled for the outer VLAN tag, stripping is done only if the outer VLAN tag has failed relevant filters. The Outer VLAN tag filter result bit is reset.
- If the Outer VLAN tag of the received frame is bypassed by the entire filter (no comparison has been made), the tag is not stripped, though the status bit is still 0.
- As multiple filters are enabled, it is possible that the received VLAN frame matches more than one filters. The VLAN tag's value is not always deterministic from the filter status bits.

- If the application strips the VLAN tag based on the filter result, it might lose the VID. If stripping is enabled for any of the tags, the tag can be put in the status. The application must enable the respective EMAC_VLANTAG_CTL.EVLRXS or EMAC_VLANTAG_CTL.EIVLRXS bits.

VLAN Filter Fail Packets Queue

When VLAN filtering is enabled, the VLAN filter fail packets can be routed to a programmable queue (EMAC_RXQ_CTL4.VFFQ) when the EMAC_MACPKT_FILT.RA bit = 1 or EMAC_MACPKT_FILT.VTFE = 0 and the enable bit (EMAC_RXQ_CTL4.VFFQE) for the queue is set.

The packets that pass the VLAN filtering are routed based on the VLAN TAG priority field. The VLAN tag priorities can be assigned to receive queues by programming the PSRQ field in the corresponding EMAC_RXQ_CTL2 and EMAC_RXQ_CTL3 registers. The packets that fail the VLAN filter are discarded if EMAC_MACPKT_FILT.RA=0 or EMAC_MACPKT_FILT.VTFE =1. However, when RA=1 or VTFE=0, the VLAN filter fail packets are still forwarded to the application. In such a scenario, when the VLAN filter fail queue enable (EMAC_RXQ_CTL4.VFFQE) bit is set, the VLAN filter fail packets are forwarded to the receive queue number programmed in the EMAC_RXQ_CTL4.VFFQ bit. If VFFQE=0, the receive queue number is determined by the VLAN priority mapping as per the PSRQ fields.

The *Receive Queue Routing Table for Unicast Tagged Packets* shows the receive queue routing table for Unicast tagged packets, with the DA/SA filter enabled.

In the following table X = don't care; * = when UFFQE is enabled else PSRQ

Table 30-46: Receive Queue Routing Table for Unicast Tagged Packets

RA	VFTE	SA/DA Filter Result	VLAN Filter Result	VFFQE	Queue Routing
X	X	Pass	Pass	X	PSRQ
0	0	Pass	Fail	0	PSRQ
0	0	Pass	Fail	1	VFFQ
0	X	Fail	X	X	Dropped
0	1	Pass	Fail	X	Dropped
1	X	Fail	X	0	UFFQ*/PSRQ
1	X	Fail	X	1	UFFQ*/PSRQ
1	X	Pass	Fail	0	PSRQ
1	X	Pass	Fail	1	VFFQ

Layer 3 and Layer 4 Frame Filtering

The MAC supports layer 3 and layer 4 based frame filtering. The layer 3 filtering refers to the IP source or destination address filtering in the IPv4 or IPv6 frames whereas layer 4 filtering refers to the source or destination port number filtering in TCP or UDP.

When layer 3 and layer 4 filtering is enabled, the frames are filtered in the following way:

Matched Packets. The MAC forwards the packets that match all enabled fields to the application along with the status. The MAC gives the matched field status only if the `EMAC_MAC_CFG.IPC` bit is set and one of the following conditions is true:

- All enabled layer 3 and layer 4 fields match
- At least one of the enabled fields match and other fields are bypassed or disabled

When multiple layer 3 and layer 4 filters are enabled, any filter match is considered as a match. IWhen more than one filter matches, the MAC provides the status of the lowest filter where filter 0 is the lowest filter and filter 3 is the highest filter. For example, when filter 0 and filter 1 match, the MAC gives the status corresponding to filter 0.

NOTE: The source or destination address and VLAN tag filters (if enabled) have precedence over layer 3 and layer 4 filter. This means that a packet which fails the source or destination address, or VLAN tag filter is dropped irrespective of the layer 3 and layer 4 filter results.

Unmatched Packets. The MAC drops the packets that do not match any of the enabled fields. Programs can use the inverse match feature to block or drop a packet with specific TCP or UDP over IP fields and forward all other packets. When a packet is dropped, the aborted or partial packets can be dropped in the MTL Rx FIFO. If the Rx FIFO operates in the threshold (cut-through) mode and the threshold is programmed to a small value, such that packet transfer to application starts before the failed layer 3 and layer 4 filter results are available, the application may receive a partial packet with appropriate abort status.

Non-TCP or UDP IP Packets. By default, all non-TCP or UDP IP packets are bypassed from the layer 3 and layer 4 filters. The program can optionally program the MAC to drop all non-TCP or UDP over IP packets.

Layer 3 Filtering

The EMAC supports perfect matching or inverse matching for IP source address and destination address. The matching compares all bits of the address except the specified lower mask bits.

For IPv6 packets filtering, the program can enable the last four data registers of a register set to contain the 128-bit IP source address or IP destination address. The IP source address or destination address should be programmed in the order defined in the IPv6 specification, that is, the first byte of the IP source address or destination address in the received packet is in the higher byte of the register and the subsequent registers follow the same order.

For IPv4 packet filtering, the program can enable the second and third data registers of a register set to contain the 32-bit IP source address and IP destination address. The remaining two data registers are reserved. The IP source address or destination address should be programmed in the order defined in the IPv4 specification, that is, the first byte of IP source address and destination address in the received packet in the higher byte of the respective register.

Layer 4 Filtering

The EMAC supports perfect matching or inverse matching for TCP or UDP source and destination port numbers. However, only one type (TCP or UDP) can be programmed at a time. The first data register contains the 16-bit source and destination port numbers of TCP or UDP, that is, the lower 16 bits for source port number and higher 16 bits for destination port number.

The TCP or UDP source and destination port numbers should be programmed in the order defined in the TCP or UDP specification, that is, the first byte of TCP or UDP source and destination port number in the received packet is in the higher byte of the register.

Layer 3 and Layer 4 Filters Registers

The MAC implements a set of registers for layer 3 and layer 4 based frame filtering. In a register set, there is a control register, such as the EMAC_L3L4_CTL[i] register (layer 3 and layer 4 control register), to control the frame filtering. In addition, there are five address registers to program the layer 3 and layer 4 fields to be matched, which are:

- EMAC_L4_ADDR[i] (layer 4 Address Register)
- EMAC_L3_ADDR0_REG[i] (layer 3 address 0 register)
- EMAC_L3_ADDR1_REG[i] (layer 3 address 1 register)
- EMAC_L3_ADDR2_REG[i] (layer 3 address 2 register)
- EMAC_L3_ADDR3_REG[i] (layer 3 address 3 register)

EMAC Station Management Interface (SMI)

The IEEE 802.3 MII station management interface, also known as the MDIO management interface, allows the processor to monitor and control one or more external Ethernet physical-layer transceivers. (Physical-layer transceivers are commonly called PHYs). The management interface physically consists of a 2-wire serial connection composed of the MDC (management data clock) output signal and the MDIO (management data input/output) bidirectional data signal. The IEEE 802.3 MII station management interface applies to both MII/RMII.

The application can address only one register in the PHY in any given time and send control data or receive status information. All the transfers are initiated by the EMAC CORE, and the PHY chip only acts as a target device.

Standard PHY control and status registers typically provide

- Device capability status bits (for example: auto-negotiation, duplex modes, 10/100 speeds, and protocols)
- Device status bits (for example: auto-negotiation complete, link status, remote fault)
- Device control bits (for example: reset, speed selection, loop back, and auto-negotiation start)

Upon power-up, an MDIO read access (at default rates) of device capabilities in PHY status registers can determine the supported PHY features.

The MII management logical interface specifies:

- A set of 16-bit device control or status registers within the PHYs, including both required registers with standardized bit definitions as well as optional vendor-specified registers.
- A 5-bit device addressing scheme which allows the MAC to select one of up to 32 externally connected PHY devices.

- A 5-bit register addressing scheme for selecting the target register within the addressed device.
- A transfer frame protocol for 16-bit read and write accesses to PHY registers through the MDC and MDIO signals under control of the MAC.

Table 30-47: Station Management Interface pins

Station Management Interface Pins	Pin Description
MDIO – Management Data I/O	A periodic clock that runs at a maximum period of 400 ns. Always driven by the EMAC to PHY.
MDC – Management Data Clock	Data signal driven by EMAC or PHY, depending on write or read access based on EMAC; synchronous to MDC.

MDC Clock Frequency

The EMAC uses the `EMAC_MDIO_ADDR.CR` bit field to determine the frequency of MDC as shown in the *MDC Clock Frequency Selection* table. The clock range selection determines the frequency of the clock relative to the CLKO7 frequency. The table shows the suggested range of CLKO7 frequency applicable for each value of the `EMAC_MDIO_ADDR.CR` field. The programmability based on CLKO7 frequency range ensures that the MDC clock frequency range is within the IEEE specifications of 1.0 MHz to 2.5 MHz. However, the EMAC MDC can also support higher frequencies for PHY devices that support the frequencies.

Table 30-48: MDC Clock Frequency Selection

Selection	Programmed Frequency Range	Frequency of MDC	Min and Max MDC Freq (Per Specifications)
0000	60–100 MHz	CLKO7/42	MIN = 1.43 MHz and MAX = 2.39 MHz
0001	100–150 MHz	CLKO7/62	MIN = 1.61 MHz and MAX = 2.42 MHz
0010	20–35 MHz	CLKO7/16	MIN = 1.25 MHz and MAX = 2.19 MHz
0011	35–60 MHz	CLKO7/26	MIN = 1.35 MHz and MAX = 2.31 MHz

The ***MDIO Frame Parameters*** table provides MDIO data transfer parameters. The write and read sequences provided in the tables, ***MDIO Write Data Sequence*** and ***MDIO Read Data Sequence***, are based on these parameters.

Table 30-49: MDIO Frame Parameters

Parameter	Description
IDLE	The MDIO line is three-state (noted as Z in sequence); there is no clock on MDC.
PREAMBLE	32 continuous bits, each of value 1
START	Start of frame is 01
OPCODE	10 for read and 01 for write
PHY ADDR	5-bit address select for one of 32 PHYs (noted as AAAAA in sequence)
REG ADDR	Register address in the selected PHY (noted as RRRRR in sequence)

Table 30-49: MDIO Frame Parameters (Continued)

Parameter	Description
TA	Turnaround is Z0 for read and 10 for write (Z = high impedance)
DATA	Any 16-bit value. Driven by MAC or PHY based on direction (noted as DDD...DDD).

Table 30-50: MDIO Write Data Sequence

IDLE	PREAMBLE	START	OPCODE	PHY ADDR	REG ADDR	TA	DATA	IDLE
Z	111...111	01	01	AAAAA	RRRRR	10	DDD... DDD	Z

Table 30-51: MDIO Read Data Sequence

MDIO Frame Structure

Both Clause 22 and Clause 45 MDIO frame structures are supported by the EMAC. The `EMAC_MDIO_ADDR.C45E` bit can be programmed to enable Clause 22 or Clause 45 mode of operation. The *MDIO Clause 45 Frame Structure* table shows the Clause 45 frame format and the *MDIO Clause 22 Frame Structure* table shows the Clause 22 frame format. In addition to normal read and write operations, the SMA also supports post-read increment address while operating in Clause 45 mode.

Table 30-52: MDIO Clause 45 Frame Structure

Field	Description
IDLE	The MDIO line is in three-state; there is no clock on MDC
PREAMBLE	32 continuous bits of value 1
START	Start of packet is 2’b00
OPCODE	00/01/10/11
PHY ADDR	5-bit address select for one of 32 PHYs
DEV ADDR	5-bit address select for one of 32 devices
TA	Turnaround is Z0 for read and 10 for write (Z = high impedance)
DATA/ADDRESS	16-bit value. For an address cycle (OPCODE = 2'b00), this frame contains the address of the register to be accessed on the next cycle. For the data cycle of a write frame, this field contains the data that is written to the register. For read or post-read increment address frames, this field contains the contents of the register read from the PHY. • In address and data write cycles, the EMAC drives the MDIO line during the transfer of these 16 bits.

Table 30-52: MDIO Clause 45 Frame Structure (Continued)

Field	Description
	• In read and post-read increment address cycles, the PHY drives the MDIO line during the transfer of these 16 bits.

Table 30-53: MDIO Clause 22 Frame Structure

Field	Description
IDLE	The MDIO line is in tri-state; there is no clock on MDC
PREAMBLE	32 continuous bits of value 1
START	Start of packet is 2'b01
OPCODE	10 for read and 01 for write
PHY ADDR	5-bit address select for one of 32 PHYs
DEV ADDR	5-bit address to select the register within each MMD
TA	Turnaround is Z0 for read and 10 for write (Z = high impedance)
DATA	Any 16-bit value. Driven by MAC or PHY based on direction (noted as DDD...DDD).

Table 30-54: MDIO Write Data Sequence

IDLE	PREAMBLE	START	OPCODE	PHY ADDR	REG ADDR	TA	DATA	IDLE

IDLE	PREAMBLE	START	OPCODE	PHY ADDR	REG ADDR	TA	DATA	IDLE
Z	111...111	01	01	AAAAA	RRRRR	Z0	DDD...DDD	Z

SMI Write Operation

When programs set the EMAC_MDIO_ADDR.GOC_1/EMAC_MDIO_ADDR.GOC_0 bit field to 2'b01 and the EMAC_MDIO_ADDR.GB bit to 1, the MAC CSR module transfers the PHY address, the register address in PHY, and the write data (EMAC_MDIO_DATA register) to the SMI to initiate a write operation into the PHY registers. At this point, the SMI module starts a write operation on the GMII Management Interface using the management packet format specified in the GMII specifications (as per IEEE 802.3-2002, Section 22.2.4.5).

When the SMA module starts a write operation, the write data packet is transmitted on the MDIO line. The MAC drives the MDIO line for complete duration of the packet. The EMAC_MDIO_ADDR.GB bit is set high until the write operation is complete. The CSR ignores the write operations performed to the EMAC_MDIO_ADDR register or the EMAC_MDIO_DATA register during this period (the EMAC_MDIO_ADDR.GB bit is high). When the write operation is complete, the SMI module indicates this to the CSR, and the CSR resets the EMAC_MDIO_ADDR.GB bit.

The *SMI Write Operation through MDIO/MDC Pins* figure shows this operation.

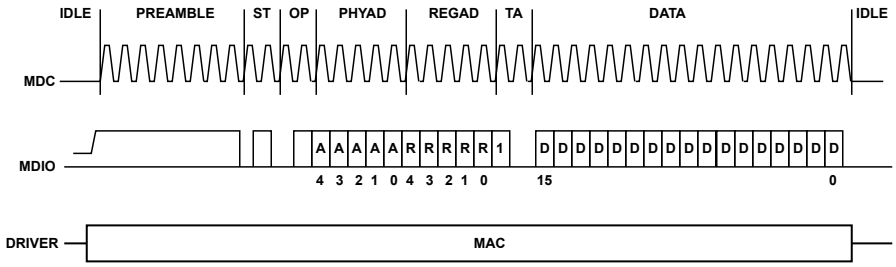

Figure 30-27: SMI Write Operation through MDIO/MDC Pins

SMI Read Operation

When programs set the EMAC_MDIO_ADDR.GOC_1/EMAC_MDIO_ADDR.GOC_0 bit field to 2'b11 and the EMAC_MDIO_ADDR.GB bit to 1, the MAC CSR module transfers the PHY address and the register address in PHY to the SMI to initiate a read operation in the PHY registers. The SMI starts a read operation on the GMII Management Interface using the management packet format specified in the GMII specifications (as per IEEE 802.3-2002, Section 22.2.4.5).

When the SMI starts a read operation on the MDIO, the CSR ignores the write operations to the EMAC_MDIO_ADDR or EMAC_MDIO_DATA registers during this period (the EMAC_MDIO_ADDR.GB bit is high) and the transaction is completed without any error. When the read operation is complete, the SMI indicates this to the CSR. The CSR resets the GB bit and updates the EMAC_MDIO_DATA register with the data read from the PHY.

The *SMI Read Operation through MDIO/MDC Pins* figure shows this operation.

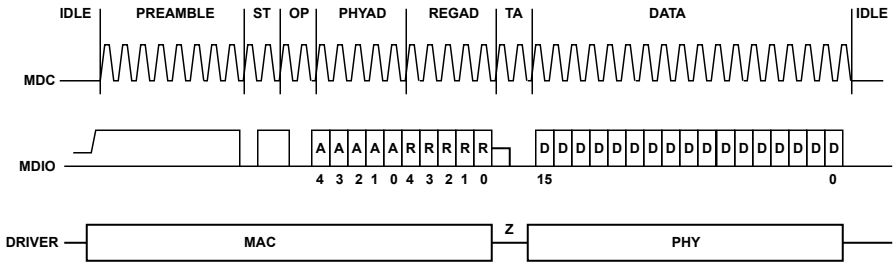

Figure 30-28: SMI Read Operation through MDIO/MDC Pins

Preamble Suppression

The IEEE standard specifies 32-bit preamble (all-ones) for the MDIO frames. The EMAC provides controls to support preamble suppression. EMAC transmits MDIO frames with only 1 preamble bit. The preamble suppression can be enabled by setting the EMAC_MDIO_ADDR.PSE bit.

Trailing Clocks and Back-to-Back Transactions

The EMAC drives MDC clock on the MDC port for duration of the MDIO frame. There is no clock driven during the idle period. The trailing clocks feature can be used if the PHY needs the MDC clock to be active for some cycles after the MDIO frame. The EMAC_MDIO_ADDR.NTC bit field allows programming of trailing clocks from 0 to 7.

The EMAC supports back to back transactions which allows start of next MDIO frame even before the trailing clocks are completed for previous MDIO frame. This feature can be enabled by setting the EMAC_MDIO_ADDR.BTB bit when trailing clocks feature is also enabled. When back to back transactions is enabled, the GMII busy is cleared immediately after MDIO frame completion. This allows the software to issue the next command, which is executed by EMAC while trailing clocks are still on for the previous MDIO frame. When back to back transactions is not enabled, the GMII busy is cleared after the trailing clocks are completed for MDIO frame.

Interrupt for MDIO Transaction Completion

The EMAC can generate an interrupt on completion of MDIO read or write transactions. Therefore, the application need not poll the GMII busy field of the EMAC_MDIO_ADDR register to know the completion of MDIO commands.

EMAC Management Counters (MMC)

The EMAC provides a comprehensive set of 32-bit MAC management counters. It uses these counters for gathering statistics on the received and transmitted frames. The MMC sub block also includes

- A control register (EMAC_MMC_CTRL) for managing the behavior of the counters
- Two 32-bit registers containing interrupts generated (EMAC_MMC_RXINT and EMAC_MMC_TXINT)
- Two 32-bit registers containing masks for the interrupt register (EMAC_MMC_RXIMSK and EMAC_MMC_TXIMSK)

The MMC receive counters are updated for frames passed by the address filtering sub block in the EMAC CORE. Statistics of frames dropped by the AFM module are not updated unless they are runt frames of less than 6 bytes. (Destination address bytes are not received fully.) The module is also capable of gathering statistics on encapsulated IPv4, IPv6, and TCP, UDP, or ICMP payloads in received Ethernet frames.

The MMC register naming conventions are as follows:

- Tx as a prefix or suffix indicates counters associated with transmission.
- Rx as a prefix or suffix indicates counters associated with reception.
- G as a suffix indicates registers that count good frames only.
- GB as a suffix indicates registers that count frames regardless of whether they are good or bad.

Transmitted frames are considered *good* when transmitted successfully. In other words, a transmitted frame is good if the frame transmission does not abort due to any of the following errors:

- Jabber timeout
- No carrier or loss of carrier
- Late collision
- Frame underflow

- Excessive deferral
- Excessive collision

Received frames are good when none of the following errors exists:

- CRC error
- Runt frame (shorter than 64 bytes)
- Alignment error
- Length error (non-type frames only)
- Out-of-range (non-type frames only, longer than maximum size)

The maximum frame size depends on the frame type, as follows:

- Untagged frame maximum size = 1518
- VLAN frame maximum size = 1522
- Jumbo frame maximum size = 9018
- Jumbo VLAN frame maximum size = 9022

The maximum receive packet size depends on the packet type and control bits (JE, S2KP, GPSLCE and EDVLP), as shown in the *Size of the Maximum Receive Packet* table.

Table 30-56: Size of the Maximum Receive Packet

JE	S2KP	GPSLCE	EDVLP	Untagged Frame maximum size in bytes	Single VLAN Frame maximum size in bytes	Double VLAN Frame maximum size in bytes
1	X	X	1	9018	9022	9026
0	1	X	X	2000	2000	2000
0	0	1	1	GPSL	GPSL+4	GPSL+8
0	0	0	1	1518	1522	1526
1	X	X	0	9018	9022	9022
0	0	1	0	GPSL	GPSL+4	GPSL+4
0	0	0	0	1518	1522	1522

The EMAC_MMC_CTRL register also contains bits that control preset, freeze and roll-over of counters. The EMAC uses the EMAC_MMC_CTRL.RSTONRD bit to enable an auto-reset feature whenever the counters are read. The EMAC uses the EMAC_MMC_CTRL.CNTRST bit to reset all the counters.

The MMC can trigger an interrupt when the corresponding bits are enabled in the transmit, receive, and IPC mask registers, and when the counter reaches half or full. The status is also updated in the corresponding interrupt register.

MMC Receive Interrupt Register

The EMAC_MMC_RXINT register maintains the interrupts that are generated when the receive statistic counters reach half their maximum values (0x80000000), and when they cross their maximum values (0xFFFFFFFF). When EMAC_MMC_CTRL.CNTSTOPRO bit is set, then interrupts are set, but the counter remains at all ones. The EMAC_MMC_RXINT register is a 32-bit wide register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (bits 7:0) of the respective counter must be read to clear the interrupt bit.

MMC Transmit Interrupt Register

The EMAC_MMC_TXINT register maintains the interrupts generated when the transmit statistic counters reach half their maximum values (0x80000000), and when they cross their maximum values (0xFFFFFFFF). When EMAC_MMC_CTRL.CNTSTOPRO is set (= 1), then interrupts are set, but the counter remains at all ones. The EMAC_MMC_TXINT register is a 32-bit wide register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (bits 7:0) of the respective counter must be read to clear the interrupt bit.

MMC Receive Checksum Offload Interrupt Register

The EMAC_MMC_IPC_RXINT register maintains the interrupts generated when receive IPC statistic counters reach half their maximum values (0x80000000), and when they cross their maximum values (0xFFFFFFFF). When the EMAC_MMC_CTL.NOROLL is set, then interrupts are set, but the counter remains at all ones. The EMAC_MMC_IPC_RXINT register is 32 bits wide. When the MMC IPC counter that caused the interrupt is read, its corresponding interrupt bit is cleared. The least-significant byte lane (bits 7:0) of the counter must be read to clear the interrupt bit.

EMAC Precision Time Protocol (PTP) Engine

The following sections describe the precision time protocol (PTP) engine.

IEEE1588 and the PTP Engine

The Ethernet MAC peripheral includes a PTP engine to assist applications requiring time synchronization. The PTP module is tightly integrated with the EMAC CORE to aid hardware time stamping defined in the IEEE1588 2002/2008 standards. Applications can use accurate hardware time stamps through TCP/IP stacks (if using network layer communication) to exchange time information across devices connected over network. Applications can also use accurate hardware time stamps through Ethernet device drivers (if using MAC layer communication) to exchange time information.

PTP Engine

For calculation of drift in time between two Ethernet devices, the device records its system time whenever a timing message is sent or received (IEEE 1588 protocol). Due to the indeterministic delay of a software system for a node, the software is unable to capture an accurate time when the message is sent or received. However, the hardware can monitor the signal on the communication media and get an accurate message of arrival and departure time.

The PTP (precision time protocol) module is closely integrated with the EMAC module. It provides hardware assistance to implement both the IEEE 1588–2002 and IEEE 1588–2008 standards on Ethernet (IEEE 802.3). It takes

one input clock signal as its PTP clock and maintains the timing information (called *system time*) at the nanosecond level.

The PTP module includes hardware for clock and system time adjustment. The pulse-per-second (PPS) signals physically represent the system time. PPS can be programmed to a fixed frequency or provide flexibility to the signal in terms of pulse width, interval, start, and stop time of the signals. The PTP module can be programmed to trigger an alarm interrupt when system time reaches specified time.

The PTP module can be programmed to detect different types of received frames, capture the system time, and time stamp those frames with the captured system time. Programs can configure any frame so that the PTP module capture the system time when it is transmitted. The PTP module can also capture the system time when an event is detected on the auxiliary snapshot trigger input pins (`EMAC_PTPAUX_MCG_IN[n]`).

IEEE 1588 Standard

Many systems require two independent devices to operate in a time synchronized fashion. If each system relied solely on its oscillator, differences between the characteristics and operating conditions of each oscillator would limit the ability of the clocks to operate synchronously. To serve applications requiring synchronized clocks, the system uses a periodic correction mechanism.

A simple way to synchronize multiple systems is to choose one system (with the best clock) as a requester. The system requester broadcasts the clock and timing information to other systems (completers); subsequently, the completers adjust their clocks and timing according to that of requester. However, this method has limitations. The requester cannot broadcast the time at infinitesimal intervals. Path delay (propagation delay) exists between a requester and a completer and the delay varies between each completer and requester.

IEEE 1588 is also known as precision time protocol or PTP. The standard specifies a protocol used to synchronize the time and clock of multiple devices, dispersed but interconnected by any communication, (for example, Ethernet IEEE 802.3). According to the protocol, timing messages are exchanged between two devices. Then, one of the devices calculates its drift from other device and corrects its system time. (Both devices must have the same representation of their system time). The protocol resolves path delay between devices. It also helps synchronize the clocks of multiple devices and all of the limitations mentioned are resolved.

IEEE 1588 was published in 2002 where four types of timing messages were defined: Sync, Follow_Up, Delay_Req, and Delay_Resp. Here the protocol synchronizes two or more devices where one is a requester and others are completers. The requester device sends Sync, Follow_Up, and Delay_Resp messages to the completer device in the system. The target sends the Delay_Req messages to the requester device. A following section provides more information on IEEE 1588–2002.

In 2008, a newer version of IEEE 1588 was introduced which provides further mechanisms to measure the peer-to-peer delay. Three more timing messages (PdelayReq, PdelayResp, and PdelayRespFollowup) were added to implement peer-to-peer synchronization. The following section provides more information on IEEE 1588–2008.

IEEE 1588–2002

The IEEE 1588–2002 standard defines the precision time protocol (PTP). The protocol allows precise synchronization of clocks in measurement and control systems that use network communication, local computing, and distributed objects. The protocol applies to systems that communicate by local area networks that support multicast

messaging, including (but not limited to) Ethernet. This protocol also allows heterogeneous systems that include clocks of varying inherent precision, resolution, and stability to synchronize. The protocol supports system-wide synchronization accuracy in the sub-microsecond range using minimal network and local clock computing resources.

The PTP is transported over UDP/IP. The system or network is classified into requester and completer nodes for distributing the timing or clock information. The ***IEEE 1588–2002 PTP Process*** figure shows the PTP process used for synchronizing a target node to a controller node by exchanging PTP messages.

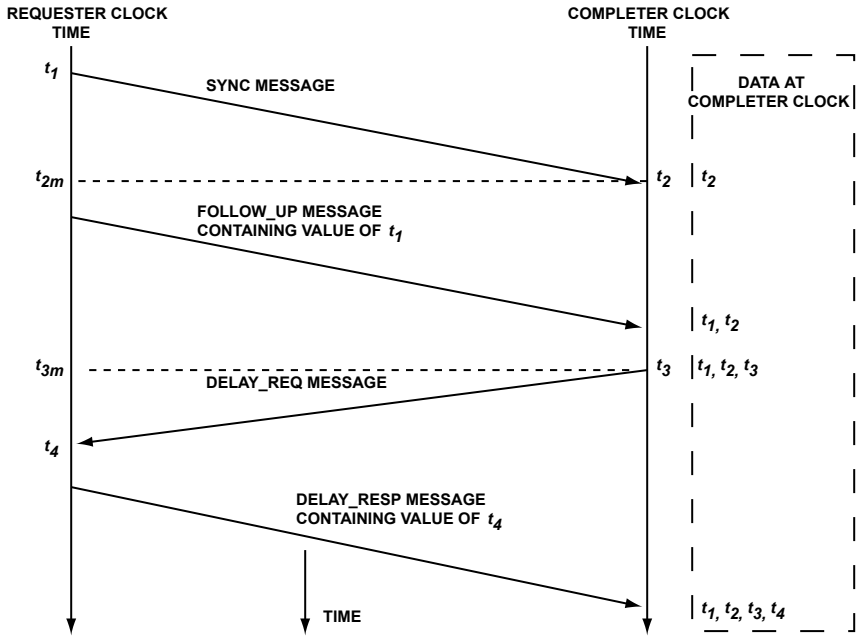

Figure 30-29: IEEE 1588–2002 PTP Process

As shown in the figure, the PTP uses the following process:

1. The requester broadcasts the PTP sync messages to all its nodes. The sync message contains the reference time information of the requester. The time at which this message leaves the system of the requester is t_1. The requester must capture this time for Ethernet ports, at RMII.
2. The completer receives the Sync message and also captures the exact time, t_2, using its timing reference.
3. The requester sends a Follow_up message to the completer, which contains t1 information for later use.
4. The completer sends a Delay_Req message to the requester, noting the exact time, t_3, at which this frame leaves the RMII.
5. The requester receives the message, capturing the exact time, t_4, at which it enters its system.
6. The requester sends the t_4 information to the completer in the Delay_Resp message.
7. The completer uses the four values of t_1, t_2, t_3, and t_4 to synchronize its local timing reference to the timing reference of the requester.

Most of the PTP implementation occurs in the software above the UDP layer. However, the hardware support must capture the exact time when specific PTP packets enter or leave the Ethernet port at the RMII. Hardware must capture this timing information and return it to the software for the proper implementation of PTP with high accuracy.

IEEE 1588–2008 Advanced Time Stamps

In addition to the basic time stamp features mentioned in IEEE 1588–2002 time stamps, the EMAC supports the following advanced time stamp features defined in the IEEE 1588–2008 standard.

- Support for the IEEE 1588–2008 (Version 2) time stamp format.
- Provides an option to take snapshot of all frames or only PTP type frames.
- Provides an option to take snapshot of only event messages.
- Provides an option to select the node to be a requester or completer.
- Identifies the PTP message type, version, and PTP payload in frames sent directly over Ethernet and sends the status.
- Provides an option to run nanoseconds time in digital or binary format.

Peer-to-Peer (P2P) PTP Message Support

The IEEE 1588–2008 version supports Peer-to-Peer PTP (Pdelay) message in addition to SYNC, Delay Request, Follow-up, and Delay Response messages. Refer to the ***Propagation Delay Calculation between Nodes Supporting P2P Path Correction*** figure. The figure shows the method to calculate the propagation delay between nodes supporting peer-to-peer path correction.

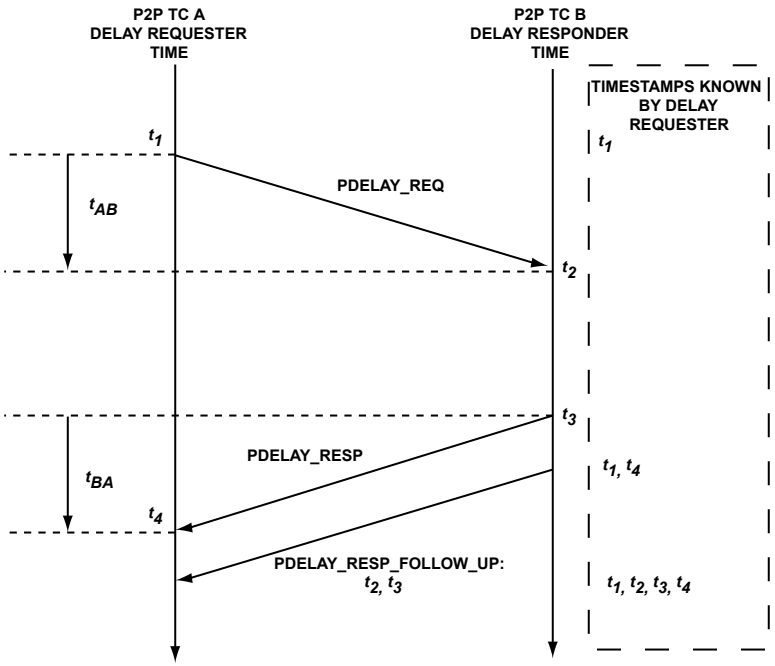

Figure 30-30: Propagation Delay Calculation between Nodes Supporting P2P Path Correction

As shown in the figure, the propagation delay is calculated in the following way:

1. Port 1 issues a Pdelay_Req message and generates a time stamp, t1, for the Pdelay_Req message.
2. Port 2 receives the Pdelay_Req message and generates a time stamp, t2, for this message.
3. Port 2 returns a Pdelay_Resp message and generates a time stamp, t3, for this message. To minimize errors due to frequency offset between the two ports, port 2 returns the Pdelay_Resp message as quickly as possible after the receipt of the Pdelay_Req message. The port 2 returns any one of the following:
   - The difference between the time stamps t2 and t3 in the Pdelay_Resp message.
   - The difference between the time stamps t2 and t3 in the Pdelay_Resp_Follow_Up message.
   - The time stamps t2 and t3 in the Pdelay_Resp and Pdelay_Resp_Follow_Up messages respectively.
4. Port 1 generates a time stamp, t4, on receiving the Pdelay_Resp message.

Port 1 uses all four time stamps to compute the mean link delay.

Block Diagram

The ***PTP Block Diagram*** figure shows the functional block diagram of PTP module.

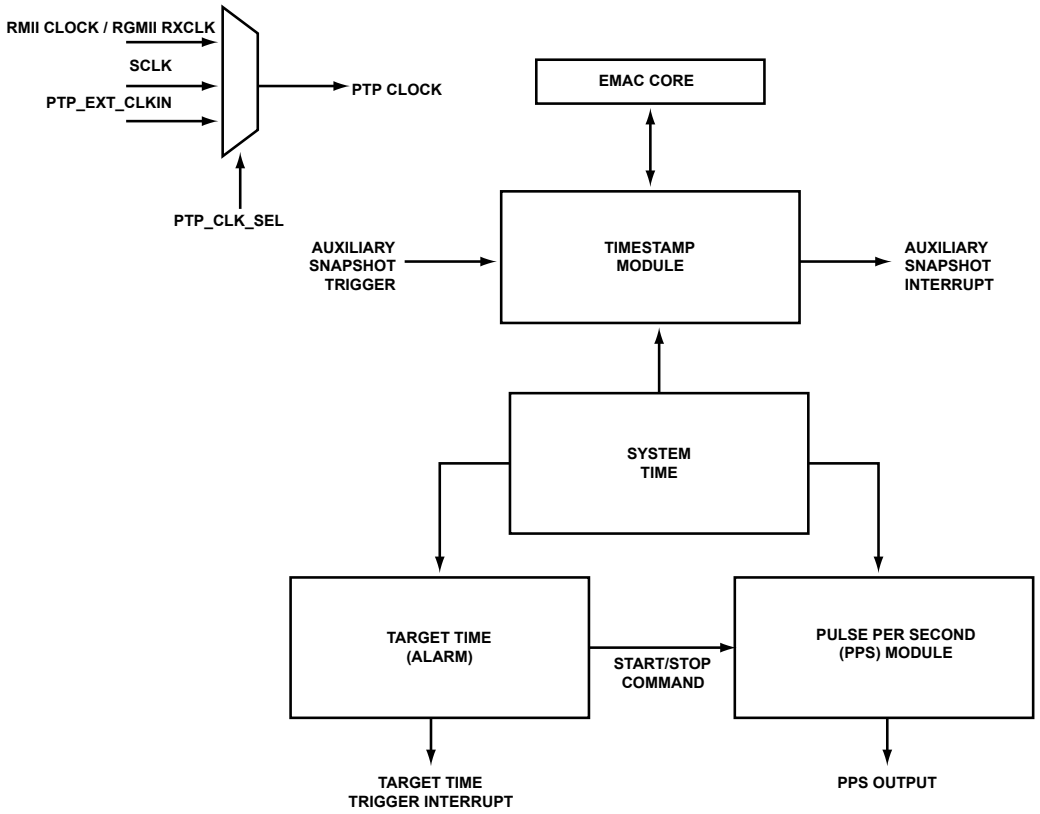

Figure 30-31: PTP Block Diagram

A system time module is present which keeps the time of PTP module. It consists of hardware which can be programmed for time initialization, time correction, and clock correction.

The time stamp module captures the time (provided by the system time module) at various conditions. For example, when the EMAC sends or receives a frame or during the rising edge of the auxiliary snapshot trigger `EMAC_PTPAUX_MCG_IN[n]` pins. When system time is captured after detection of a frame, the time stamp module automatically includes the time information in the frame descriptor. Time stamping on the detection of a frame can be programmed on a per frame basis.

The PTP clock drives the PTP module. This clock can be selected from three different clock sources.

The Pulse per Second (PPS) module generates a pulse or train of pulse on the PPS output pins, (`EMAC_PTPPPS[n]`). It is the physical representation of system time. PPS can be fixed (where only frequency varies) or flexible (where width, interval, start time, and stop time can be programmed).

The target time module acts as an alarm for the PTP module. Whenever system time reaches a value equal to programmed target time, the target time trigger interrupt is generated. By appropriate programming, The target time trigger can also start or stop flexible PPS output at specific time.

PTP Module Clock

The PTP module clock features include Clock Source Selection and Clock Frequency Range .

Clock Source Selection

The PTP module can take one of these clock sources as its input clock — CLKO7, RMII reference RGMII Rx clock, or PTP external clock.

As shown in the ***PTP Clock Source Selection*** table, the `PADS_PCFG0` register [bits 1:0] selects the PTP clock source.

Table 30-57: PTP Clock Source Selection

PADS_PCFG0 [1:0]	PTP Clock Source	Clock Description
00 – RMII or MII	ETH0_RXCLK_REFCLK/ ETH1_REFCLK	MII/RMII reference clock
00 – RGMII	CLKO7	Processor Ethernet clock
10	PTP external clock	Clock available on EMAC_PTPCLKIN[n] pin
01 or 11	SCLK0	Processor system clock

Clock Frequency Range

The resolution, or granularity, of the reference time source determines the accuracy of the synchronization. Therefore, a higher PTP clock frequency gives better system performance. The timing constraints achievable for logic operating on the selected PTP clock source limit the maximum PTP clock frequency.

The minimum PTP clock frequency depends on the time required between two consecutive frames. The IEEE specification determines the RMII clock frequency. The minimum PTP clock frequency required for proper operation depends on the operating mode and operating speed of the MAC. See the ***Minimum PTP Clock Frequency*** table.

A minimum delay required between two consecutive time stamp captures is 8 clock cycles of RMII and 3 clock cycles of PTP clocks. If the delay between two time stamp captures is less than this delay, the EMAC does not take a time stamp snapshot for the second frame.

The ***Minimum PTP Clock Frequency*** table assumes:

- Minimum Ethernet packet size = 64 bytes
- Mininum IFG = 96 bit times or 12 bytes
- Preamble = 8 bytes
- 3 PTP clock + 4 GMII/MII clock minimum gap between two SFDs (start of frame delimiters)
- 3 PTP clock + 8 RMII clock minimum gap between two SFDs

Table 30-58: Minimum PTP Clock Frequency

Mode (Full Duplex in all cases)	Minimum Gap between two SFDs	PTP clock	Comments
10 Mbps RMII	64 bytes of data + 8 bytes of preamble + min IFG	3 PTP clock cycle + 8RMII clock cycle 3360 RMII clock cycles	In RMII @ 10 Mbps, 1 byte transmitted in 40 clock cycles
	(2560 + 320 + 480) RMII clock cycles	3 PTP clock cycle 3352 RMII clock cycles	RMII clock = 50 MHz
	3360 RMII clocks	PTP clock cycle 1117.33 20 ns = 22346 ns	1 RMII clock cycle = (1/50 MHz) = 20 ns
		PTP frequency min = 0.045 MHz	
100 Mbps RMII	64 bytes of data + 8 bytes of preamble + min IFG	3 PTP clock cycle + 8RMII clock cycle 336 RMII clock cycles	In RMII, 1 byte transmitted in 4 clock cycles
	(256 + 32 + 48) RMII clock cycles	3 PTP clock cycle 328 RMII clock cycles	RMII clock = 50 MHz
	336 RMII clocks	PTP clock cycle 109.33 20 ns = 2186 ns	1 RMII clock cycle = (1/50 MHz) = 20 ns
		PTP frequency min = 0.45 MHz	

The minimum PTP clock frequency also depends on the maximum value of the `EMAC_TM_SUBSEC` register. Even at the highest `EMAC_TM_SUBSEC.SSINC` value, the `EMAC_TM_SEC` register value can be incremented every second. Since the `EMAC_TM_SUBSEC.SSINC` is an 8-bit field, the minimum PTP clock frequency allowed is approximately 4 MHz.

Time Stamp Module

The time stamp module captures time in seconds and nanoseconds maintained as system time. The time stamp module also captures time when specific events occur. Events include detection of a frame transmitted or received

over the EMAC and a rising edge on the EMAC_PTPAUX_MCG_IN[n] pins. The time stamp module does not need to time stamp all of the transmitted or received frames over the EMAC. The PTP module can be programmed to detect specific kinds of frames for time stamping.

Frame Detection and Time Stamping

The PTP module automatically monitors all received and transmitted IEEE 1588 event messages on the Ethernet. If the module detects an event message, it takes a snapshot of the system time. The PTP module stores the value to the 64-bit fields in transmit or receive descriptor.

The time stamping occurs at the EMAC RMII/RGMII interface when the module sees the start of frame of an event message packet.

Transmit Path Time Stamping

The MAC captures a time stamp when the Start Packet Delimiter (SFD) of a packet is sent on the MII/RMII/RGMII interface. The packets for which the time stamps must be captured, can be controlled on per-packet basis. Each transmit packet can be marked to indicate whether a time stamp should be captured for it.

The MAC does not process the transmitted packets to identify the PTP packets. The program needs to specify the packets to capture time stamps.

The program can specify the packets by using the control bits in the transmit descriptor. The MAC returns the time stamp to the software inside the corresponding transmit descriptor, connecting the time stamp automatically to the specific PTP packet. The 64-bit time stamp information is written to the TDES0 and TDES1 fields. The TDES0 field holds the 32 least significant bits of the time stamp.

Receive Path Time Stamping

The MAC can be programmed to capture the time stamp of all packets received on the GMII or MII interface or to process packets to identify the valid PTP messages. Use the following options of the EMAC_TM_CTL register to control the snapshot of the time to be sent to the application:

- Enable snapshot for all packets
- Enable snapshot for IEEE 1588 version 1 or version 2 time stamp
- Enable snapshot for PTP packets transmitted directly over Ethernet or UDP-IP-Ethernet
- Enable time stamp snapshot for the received packet for IPv4 or IPv6
- Enable time stamp snapshot only for event messages (Sync, Delay_Req, Pdelay_Req, or Pdelay_Resp)
- Enable the node to be a main or target and select the snapshot type

This feature controls the type of messages for which snapshots are taken.

Refer to the ***PTP Frame Type Selections*** table.

Table 30-59: PTP Frame Type Selections

TSENALL (bit 8)	SNAPTYPSEL (bits [17:16])	TSMSTRENA (bit 15)	TSEVNTENA (bit 14)	Frames
1	X	X	X	All
0	00	X	0	Sync, Follow_Up, Delay_Req, Delay_Resp
0	00	0	1	Sync
0	00	1	1	Delay_Req
0	01	X	0	Sync, Follow_Up, Delay_Req, Delay_Resp, Pdelay_Req, Pdelay_Resp, Pdelay_Resp_ Follow_Up
0	01	0	1	Sync, Pdelay_Req, Pdelay_Resp
0	01	1	1	Delay_Req, Pdelay_Req, Pdelay_Resp
0	10	X	X	Sync, Delay_Req
0	11	X	X	Pdelay_Req, Pdelay_Resp

Time Stamp Correction

According to the IEEE 1588 specification, a time stamp must be captured when the PTP message time stamp point (leading edge of the first bit of the octet immediately following the SFD octet) crosses the boundary between the node and the network.

Because the MAC takes the time stamp at an internal point far from the actual boundary of the node and network, this captured time stamp is corrected/updated for the ingress/egress path latency (including the delay in the PHY layers). Further correction is done for the inaccuracies/errors introduced due to the clock (RGMII Tx, Rx clock). The clock can be different at the capture point when compared with the PTP clock that is used to generate the time. The resultant Clock Domain Crossing (CDC) circuits add error, depending on the clock period of the GMII and PTP clocks.

Ingress Correction

In the receive side, the time stamp captured at the internal snapshot point is delayed (later in time) as compared to the time at which that packet's SFD bit is received at the port's boundary. Therefore, the captured time stamp must be reduced by the ingress latency and the errors in CDC sampling. This correction value must be determined/calculated by the software and written into the `EMAC_TM_INGCORR_NSEC` and `EMAC_TM_INGCORR_SNSEC` registers.

The correction value consists of the following components:

1. External latency in the PHY layer between boundary point and the input of the core. If the PHY is compliant with the IEEE 802.3 Clause 45 MMD registers, it has a register indicating the maximum and minimum ingress latency. The software can read these registers and determine the average ingress latency in the PHY. Alternatively (if the PHY does not support these registers), the ingress latency must be determined from its data sheet or timing characteristics.

2. Internal latency from the input of the core to the internal capture point. The internal ingress latency can be read from the EMAC_TM_ING_LTNCY register. This read-only register gives the latency in scaled nanoseconds format, as defined in IEEE 1588 Clause 5.3.2. The latency differs based on the active PHY interface (RGMII, RMII, so on) and the operating speed. Therefore, the software must read this register after any speed change in the MAC to determine the current internal latency.
3. CDC Synchronization. The CDC synchronization error is approximately equal to two times the clock period of the PTP clock.

Software should add the values determined from these components and write them into the EMAC_TM_INGCORR_NSEC.TSIC and EMAC_TM_INGCORR_SNSEC.TSICSNS bit fields.

NOTE: The value written to the register must be negative (two's complement), because it must be subtracted from the captured time stamp. The MAC receiver adds the value in this register to the captured time stamp and then gives the resultant value as the time stamp of the received packet.

When the EMAC_TM_CTL.TSCTRLSSR bit is set, the nanoseconds field of the captured time stamp is in decimal format with a granularity of 1 ns. So, bit 31 of EMAC_TM_INGCORR_NSEC.TSIC must be set (= 1) (for negative value). Bits[30:0] must be written with "109 - total ingress_correction_value[nanosecond part]" represented in binary. For example, if the required correction value is -5 ns, the value is 0xBB9A_C9FB.

When EMAC_TM_CTL.TSCTRLSSR bit is reset, the nanoseconds field of the captured time stamp is in binary format with a granularity of ~0.466 ns. Therefore, bits [30:0] must be written with "231 - total ingress_correction_value" represented in binary with bit[31] = 1.

Egress Correction

In the transmit side, the time stamp captured at the internal snapshot point is earlier (advanced in time) when compared with the time at which that packet's SFD bit is output at the port's boundary. Therefore, the captured time stamp must be compensated by the egress latency and the errors in CDC sampling. Software determines/calculates this correction value and writes it into the EMAC_TM_EGCORR_NSEC and EMAC_TM_EGCORR_SNSEC registers.

The correction value consists of the following components:

1. External latency in the PHY layer between the output of the core and the boundary of the port and the network. If the PHY is compliant to the IEEE 802.3 Clause 45 MMD registers, it has a register indicating the maximum and minimum egress latency. The software can read these registers and determine the average egress latency in the PHY. Otherwise, (if the PHY does not support these registers), the egress latency must be determined from its data sheet or timing characteristics.
2. Internal latency from the internal capture point and the output of the core. This internal egress latency can be read from the EMAC_TM_EG_LTNCY register. This read-only register gives the latency in scaled nanoseconds format as defined in IEEE 1588 Clause 5.3.2. The latency differs based on the active PHY interface (RGMII, RMII, so on) and the operating speed. Therefore, the software must read this register after any speed change in the MAC to determine the current internal latency.

3. CDC synchronization error. The CDC synchronization error value depends on the one-step time stamping mode. When one-step time stamping is enabled, the value = (1 x period of PTP clock + 4 x period of Tx clock).

The ***PHY Interface Latency*** table lists the egress and ingress latency for various PHY interfaces.

Table 30-60: PHY Interface Latency

PHY Interfaces		Egress Latency	Ingress Latency
RGMII	1.0 Gbps	12	12
RGMII	100 Mbps	40	40
RGMII	10 Mbps	400	400
RMII	100 Mbps	40	40
RMII	10 Mbps	400	400

PTP Processing and Control

When the EMAC module receives a frame, frame detection and time stamping are based on some of the PTP fields in the frame. The ***PTP Message Format (IEEE 1588–2008)*** table shows the common message header for the PTP messages. This format is derived from the IEEE standard 1588–2008. When the EMAC module sends a PTP frame, the frame follows this format.

When a frame is received, the PTP module compares these fields with standard values and finds out the type of PTP frame and other information (for example, PTP version, IP version, and others). The module then updates the related fields in RDES4. When a frame is transmitted, programs must ensure that all the fields are appropriate. The PTP module on the other end of a communication must correctly detect and decode the frame.

Table 30-61: PTP Message Format (IEEE 1588–2008)

Bits								Octets	Offset

Table 30-61: PTP Message Format (IEEE 1588–2008) (Continued)

Bits	Octets	Offset
controlField (used in version 1. For version 2, messageType field is used for detecting different message types.)	1	32
logMessageInterva	1	33

There are some fields in the Ethernet payload that can be used to detect the PTP packet type and control the snapshot taken. These fields are different for the following PTP frames:

- PTP Frames Over IPv4
- PTP Frames Over IPv6
- PTP Frames Over Ethernet

For these PTP frames, EMAC does not consider the PTP version 1 messages as valid when the frame consists of peer delay multicast address as destination address (DA).

PTP Frame Over IPv4

The ***IPv4-UDP PTP Frame Fields Required for Control and Status*** table provides information about the fields that are matched to control snapshot for the PTP packets. The packets are sent over UDP over IPv4 for IEEE 1588 version 1 and 2. The octet positions for the tagged frames are offset by 4. The positions are based on IEEE 1588–2008 standards and the message format. The format is defined in the ***PTP Message Format (IEEE 1588–2008)*** table in the PTP Processing and Control section.

Table 30-62: IPv4-UDP PTP Frame Fields Required for Control and Status

Field Matched	Octet Position	Matched Value	Description
MAC Frame type	12, 13	0x0800	IPv4 datagram
IP Version and Header Length	14	0x45	IP version is IPv4
Layer 4 Protocol	23	0x11	UDP
IP Multicast Address (IEEE 1588 Version 1)	30, 31, 32, 33	0xE0,0x00, 0x01,0x81 (or 0x82 or 0x83 or 0x84)	Multicast IPv4 addresses allowed 224.0.1.129 224.0.1.130 224.0.1.131 224.0.1.132
IP Multicast Address (IEEE 1588 Version 2)	30, 31, 32, 33	0xE0, 0x00, 0x01, 0x81 (Hex) 0xE0, 0x00, 0x00, 0x6B (Hex)	PTP-Primary multicast address: 224.0.1.129 PTP-Peer delay multicast address: 224.0.0.107

Table 30-62: IPv4-UDP PTP Frame Fields Required for Control and Status (Continued)

Field Matched	Octet Position	Matched Value	Description
UDP Destination Port	36, 37	0x013F 0x0140	0x013F - PTP Event Messages. These are SYNC, Delay_Req (IEEE 1588 version 1 and 2) or Pdelay_Req, Pdelay_Resp (IEEE 1588 version 2 only). 0x0140 - PTP general messages
PTP Control Field (IEEE version 1)	74	0x00/0x01/0x02/ 0x03/0x04	0x00 - SYNC 0x01 - Delay_Req 0x02 - Follow_Up 0x03 - Delay_Resp 0x04 - Management
PTP Message Type Field (IEEE version 2)	42 (nibble)	0x0/0x1/0x2/0x3/0x8/0x9/0xA/0xB/ 0xC/0xD	0x0 - SYNC 0x1 - Delay_Req 0x2 - Pdelay_Req 0x3 - Pdelay_Resp 0x8 - Follow_Up 0x9 - Delay_Resp 0xA - Pdelay_Resp_Follow_Up 0xB - Announce 0xC - Signaling 0xD - Management
PTP Version	43 (nibble)	0x1 or 0x2	0x1 - Supports PTP version 1 0x2 - Supports PTP version 2

PTP Frame Over IPv6

The ***IPv6-UDP PTP Frame Fields Required for Control And Status*** table provides information about the fields that are matched to control the snapshots for the PTP packets. The packets are sent over UDP over IPv6 for IEEE 1588 version 1 and 2. The octet positions for the tagged frames are offset by 4. The positions are based on IEEE 1588–2008 standards and the message format defined in PTP Message Format (IEEE 1588–2008).

Table 30-63: IPv6-UDP PTP Frame Fields Required for Control and Status

Field Matched	Octet Position	Matched Value	Description
MAC Frame type	12, 13	0x86DD	IP datagram
IP Version	14 (bits [7:4])	0x06	IP version is IPv6
Layer 4 Protocol	20 (IPv6 extension header not defined for PTP packets)	0x11	UDP

Table 30-63: IPv6-UDP PTP Frame Fields Required for Control and Status (Continued)

Field Matched	Octet Position	Matched Value	Description
PTP Multicast Address	38–53	FF0x:0:0:0:0:0:0:0:181 (Hex) FF02:0:0:0:0:0:0:0:6B (Hex)	PTP - primary multicast address: FF0x: 0:0:0:0:0:0:0:181 (Hex) PTP - Peer delay multicast address: FF02:0:0:0:0:0:0:0:6B (Hex)
UDP Destination Port	56, 57 (IPv6 extension header not defined for PTP packets)	0x013F, 0x0140	0x013F - PTP event messages 0x0140 - PTP general messages
PTP Control Field (IEEE 1588 version 1)	93 (IPv6 extension header not defined for PTP packets)	0x00/0x01/0x02/ 0x03/0x04	0x00 - SYNC 0x01 - Delay_Req 0x02 - Follow_Up 0x03 - Delay_Resp 0x04 - Management (version1)
PTP Message Type Field (IEEE version 2)	74 (nibble) (IPv6 extension header not defined for PTP packets)	0x0/0x1/0x2/0x3/0x8/0x9/0xA/0xB/ 0xC/0xD	0x0 - SYNC 0x1 - Delay_Req 0x2 - Pdelay_Req 0x3 - Pdelay_Resp 0x8 - Follow_Up 0x9 - Delay_Resp 0xA - Pdelay_Resp_Follow_Up 0xB - Announce 0xC - Signaling 0xD - Management
PTP Version	75 (nibble)	0x1 or 0x2	0x1 - Supports PTP version 1 0x2 - Supports PTP version 2

PTP Frame Over Ethernet

Refer to the ***Ethernet PTP Frame Fields Required for Control and Status*** table. The table provides information about the fields that are matched to control the snapshots for the PTP packets sent over Ethernet for IEEE 1588 version 1 and 2. The octet positions for the tagged frames are offset by 4. The positions are based on IEEE 1588–2008 standards and the message format defined in the table.

Table 30-64: Ethernet PTP Frame Fields Required for Control and Status

Field Matched	Octet Position	Matched value	Description
MAC Destination Multicast Address (The address match of destination address (DA) programmed in MAC address 0 is used when the EMAC_TM_CTL.TSENMACADDR bit is set)	0–5	01-1B-19-00-00-00 01-80-C2-00-00-0E	All PTP messages can use any of the following multicast addresses: 01-1B-19-00-00-00 01-80-C2-00-00-0E
MAC Frame Type	12, 13	0x88F7	PTP Ethernet frame
PTP control field (IEEE Version 1)	45	0x00/0x01/0x02/ 0x03/0x04	0x00 - SYNC 0x01 - Delay_Req 0x02 - Follow_Up 0x03 - Delay_Resp 0x04 - Management
PTP Message Type Field (IEEE version 2)	14 (nibble)	0x0/0x1/0x2/0x3/0x8/0x9/0xA/0xB/ 0xC/0xD	0x0 - SYNC 0x1 - Delay_Req 0x2 - Pdelay_Req 0x3 - Pdelay_Resp 0x8 - Follow_Up 0x9 - Delay_Resp 0xA - Pdelay_Resp_Follow_Up 0xB - Announce 0xC - Signaling 0xD - Management
PTP Version	15(nibble)	0x1 or 0x2	0x1 - Supports PTP version 1 0x2 - Supports PTP version 2

Auxiliary Time Stamp Snapshot

The auxiliary snapshot feature stores snapshots of the system time whenever a rising edge is detected on the EMAC_PTPAUX_MCG_IN[n] pins.

The PTP stores 64 bits of the captured time stamp in a 16-deep FIFO. Only 64 bits of the time stamp are stored in the FIFO. The upper 16 bits of seconds can be read from the EMAC_TM_HISEC register when it is present. When a snapshot is stored, the PTP indicates this event to the EMAC with the auxiliary snapshot interrupt. The EMAC_TM_STAT.AUXTSTRIG bit is set (=1). The value of the snapshot is read through the EMAC_TM_AUXTS_SEC and EMAC_TM_AUXTS_NSEC registers. If the FIFO becomes full and an external trigger to take the snapshot is asserted, then the snapshot trigger missed (EMAC_TM_STAT.ATSSTM) bit is set (=1). The latest snapshot is not written to the FIFO when it is full.

When a host reads the 64-bit time stamp from the FIFO through the EMAC_TM_AUXTS_SEC and EMAC_TM_AUXTS_NSEC registers, the space becomes available to store the next snapshot.

NOTE: A space in the FIFO is created whenever the EMAC_TM_AUXTS_SEC register is read. Therefore, read the EMAC_TM_AUXTS_NSEC register before reading the EMAC_TM_AUXTS_SEC register.

The program can clear the FIFO by setting the EMAC_TM_AUX_CTL.ATSFC bit. When multiple snapshots are present in the FIFO, the EMAC_TM_STAT.ATSNS bits indicate the count.

NOTE: The minimum gap between two events on the EMAC_PTPAUX_MCG_IN[n] pin must be 4 cycles of PTP_CLK + 3 cycles of CLKO7). Otherwise, the logic misses the rising edge of the trigger.

System Time

To get a snapshot of the time, the EMAC requires a reference time in 64-bit format as defined in the IEEE 1588 specification. The PTP module maintains 80-bit time, known as system time. The PTP clock updates system time.

The 80-bit timing reference is split into the following registers:

- EMAC_TM_NSEC–32-bit nanoseconds register which provides time in nanoseconds
- EMAC_TM_SEC–32-bit seconds register which provides time in seconds
- EMAC_TM_HISEC–16-bit high seconds register which provides time beyond the seconds register. The IEEE 1588 standard does not include this register. Its use is application specific.

The 64-bit system time (seconds and nanoseconds) is the source for taking time stamps for Ethernet frames being transmitted or received at the RMII.

Since the PTP clock frequency does not correspond to a 1 ns period, the EMAC_TM_NSEC register is incremented with a value equal to the PTP clock period for every PTP clock cycle. The function uses the EMAC_TM_SUBSEC register. The EMAC_TM_NSEC value is incremented with the value programmed in EMAC_TM_SUBSEC register every PTP clock cycle.

Whenever the EMAC_TM_SEC register overflows from 0xFFFFFFFF to 0x00000000, the seconds overflow interrupt is triggered. The EMAC uses the EMAC_TM_STAT.TSSOVF bit to indicate the event. After a seconds overflow, the EMAC_TM_HISEC register increments by one.

The system time module supports the following types of rollover modes for the EMAC_TM_NSEC register.

- Digital rollover mode. The maximum value in the nanoseconds field is 0x3B9AC9FF, that is, 10^9 nanoseconds. After it reaches this value, the EMAC_TM_SEC register increments and the EMAC_TM_NSEC register restarts counting from zero. Accuracy in digital rollover mode it is 1 ns per bit.
- Binary rollover mode. The nanoseconds field rolls over and increments the seconds field after the value reaches 0x7FFFFFFF. Accuracy in binary rollover mode is ~0.466 ns per bit.

System Time Adjustment

The following sections describe the process for system time adjustment.

System Time Initialization

System time can be initialized with 64-bit time when the PTP module is enabled. The initial value is written to the EMAC_TM_SECUPDT and EMAC_TM_NSECUPDT system time update registers. The system time counter is written with the value in the registers when EMAC_TM_CTL.TSINIT =1.

Coarse Correction Method

If the complete system time has an offset based on the system time of the requester, the coarse correction method can correct it. The time offset value is written to the EMAC_TM_SECUPDT and EMAC_TM_NSECUPDT registers. The offset value is then added to or subtracted from the system time when the EMAC_TM_CTL.TSUPDT bit is set (=1). Use the EMAC_TM_NSECUPDT.ADDSUB bit to choose addition or subtraction. System time correction occurs in one clock cycle using the coarse correction method.

NOTE: During subtraction, the EMAC_TM_SECUPDT register value must be less than the value of the EMAC_TM_SEC register. Check the value prior to subtracting using coarse correction.

Fine Correction Method

If a target PTP clock frequency has a drift based on the requester PTP clock (as defined in IEEE 1588), it can be corrected using the fine correction method. Using this method, system time is corrected over a period (unlike coarse correction where it happens in one clock cycle). This correction helps maintain linear time and does not introduce drastic changes (or a large jitter) in the reference time between PTP sync message intervals.

Using this method, an accumulator sums the contents of the EMAC_TM_ADDEND register. The ***System Time Update, Fine Correction Method*** figure shows the method. The arithmetic-carry that the accumulator generates acts as a pulse to increment the system time counter. The accumulator and the addend are 32-bit registers. Here, the accumulator acts as a high-precision frequency divider.

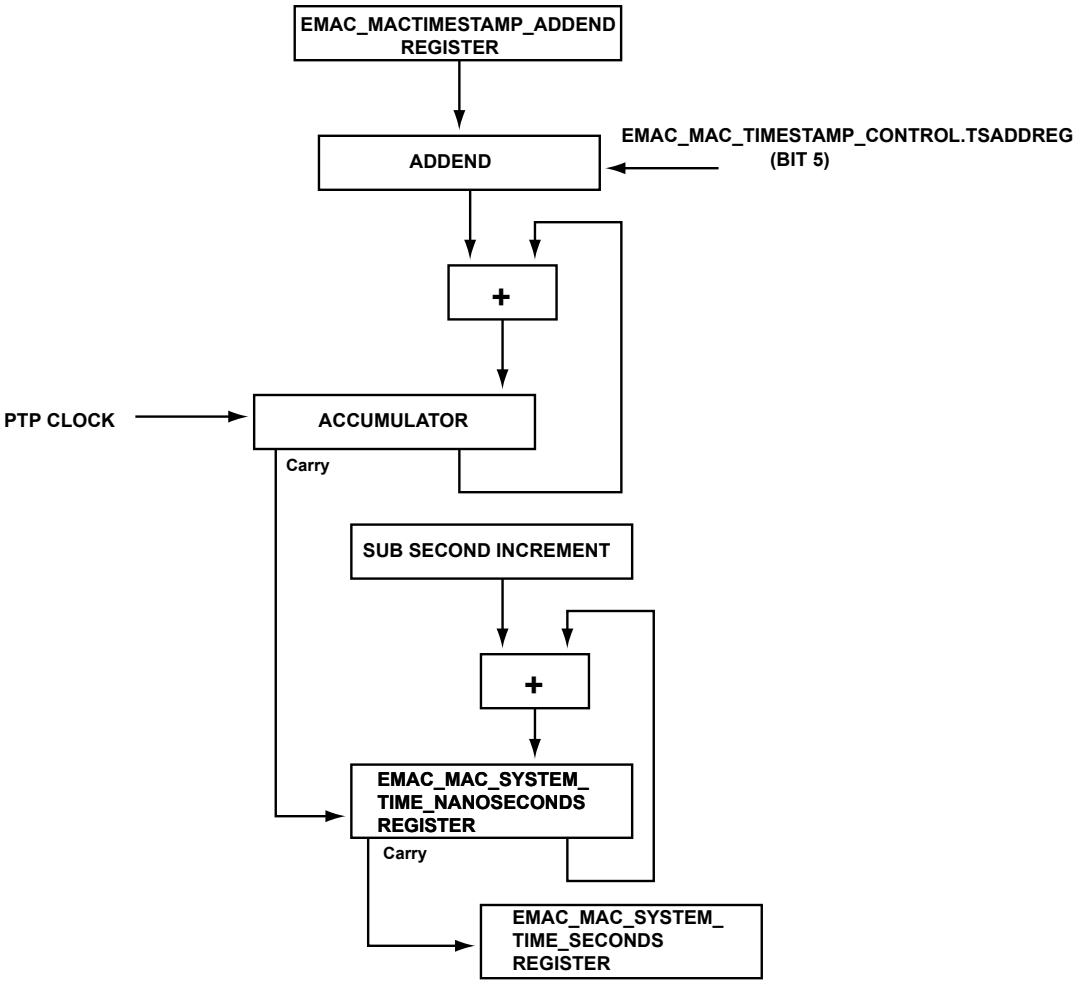

Figure 30-32: System Time Update, Fine Correction Method

Calculating Addend Value

The example in this section uses the fine correction process for system time.

In this example, the requester clock runs at 50 MHz and the completer clock has drifted to 66 MHz. The goal is to adjust the completer system time to 50 MHz, so that the completer PTP module synchronizes with the requester. Using the figure in Fine Correction Method, the nanoseconds increment signal runs at 50 MHz. The nanoseconds increment is the carry from accumulator register. The addend value increments the carry from accumulator at the rate of the completer clock (66 MHz).

The accumulator overflows and generates a carry every N addend value, so N × Addend = 2^{32}.

The accumulator increments at 66 MHz. This addition brings the carry to 50 MHz N = 66/50 = 1.32.

Hence, the addend = 2^{32}/1.32 = 0xC1F07C1F.

Therefore, if the addend is programmed with 0xC1F07C1F, the completer system time runs at 50 MHz, which synchronizes with the requester.

In the Fine Correction Method figure, the sub second increment is the value programmed in the EMAC_TM_SUBSEC register. It increments the EMAC_TM_NSEC register according to the frequency of the nanoseconds increment signal.

In the example, the sub second increment is 20 (for digital rollover) or 43 (for binary rollover). This addition increments the EMAC_TM_NSEC register by 20 ns (1/50 MHz).

The software must calculate the drift in frequency and update the EMAC_TM_ADDEND register accordingly.

NOTE: The PTP reference clock is the clock at which the system time is updated. When the EMAC_TM_CTL.TSCFUPDT bit is cleared (= 0), this clock equals the PTP clock. Using fine correction, the PTP reference clock is generated on the nanoseconds increment signal at which the system time updates.

Target Time Trigger (Alarm)

The PTP module provides an alarm function by triggering an alarm at a preset time. It sets the EMAC_TM_STAT.TSTARGT0 bit when the system time matches the value of the EMAC_PPS[n]_TGTM_SEC and EMAC_PPS[n]_TGTM_NSEC registers. This trigger can generate an interrupt and command the flexible PPS module to start or stop PPS output, depending on value programmed in the EMAC_PPS_CTL.TRGTMODSEL0 field.

The trigger is enabled by programming the EMAC_PPS[n]_TGTM_SEC and EMAC_PPS[n]_TGTM_SEC registers. Once an alarm has occurred, if the PTP needs another alarm, the software must:

- Clear the status bit,
- Reprogram the EMAC_PPS[n]_TGTM_SEC and EMAC_PPS[n]_TGTM_NSEC registers to a future value, and
- If the time programmed in the target time registers has elapsed, indicate a target time programming error by setting the EMAC_TM_STAT.TSTRGTERR0 bit.

The alarm time is represented in absolute units, not relative units. For example, if the software must generate an alarm after 10 seconds, it must read the current system time value. Then, the software must add the number corresponding to 10 seconds, and write the result back to the target time registers.

Pulse-Per-Second (PPS)

Pulse-per-second (PPS) is a physical representation of system time. It consists of a single pulse or train of pulses. The PTP uses PPS for extra synchronization or to monitor the synchronization performance between clocks. With proper configuration, the PTP module can generate PPS signals that are output on the EMAC_PTPPPS[n] pins. The PTP supports two kinds of PPS output: fixed and flexible.

Fixed Pulse-Per-Second Output

The EMAC module supports a fixed pulse-per-second (PPS) output that indicates 1 second intervals (default). Change the frequency of the PPS output by configuring the EMAC_PPS_CTL.PPSCTRL_PPSCMD bits. The default value for these bits is 0000, which configures a 1 Hz signal with a pulse width equal to the period of the PTP clock.

The ***PPS Output Frequencies*** table shows various PPS output frequencies.

Table 30-65: PPS Output Frequencies

PPSCTL Bit Setting	Binary Rollover	Digital Rollover
0001	2 Hz	1 Hz
0010	4 Hz	2 Hz
0011	8 Hz	4 Hz
...	...	...
1111	32.768 kHz	16.384 kHz

In binary rollover mode, the PPS output (ETH)_PTPPS0) has a duty cycle of 50% with these frequencies.

In digital rollover mode, the PPS output frequency is an average number. The actual clock is a different frequency that is synchronized every second. PPS output pulses have different periods and duty cycles. This behavior is because of the non-linear toggling of the bits in digital rollover mode. For example:

- When `EMAC_PPS_CTL.PPSCTRL_PPSCMD` = 0001, the PPS (1 Hz) has a low period of 537 ms and a high period of 463 ms.
- When `EMAC_PPS_CTL.PPSCTRL_PPSCMD` = 0010, the PPS (2 Hz) is a sequence of:
  - One clock of 50 % duty cycle and 537 ms period
  - Second clock of 463 ms period (268 ms low and 195 ms high)
- When `EMAC_PPS_CTL.PPSCTRL_PPSCMD` = 0011, the PPS (4 Hz) is a sequence of:
  - Three clocks of 50 % duty cycle and 268 ms period
  - Fourth clock of 195 ms period (134 ms low and 61 ms high)

Flexible Pulse-Per-Second Output

The EMAC module also provides the flexibility to program the start or stop time, width, and interval of the pulse generated on the PPS output. Enable this feature, called flexible PPS, by setting the `EMAC_PPS_CTL.PPSEN0` bit.

The flexible PPS output options are:

- Program the start point of the single pulse and start and stop points of the pulse train in terms of system time. The target time registers program the start and stop time.
- Program the stop time in advance. Programs can configure the stop time before the actual start time has elapsed.
- Program the width, between the rising edge and corresponding falling edge of the PPS signal output, in terms of number of units of subsecond increment. This value is configured in the `EMAC_TM_SUBSEC` register.

- Program the interval, between the rising edges of PPS signal, in terms of number of units of subsecond increment. This value is configured in the EMAC_TM_SUBSEC register.
- Cancel the programmed PPS start or stop request.
- Indicate an error if the start or stop time programmed has already elapsed.

PPS Start or Stop Time

Start time can initially be programmed in the target time registers. If necessary, the start or stop time can be programmed again, but, only after the earlier programmed value is synchronized to the PTP clock domain. The EMAC_PPS[n]_TGTM_NSEC.TRGTBUSY bit indicates the status of synchronization. Programs can configure the start or stop time in advance, even before the earlier stop or start time has elapsed.

Program the start or stop time with advanced system time to ensure proper PPS signal output. If the application programs a start or stop time that has already elapsed, the EMAC module sets the EMAC_TM_STAT.TSTRGTERR0 bit indicating the error. If enabled, the EMAC module also sets the target time trigger (alarm) interrupt event. The application can cancel the start or stop request only when the corresponding start or stop time has not elapsed. If the time has elapsed, the cancel command has no effect.

PPS Width and Interval

The PPS width and interval are programmed in terms of granularity of system time, that is, the number of the units of subsecond increment value. For example, with the PTP reference clock of 50 MHz, a PPS pulse width of 40 ns, and an interval of 100 ns, program the width and interval to 2 and 5, respectively.

Use a faster PTP reference clock to achieve smaller granularity. Before commanding to trigger a pulse or pulse train on the PPS output, programs must configure or update the interval and width of the PPS signal output.

PPS Command

When the PPS module has a flexible PPS output configuration, the PTP can use the EMAC_PPS_CTL.PPSCTRL_PPSCMD bits to command the PPS module to use any of the flexible PPS features. Programming these bits with a non-zero value instructs the PPS module to initiate an event. Once the command transfers or synchronizes to the PTP clock domain, these bits clear automatically. Software must ensure that these bits are programmed only when they are all-zero.

The ***Flexible PPS Output Commands*** table describes the different commands and their functions.

Table 30-66: Flexible PPS Output Commands

PPSCTL (Bits 3–0)	Command	Description
0000	No Command	
0001	Start Single Pulse	Generates a single pulse rising at the start point defined in the target time registers and of the duration defined in the EMAC_PPS[n]_WID register.

Table 30-66: Flexible PPS Output Commands (Continued)

PPSCTL (Bits 3–0)	Command	Description
0010	Start Pulse Train	Generates a train of pulses rising at the start time configured in the target time registers and of the duration configured in the EMAC_PPS[n]_WID register. The train of pulses repeats at the interval configured in the EMAC_PPS[n]_INTVL register. By default, the PPS pulse train is runs freely unless shalted by a Stop Pulse Train at Time command or a Stop Pulse Train Immediately command.
0011	Cancel Start	Cancels the Start Single Pulse and Start Pulse Train commands when the system time has not crossed the programmed start time.
0100	Stop Pulse Train at Time	Stops the train of pulses initiated by the command for start pulse train after the time programmed in the target time registers elapses.
0101	Stop Pulse Train Immediately	Immediately stops the train of pulses initiated by the command for start pulse train.
0110	Cancel Stop Pulse Train	Cancels the stop pulse train at time command when the programmed stop time has not elapsed. The PPS pulse train switches to free-running on the successful execution of this command.
0111-1111	Reserved	

PTP Interrupts

Set the EMAC_MAC_IEN.TSIE bit to enable interrupts from the PTP module. The EMAC module uses the EMAC_MAC_ISTAT.TSIS bit to indicate the status of the interrupt. The PTP supports the following three types of interrupts.

Auxiliary Snapshot Trigger

When an external event occurs on the EMAC_PTPAUX_MCG_IN[n] pins and a time stamp snapshot occurs, an auxiliary snapshot interrupt is triggered. The EMAC module uses the EMAC_TM_STAT.AUXTSTRIG bit to indicate the interrupt.

Target Time Reached

This interrupt is triggered when the system time becomes equal to the value written in the EMAC_PPS[n]_TGTM_SEC and EMAC_PPS[n]_TGTM_NSEC registers. This interrupt can be used as an alarm and is indicated on the EMAC_TM_STAT.TSTARGT0 bit.

System Time Seconds Register Overflow

The system time seconds register overflow interrupt is triggered when the EMAC_TM_SEC register overflows from 0xFFFF FFFF to 0x0000 0000. This interrupt is indicated on the EMAC_TM_STAT.TSSOVF bit. As soon as EMAC_TM_SEC register overflows, the EMAC_TM_HISEC register increments by one.

Media Clock Generation and Recovery (MCGR)

The EMAC module supports dedicated hardware for media clock recovery. This hardware generates a reference clock, which is multiplied to get the desired media clock. The hardware clock multiplier is external to the EMAC.

The media clock generation and recovery process is mainly hardware-based and involves insignificant software.

NOTE: The PPS and MCGR modes are mutually exclusive in that all the instances selected in the configuration must operate either in PPS mode or in MCGR mode. Mixed operation mode, where a few instances operate in PPS mode and others in MCGR mode, is not supported. Therefore, program all the instances to the same mode, irrespective of whether they are used or not.

The media clock generation and recovery support involve a dedicated external hardware and a thin layer of software. The dedicated hardware generates the reference clock (for example, 6 kHz or 8 kHz for AVB class A stream) which is then multiplied to get the desired media clock (for example an audio MCLK of 12.288 MHz).

The media clock recovery process involves host software extracting the presentation time from the 1722 frames and programming them into a CSR register, which is read by the EMAC to generate a reference clock. When the timer expires, the previous value is either toggled or a pulse is sent. The output at the recovered clock pin is generally a wave of 750 Hz ranging up to 8 kHz depending on the application that the clock is synced with, at the other end of the network.

As shown in the *Media Clock Generation and Recovery Block Diagram*, the time stamp array and the DMA module are external to the EMAC block.

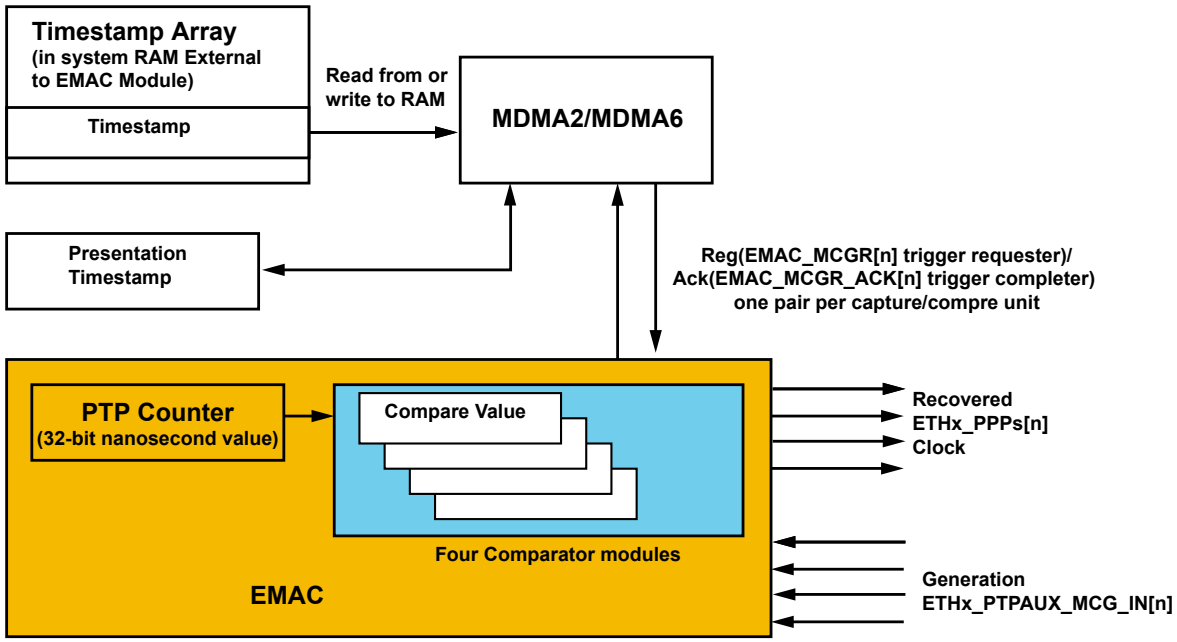

Figure 30-33: Media Clock Generation and Recovery Block Diagram

For the operation of the media clock generation and recovery, the EMAC supports:

- A 32-bit presentation time nanosecond counter that wraps at the full 32-bit value (and not after one second) to match up with the 1722 presentation time format.
- A mechanism to handshake with an external application (such as DMA) to program the presentation time into the CSR register. The hardware compares the programmed time stamp value with the presentation time and generates a wave based on the programmable settings.

Presentation Time Counter

The presentation time counter follows the 1722 presentation time format. In this format, time is represented as a 32-bit counter in nanoseconds that does a binary rollover on reaching the maximum value of 32'hFFFF_FFFF. This counter is another view of the PTP system time (1588 timer). For a given PTP, system time (PTP[63:32] represents time in seconds; PTP[31:0] represents time in nanoseconds. There exists a corresponding presentation time (32-bit value in nanosecond). The presentation time computed is referred to as the Current Presentation Time (CPT).

The CPT can be viewed as derived from 64-bit PTP system time as:

PTPNS [63:0] = (PTP[63:32] × 32'd1,000,000,000) + PTP[31:0]

where,

PTPNS is the PTP system time converted into a 64-bit nanosecond value

CPT [31:0] = PTPNS [31:0]

Media clock recovery is possible when the system time is internally generated in the EMAC module. CPT is computed in the same way as the internal PTP system time generation. Because CPT and system time values are in nanoseconds, and must be synchronous, the increment cycle of both the timers are same.

The timer is updated at the same instance; however, the updated value could be different. The software must compute a separate 32-bit update value in nanoseconds for the CPT update. A CPT sampled at different edges of a triggering input results in the generation of media clock time stamps which are inserted in 1722-based AVBTP packets to recover the clock at the destination.

NOTE:
- The value of CPT can be obtained by reading the `EMAC_PRSNTM_NSEC` register.
- The EMAC module supports both fine grain and coarse grain correction modes.
- Only the digital rollover mode must be used for the PTP time. The CPT also uses the same increment value and CPT requires the time to be in nanoseconds.

Comparator Modules

As shown in Figure 30-33 Media Clock Generation and Recovery Block Diagram, the EMAC module supports four comparator modules to handle multiple media clocks that might be required.

The comparator modules handshake with the application to:

- Program the time stamps into the `EMAC_PPS[n]_TGTM_SEC` register when `EMAC_TM_CTL.PTGE` =1.
- Set the presentation time control bits of the instance for recovery mode

The time stamps received from the application are referred as Target Presentation Time (TPT).

The MCGR and PPS modes are mutually exclusive. When the `EMAC_PPS_CTL.MCGREN3` through `EMAC_PPS_CTL.MCGREN0` bits are set (= 1), the corresponding PPS instance[n] operates in MCGR mode. Otherwise, by default, the PPS instance[n] operates in PPS mode.

The comparator module sends up to two requests to the application for TPT write, when EMAC_TM_CTL.PTGE = 1, and the presentation time control bits of the instance are configured for MCGR mode. Subsequent requests are generated each time a presentation time match occurs. (CPT transitions from a value less than TPT, to a value greater than or equal to CPT). The first request is asserted when a specific comparator instance is configured to MCGR mode with a non-zero presentation time control; an additional request is made when the first data is received into the comparator. This sequence allows the application to write the next TPT value while the EMAC module processes the previous TPT value for a match.

The TPT read from the EMAC_PPS[n]_TGTM_SEC register is considered as a future time. A toggle/pulse is generated in the next cycle when a match is detected. When a match is detected, the EMAC_PTPAUX_MCG_IN[n] trigger requester request for that comparator is asserted (to obtain next TPT) until the corresponding application acknowledgment is set.

The presentation control bits (for example, EMAC_PPS_CTL.PPSCMD1) determine the shape of the generated waveform. Also, these bits can be programmed to either toggle or generate a high/low pulse for one PTP clock cycle, upon match.

Clock Recovery

A match is when the free-running CPT value matches the received TPT value. An output signal, EMAC_PTPPPS[n], is asserted (toggle, low pulse, or high pulse) based on the programmed presentation control value.

Clock Generation

Based on the presentation control value programmed in the EMAC_PPS_CTL register, the comparator captures the presentation time and programs it into the EMAC_PPS[n]_TGTM_SEC register. A request is raised to the application to read the captured time stamp. Until the acknowledgment that the read operation is complete is received from the application, no new time stamps are captured.

Media Clock Generation and Recovery Flow

The *Media Clock Generation and Recovery Flow* figure shows the media clock generation and recovery flow.

For both media clock generation and recovery, set the EMAC_TM_CTL.PTGE field for CPT generation and set the EMAC_PPS_CTL.MCGREN3 through EMAC_PPS_CTL.MCGREN0 field for the corresponding instance to enable MCGR mode.

For media clock generation, the generated presentation time is sampled at positive, negative or at both the edges of trigger inputs (EMAC_PTPAUX_MCG_IN[n]) based on the mode programmed in the EMAC_PPS_CTL register. The sampled value is captured in the EMAC_PPS[n]_TGTM_SEC registers. After these registers are updated with the presentation time, the EMAC asserts the EMAC_PTPAUX_MCG_IN[n] trigger to request the application to read the presentation time. The application acknowledges that it has read the captured time stamp by asserting the corresponding EMAC_PTPAUX_MCG_IN[n] trigger completer.

For media clock recovery, the PPS instance asserts the EMAC_PTPAUX_MCG_IN[n] trigger to tell the application to program the target time seconds registers with the TPT value and acknowledge the corresponding request using the EMAC_PTPAUX_MCG_IN[n] trigger completer. When the application programs the target time seconds registers with the TPT value, the particular comparator compares the programmed TPT value with the CPT and

generates the waveform on EMAC_PTPPPS[n] based on the presentation time control value programmed in the EMAC_PPS_CTL register.

NOTE:
- The consecutive triggers to sample the presentation time should always be asserted after a few PTP clock cycles to allow for synchronization delays. (This is not an issue when the input trigger maximum frequency is 8 kHz and the PTP clock is running at least at 1 MHz).
- DMA acknowledgment can be both posted as well as non-posted, in the media clock recovery mode.

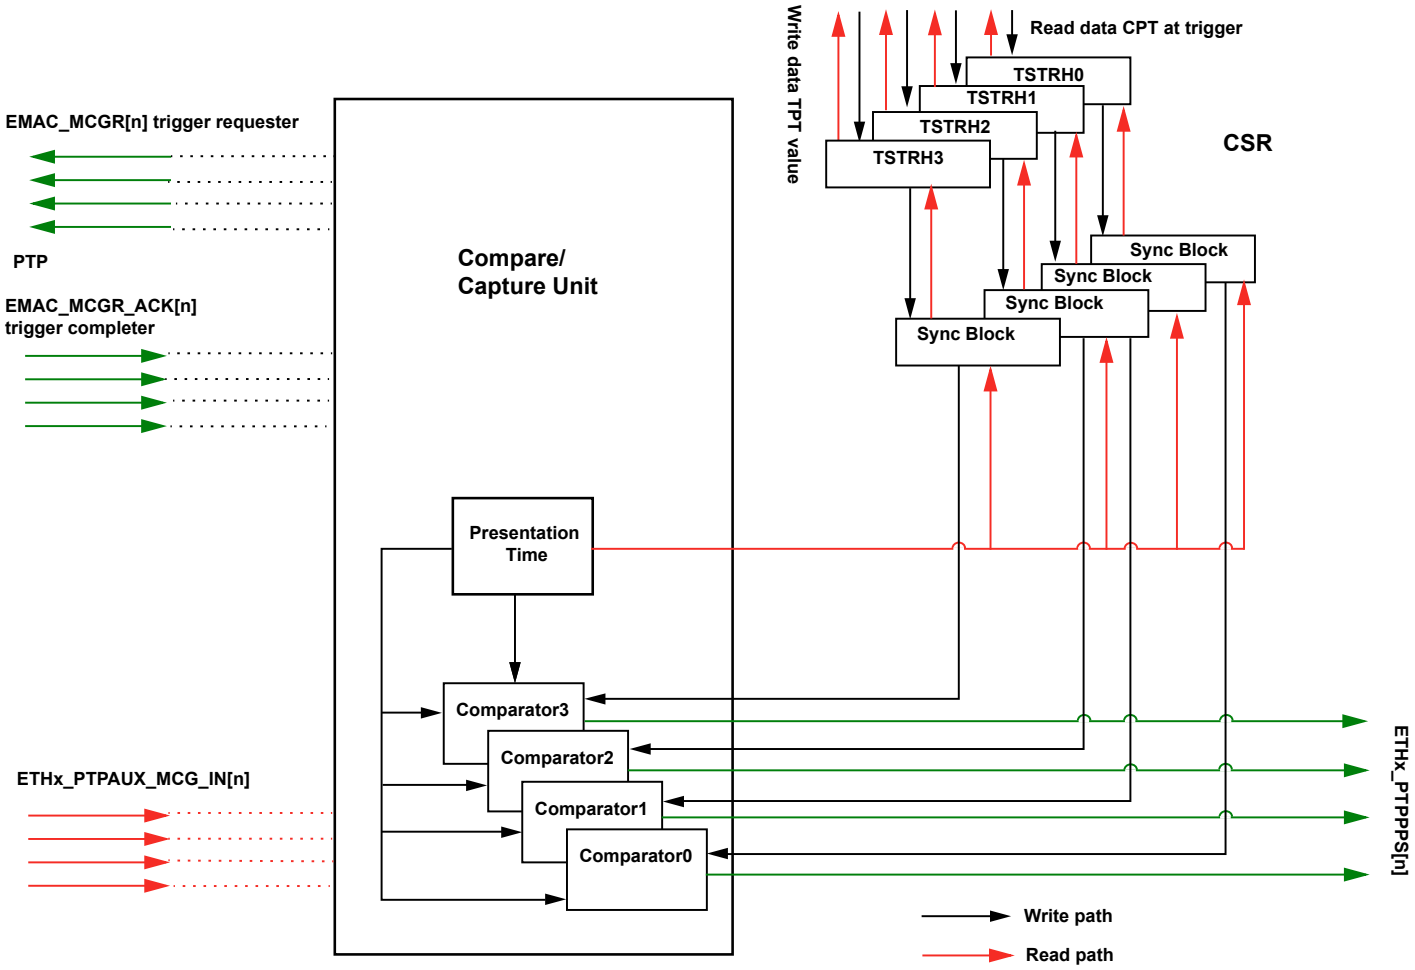

Figure 30-34: Media Clock Generation and Recovery Flow

PTP Time Stamp Offload Function

The PTP time stamp offload function enables the automatic generation of specific PTP packets when the MAC is working as a specific node in the PTP network. These packets may be generated periodically or triggered by the host software. In other modes, this feature can parse the incoming PTP packets on the receiver, and automatically generate and respond to the required PTP packets. This functionality helps in offloading certain functions of a PTP node with better accuracy and lower latency of responses.

Based on the programmed mode, the MAC generates PTP Ethernet messages periodically or from the application or based on reception of a particular PTP message.

The ***PTP Message Generation Criteria*** table indicates the PTP message generation criteria. Note that all other programming combinations are invalid for the PTP offload feature.

Table 30-67: PTP Message Generation Criteria

Programming (EMAC_TM_CTL)			Mode	Criteria for Generation of PTP Messages	PTP Message Type Generated
SNAPTYPSEL	TSMSTRENA	TSEVNTENA			
2'b00	0	1	Ordinary or boundary completer	SYNC message reception	Delay_Req
2'b00	1	1	Ordinary or boundary requester	Periodic or on trigger from application	SYNC
				Delay_Req message reception	Delay_Resp
2'b01	0	1	Transparent completer	Periodic or on trigger from application	Pdelay_Req
				Pdelay_Req message reception	Pdelay_Resp
				SYNC message reception	Delay_Req
2'b01	1	1	Transparent requester	Periodic or on trigger from application	Pdelay_Req
				Pdelay_Req message reception	Pdelay_Resp
				Periodic or on trigger from application	SYNC
				Delay_Req message reception	Delay_Resp
2'b11	X	X	Peer-to-peer transparent	Periodic or on trigger from application	Pdelay_Req
				Pdelay_Req message reception	Pdelay_Resp

NOTE: Clocks that support the peer delay mechanism must not generate delay request/delay response messages, according to the IEEE 1588-2008 specification. However, the EMAC supports this for flexibility, with a programmable control bit (EMAC_PTO_CTL.DRRDIS). Programs can use this bit to control the response generation for delay request/delay response message. For example, in transparent completer mode, delay request is generated in response to received sync only when the bit is reset.

For example, when the MAC is set as an ordinary or boundary completer clock in the PTP network, it can respond to the reception of SYNC messages with an automatic generation and transmission of the corresponding Delay_Req

message. Similarly, various other modes of operation are explained in the *PTP Message Generation Criteria* table. The MAC supports the multicast communication model for the generation of SYNC and Pdelay_Req PTP messages. For instance, the destination address field of the generated PTP over Ethernet packet is the defined special multicast addresses (0x011B19000000 for all except peer delay mechanism messages and 0x0180C200000E for peer delay mechanism messages).

When the MAC responds to received SYNC, Delay_Req, and Pdelay_Req PTP messages with a special multicast destination address, it also uses the corresponding special multicast address in the DA field of the automatically generated Delay_Req, Delay_Resp, and Pdelay_Resp PTP messages, respectively.

When the MAC responds to received SYNC, Delay_Req, and Pdelay_Req PTP messages with a unicast destination address, it takes the SA field of the received packets and makes them as the DA field of the automatically generated Delay_Req, Delay_Resp, and Pdelay_Resp PTP messages, respectively.

At the same time, all received PTP messages are forwarded to the application along with the receive status, indicating whether the response was generated by the MAC and whether it satisfies the packet filtering logic of the MAC receiver.

When the MAC automatically generates a PdelayReq or responds with a Delay_Req, the egress time stamp of these two PTP messages are provided in the transmit TS status (`EMAC_TM_STAT`) register; an interrupt is generated.

In addition to matching messageType and versionPTP fields for basic PTP over Ethernet message detection, the following fields are matched to qualify the received PTP message type:

1. The domainNumber field is checked for a match against the value programmed in the CSR.
2. The twoStepFlag in flagField field is checked for one step indication (1'b0).

The transportSpecific field is checked for the default PTP over Ethernet (4'h0) or 802.1AS mode (4'h1), when enabled.

Packet Generation

When enabled, the MAC can automatically generate PTP packets. The *Common PTP Message Header Fields* table describes the fields of specific PTP packets generated. The format and content of the packets are described in the following sections.

Table 30-68: Common PTP Message Header Fields

Bits								Octets	Offset
7	6	5	4	3	2	1	0		
transportSpecific				messageType				1	0
Reserved				versionPTP				1	1
messageLength								2	2
domainNumber								1	4
Reserved								1	5

Table 30-68: Common PTP Message Header Fields (Continued)

Bits								Octets	Offset
7	6	5	4	3	2	1	0		
flagField								2	6
correctionField								8	8
Reserved								4	16
sourcePortIdentity								10	20
sequenceId								2	30
sequenceId								2	30
controlField								1	32
logMessageInterval								1	33

messageType

The following encoded values are used for PTP message types:

- SYNC – 4'h0
- Delay_Req – 4'h1
- Pdelay_Req – 4'h2
- Pdelay_Resp – 4'h3
- Delay_Resp – 4'h9

transportSpecific

The following transport protocol encoding is used:

- Default PTP over Ethernet – 4'h0
- 802.1AS mode – 4'h1

versionPTP

It is always configured to 2 because PTP version 2 is supported.

domainNumber

This contains the value from the `EMAC_PTO_CTL` register.

flagField

The following values are used:

- alternateMasterFlag (Octet 0 bit 0) – 1b0 for SYNC and Delay_Resp
- twoStepFlag (Octet 0 bit 1) – 1'b0 for SYNC and Pdelay_Resp
- unicastFlag (Octet 0 bit 2) – 1'b0 for Multicast Address, 1'b1 for Unicast Address

correctionField

For more information, see the Table 30-69 MAC Transmit PTP Modes table.

sourcePortIdentity

This field takes the value programmed in the EMAC_SRCPRT_IDNTY0 - EMAC_SRCPRT_IDNTY2 registers.

sequenceId

Pdelay_Resp and Delay_Resp use the same sequenceId field from received Pdelay_Req and Delay_Req PTP messages. For SYNC/Delay_Req, Pdelay_Req, a separate sequenceId counter is maintained. These sequenceId counters get incremented by 1 every time the corresponding message is generated and transmitted.

controlField

The following encoded values are used for controlField:

- SYNC – 8'h00
- Delay_Req – 8'h01
- Pdelay_Req – 8'h02
- Pdelay_Resp – 8'h05
- Delay_Resp – 8'h03

logMessageInterval

- SYNC – This contains logSyncInterval from the corresponding EMAC_LOG_MSG_INTVL register.
- Delay_Resp – This contains the sum of DRSYNCR and logSyncInterval value taken from the EMAC_LOG_MSG_INTVL register for a multicast PTP message and 8'h7F for unicast PTP message.
- Delay_Req, Pdelay_Req and Pdelay_Resp – 8'h7F where logSyncInterval = log2 (Mean Value of Interval in seconds)

The MAC supports values of -15 to 15 for logSyncInterval fields, which translates to a range from 32.768 microsecond (2-15) to 215 second. For a given value of log sync interval (N), the time interval between two SYNC packets is given by the following:

- 2(30+N) ns, when N is negative (-1 to -15)
- 2N seconds, when N is positive (0 to 15)

For example:

- When logSyncInterval is programmed to 1, the interval is 21; therefore, the SYNC message is sent once every 2 seconds.
- When logSyncInterval is programmed to -1, the interval is 2-1 = 0.536 seconds; therefore, the SYNC message is sent once every 536 milliseconds. The value is 0.536 seconds, because 2-30 = 1 ns.
- When logSyncInterval is programmed to -5, the interval is 2-5 = 33.55 ms; therefore, the SYNC message is sent once every 33.55 milliseconds.

NOTE: The MAC uses the PTP system time to generate the intervals for periodic packet transmission. For negative values of log message interval programmed, the generated period may deviate from the value given by the equation 2(30+N), because of the non-binary nature of the nanoseconds field of the system time.

PTP Message Specific Fields

The PTP includes the following fields for messaging:

messageLength

There is no suffix supported; therefore, this field contains the length of the PTP message that includes 34 byte PTP common header and the body specific to the message type.

For SYNC and Delay_Req packets, this field contains 44, whereas for Delay_Resp, Pdelay_Req and Pdelay_Resp, it contains 54.

originTimestamp

This field is the captured egress time stamp for SYNC, Delay_Req, and Pdelay_Req PTP messages receiveTimestamp. For Delay_Resp PTP message, this field is the ingress time stamp of the corresponding received Delay_Req PTP message.

requestingPortIdentity

For Delay_Resp and Pdelay_Resp PTP messages, this field is the sourcePortIdentity field taken from the corresponding received Delay_Req and Pdelay_Req PTP messages.

requestReceiptTimestamp

For the Pdelay_Resp PTP message, this field = 0.

One Step Time Stamp

The EMAC supports the one step time stamp feature. When the feature is enabled, the MAC identifies the offset in the packet and inserts the time stamp received from the application at that offset.

Depending upon the type of message and its mode, the MAC updates the following fields of transmit PTP packets:

- correctionField in the PTP header of messages.

- originTimestamp in SYNC, Delay_Req, and Pdelay_Req messages

The *MAC Transmit PTP Modes* table shows how the PTP mode is selected for the one step time stamp operation based on the configuration of `EMAC_TM_CTL.SNAPTYPSEL`, `EMAC_TM_CTL.TSMSTRENA`, and `EMAC_TM_CTL.TSEVNTENA` bits. The bits are updated for the incoming PTP packets based on the message type in that mode, during the one step time stamping operation.

Table 30-69: MAC Transmit PTP Modes

Programming			Mode	Per Packet Control[*1]			Messages Processed on Tx
SNAPTYPSE	TSMSTRENA	TSEVNTENA		TTSE[*2]	OSTC[*3]	TTS[*4]	
X	X	X	N/A	1	X	X	Time stamp is captured and returned to application
X	X	X	N/A	X	0	X	OST operation is not performed (PTP packet is not modified)
2'b00	X	0	End-to-end transparent	0	1	Ingress TS	Sync (correction field for residence time and Ingress Asym cor)
							Delay_Req (correction field for residence time and Egress Asym Cor
2'b00	0	1	Ordinary or boundary completer	1	1	X	Delay_Req (originTimestamp field) Delay_Req (correction field for Egress Asym Cor)
2'b00	1	1	Ordinary or boundary requester	0	1	X	Sync (originTimestamp field) sync (correction field for sub nanosecond cor)

Table 30-69: MAC Transmit PTP Modes (Continued)

Programming			Mode	Per Packet Control*1			Messages Processed on Tx
SNAPTYPSE	TSMSTRENA	TSEVNTENA		TTSE*2	OSTC*3	TTS*4	
2'b11	X	X	Peer-to-peer transparent	0	1	Ingress TS	Sync (correction field for residence time and Ingress Asym Cor)
				1	1	X	Pdelay_Req (originTimestamp field) Pdelay_Req (correction field for Egress Asym Cor)
				0	1	Ingress TS for Pdelay_Req	Pdelay_Resp (correction field for turnaround time and Ingress Asym Cor)

*1 The per packet control values provided here are the recommended settings used by devices in typical PTP operation, for the programmed mode.

*2 TTSE represents TTSE bit of transmit descriptor. The TTSE function is independent of the OST function and the programmed operation mode for OST. The MAC captures and returns the time stamp when the TTSE bit is set.

*3 OSTC represents OSTC bit of transmit descriptor.

*4 TTS represents the time stamp value provided in the TTSH, TTSL fields of transmit descriptor.

NOTE: Residence time/ turnaround time is calculated as the difference between the captured time stamp (egress time stamp) and the ingress time stamp. When the sub nanosecond feature is enabled, the residence time calculation includes sub nanosecond accuracy. Clocks supporting peer delay mechanism do not use delay request or response; however, it is included in OST for flexibility.

Enabling One Step Time Stamp

Programs can enable the one step time stamp feature for a packet by setting bit 20 (OSTC) in the transmit descriptor. For updating the correction field in certain PTP packets, the ingress time stamp must be given in the TSSL and TSSH fields. When the added IEEE 1588 higher word register option is selected, the time stamp is 80 bits. It also contains the content of the higher 16 bits of the `EMAC_TM_HISEC` register.

One Step Time Stamping for PTP Over UDP

The EMAC supports one step time stamp operation for PTP messages sent over UDP/IPv4 and UDP/IPv6. Because origin time stamp and/or correction field (based on the PTP message type and the programmed PTP mode) in the

PTP message are updated as part of the one-step time stamp operation, it also requires update to the checksum field of the PTP message sent over UDP/IP.

Checksum Update for One-Step Timestamping for PTP Over UDP

In the EMAC, checksum is updated for a packet, in the MTL before the packet is sent to the MAC where the PTP message is updated for one step time stamp operation. PTP requires the time stamp to be captured while the packet (SFD of the packet) is on the line and one step time stamp requires the origin time stamp and/or correction field to be updated in the PTP header while the packet is being transmitted on the line. Because the PTP message is present in the UDP payload, it is not possible to update the checksum field in the UDP header for modifications made to the PTP message, because it is already transmitted by then. Instead, the following options are supported that are in line with specification mentioned in Annex D and E of IEEE 1588-2008:

- When PTP message is sent over UDP/IPv4, the UDP checksum may be set to 0. The application must set the UDP checksum to 0 and set CIC to 0 or 1 while providing the packet to the MAC and the MAC does not update checksum for changes in origin time stamp or correction field.
- When PTP message is sent over UDP/IPv6, a transmitting node extends the UDP payload of all PTP messages by 2 octets beyond the end of the PTP message. The contents of the UDP checksum field or the final 2 octets of the UDP payload might be modified to ensure that the UDP checksum remains intact after modification of PTP fields. The application must add the two extra bytes at the end of the PTP message while providing the packet to the MAC and the MAC updates these two bytes to keep the checksum correct.

A programmable option (`EMAC_TM_CTL.CSC` field) supports UDP with a non-zero checksum for IPv4. When set, the two bytes at the end of the PTP message are updated to keep the UDP checksum correct as with PTP over UDP/IPv6. The application must add two bytes at the end of the PTP message sent to the EMAC and the EMAC updates these two bytes to keep the checksum correct.

Updating the pad bytes to keep the checksum correct requires the old value of correction field and/or origin time stamp in the packet. To get better latency and area, the application can set the origin time stamp field to zero, for PTP message in particular modes in which EMAC overwrites the origin time stamp. For example, EMAC operating in ordinary/boundary requester mode overwrites the origin time stamp field of the sync message, when OSTC is set. Because the sync message is originated by the port operating in ordinary/boundary requester mode, it is possible for the application generating the message to set the origin time stamp field to zero.

The transmit checksum engine is automatically enabled when this feature is selected. The EMAC uses the transmit checksum engine to identify the start of a PTP message in the UDP/IP packet. The checksum engine has the capability to detect errors in the header (L3) and payload (L4). These errors are not computed for some type of packets, which is indicated by "No" in the *Transmit Checksum Offload Engine Functions for Different Packet Types* table in the *Synopsis DesignWare® Cores Ethernet Quality-of-Service Databook*.

For one step, operation the packet is free of those errors and have "Yes/Not applicable" for the corresponding packet type in the *Transmit Checksum Offload Engine Functions for Different Packet Types* table. If an error is reported by the checksum engine or there is a "No" in For PTP messages sent over UDP/IP, no update is performed on the PTP message. See “Transmit Checksum Offload Engine” of the *Synopsis DesignWare® Cores Ethernet Quality-of-Service Databook* for more details about the errors detected by transmit checksum engine.

NOTE:
- The packet is sent with specific IP address and UDP port numbers and does not have IPv4 options/ IPv6 extension headers. Applications must take care of these requirements before giving the packet to the EMAC. EMAC does not validate them. As PTP is identified by specific value in the UDP destination port and as EMAC does not investigate these fields, it assumes an IP packet with OSTC set as a PTP packet, and it is the responsibility of the application to set the OSTC bit only for IP packets which contains PTP messages.
- For PTP over UPD/IPv6 and PTP over UDP/IPv4 with CSC set, the EMAC does not verify the presence of the two pad bytes, instead it overwrites the two bytes after the PTP message.
- When the enable one step time stamp for PTP over UDP/IP feature is selected, the enable transmit TCP/IP checksum offload feature is automatically enabled, and this is enabled only for queue 0 in multiple transmit queue configurations. If the application requires OST support for PTP messages sent over UDP/IP for packets sent from queues other than 0, transmit checksum engine must be manually enabled for those transmit queues. If checksum engine is not enabled, no updates are done for PTP messages sent over UDP/IP even though OSTC is set.
- One step time stamp operation is not supported for tunneled packets

Multiple Channels and Queues Support

The EMAC supports up to eight queues and channels on transmit and receive paths. The EMAC Block Diagram and Interfaces figure shows the architecture of EMAC with multiple queues and channels.

Multiple Queues Support in the Transmit Path

The EMAC supports up to eight queues and channels on transmit and receive paths.

NOTE: EMAC0 supports eight transmit DMA channels and queues. EMAC1 supports one transmit DMA channel and queue.

The number of transmit DMA channels is equal to the number of transmit queues and is direct one-to-one mapping. This enables the interleaving of packet/data transfer of multiple transmit DMA on the host/system bus and each transmit queue is reserved for the corresponding transmit DMA. Therefore, the integrity of packet transfer by each transmit DMA is maintained in the transmit queue and enables efficient use of the host bus for data transfers among multiple transmit DMAs without depending on the packet length, transmit buffer availability and so on.

When two transmit DMAs can transfer data into the same transmit queue, then a transmit DMA starts a packet transfer, the other transmit DMA cannot transfer data to the same transmit queue unless the previous packet transfer is complete. This means that the second DMA remains idle until the first packet transferred is complete, which is effectively a one-to-one mapping of the transmit DMA to the transmit queue.

This section describes how multiple queues and channels are operated in the EMAC.

Fixed Priority Scheme

The fixed priority scheme does not necessarily cause “starving” of lower priority channels for the SCB bus because of the capabilities of the SCB protocol and characteristics of the transmit DMA, described as follows:

- Read command requests from a transmit DMA for a burst of data transfers is driven on a separate SCB channel and is executed in one clock cycle itself. The actual data transfer transfers start on a separate SCB channel only after the request is accepted and it takes multiple clock cycles to complete with relatively large read access latencies.
- SCB requester is free to drive out subsequent requests even before the previous data transfers are completed.
- Transmit DMA requests for another data transfer only after the data transfer for its previous request is completed and transferred to the MTL TxQ, and space is available in TxQ to take in the next request.
- The EMAC can be programmed to control the maximum number of outstanding requests, requested burst sizes by DMA, and the burst sizes of each data transfer on the SCB with the help of the `EMAC_DMA_SYSBMODE` register.

When all transmit DMAs place a request simultaneously and are serviced by the fixed priority algorithm, all the requests are placed on the SCB bus in a window of 32 clocks (two clocks per SCB request, two SCB burst requests per transmit DMA request). The data transfer of the first request takes 32 clock cycles + the read-access latencies (when there are tens of cycles). Therefor the transmit DMA arbiter is already IDLE and has completed servicing all the transmit DMA requests before this data transfer completes.

Effectively, all the transmit DMA channels get equal access to SCB bus and the corresponding TxQs are filled up at the same rate. The data is read out from the TxQs as per the traffic class scheduler in the MTL. At a steady state (assuming that SCB bandwidth available to fetch data from system memory is always more than the operating line rate), the bandwidth for each channel is controlled by the priorities and settings of the traffic scheduler in the MTL.

Multiple Queues in the Receive Path

The EMAC supports up to eight receive channels. The number of receive channels is independent of the receive queues.

NOTE: EMAC0 supports eight receive DMA channels and queues. EMAC1 supports 1 receive DMA channel and queue.

The EMAC supports independent selection of the number of receive DMA channels and the number of receive queues in the MTL receive buffer. Therefore, the packets from any receive queue can be serviced by any of the receive DMA. As all the packets of receive queues are stored in a shared RXFIFO buffer in the MTL, the receive scheduler selects the receive queue whose packet data is to be transferred to the destination receive DMA, which then forwards the packet data to the host memory. The sequence of events in time are as follows:

1. Each receive DMA indicates whether it is ready to transfer data, that is, when the receive DMA has fetched the descriptor and has a receiver buffer ready, to accept the packet data. Each receive DMA also indicates the number of words that it can transfer, based on the space available in the receive buffer and the value programmed in the `EMAC_DMA[n]_CTL.PBLX8` bit field.
2. The MTL receive scheduler matches the number of bytes/packets available for transfer at the top of all receive queues with the corresponding receive DMA ready status and the number of bytes requested by it.
3. If there are multiple successful matches, the scheduler selects the receive queue to be serviced, based on the arbitration schemes (strict priority or weighted strict priority) decided by the `EMAC_MTL_OPMODE.RAA` bit

field. In the weighted strict priority scheme, the weights of each receive queue is set in the EMAC_RQ[n]_CTL.RXQ_WEGT bit field.

4. The MTL receive controller fetches the data of the selected receive queue from the shared RXFIFO memory and starts the transfer of the requested PBL number of bytes to the DMA block or until the end of packet and the corresponding receive status is transferred (whichever is first).
5. After completing the current request, the scheduler repeats the process by starting a new arbitration cycle. However, it selects the same queues queue for servicing, if the end of packet is not transferred and the EMAC_RQ[n]_CTL.RXQ_FRM_ARBIT bits are 1, for the receive queue.

Receive Queue to DMA Mapping

The packets in the MTL receive queues can be routed to any one of the multiple DMA channels by programming the following registers:

- EMAC_RXQ_DMA_MAP0 register (for queues 0, 1, 2 and 3)
- EMAC_RXQ_DMA_MAP1 register (for queues 4, 5, 6 and 7)

The following types of receive queue to DMA mapping is possible EMAC_DMA[n]_IEN.RSE through programming:

- Static mapping
- Dynamic (per packet) mapping

Static Mapping

In static mapping mode, all packets of a receive queue are connected to a specific DMA channel. For example, all the packets from receive queue 0 can be routed to a DMA channel by programming the EMAC_RXQ_DMA_MAP0.Q0MDMACH and EMAC_RXQ_DMA_MAP0.Q0DDMACH bit fields.

Similarly, packets from other receive queues can be routed to any DMA channel by programming register fields corresponding to each queue.

Dynamic Mapping

In Dynamic (per packet) mapping mode, the destination DMA channel is chosen by the MAC core receiver for each packet.

In this mode, the destination DMA channel of a packet being read from a receive queue is not constant but decided independently for each packet. For example, if the EMAC_RXQ_DMA_MAP0.Q1MDMACH bit is set, the static mapping is disabled for receive queue 1 and the value in the EMAC_RXQ_DMA_MAP0.Q1MDMACH bit is ignored. The destination DMA channel is chosen by the MAC receiver for each packet, depending on the following in decreasing order of priority.

1. L3-L4 filter Based DMA Selection. When the enable layer 3 and layer 4 packet filter feature is present and enabled in the program configuration, the TCP/UDP and IP header fields of the received packet are matched against the corresponding values programmed and enabled for comparison in the EMAC_L3L4_CTL[i] register. If the match is successful, the DMA channel number programmed in the EMAC_L3L4_CTL[i].DMCHN bit field is selected as the destination DMA channel number provided the

EMAC_L3L4_CTL[i].DMCHEN bit of the same register is set. If none of the L3-L4 registers give a comparison match, the EMAC proceeds to the next step.

2. Extended VLAN Based DMA Selection. Extended routing is applicable only if the VLAN filter has passed. Routing is only based on perfect filter result. Each perfect filter has a programmable DMA channel enable and a DMA channel number field. Routing is applicable for a filter when the DMA channel enable bit is set.

   The frame is routed to the smallest matching filter's DMA channel provided it is enabled. If that filter's DMA channel number is not enabled, the frame gets routed to channel 0. For example, if a frame's VLAN tag matches filters 7, 3, and 1. Then the MAC checks if filter 1's DMA channel number is enabled through programming. If yes, the frame is routed to the programmed value; otherwise it is routed to channel 0. When the inverse filter is enabled, the frame is routed to the least mismatched filter's DMA channel number provided it is enabled. If the DMA channel enable bit is not set, then the frame is routed based on DA based addressing or to channel 0.

   If the hash filter is also enabled, it is used to determine the filter result only. Routing still depends on the enabled perfect filters. If none of the perfect filters are enabled or if all of them are bypassed, the VLAN filter based routing is not performed. The frame is routed through DA based addressing or to channel 0. If all the perfect filters give a fail result and the hash filter has passed, the VLAN filter result is a pass. However, routing is based on DA based addressing or to channel 0. The behavior is similar when inverse filtering is enabled.

3. Ethernet DA-Based DMA Selection. The DA address of the received packet is compared against the programmed DA values in MAC address registers. If the address matches any of the programmed values, the corresponding EMAC_ADDR[i]_HI.DCS bit field (when enabled) determines the destination DMA channel number. If none of the previous operations can make a successful match/decision, then the packet is routed to DMA channel 0 by default.

Broadcast/Multicast Packet Duplication

The EMAC supports the Broadcast/Multicast Packet Duplication feature to send the received broadcast/multicast packets to multiple DMA channels.

In a virtual system that supports multiple guest OS's (for instance, each OS owning a DMA channel), where each DMA could act as an independent Ethernet node, it may be required to route the received multicast/broadcast packets to all/multiple DMA channels. This is implemented by using the MTL RX FIFO read controller to read the packet from the same queue multiple times and route the same packet to the specified multiple DMA channels.

To maintain backward compatibility, through software control, the DMA channel selection (EMAC_ADDR[i]_HI.DCS) field are redefined to denote multiple DMA channels.

The EMAC_ADDR[i]_HI.DCS bit field determines the DMA channel number to which the received packet (that matches the MAC address present in that register) must be routed.

The EMAC_ADDR[i]_HI.DCS is a programmable field that supports more than one DMA channel number to be selected.

The EMAC_ADDR[i]_HI.DCS field can hold any one of the following values:

- Binary value of the channel number when the EMAC_MAC_EXT_CFG.PDC bit is set to 0

- One-hot value of the channel number when the EMAC_MAC_EXT_CFG.PDC bit is set to 1

Use DA based routing to enable the multicast/broadcast packets to route to multiple DMA channels. Packet duplication is not supported in other DMA channel routing mechanisms such as extended VLAN, or L3-L4 based routing. In other words if the destination DMA channel is decided by the VLAN or L3-L4 filter result, it is routed only to the specific channel even if the DA of the packet matches the multicast address in the EMAC_ADDR[i]_HI/EMAC_ADDR[i]_LO registers.

The packet duplication feature is supported only on the highest MTL queue configured. Therefore, packet duplication for broadcast/multicast packets requires that the EMAC_RXQ_CTL1.MCBCQ bit field is programmed to the highest RxQ present in the configuration.

In packet duplication, the MTL read controller sequentially transfers the same packet to all the required receive DMA channels. This packet is removed from the MTL FIFO only after the packet transfer completes. Therefore, this feature is suitable for smaller packet sizes or very low bandwidth traffic. This ensures that the MTL RxQ does not overflow due to the long period when the packet remains in the queue during the packet duplication.

NOTE: When more than one bit is set for the DMA channel number, a packet that is not routed to the highest receive queue is routed to only one DMA channel as indicated by the lowest bit set in the EMAC_ADDR[i]_HI.DCS bit field.

Assigning Tag Priorities to Transmit and Receive Queues

The EMAC supports assigning tag priorities to transmit and receive queues through programming registers.

The VLAN tag priorities can be assigned to transmit queues by programming the EMAC_TXQ_PRTY_MAP0.PSTQ0 through EMAC_TXQ_PRTY_MAP1.PSTQ7 bit fields in the following registers:

- EMAC_TXQ_PRTY_MAP0 (for transmit queues 0 to 3)
- EMAC_TXQ_PRTY_MAP1 (for transmit queues 4 to 7)

For example, if the program needs to assign a VLAN tag priority of 3 to transmit queue 0, set bit [3] in the EMAC_TXQ_PRTY_MAP0.PSTQ0 bit field.

The same VLAN tag priority can be set for multiple transmit queues. The transmit packet association to transmit queue is governed by the application, so the MAC does not route the packet based on transmit queue priority mapping; it is only used for Pause Flow Control (PFC). The settings in the PSTQ[n] field determines the transmit queues blocked for transmission when the PFC packet is received with corresponding VLAN tag priorities enabled.

The VLAN tag priorities can be assigned to receive queues by programming the EMAC_RXQ_CTL2.PSRQ0 through EMAC_RXQ_CTL3.PSRQ7 bit fields. The bit corresponding to the VLAN tag priority can be set in the PSRQ field for assigning that priority to the receive queue. For example, to assign a VLAN tag priority of 3 to receive queue 0, set bit [3] in the EMAC_RXQ_CTL2.PSRQ0 bit field. The VLAN tag priority assigned to the receive queue must be unique, that is, more than one receive queue cannot be assigned the same VLAN tag priority. However, more than one VLAN tag priority can be assigned to same receive queue.

The settings in the PSRQ bit field is used for VLAN tagged receive packet routing to receive queues as well as for PFC based transmit flow control. The received VLAN tagged receive packet is routed to the receive queue that has the VLAN tag priority match. In PFC based transmit flow control, the PSRQ bit field corresponding to a particular receive queue is used for enabling VLAN tag priorities in the PFC packet transmitted when corresponding receive queue threshold levels are reached.

Distribution of Receive Packets from MAC to Receive Queues

The EMAC provides multiple receive queues to support classification and distribution of ingress packets. The MAC receiver pushes the ingress packets to the receive queues based on packet type (tagged, untagged, multicast, PTP, AVB, DCB, and so on), tag priorities, MAC packet filter results, preemptable or express packet, and so on. The distribution is controlled by the settings of the `EMAC_RXQ_CTL0` through `EMAC_RXQ_CTL4` and `EMAC_MACPKT_FILT` register fields.

EMAC additionally supports distribution of ingress packets based on the user-defined type field of the ingress packets when the `EMAC_RXQ_CTL1.TBRQE` bit is enabled. Up to 8 types for matching are programmed in the MAC_TMRQ_Regs(n) registers which are accessible through the `EMAC_INDR_ACC_CTL` and `EMAC_INDR_ACC_DAT` registers. Each MAC_TMRQ_Regs(n) contains

- TYP field: contains 16-bit type value of the packet that needs to be compared with the received Ethernet packet. This field is valid when programmed to a value greater than or equal to 0x0600.
- TMRQ field: contains the receive queue number to which ingress packet is pushed when its type field matches TYP.
- PFEX field: This bit indicates whether the TYP is applicable for express packets or preemptable packets.

Based on the packet filter settings, the MAC receiver decides to either drop or forward the ingress packet. However, the results of layer 3 and layer 4 filtering, mentioned in Layer 3 and Layer 4 Frame Filtering are not considered for the distribution of ingress packets into the receive queues. Only the results of DA/SA/VLAN filters mentioned in Source Address or Destination Address Filtering and VLAN Filtering are applicable.

Filtering of the broadcast packets is exclusively controlled by the `EMAC_MACPKT_FILT.DBF` bit. The filtering of multicast packets is controlled by the `EMAC_MACPKT_FILT.PM` bit, in addition to the DA/SA match.

By default, packets that fail any of the DA/SA filters, are dropped by the MAC receiver. However, packets that fail the DA/SA/VLAN filter can still be forwarded to the application when the `EMAC_MACPKT_FILT.RA` bit is 1. Even when the RA field is 0, VLAN filter fail packets can be forwarded if the `EMAC_MACPKT_FILT.VTFE` bit is 0.

The ingress packets go through the following operations in the decreasing order of priority.

RA = 0: Ingress packets are dropped when any one of the following conditions is true.

- DA/SA filter fail
- VLAN filter fail and `EMAC_MACPKT_FILT.VTFE` bit is 1

`EMAC_MACPKT_FILT.RA` = 1: Ingress packets that fail the DA/SA filter are also forwarded to the receive queue as mentioned in the *Routing DA/SA Failed Packets to Receive Queue* table.

Table 30-70: Routing DA/SA Failed Packets to Receive Queue

Packet Type	TSN Type	Destination Receive Queue Determined By
Broadcast/Multicast	Express	if MFFQE = 1, MFFQ; else if VFFQE = 1, VFFQ; (only for tagged packets) else RxQ0
Unicast	Express	if MFFQE = 1, MFFQ; else if VFFQE = 1, VFFQ; (only for tagged packets) else RxQ0
All	Preemptable	FPRQ field

`EMAC_MACPKT_FILT.RA` = 1 and `EMAC_MACPKT_FILT.VTFE` = 0: Ingress tagged packets that pass the DA/SA filter but fail the VLAN filter, are forwarded to the receive queue as mentioned in the *Routing DA/SA Pass But VLAN Filter Fail Packets to Receive Queue* table.

Table 30-71: Routing DA/SA Pass But VLAN Filter Fail Packets to Receive Queue

TSN Packet Type	Destination Receive Queue Determined By
Express	if VFFQE = 1, VFFQ; else RxQ0
Preemptable	RQ field

Ingress packets that pass the DA/SA/VLAN filters are forwarded to the receive queue. The *Priority Routing of Filter Pass Packets When OMCBCQ = 0* table shows the routing priority in the decreasing order when the `EMAC_RXQ_CTL1.OMCBCQ` bit field is 0.

Table 30-72: Priority Routing of Filter Pass Packets When OMCBCQ = 0

Packet Type	TSN Type	Tagged	Destination Receive Queue Determined By
Broadcast/Multicast	Express	Yes	if MCBCQEN = 1, MCBCQ; else if TBRQE = 1, TBRQ; else PSRQ
		No	if MCBCQEN = 1, MCBCQ; else if TBRQE = 1, TBRQ; else UPQ
Unicast AVTP Control	Express	No	AVCPQ
		Yes	if TACPQE = 1, AVCPQ; else PSRQ
Unicast PTP over Ethernet	Express	No	PTPQ
		Yes	PTPQ or PSRQ based on the value of TPQC
Unicast DCB/LLDP Control	Express	No	DCBPQ

Table 30-72: Priority Routing of Filter Pass Packets When OMCBCQ = 0 (Continued)

Packet Type	TSN Type	Tagged	Destination Receive Queue Determined By
Remaining Unicast	Express	No	If TBRQE = 1, TBRQ; else UPQ
		Yes	If TBRQE = 1, TBRQ; else PSRQ
All Packets	Preemptable	No	If TBRQE = 1, TBRQ; else FPRQ
		Yes	If TBRQE = 1, TBRQ; else PSRQ

The *Priority Routing of Filter Pass Packets When OMCBCQ = 1* table shows the routing priority in the decreasing order when the `EMAC_RXQ_CTL1.OMCBCQ` bit field is 1.

Table 30-73: Priority Routing of Filter Pass Packets When OMCBCQ = 1

Packet Type	TSN Type	Tagged	Destination Receive Queue Determined By
All AVTP Control	Express	No	AVCPQ
		Yes	if TACPQE = 1, AVCPQ; else PSRQ
All PTP over Ethernet	Express	No	PTPPQ
		Yes	PTPQ or PSRQ based on TPQC
Remaining Broadcast/ Multicast	Express	Yes	if MCBCQEN = 1, MCBCQ; else if TBRQE = 1, TBRQ; else PSRQ
		No	if MCBCQEN = 1, MCBCQ; else if TBRQE = 1, TBRQ; else UPQ
Unicast DCB/LLDP Control	Express	No	DCBPQ
Remaining Unicast	Express	No	If TBRQE = 1, TBRQ; else UPQ
		Yes	If TBRQE = 1, TBRQ; else PSRQ
All Packets	Preemptable	No	If TBRQE = 1, TBRQ; else FPRQ
		Yes	If TBRQE = 1, TBRQ; else PSRQ

NOTE: If the RxQ pointed to by the various fields in tables above is not enabled in the `EMAC_RXQ_CTL0` register as per the packet type, the packet is written to

- RxQ0 for express packets
- FPRQ field for preemptable packets
- If RxQ0/FPRQ is not enabled, the packet is dropped.

If the `EMAC_TM_CTL.AV8021ASMEN` bit is 1, the MAC receiver checks only for untagged PTP packets. Tagged packets with a PTP payload are considered as remaining (Unicast/Broadcast/Multicast) tagged packets in the above tables.

Traffic Shaper

Traffic shaping is the process of distributing frames/packets evenly in time to smooth out network traffic. This reduces traffic bursts which can overwhelm the network. The following sections describe how to implement and manage this feature.

Data Center Bridging

The data center bridging feature supports three types of algorithms: weighted round robin, deficit weighted round robin, and weighted fair queuing.

Weighted Round Robin

In the Weighted Round Robin algorithm used in the Data Center Bridging feature, all queues are serviced in round-robin order based on weight setting.

In Weighted Round Robin (WRR) algorithm, each queue is assigned a weight based on the percentage of configured bandwidth. All queues are serviced in the round-robin order according to the weight settings. This algorithm is less complex and requires less hardware as compared to other algorithms. Large packets get more bandwidth in this algorithm.

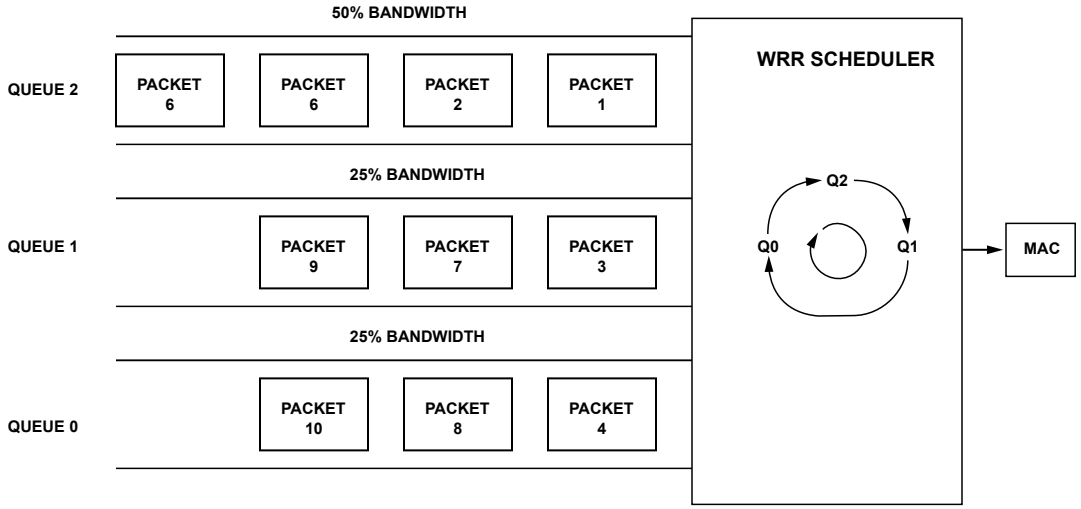

Figure 30-35: Weighted Round Robin Example

In the *Weighted Round Robin Example* figure, Queue 2, Queue 1, and Queue 0 are configured for 50%, 25%, and 25% bandwidth, respectively. The corresponding weights are two, one, and one. Before the WRR scheduler is started, Queue 2 has four packets; Queue 1 has three packets; and Queue 0 has three packets. The packets are transmitted in the following order:

Table 30-74: Weighted Round Robin Sequence Example

Packet Sequence	Queue Number
Packet 1	Queue 2
Packet 2	Queue 2
Packet 3	Queue 1
Packet 4	Queue 0

Table 30-74: Weighted Round Robin Sequence Example (Continued)

Packet Sequence	Queue Number
Packet 5	Queue 2
Packet 6	Queue 2
Packet 7	Queue 1
Packet 8	Queue 0
Packet 9	Queue 1
Packet 10	Queue 0

Deficit Weighted Round Robin

When the Data Center Bridging feature is supported, programs can use the deficit weighted round robin algorithm to assign a weight based on the percentage of configured bandwidth. A deficit counter holds the credit for transmission.

In Deficit Weighted Round Robin (DWRR) algorithm, each queue is assigned a weight based on the percentage of configured bandwidth. A deficit counter holds the credit for transmission. The quantum value, proportional to the bandwidth, is added to the deficit counter every time a queue is scanned. The packet in the queue is selected for transmission only if the credit in the deficit counter is less than or equal to the size of the packet available at the head of the queue. A selected queue is serviced until the outstanding credit is lesser than the packet size at the head of the queue during a particular queue scan cycle. After this, the next lower priority queue is serviced. When the packets in a queue are over, the credit becomes zero for that queue scan cycle. This algorithm is less complex, and it provides more fairness in scheduling as compared to other algorithms.

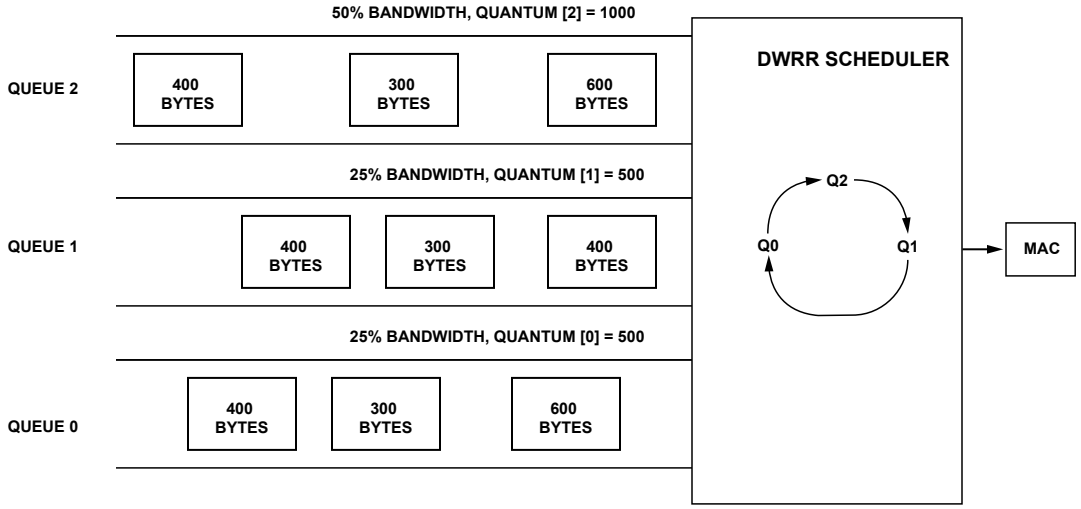

Figure 30-36: Deficit Weighted Round Robin Example

In the *Deficit Weighted Round Robin Example* figure, Queue 2, Queue 1, and Queue 0 are configured for 50%, 25%, and 25% bandwidth, respectively. The corresponding quantum values are 1000, 500, and 500. Before the DWRR scheduler is started, each queue has three packets. The *Deficit Weighted Round Robin* table shows the queues scan

cycle number and the packet size at the head of queues, deficit counter value before and after packet in selected queue is transmitted, and queue scheduled for transmission.

Table 30-75: Deficit Weighted Round Robin

Queues Scan Cycle Number	Packet Size at the Head of Queue			Deficit Counter Value Before the Packet is Transmitted in Selected Queue			Deficit Counter Value after the Packet is Transmitted in Selected Queue			Queue Scheduled for Transmission
Queue	Q2	Q1	Q0	Q2	Q1	Q0	Q2	Q1	Q0	
1	600	400	600	1000	500	500	400	500	500	Q2
	300	400	600	400	500	500	100	500	500	Q2
	400	400	600	100	500	500	100	100	500	Q1
	400	300	600	100	100	500	100	100	500	None
2	400	300	600	1100	600	1000	700	600	1000	Q2
	N/A	300	600	0	600	1000	0	300	1000	Q1
	N/A	400	600	0	300	1000	0	300	400	Q0
	N/A	400	300	0	300	400	0	300	100	Q0
	N/A	400	400	0	300	100	0	300	100	None
3	N/A	400	400	0	800	600	0	400	600	Q1
	N/A	N/A	400	0	N/A	600	0	0	200	Q0
	N/A	N/A	N/A	0	N/A	N/A	0	0	0	None

Weighted Fair Queuing

In the Weighted Fair Queuing (WFQ) algorithm used in the Data Center Bridging feature, each queue is assigned a weight based on the percentage of configured bandwidth. The algorithm computes the finish time of packets at the head of the queues based on the packet size and weights for the queue. The packets with earliest finish time is scheduled or transmission first. The algorithm is more complex and less scalable as compared to other algorithms.

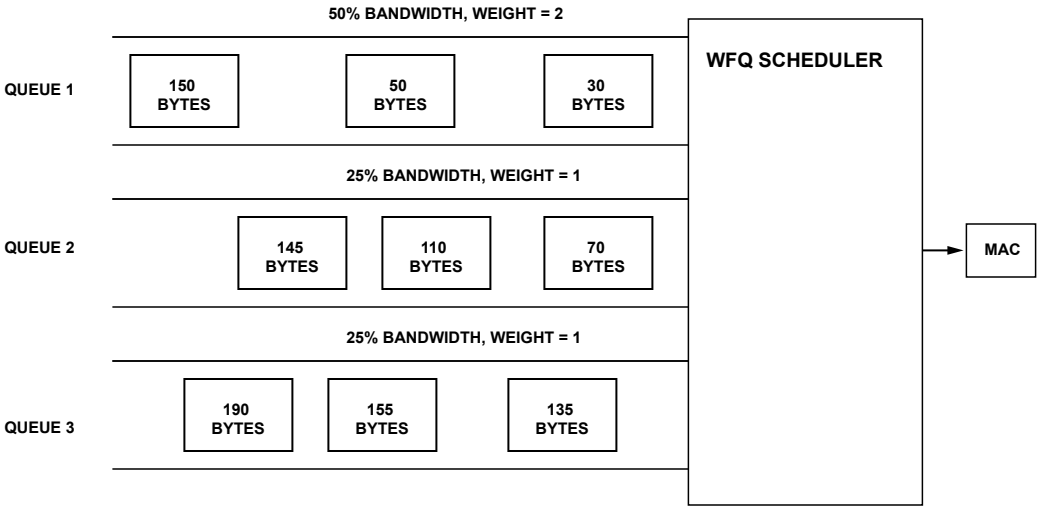

Figure 30-37: Weighted Fair Queuing Example

In the *Weighted Fair Queuing Example* figure, Queue 2, Queue 1, and Queue 0 are configured for 50%, 25%, and 25% bandwidth, respectively. The corresponding weights are 2, 1, and 1. Before the WFQ scheduler is started, each queue has three packets. The *Weighted Fair Queuing Algorithm Example Values* table shows the packet size at the head of the queue, computed finish time, and the queue scheduled for transmission.

Table 30-76: Weighted Fair Queuing Algorithm Example Values

Packet size at the Head of the Queue			Computed Finish Time in Clock Cycles (packet size or weights)			Queue Scheduled for Transmission
Q2	Q1	Q0	Q2	Q1	Q0	
30	70	135	15	70	135	Q2
50	70	135	25	70	135	Q2
150	70	135	75	70	135	Q1
150	110	135	75	110	135	Q2
N/A	110	135	N/A	110	135	Q1
N/A	145	135	N/A	145	135	Q0
N/A	145	155	N/A	145	155	Q1
N/A		155	N/A	N/A	155	Q0
N/A		190	N/A	N/A	190	Q0

Audio Video Bridging

The EMAC supports the AV data transfer in 100 Mbps and 1000 Mbps modes. The AV feature enables transmission of time-sensitive traffic over bridged local area networks (LANs). The following standards define various aspects of the AV feature implementation:

- IEEE 802.1Qav-2009: Allows the bridges to provide time-sensitive and loss-sensitive real-time audio video data transmission (AV traffic). It specifies the priority regeneration and controlled bandwidth queue draining algorithms that are used in bridges and AV traffic sources.
- IEEE 802.1Qat-2009: Allows the network resources to be reserved for specific traffic streams traversing a bridged local area network.
- IEEE 802.1AS-2011: Specifies the protocol and procedures used to ensure that the synchronization requirements are met for time-sensitive applications such as audio and video across bridged and virtual-bridged LANs consisting of LAN media where the transmission delays are fixed and symmetrical. For example, IEEE 802.3 full-duplex links include the maintenance of synchronized time during normal operation followed by addition, removal, or failure of network components and network reconfiguration.

While the AVB standards were originally designed for audio and video over standard Ethernet, extending these to control streams additionally benefits the industrial and automotive sectors. Time Sensitive Networking (TSN) is a set of standards developed by the Time Sensitive Networking Task Group with the intent to extend the future AVB enhancements to other sectors that could benefit.

Bridges are increasingly used to interconnect devices that support scheduled applications (for example, industrial automation, process control and vehicle control). The IEEE 802.1Qbv-2015 (Enhancements to Scheduling Traffic) provides performance assurances of latency and delivery variation to enable these applications in an engineered LAN while maintaining the existing guarantees for the credit-based shaper and best-effort traffic.

The IEEE 802.3br (Interspersing Traffic) and IEEE 802.1Qbu (Frame Preemption) enables the suspension of a large preemptable packet being transmitted by the MAC layer to allow one or more express packets to be transmitted before the transmission of the preemptable packet is resumed. This provides the capability to schedule express traffic packets with minimal delays/latencies or at predictable times with efficient utilization of the line bandwidth.

Transmit Path Functions

Transmit paths of queue 0 and the highest enabled queue are enabled by default.

The transmit path of queue 0 supports the strict priority algorithm, and it is used for best-effort traffic. For a queue, the strict priority algorithm determines that a packet is available for transmission if the queue contains one or more packets. When the threshold mode for the MTL Tx FIFO is enabled, the strict priority algorithm determines that a packet is available for transmission if the queue contains a partial packet of a size equal to the programmed threshold limit.

The transmit paths of additional queues support traffic management by using the credit-based shaper algorithm. For a queue, the credit-based shaper algorithm determines that a queue is available for transmission if the following conditions are true:

- The queue contains one or more packets
- The credit for the queue is positive as per the algorithm

The credit-based shaper algorithm can be disabled for all queues or lower-priority queues. For example, the program can either disable the credit-based shaper algorithm for queue 1 and queue 2 or only for queue 1. The program

should not disable the credit-based shaper algorithm for queue 2 and enable it for queue 1. When the credit-based shaper algorithm for a queue is disabled, the channel uses the default strict priority algorithm.

Each transmit DMA has a separate descriptor chain for fetching the transmit data. The transmit channel that gets the access to the system bus depends on the DMA arbiter.

The transmit path has a shared FIFO (MTL layer) for each queue. The data fetched by the DMA is put in the respective part of the FIFO. The MTL transmit queue scheduler controls which part of the FIFO data is transmitted by the MAC. If the credit-based shaper algorithm is enabled for a queue, the corresponding queue is selected for transmission if the following conditions are true:

- If the packet is available in the channel and has a positive or zero credit
- If the higher priority queue has no packet waiting in the FIFO

If the credit-based shaper algorithm is disabled for all queues, the packet transmitted from a queue is selected based on the priority scheme described in the following table.

Table 30-77: Weight for DMA Channels

`EMAC_DMA[n]_TXCTL.TCW` Field	**Transmit Channel Weight**
000	1
001	2
010	3
011	4
100	5
101	6
110	7
111	8

Receive Path Functions

The receive path of Queue 0 is enabled by default. All traffic is received on this channel. Programs can enable the receive paths of additional queues. By enabling the receive paths of multiple channels, the received data is demultiplexed and sends the packets into separate receive channels.

To differentiate between the AV and non-AV traffic, the MAC provides a status that indicates if it is an AV packet and its corresponding VLAN priority tag value. This status is updated in the extended status field of the receive descriptor as explained in Receive Descriptor.

All received packets with the EtherType field of 0x22F0 are detected as AV packets. The AV packets can be of the following two types:

- AV data packets: The AV data packets are always tagged. The tagged AV data packets are received based on the programmed priority value. To specify the channel to which an AV packet with a given priority must be sent, program bits[15:8] in the `EMAC_Q[i]_TXFLOW_CTL` register of the corresponding queue.

- AV control packets: The AV control packets can be either tagged or untagged. The untagged AV control packets are received on Queue 0, by default. To receive these packets on any other queue, program`EMAC_RXQ_CTL1.AVCPQ` bit field. Like the AV data packets, the tagged AV control packets are received based on the programmed priority value.

In addition to the AV packets, the untagged PTP packets on any queue ca also be received. By default, the PTP packets (tagged or untagged) are received on queue 0. To receive these packets on any other queue, program the `EMAC_RXQ_CTL1.PTPQ` bits.

Credit-Based Shaper Algorithm

The MTL Queue Scheduler uses the credit-based shaper algorithm to arbitrate the AV traffic in all queues and the legacy Ethernet traffic in queue 0. The additional queues can be programmed to use the credit-based shaper algorithm.

The following sections provide information for implementing the credit-based shaper algorithm:

- Credit value
- idleSlopeCredit and sendSlopeCredit values
- Bandwidth status

Credit Value

The credit value is part of the credit-based sharper algorithm used by the MTL queue scheduler. The credit value is accumulated every transmit clock cycle, that is, 40 ns for 100 Mbps and 8 ns for 1000 Mbps. The credit to add or subtract per cycle can be fractional based on the required idleSlope and sendSlope values, as described in the following table.

Table 30-78: Credit Value per Transmit Cycle Example

Mode	Values	Description
100 Mbps	portTransmitRate = 100 Mbps idleSlope = 70 Mbps (assuming 70% bandwidth reserved for a higher priority traffic class) sendSlope = 30 Mbps	credit = 2.8 bits accumulates per cycle (40 ns) for the higher priority traffic class when best-effort packet is being transmitted. credit = 1.2 bits drains per cycle (40 ns) when higher priority traffic class packet is being transmitted.

The DMA stores the queue traffic in the respective part of the Tx FIFO based on the slot number in the transmit descriptor (if enabled) or the bandwidth availability on the application bus.

The credit for a queue builds up only when the packet is available, but it cannot be transmitted because the MAC is sending a packet from another queue. The EMAC supports another mode in which the credit can build up in advance for a queue in which no packet is available in respective part of the FIFO. This enables sending a burst of high priority traffic in a queue as soon as the data is available. You can enable this mode is enabled using the `EMAC_TQ[n]_ETS_CTL.AVALG` bit of corresponding queues.

When reset, the accumulated credit parameter in the credit-based shaper algorithm is set to zero if there is positive credit, and there is no packet to transmit in a queue. The credit does not accumulate when there is no packet

waiting in a queue and other queues are transmitting. When set, the accumulated credit parameter in the credit-based shaper algorithm is not reset to zero if there is positive credit and no packet to transmit in a queue. The credit accumulates even when there is no packet waiting in a queue and other queues are transmitting.

idleSlopeCredit and sendSlopeCredit Values

The software must program the idleSlopeCredit and sendSlopeCredit values. The programmed values should be the credit accumulated or drained per clock cycle scaled by 1024, such as, 2.8 x 1024 = 2867 and 1.2 x 1024 = 1229. In addition, the software must program the hiCredit and loCredit values, scaled by 1024, to adjust for scaling of the idleSlopeCredit and sendSlopeCredit values. This means that if computed hiCredit and loCredit values are 12,000 bits and 3,036 bits respectively, the values programmed in the hiCredit and loCredit registers of the corresponding channel are 12000 x 1024 bits and two's complement of 3036 x1024, respectively.

Bandwidth Status

The hardware maintains the status of the actual bandwidth consumed by each higher priority queue in the `EMAC_TQ[n]_ETS_STAT` registers. This enables the software to estimate the average bandwidth consumed by numerically higher traffic classes as compared to the reserved bandwidth.

The `EMAC_TQ[n]_ETS_STAT` registers show the average number of bits transmitted during the previous programmed slot interval (1, 2, 4, 8, or 16 slots of 125 µs) in a queue. The status register is updated even if the credit-based shaper algorithm is not enabled for a queue. The number of slots over which the average bits transmitted per slot are computed is programmed in the `EMAC_TQ[n]_ETS_CTL.SLC` bit field of the respective queue. For example, when programming two slots, the average bits are computed over slot numbers 0–1, 2–3, 4–5, and so on.

The value programmed in the idleSlopeCredit register of a queue is proportional to the bandwidth reserved for the queue. The software can allocate any bandwidth that is not used by the higher priority queue to the reserved bandwidth of the lower priority queue.

A lower priority queue that uses the credit-based shaper algorithm, cannot use the unused reserved bandwidth of any higher priority queue that is using the credit-based shaper algorithm. However, a lower priority queue that uses the strict-priority algorithm, can use the unused reserved bandwidth of any higher priority queue that uses the credit-based shaper algorithm. For example, queue 1 and queue 2 use the credit-based shaper algorithm (with reserved bandwidth of 50% and 25%, respectively) and queue 0 uses the strict-priority algorithm. If queue 1 uses only 40% of reserved bandwidth, the remaining 10% is used by queue 0. Queue 2 cannot exceed the reserved bandwidth of 25%.

Slot Number Function

The slot number function is used to schedule the data fetch from the system memory by the DMA. This feature is useful when the source AV data needs to be transmitted at specific intervals.

The slot number at which the DMA fetches the data from system memory is programmed in the Transmit Descriptor Word 3 (TDES3) register. This 4-bit field allows the application to schedule data up to 16 slots; a programmable slot interval that ranges from 1µs to 4096 µs with a granularity of 1µs. This field is applicable only for the AV channels.

When the DMA fetches a transmit descriptor, it compares the slot number of the transmit descriptor with the internally generated reference slot interval. The slot interval is a counter that is updated based on a programmable slot interval (with a range of from 1µs to 4096 µs) of the IEEE 1588 system time. In addition, the slot interval counter is initialized to zero when the seconds field of the system time is incremented, that is, the sub-second counter rolls over. The DMA fetches the data only if it matches the current slot or the next slot. The DMA remains in the descriptor fetch state until there is a match.

To enable the DMA to fetch the data only if it matches the current slot or the next two slots, program the EMAC_DMA[n]_SFN_CTLSTAT.ASC bit of the corresponding DMA channel.

NOTE: If the slot number in the descriptor is less than the reference slot number, the DMA takes it as a future slot.

The program also enables the check for slot number by setting EMAC_DMA[n]_SFN_CTLSTAT.ASC bit. When this check is not enabled, the packets are fetched immediately after the descriptor is read. In addition, the EMAC_DMA[n]_SFN_CTLSTAT.RSN bits indicate the value of the reference slot number in DMA.

Queue Modes

Programs can enable a transmit queue for generic DCB and AV traffic. When the program selects multiple transmit queues without selecting the DCB feature, the queues are enabled for generic queuing using the WRR or WSP algorithms.

When the program selects the enable data center bridging feature, DCB is enabled for all selected transmit queues and queuing is based on the WRR, WSP, DWRR, or WFQ algorithms. To enable a transmit queue for AV, select the enable audio video bridging option and then the enable support for AV in transmit Queue # option. The queuing is based on the CBS or SP algorithms.

The program can enable a receive queue for generic, DCB, or AV traffic. A particular queue enabled for generic DCB or AV based routing is determined by the RXQ#EN bit field (EMAC_RXQ_CTL0 register) of the corresponding queue. The following sections explain how receive queues are enabled based on the selected features.

Multiple Receive Queues without the DCB Feature

When this mode is selected, all queues are enabled for generic queuing based on the VLAN tag priority. The VLAN tag priority should match the PSRQ field of the EMAC_RXQ_CTL2 and EMAC_RXQ_CTL3 registers. By default, untagged packets are routed to the receive queue specified in the EMAC_RXQ_CTL1.UPQ bit field. Queue 0 is the default value of the UPQ field. The program can override the default value with any other value for the UPQ field. The receive packets can also be routed to a particular DMA channel based on the EMAC_ADDR[i]_HI.DCS bit field.

Multiple Receive Queues with DCB Feature

When this mode is selected, DCB is enabled for all selected receive queues. The queuing is done based on the VLAN tag priority for DCB data packets. The VLAN tag priority should match the PSRQ field of the EMAC_RXQ_CTL2 and EMAC_RXQ_CTL3 registers. The receive packets can also be routed to a particular DMA

channel based on the EMAC_ADDR[i]_HI.DCS bit field. The DCB control packets are routed based on the EMAC_RXQ_CTL1.DCBCPQ bit field.

Multiple Receive Queues with AV Feature

When this mode is selected, AV is enabled for all selected receive queues. The queuing is done based on the VLAN tag priority for DCB data packets. The VLAN tag priority should match the PSRQ field of the EMAC_RXQ_CTL2 and EMAC_RXQ_CTL3 registers. The receive packets can also be routed to a particular DMA channel based on the EMAC_ADDR[i]_HI.DCS bit field. The AV control packets (tagged or untagged) are routed based on the EMAC_RXQ_CTL1.AVCPQ bit field. The PTP over Ethernet packets are routed based on the EMAC_RXQ_CTL1.PTPQ bit field.

Queue Priorities

The transmit queue priorities are programmed using the EMAC_TXQ_PRTY_MAP0 and EMAC_TXQ_PRTY_MAP1 registers. The receive queue priorities are programmed using the EMAC_RXFLOW_CTL register.

The priority of a receive queue is programmed using the corresponding field of the EMAC_RXQ_CTL2 and EMAC_RXQ_CTL3 registers. Assign the priority in the following order:

1. AV queue (high priority)
2. DCB queue (medium priority)
3. Best-effort queue (low priority)

The software should put packets with correct priorities in the respective programmed queue on transmit side. The MAC uses the programmed priorities for blocking the transmit queues when a PFC packet is received. If a single queue is selected for multiple priorities and PFC is enabled, the entire queue is paused if one or more priorities in the queue are paused.

TCP/IP Offloading Features

Communication protocols such as TCP and UDP implement checksum fields, which help determine the integrity of data transmitted over a network. The most widespread use of Ethernet is to encapsulate TCP and UDP over IP datagrams. Therefore, the MAC has an Checksum Offload Engine (COE) to support checksum calculation and insertion in the transmit path, and error detection in the receive path.

The TCP Segmentation Offload (TSO) engine is useful in offloading the TCP segmentation functions to the hardware.

This section contains the following sub-sections:

- Transmit Checksum Offload Engine
- Receive Checksum Offload Engine
- TCP/IP Segmentation Offload (TSO) Engine

- UDP/IPv4 Fragment Offload (UFO) Engine
- IPv4 ARP Offload Engine

Transmit Checksum Offload Engine

The MAC has a Checksum Offload Engine (COE) to support checksum calculation and insertion in the transmit path where the software can offload the checksum insertion task to the hardware. In the transmit path the MAC calculates the checksum and inserts it in the transmit packet. This feature reduces the load on the software and can improve the overall throughput of the system. The checksum engine can be controlled for each packet by setting the CIC bits (TDES3 Bits[17:16]).

NOTE: The checksum for TCP, UDP, or ICMP is calculated over a complete packet, and then inserted into its corresponding header field. Because of this requirement, when this function is enabled, the transmit FIFO automatically operates in the store-and-forward mode even if the EMAC is configured for threshold (cut-through) mode.

NOTE: The application must ensure that the transmit FIFO is deep enough to store a complete packet before that packet is transferred to the MAC transmitter. The reason being that when space is not available to accept the programmed burst length of data, then the MTL transmit FIFO starts reading to avoid deadlock. In such a case, the COE fails as the start of the packet header is read out before the payload checksum can be calculated and inserted. Therefore, the program must enable the checksum insertion only in the packets that are less than the number of bytes, given by the following equation:

Packet size < TxQSize() – (PBL + 7) x 4,

Where, TxQSize is indicated by the `EMAC_TQ[n]_OPMODE.TQS` bit field and PBL by the `EMAC_DMA[n]_TXCTL.TXPBL` bit field.

IP Header Checksum Engine

In IPv4 datagrams, the integrity of the header fields is indicated by the 16-bit header checksum field (the eleventh and twelfth bytes of the IPv4 datagram). The COE detects an IPv4 datagram when the type field of IPv4 datagrams. The integrity of the header fields is indicated by the 16-bit header checksum field (the eleventh and twelfth bytes of the IPv4 datagram). The COE detects an IPv4 datagram when the type field of Ethernet packet has the value 0x0800 and the version field of an IP datagram has the value 0x4. The checksum field of the input packet is ignored during calculation and replaced with the calculated value.

NOTE: IPv6 headers do not have a checksum field. Therefore, the COE does not modify the IPv6 header fields.

The result of this IP header checksum calculation is indicated by the IP header error status bit in the transmit status (bit 0 in RDES3 Normal Descriptor (Write-Back Format)). This status bit is set whenever the values of the Ethernet Type field and the Version field of IP header are not consistent, or when the Ethernet packet does not have enough data, as indicated by the IP header Length field. In other words, this bit is set when an IP header error is asserted under the following circumstances:

- For IPv4 datagrams:
  - The received Ethernet type is 0x0800, but the version field of IP header is not equal to 0x4.

  - The IPv4 header length field indicates a value less than 0x5 (20 bytes).
  - The total packet length is less than the value given in the IPv4 header length field.
- For IPv6 datagrams:
  - The Ethernet type is 0x86dd but the IP header version field is not equal to 0x6.
  - The packet ends before the IPv6 header (40 bytes) or extension header (as given in the corresponding header length field in an extension header) is completely received.

TCP/UDP/ICMP Checksum Engine

The TCP/UDP/ICMP Checksum Engine processes the IPv4 or IPv6 header (including extension headers) and determines whether the encapsulated payload is TCP, UDP, or ICMP. The checksum is calculated for the TCP, UDP, or ICMP payload and inserted into its corresponding field in the header. The transmit COE can work in the following two modes:

- The TCP, UDP, or ICMPv6 pseudo-header is not included in the checksum calculation and is assumed to be present in the checksum field of the input packet. This engine includes the checksum field in the checksum calculation, and then replaces the checksum field with the final calculated checksum.
- The engine ignores the checksum field, includes the TCP, UDP, or ICMPv6 pseudo-header data into the checksum calculation, and overwrites the checksum field with the final calculated value.

NOTE: For ICMP-over-IPv4 packets, the checksum field in the ICMP packet must always be 16'h0000 in both modes, because pseudo-headers are not defined for such packets. If it does not equal 16’h0000, an incorrect checksum may be inserted into the packet.

The result of this operation is indicated by the payload checksum error status bit in the transmit status vector (bit 12 of TDES3). This engine sets the payload checksum error status bit when it detects that the packet has been forwarded to the MAC transmitter engine in the store-and-forward mode without the end of packet (EOP) being written to the FIFO, or when the packet ends before the number of bytes indicated by the payload length field in the IP Header is received. When the packet is longer than the indicated payload length, the COE ignores them as stuff bytes, and no error is reported. When this engine detects the first type of error, it does not modify the TCP, UDP, or ICMP header. For the second error type, it still inserts the calculated checksum into the corresponding header field.

The following table describes the functions supported by Transmit Checksum Offload engine based on the packet type. When the MAC does not insert the checksum, it is indicated as “No” in the table.

Table 30-79: Transmit Checksum Offload Engine Functions for Different Packet Types

Packet Type	Hardware IP Header Checksum Insertion	Hardware TCP/UDP Checksum Insertion
Non-IPv4 or IPv6 packet	No	No
IPv4packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad support for 2K packets is enabled in MAC) but less than or equal to the frame size constraint specified in Transmit Checksum Offload Engine.	Yes	Yes

Table 30-79: Transmit Checksum Offload Engine Functions for Different Packet Types (Continued)

Packet Type	Hardware IP Header Checksum Insertion	Hardware TCP/UDP Checksum Insertion
IPv6packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad support for 2K packets is enabled in MAC) but less than or equal to the frame size constraint specified in Transmit Checksum Offload Engine.	Not Applicable	Yes
IPv4 with TCP, UDP, or ICMP	Yes	Yes
IPv4 packet has IP options (IP header is longer than 20 bytes)	Yes	Yes
Packet is an IPv4 fragment	Yes	No
IPv6packet with the following next header fields in main or extension headers: • Hop-by-hop options (in IPv6 main header) • Hop-by-hop options (in IPv6 extension header) • Destinationsoptions • Routing (with segment left = 0) • Routing (with segment left > 0) • TCP, UDP, orICMP • Authentication • Any other next header field in main or extension headers	 Not Applicable Not Applicable Not Applicable Not Applicable Not Applicable Not Applicable Not Applicable Not Applicable	 Yes No Yes No No Yes No No
IPv4 packet has TCP header with Options fields	Yes	Yes
IPv4 Tunnels: • IPv4 packet in an IPv4 tunnel • IPv6 packet in an IPv4 tunnel	 Yes (IPv4 tunnel header) Yes (IPv4 tunnel header)	 No No
IPv6 Tunnels: • IPv4 packet in an IPv6 tunnel • IPv6 packet in an IPv6 tunnel	 Not applicable Not applicable	 No No
IPv4 packet has 802.3ac tag (with C-VLAN tag or S-VLAN tag when enabled).	Yes	Yes
IPv6 packet has 802.3ac tag (with C-VLAN tag or S-VLAN tag when enabled).	Not applicable	Yes
IPv4 frames with security features (such as encapsulated security payload)	Yes	No
IPv6 frames with security features (such as encapsulated security payload)	Not applicable	No

Receive Checksum Offload Engine

The EMAC provides the Checksum Offload Engine that is used to detect any error in an IPv4 or IPv6 packet in the receive path. The MAC verifies the checksum field of the received packet with the internally calculated checksum

and provides the status. This engine also identifies a TCP, UDP, or ICMP payload in received IP packets and calculates the checksum of such payloads appropriately.

Here, both IPv4 and IPv6 packet in the received Ethernet packets are detected and processed for data integrity. The MAC receiver identifies IPv4 or IPv6 packets by checking for value 0x0800 or 0x86DD, respectively, in the type field of the received Ethernet packet. This identification is applicable to single VLAN-tagged packets. It is also applicable to double VLAN-tagged packets when the enable double VLAN processing option is selected and the `EMAC_VLANTAG_CTL.EDVLP` bit is set.

The receive COE calculates the IPv4 header checksums and checks that they match the received IPv4 header checksums. The result of this operation (pass or fail) is given to the RFC module for insertion into the receive status word. The IP Header Error bit is set for any mismatch between the indicated payload type (Ethernet Type field) and the IP header version, or when the received packet does not have enough bytes, as indicated by the Length field of the IPv4 header (or when fewer than 20 bytes are available in an IPv4 or IPv6 header).

Packets with TCP/IP errors (header or payload) are dropped in MTL when the `EMAC_RQ0_OPMODE.DIS_TCP_EF` bit is reset and the `EMAC_RQ0_OPMODE.FEP` bit is set.

This engine also identifies a TCP, UDP, or ICMP payload in the received IP datagrams (IPv4 or IPv6) and calculates the checksum of such payloads properly, as defined in the TCP, UDP, or ICMP specifications. This engine includes the TCP, UDP, or ICMPv6 pseudo-header bytes for checksum calculation and checks whether the received checksum field matches the calculated value. The result of this operation is given as a payload checksum error bit in the receive status word. This status bit is also set if the length of the TCP, UDP, or ICMP payload does not match the expected payload length given in the IP header.

The following table describes the functions supported by the receive COE based on the packet type. When the payload of an IP packet is not processed (indicated as "No" in the table), the information (whether the checksum engine is bypassed or not) is given in the receive status.

NOTE: The MAC does not append any payload checksum bytes to the received Ethernet packets.

Table 30-80: Transmit Checksum Offload Engine Functions for Different Packet Types

Packet Type	Hardware IP Header Checksum Checking	Hardware TCP/UDP Checksum Checking
Non-IPv4 or IPv6 packet	No	No
IPv4packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad support for 2K packets is enabled in MAC)	Yes	Yes
IPv6packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in MAC)	Not Applicable	Yes
IPv4 with TCP, UDP, or ICMP	Yes	Yes
IPv4 header's protocol field contains a protocol other than TCP, UDP, or ICMP	Yes	No
IPv4 packet has IP options (IP header is longer than 20 bytes)	Yes	Yes

Table 30-80: Transmit Checksum Offload Engine Functions for Different Packet Types (Continued)

Packet Type	Hardware IP Header Checksum Checking	Hardware TCP/UDP Checksum Checking
Packet is an IPv4 fragment	Yes	No
IPv6 packet with the following next header fields in main or extension headers: • Hop-by-hop options (in IPv6 mainheader) • Hop-by-hop options (in IPv6 extensionheader) • Destinations options • Routing (with segment left 0) • Routing (with segment left >0) • TCP, UDP, or ICMP • Any other next header field in main or extension headers	 Not Applicable Not Applicable Not Applicable Not Applicable Not Applicable Not Applicable Not Applicable	 Yes No Yes Yes No Yes No
IPv4 packet has TCP header with Options fields	Yes	Yes
IPv4 Tunnels: • IPv4 packet in an IPv4 tunnel • IPv6 packet in an IPv4 tunnel	 Yes (IPv4 tunnel header) Yes (IPv4 tunnel header)	 No No
IPv6 Tunnels: • IPv4 packet in an IPv6 tunnel • IPv6 packet in an IPv6 tunnel	 Not applicable Not applicable	 No No
IPv4 packet has 802.3ac tag (with C-VLAN tag or S-VLAN tag when enabled).	Yes	Yes
IPv6 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled).	Not applicable	Yes
IPv4 frames with security features (such as encapsulated security payload)	Yes	No
IPv6 frames with security features (such as encapsulated security payload)	Not applicable	No

Header-Payload Split

The MAC can identify the boundary between header and payload of the received packet and store them into separate buffers. This feature is useful for multiple reasons:

- Header buffers can be lin faster memory/cache while payload buffers are in slower DRAM memory. This enables the software stack to process the headers faster.
- Buffers used for payload can be directly forwarded to the application layer without the need to copy the payload into application buffer.

- When the Large Receive Offload (LRO) function is implemented in the software/driver layer, it is easy to link the buffers of multiple and contiguous payload data and form a bigger packet with a new header. This reduces the number of packets forwarded to the upper layer and thus improves system software performance.

The EMAC supports multiple methods and packet types for header-payload splitting. This is controlled by the setting the `EMAC_SPLM_OFST_CFG.SPLM` bit field and described in the following table.

Table 30-81: Split Header Support Depending on the Packet Type

Packet Type	SPLM	Description
TCP or UDP packet	00 (L3/L4 split)	The DMA writes the Ethernet header + IP header + TCP or UDP header into the header buffer.
IP packet (not TCP/ UDP)		The DMA writes the Ethernet header + IP header into the header buffer.
Non-IP packet		The DMA does not split the header and payload
Any packet	01 (L2 split)	The DMA writes the Ethernet header • For AV type packets using AV type Split Offset (SAVO) when split AV Enable (SAVE) field is set to 1. • For non-AV type packets using SPLOFST
IP packet	10 (combination of L2 or L3/L4 split)	L3/L4 split
Non-IP packet		L2 split
N/A	11	Reserved

NOTE:
- L3/L4 split is applicable for IP packets that are either untagged or VLAN stripped. If VLAN tag is retained in the packet forwarded to the DMA, L3-L4 split is not performed. When SPLM field is set to 2, L2 Split is performed for IP packets which are VLAN tagged.
- For AV packets, program the `EMAC_SPLM_OFST_CFG.SAVE` and `EMAC_SPLM_OFST_CFG.SAVO` bit fields to specify an alternative L2 split value.

The IP header includes IPv4 options in case of a IPv4 packet, and IPv6 extension headers in case of IPv6 frames. The points at which the L3/L4 header is split are shown in the following figure.

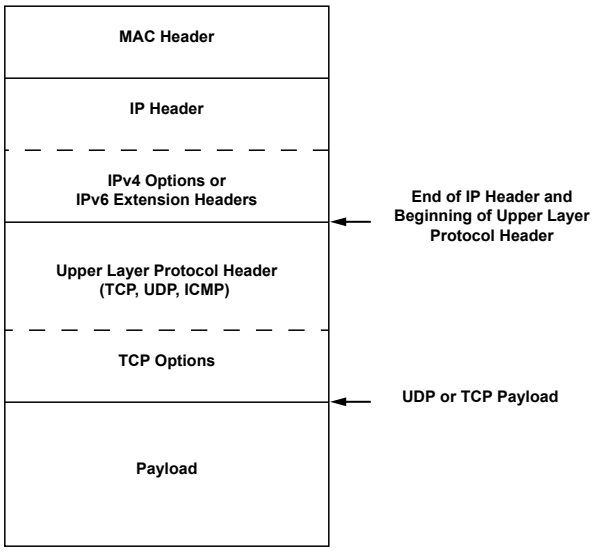

Figure 30-38: L3/L4 Header Split Points

The Figure 30-39 L2 Header Split figure shows the L2 split boundary. In this mode, the header payload boundary is determined for received packets at a fixed length offset starting from the length/type field, as indicated by the `EMAC_SPLM_OFST_CFG.SPLOFST` bit field. This mode is applicable for all received packets when `EMAC_SPLM_OFST_CFG.SPLM` = 01 and only for non-IP packets when SPLM = 10.

The following table shows the split offset for various packet types, when SPLOFST field is set to 2.

Table 30-82: Split Offset Calculation Example: SPLOFST = 2

Packet Type	Split Offset (From the Beginning of LT Field)
Untagged packet	DA + SA + LT = 14
Single VLAN tagged packet with VTAG stripped	
Double VLAN tagged packet with both VTAGs stripped	
Double VLAN tagged packet with both VTAGs stripped	DA + SA + VTAG + LT = 18
Double VLAN tagged packet with only one VTAG stripped	
Double VLAN tagged packet with no stripping	DA + SA +2 x VTAG + LT = 22

The split offset reference is always from the beginning of the LT field, whether the VLAN tag is present or stripped. For more details about the descriptor structure for the split header feature, see

Descriptor Structure for Split Header Support

.

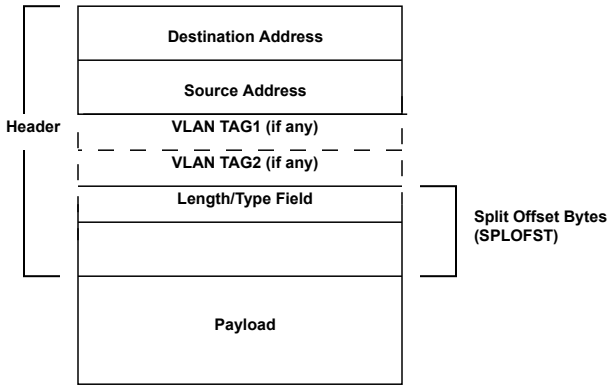

Figure 30-39: L2 Header Split

For programming details see the Programming Header Payload Split Receive section.

TCP/IP Segmentation Offload (TSO) Engine

The TCP Segmentation Offload (TSO) engine is useful in offloading the TCP segmentation functions to the hardware.

It also supports UDP Segmentation Offload (USO) in which the UDP payload is segmented in the hardware. There are no sequencing/ordering controls available or updated in the segments, so it can be used in point to point applications in which out of order packets are not expected by the receiver. The description and flow of TSO mentioned in this section is same as USO, any deviation is provided as notes.

In the TCP segmentation offload (TSO) feature, the DMA splits a large TCP packet into multiple small packets and passes these packets to the MTL as shown in the TCP Segmentation Offload Overview figure.

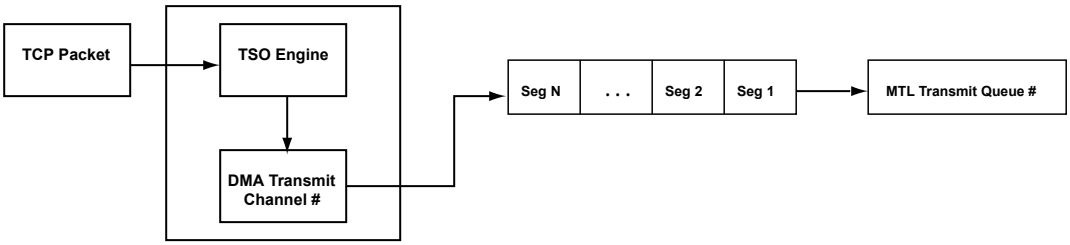

Figure 30-40: TCP Segmentation Offload Overview

DMA Operation with TSO Feature

The TCP Segmentation Offload Flow figure shows the TSO flow.

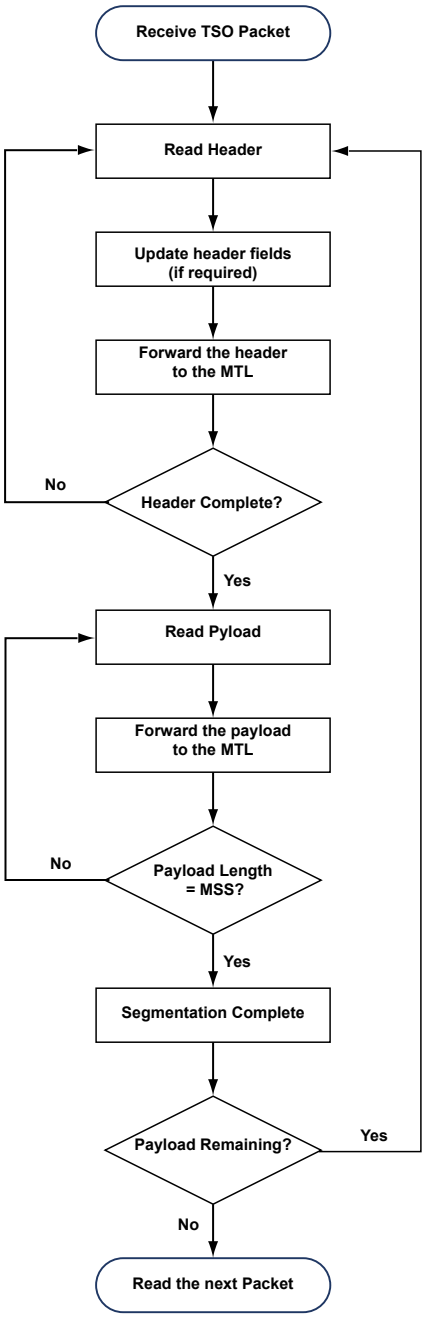

Figure 30-41: TCP Segmentation Offload Flow

For the TSO feature, the transmit DMA operation is as follows:

1. The application sets up the transmit descriptor (TDES0-TDES3) and sets the Own bit (TDES3[31]) after setting up the corresponding data buffer(s) with Ethernet Packet data.
2. The application increases the offset value of the descriptor tail pointer of the DMA transmit channel.
3. While in the Run state, the DMA fetches the next available descriptor and does one of the following:

a. If the descriptor is a context descriptor and the context is not between the first and last descriptors of a packet, the DMA stores the context values.

b. If the descriptor is a context descriptor and the context is between the first and last descriptors of a packet, the DMA closes the context descriptor indicating a context descriptor error (TDES3[23]) and fetches the next descriptor.

c. If the descriptor is a normal descriptor, the DMA checks for the TSE bit. If the TSE bit is not set, the DMA continues with the default mode of operation or OSF operation (if enabled).

4. The DMA calculates the number of segments from the TCP payload length (TDES3[17:0]) and the MSS value.
5. The DMA goes through channel arbitration to fetch the data buffers. The DMA fetches the header and payload separately.
6. For the first segment, the DMA fetches the header from the system memory and stores it in the TSO memory (when the length of header is not greater than the TSO memory size). If the current segmented packet is not the first segment, the DMA fetches the header from the local TSO memory. Otherwise, it fetches the header buffer in system memory again, as done for the first segment. In such cases (header not available is TSO memory), the DMA does not close the first descriptor containing the header buffer, until the header for last segment is fetched.
7. The required fields in the header bytes are modified/updated as per the segmentation requirements and written into the corresponding MTL TxQ.
8. The DMA then takes the payload buffer pointer, fetches the MSS number of payload bytes from the system memory and directly pushes it into the MTL TxQ. In case the buffer(s) in the descriptor do not have enough data for the MSS payload (except for the last segment), the DMA closes this descriptor.
9. The DMA jumps to Step 3 and repeats the process until the last segment is written into the TxQ.
10. The DMA closes the last descriptor and the first descriptor (containing the header buffer when it is not stored in TSO memory) and then moves on to the next packet transfer.

The DMA repeats all these steps if more descriptors are available. When no descriptor is available, the DMA enters the suspend state.

NOTE:
- The TSO memory size on ADSP-SC59x processor is 256 bytes per channel.
- The TSO engine determines whether to perform TSO or USO operation based on the THL field (TCP Header Length) in TDES3 of first normal transmit descriptor for the packet. The value of 2 indicates USO and any value greater than or equal to 5 indicates TSO.

The DMA repeats all these steps if more descriptors are available. When no descriptor is available, the DMA enters the suspend state.

TCP/IP Header Fields

While segmenting a TCP packet, the DMA automatically updates the TCP/IP header fields. The following table describes how the TCP and IP headers are updated.

Table 30-83: TSO: TCP and IP Header Fields

Packet Sequence	TCP Header	IP Header
First packet	1. The sequence number is not updated. The value provided in the header is used. 2. The TCP checksum is calculated again. 3. If set, the FIN and PSH flags are cleared.	IPv4 Header: • Total Length = MSS + TCP Header Length + IP Header Length • Identification field is not modified. It is sent as per the header provided by the software • IPv4 Header Checksum is recalculated. IPv6 Header: Payload Length = MSS + TCP Header Length + IPExtension Header Length
Subsequent packets	1. The sequence number is updated. The MSS value is added to the sequence number value of previous segment. 2. If set, the FIN and PSH flags are cleared. 3. The TCP checksum is calculated again.	IPv4 Header: • Total Length = MSS + TCP Header Length + IP Header Length • Identification field = Previous Identification Field + 1 • IPv4 Header Checksum is recalculated. IPv6 Header: Payload Length = MSS + TCP Header Length + IPExtension Header Length
Last packet	1. The sequence number is updated. The MSS value is added to the sequence number value of previous segment. 2. If FIN and PSH flags were set in original header, these flags are set. 3. The TCP checksum is calculated again.	IPv4 Header: • Total Length = Remaining Payload + TCP Header Length + IP Header Length • Identification Field = Previous Identification Field + 1 • IPv4 Header Checksum is recalculated. IPv6 Header: Payload Length = Remaining Payload Length + TCP Header Length + IP Extension Header Length

NOTE: In case of USO, the engine updates only the following fields in the IP-UDP headers:

- Total length, identification field, and header checksum field in IPv4 header
- Payload length field in IPv6 header
- Length and checksum field in UDP header

Header and Payload Fields of Segmented Packets

After segmentation, the split packets use the same header as the parent TCP packet for header fields other than the ones described in the Table 30-83 TSO: TCP and IP Header Fields table. The *Header and Payload Fields of Segmented Packets* figure shows how the same header is used for the header fields of segmented packets.

The application must create the header in buffer 1 of the first descriptor of the packet to be segmented and provide the header length in TDES2 of the first descriptor (FD = 1). When the FD bit is set, the DMA reads the header from the header buffer to which the TDES0 is pointing. Buffer 2 of the first descriptor can be used for payload and TDES0 and TDES1 of subsequent descriptors. For subsequent descriptors (FD = 0), the address to which the TDES0 and TDES1 are pointing is treated as payload buffer address of the same packet.

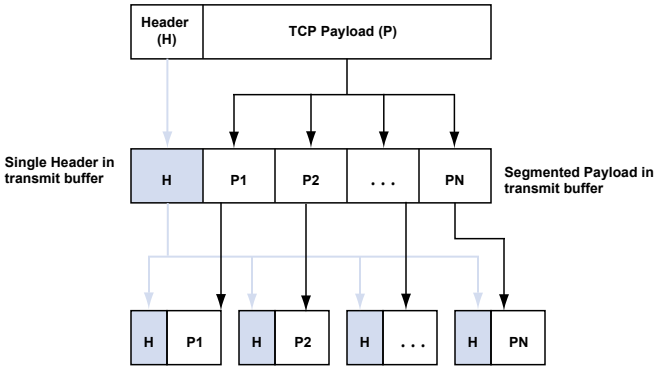

Figure 30-42: Header and Payload Fields of Segmented Packets

Context Descriptor Sequence

Programs can use the context descriptor to provide the MSS value for segmentation. The application must provide the context descriptor before the normal descriptor to be used for the corresponding TCP packet. If the application wants to provide a new MSS, it must create the context descriptor in the descriptor list before the first normal descriptor of the packet to be segmented with the new MSS value. The MSS value in the context descriptor is valid only if the TCMSSV bit of TDES3 in context descriptor is set and the OSTC bit is reset.

When the application provides a context descriptor with a valid MSS value, the DMA internally stores the MSS value and uses this MSS value for all subsequent packets that have the TSO Enabled through the TSE bit of TDES3 normal descriptor.

If the application places a context descriptor in the middle of a packet (between the first and last descriptors of a packet), the DMA does the following:

1. The DMA ignores the context and closes the descriptor
2. The DMA indicates the error in descriptor status
3. The DMA generates an interrupt if the `EMAC_DMA[n]_IEN.CDEE` bit is set corresponding to a DMA channel

The application can read the interrupt status through the CDE bit of the status register corresponding to a DMA channel.

Building the Descriptor and the Packet for the TSO Feature

Set the TSE bit of TDES3 of the first normal descriptor. If the TSE bit is set in TDES3 for a non TCP/IP packet, the DMA behavior is unpredictable.

The application must program the length of the TCP packet payload in TDES3[17:0] and the TCP header in TDES3[22:19]. The maximum length of TCP packet payload that can be segmented is 256 KB.

NOTE: The TDES3[22:19] field is used as slot number in case of AV configurations. If both TSO and AV are enabled for the same DMA transmit channel (the `EMAC_DMA[n]_TXCTL.TSE` bit is set), then slot checking for that DMA transmit channel must not be enabled (do not set the `EMAC_DMA[n]_SFN_CTLSTAT.ESC` bit).

The header of the packet including the Ethernet header, L3 header and L4 header should be provided in buffer 1 of the first normal descriptor of the TSO packet. Only buffer 1 of the first normal descriptor of a packet enabled for TSO is taken as the buffer containing the header.

The TCP payload can begin from buffer 2 of the first normal descriptor and continue to buffer 1 and buffer 2 of second normal descriptor and subsequent descriptors.

The TCP payload may span across multiple buffers and multiple descriptors. The size of buffers containing the TCP payload should add up to and be equal to the TCP payload length provided in TDES3[17:0] of the first normal descriptor.

The MAC always calculates and appends CRC and inserts padding (if required) for all packets segmented by the DMA. If the TSE bit of TDES3 is enabled, the CRC PAD control (CPC) field of TDES3 is reserved. To determine the size of a TCP packet after segmentation, the DMA uses the maximum segment size (MSS) provided by the application through context descriptor. The DMA segments only those packets which have payload size greater than MSS. The application must provide the MSS by either programming the `EMAC_DMA[n]_CTL.MSS` value or by providing a context descriptor. The DMA uses the last programmed value of MSS or the last MSS value provided through context (whichever is provided later).

The header length plus the MSS size (which is equal to the size of each TCP segment) should not exceed 16383 bytes, otherwise the MAC transmitter truncates the packet after 16383 bytes causing a CRC error.

The header length plus MSS size plus programmed PBL value in the `EMAC_DMA[n]_TXCTL` register should be lesser than the Tx Queue size programmed in the `EMAC_TQ0_OPMODE.TQS` bit field. It is recommended that MSS + header is equal to half the programmed transmit queue size.

The DMA also supports segmentation of VLAN tagged TCP/IP frames, so if the TCP packet has a VLAN tag, then the same tag is used for all the segments irrespective of the VLAN tag type provided (C-VLAN or S-VLAN). The VLAN tag insert/replace control bits are used for all segments.

If the double VLAN feature is selected, then the DMA passes both the tags for all segments irrespective of the VLAN tag types provided (C-VLAN or S-VLAN). The VLAN tag insert/replace control bits for both tags is applicable for all segments.

If the double VLAN feature is not selected, then the application must not set the TSE bit in TDES3 for a TCP/IP packet with two tags. The DMA behavior in this scenario is unpredictable.

If the TSE bit is set in TDES3 for the packet and TCP header length provided is less than 5 (meaning an invalid TCP header because it is less than 20 bytes), the DMA does not perform segmentation, instead it transmits the entire packet as a single packet. In this scenario, the CRC pad control bits are forced by DMA to 2'b00 (MAC does CRC and padding) and checksum insertion control bits are forced to 2'b11 (hardware does the checksum calculation for both header and payload).

See the Programming TSO section for more details on how to program the TSO engine.

UDP/IPv4 Fragment Offload (UFO) Engine

The EMAC supports breaking a large UDP packet into smaller and multiple packets for transmission, using IPv4 Fragmentation. Each IPv4 fragment contains the following header or payload information:

- Ethernet Header
- IP Header
- UDP Header (only in the first fragment)
- UDP Payload

NOTE:
- Fragmentation is supported only for UDP over IP. Fragmentation is not supported for TCP packets.
- Fragmentation of UDP is supported only over IPv4. This support is not available over IPv6.

The UDP Fragment Offload (UFO) Engine is an add-on function of the TSO engine. Therefore, both UFO and TSO functions can be enabled on the same transmit DMA channel. In this mode, the UDP packets are fragmented and TCP packets are segmented. If the UFO function is not enabled, then both TCP packets and UDP packets are segmented into smaller packets as described in TCP/IP Segmentation Offload (TSO) Engine.

The UFO breaks down a large UDP packet into smaller packets using IPv4 fragmentation. In this mode, the MSS field in the context Descriptor (TDES2[17:0]) and the `EMAC_DMA[n]_CTL.MSS` bit are interpreted as Maximum Fragmentation Size (MFS). This is the maximum size of the payload after the IPv4 header in each fragment. When UFO is enabled, the MSS field must be programmed in multiples of 8 bytes because the IP fragments offset is defined in terms of 8 bytes.

The UFO functions in two modes:

- UFO with valid UDP checksum
- UFO with no UDP checksum

UFO with Valid UDP Checksum

In this mode, the UFO engine calculates the UDP payload checksum and inserts it in the respective UDP header field. However, as the checksum must be calculated over the complete payload ending in the last fragment and then inserted in the UDP header encapsulated in the first IPv4 fragment, the fragments are not transmitted in order. The first IPv4 fragment containing the UDP header is sent last. The *Fragmentation Flow With Checksum* figure shows this sequence.

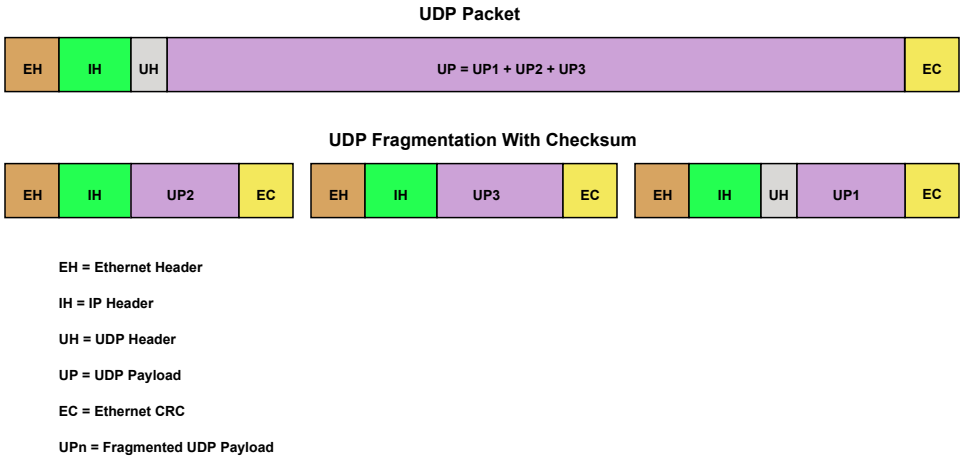

Figure 30-43: Fragmentation Flow With Checksum

The following table shows the details of the IP/UDP Header updates performed in each fragment by the UFO Engine in this mode.

Table 30-84: Details of IPv4 Fragmentation with UDP Checksum

Packet Sequence	UDP Header	IPv4 Header	Comments
First fragment (This segment is sent last)	Calculate the UDP header checksum	1. Total length = 32 bytes + IPv4 header length 2. DF = 0 (do not fragment) 3. MF = 1 4. Fragment offset = 0 5. Update the IPv4 header checksum	The header (and 32 bytes IPv4 fragment payload) data is stored in TSO memory in this step.
Second fragment	NA (No UDP header)	1. Total length = MFS + IPv4 header length 2. DF = 0 (do not fragment) 3. MF = 1 4. Fragment offset = previous fragment offset + (32/8) 5. Update the IPv4 header checksum	The header data is read from the TSO memory. Only the Ethernet + IPv4 header is read.

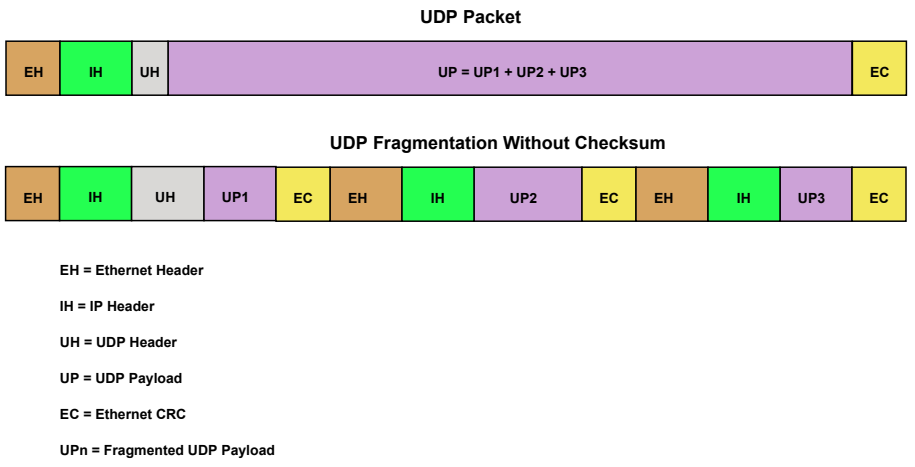
Table 30-84: Details of IPv4 Fragmentation with UDP Checksum (Continued)

Packet Sequence	UDP Header	IPv4 Header	Comments
Intermediate (non-first and non-last) fragment	NA (No UDP header)	1. Total length = MFS + IPv4 header length 2. DF = 0 (do not fragment) 3. MF = 1 4. Fragment offset = previous fragment offset + (MFS/8) 5. Update the IPv4 header checksum	The header data is read from the TSO memory. Only the Ethernet + IPv4 header is read.
Last fragment	NA (No UDP header)	1. Total length = remaining payload + IPv4 header Length 2. DF = 0 (do not Fragment) 3. MF = 0 4. Fragment offset = previous fragment offset + (MFS/8) 5. Update the IPv4 header checksum	The header data is read from the TSO memory. Only the Ethernet + IPv4 header is read.

UFO with no UDP Checksum

In this mode, the UDP payload checksum is not calculated and an all-zero value is inserted in the corresponding checksum field of the UDP header and all the IP fragment packets are transmitted in sequence. the *Fragmentation Flow Without UDP Checksum* figure shows the sequence of fragmented packets created and transmitted by the UFO engine.

Figure 30-44: Fragmentation Flow Without UDP Checksum



The following table shows the details of IPv4/UDP header updates performed in each fragment of the UFO engine, in this mode.

Table 30-85: Details of IPv4 Fragmentation without UDP Checksum

Fragment Sequence	UDP Header	IPv4 Header	Comments
First fragment	Replace the UDP checksum field with all 0s	1. Total length = MFS (MSS field) + IPv4 header length 2. DF = 0 (do not fragment) 3. MF = 1 4. Fragment offset = 0 5. Update the IPv4 header checksum	The header data is stored in the TSO memory in this step.
Intermediate (non-first and non-last) fragment	NA (No UDP header)	1. Total length = MFS (MSS field) + IPv4 header length 2. DF = 0 (do not fragment) 3. MF = 1 4. Fragment offset = previous fragment offset + (MSS/8) 5. Update the IPv4 header checksum	The header data is read from the TSO memory. Only the Ethernet + IPv4 header is read.
Last fragment	NA (No UDP header)	1. Total length = remaining payload + IPv4 header length 2. DF = 0 (do not fragment) 3. MF = 0 4. New fragment offset = previous fragment offset + (MSS/8) 5. Update the IPv4 header checksum	The header data is read from the TSO memory. Only the Ethernet + IPv4 header is read.

Segmentation Versus Fragmentation

The following table shows the differences between UDP packet fragmentation performed by the UFO and UDP segmentation performed by the TSO engine.

Table 30-86: Segmentation Versus Fragmentation

Segmentation	Fragmentation
The UDP header is replicated for each segment. The length field in the UDP header is updated for each segment	The UDP header is not updated; however, checksum field in the UDP header is updated.
MSS field indicates the size of the maximum segment after the L4(TCP/UDP) header	MFS field indicates the size of the fragment after the L3 (IPv4) header
The TCP packet is broken down into multiple chunks by keeping L2+L3+L4 header	The UDP packet is broken down into multiple chunks by keeping the L2 + L3 header

IPv4 ARP Offload Engine

The EMAC supports the Address Recognition Protocol (ARP) offload for IPv4 packets. This feature allows the processing of the IPv4 ARP request packet in the receive path and generating corresponding ARP response packet in the

transmit path. EMAC generates the ARP reply packets for appropriate ARP request packets. The ARP packet for IPv4 is a L2 layer packet with length/type of 0x0806.

The ARP offloading process is as follows:

1. The MAC receiver gets an ARP request if the target protocol address of request matches the IPv4 address programmed in the EMAC_ARP_ADDR register of the MAC.
2. The MAC generates an ARP reply packet.
3. The MAC copies the sender hardware address field in the ARP request to the following fields:
   - DA field of the Ethernet packet header
   - Target hardware address field of the ARP reply packet
4. The MAC copies the Sender Protocol Address field in the ARP request to the target protocol address field in the ARP reply packet.
5. The MAC places its MAC address in the following fields:
   - SA field of the Ethernet packet header
   - Sender Hardware Address field of the ARP reply packet
6. The MAC copies the target protocol address field in the ARP request to the sender protocol address field in the ARP reply packet.
7. The MAC sets the opcode field in ARP reply packet to 2 indicating ARP reply.
8. The MAC recalculates the CRC and performs padding for generated ARP reply packet.
9. The MAC transmitter sends the ARP reply.

The MAC processes only one ARP request at a time. It does not store the fields of multiple ARP requests. If the MAC receives an ARP request when it is already processing an earlier ARP request, the MAC does not generate the ARP reply for new ARP request. The MAC forwards the new ARP request packet to application with ARP reply not generated (bit 34) status bit set. However, in power-down mode, if the MAC receives an ARP request when it is already processing an earlier ARP request, the MAC drops the new ARP request.

If the disable CRC check bit of the MAC extension configuration bit is set, then the MAC does not check for valid CRC of a ARP request packet. It can generate an ARP response packet if the other conditions are valid.

NOTE: When the received ARP request is less than 64 bytes packet length, EMAC does not send a ARP response. It is treated as normal packet and forwarded to the application based on the EMAC filter settings.

Energy Efficient Ethernet (EEE) Mode

EEE is an operational mode that enables the IEEE 802.3 Media Access Control (MAC) sub layer along with a family of physical layers to operate in the Low-Power Idle (LPI) mode. The EEE operational mode supports the IEEE 802.3 MAC operation at 100 Mbps, 1000 Mbps, and 10 Gbps. The EMAC supports the IEEE 802.3az-2010 for EEE.

The LPI mode allows power saving by switching off the parts of the communication device functionality when there is no data to be transmitted and received. The systems on both sides of the link can disable some functions to save power during the periods of low-link use. The MAC controls whether the system should enter or exit the LPI mode and communicates this to the PHY.

The EEE specifies the capabilities negotiation methods that the link partners can use to determine whether EEE is supported, and then select the set of parameters that are common to both devices.

Transmit Path Functions

The transmit path functions include tasks that the MAC must perform to make the PHY to enter the LPI state.

In the transmit path, the software must set the `EMAC_LPI_CTLSTAT.LPIEN` bit to indicate to the MAC to stop transmission and initiate the LPI protocol. The MAC completes the transmission in progress, generates its transmission status, and starts transmitting the LPI pattern instead of the IDLE pattern if the link status has been up continuously for a period specified in the `EMAC_LPI_TMRSCTL.LST` bit field. The PHY link status (`EMAC_LPI_CTLSTAT.PLS` bit) indicates the link status of the PHY.

To make the PHY enter the LPI state, the MAC performs the following tasks:

1. Deasserts TXEN
2. Asserts TX_ER
3. Sets `EMAC_TXD[n]`[3:0] to 0x1 (for 100 Mbps) or TXD[7:0] to 0x01 (for 1,000 Mbps)
4. Updates the status (`EMAC_LPI_CTLSTAT.TLPIEN` bit) and generates an interrupt.

To bring the PHY out of the LPI state, that is, when the software resets the TLPIEN bit, the MAC performs the following tasks:

1. Stops transmitting the LPI pattern and starts transmitting the IDLE pattern
2. Starts the LPI TW TIMER. The MAC cannot start the transmission until the wake-up time specified for the PHY expires. The auto-negotiated wake-up interval is programmed in the `EMAC_LPI_TMRSCTL.TWT` bit field.
3. Updates the LPI exit status (`EMAC_LPI_CTLSTAT.TLPIEX` bit) and generates an interrupt

The *LPI Transitions (Transmit)* figure shows the behavior of the TXEN, TX_ER, and `EMAC_TXD[n]` [3:0] signals during the LPI mode transitions.

NOTE:
- Gating of EMAC_TXCLK is not supported on EMAC.
- If the MAC is in the LPI mode and the application issues a soft or hard reset, the MAC transmitter comes out of the LPI mode.

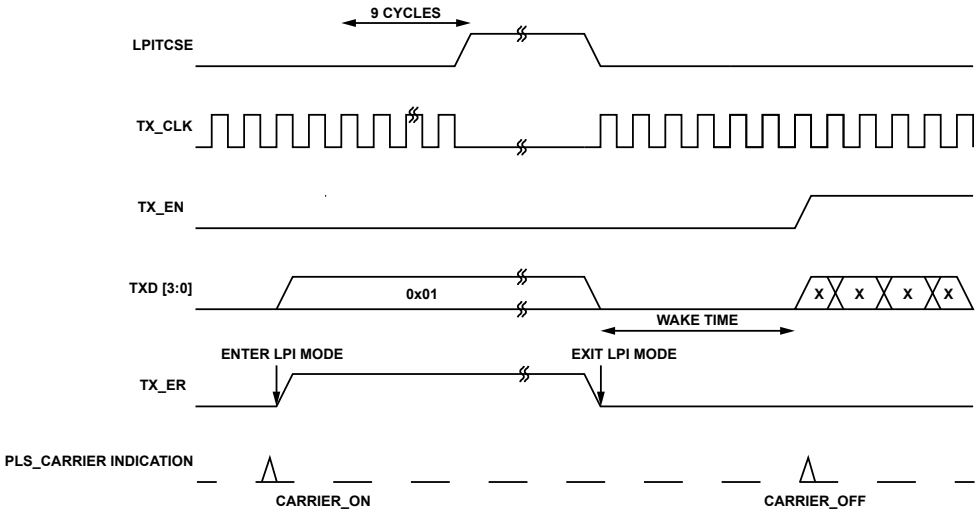


Figure 30-45: LPI Transitions (Transmit)

Automated Entry/Exit of LPI Mode

The MAC transmitter can be programmed to enter and exit LPI IDLE mode automatically based on whether it is IDLE for a specific period or has a packet to transfer. These modes are enabled and controlled by the `EMAC_LPI_CTLSTAT` register.

When the `EMAC_LPI_CTLSTAT.LPITXA` and `EMAC_LPI_CTLSTAT.LPIEN` are set, the MAC transmitter enters LPI IDLE state when the MAC transmit path (including the MTL layers and DMA layers) are idle. The MAC transmitter exits the LPI IDLE state and clear the LPIEN bit as soon as any of functions in the transmit path (DMA, MTL or MAC) becomes non-idle due to initiation of a packet transfer.

In addition, when (`EMAC_LPI_CTLSTAT.LPIATE`) is also set, the MAC transmitter enters LPI IDLE state only when the Transmit path remains in idle state (no activity) for the period indicated by the value in the `EMAC_LPI_ENTR_TMR` register. In this mode also, the MAC transmitter exits the LPI IDLE state as soon as any of the functions becomes non-idle. However, the LPIEN bit is not cleared but remains active so that reentry to LPI IDLE state is possible without any software intervention when the MAC becomes idle again.

When both the `EMAC_LPI_CTLSTAT.LPIATE` and `EMAC_LPI_CTLSTAT.LPITXA` bits are cleared, the program can directly control the entry and exit of LPI IDLE state by programming the LPIEN bit.

Receive Path Functions

The receive path functions include the tasks that the PHY and MAC must perform when the PHY receives signals from the link partner to exit the LPI state.

In the receive path, when the PHY receives the signals from the link partner to enter into the LPI state, the PHY and MAC perform the following tasks:

1. The PHY asserts `EMAC_RXERR`
2. The PHY sets `EMAC_RXD[n]`[7:0] to 0x01
3. The PHY deasserts RX_DV

4. The MAC updates the EMAC_LPI_CTLSTAT.RLPIEN bit and immediately generates an interrupt

NOTE:
- The PHY maintains the same state of the EMAC_RXERR, EMAC_RXD[n], and RX_DV signals for the entire duration during which it remains in the LPI state.
- If the LPI pattern is detected for a very short duration (that is, less than two cycles of receive clock), the MAC does not enter the receive LPI mode.
- If the duration between end of the current receive LPI pattern and start of the next receive LPI pattern, is very short (that is, less than two cycles of receive clock), then the MAC exits and again enters the receive LPI mode. The MAC does not give the receive LPI exit and entry interrupts

When the PHY receives signals from the link partner to exit the LPI state, the PHY and MAC perform the following tasks:

1. The PHY deasserts EMAC_RXERR and returns to a normal inter-packet state.
2. The MAC updates the EMAC_LPI_CTLSTAT.RLPIEX bit and generates an interrupt immediately.

The following figure shows the behavior of the EMAC_RXERR, RX_DV, and EMAC_RXD[n][3:0] signals during the LPI mode transitions.

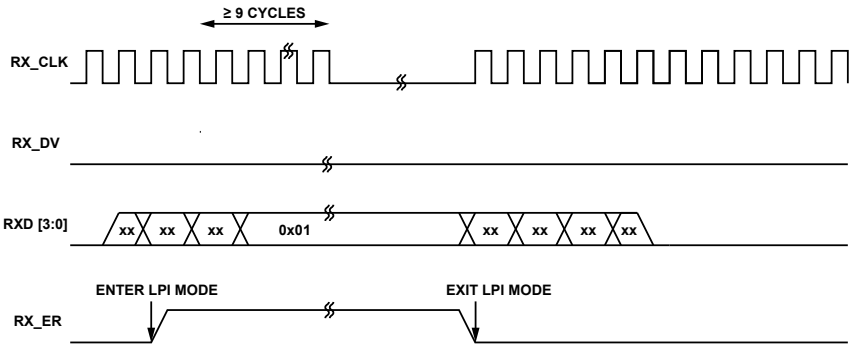

Figure 30-46: LPI Transitions (Receive)

NOTE:
- If the RX_CLK_stoppable bit (in the PHY register written through MDIO) is asserted when the PHY is indicating LPI to the MAC, the PHY may halt the RX_CLK at any time more than nine clock cycles after the start of the LPI state as shown in the *LPI Transitions (Receive)* figure.
- If the MAC is in the LPI mode and the application issues a soft or hard reset, the MAC receiver comes out of the LPI mode during reset. If the LPI pattern is still received after the reset is de-asserted, the MAC receiver again enters the LPI state.
- If the receive clock is stopped in the RX LPI mode, the application should not write to the CSR registers that are being synchronized to the receive clock domain.
- When the PHY sends the LPI pattern and if the EMAC_MAC_CFG.RE bit is set, the MAC automatically enters the LPI state. There is no other software control to prevent the MAC from entering the LPI state.

LPI Timers

The transmitter maintains the LPI LS TIMER, LPI TW TIMER, and LPI AUTO ENTRY TIMER timers. The following sections describe the LPI timers that are loaded with the respective values from the EMAC_LPI_TMRSCTL and EMAC_LPI_ENTR_TMR registers:

LPI LS Timer

The LPI LS TIMER counts, in milliseconds, the time expired since the link status is up. Programs can enable the monitoring of the EMAC_PHYIF_CTLSTAT.LUD bit by setting the EMAC_LPI_CTLSTAT.PLSEN bit.

The link status is indicated to the MAC by the EMAC_PHYIF_CTLSTAT.LNKSTS bit or the value programmed by the software in the EMAC_LPI_CTLSTAT.PLS bit. If the link status is not available in the EMAC_PHYIF_CTLSTAT, the software can get the PHY link status by reading the PHY register and accordingly update the PLS bit.

This timer is cleared every time the link goes down. It starts to increment when the link is up again and continues to increment until the value of the timer becomes equal to the terminal count. Once the terminal count is reached, the timer remains at the same value as long as the link is up. The terminal count is the value programmed in the EMAC_LPI_TMRSCTL.LST bits. The RGMII interface does not assert the LPI pattern unless the terminal count is reached. This ensures a minimum time for which no LPI pattern is asserted after a link is established with the remote station. This period is defined as 1 second in the IEEE 802.3-az-2010. The LPI LS TIMER is 10-bit wide. Therefore, the software can program up to 1023 milliseconds.

LPI TW Timer

The LPI TW TIMER counts, in microseconds, the time expired since the de-assertion of LPI. The terminal count is programmed using the EMAC_LPI_TMRSCTL.TWT bit field. The terminal count of the timer is the value of resolved transmit TW that is the auto-negotiated time after which the MAC can resume the normal transmit operation. After exiting the LPI mode, the MAC resumes its normal operation after the TW timer reaches the terminal count. The MAC supports the LPI TW TIMER in units of microseconds. The LPI TW TIMER is 16 bits wide. Therefore, the software can program up to 65535 µs.

LPI Auto Entry Timer

This timer counts in steps of eight microseconds, the time for which the MAC transmit path must remain in idle state (no activity), before the MAC transmitter enters the LPI IDLE state and starts transmitting the LPI pattern. This timer is enabled when the EMAC_LPI_CTLSTAT.LPIATE bit is set.

NOTE: Program the EMAC_LPI_CTLSTAT.PLS bit to 1'b0 before switching between the GMII and MII modes. This resets the internal timers. If the mode is changed after the LPI LS TIMER or LPI TW TIMER starts, the change in the transmit clock frequency can result in incorrect timeout

Low Power Interrupt (LPI)

The MAC generates the LPI interrupt when the transmit or receive side enters or exits the LPI state. The LPI interrupt can be cleared by reading the EMAC_LPI_CTLSTAT register.

For detailed programming guidelines see Programming Energy Efficient Ethernet.

Time-Sensitive Networking

The Time-Sensitive network (TSN) is a set of standards developed by the IEEE 802.1 work group. The standards define mechanisms for the time-sensitive transmission of data over the Ethernet.

This section contains the following topics:

- Enhancements to Scheduled Traffic (EST)
- Frame Preemption (FPE)
- Time-Based Scheduling

Enhancements to Scheduled Traffic (EST)

The IEEE 802.1Qbv-2015 specification defines the schedule for each of the queues on every egress port which makes the implementation aware of traffic arrival schedule. This information can be used to block the lower priority traffic from transmission in this time window/slot. This ensures that scheduled traffic is forwarded from sender to receiver through all the network nodes with a deterministic delay. The ***Time Aware Shaper Implementation*** figure shows the scheduled traffic windows for periodic priority data.

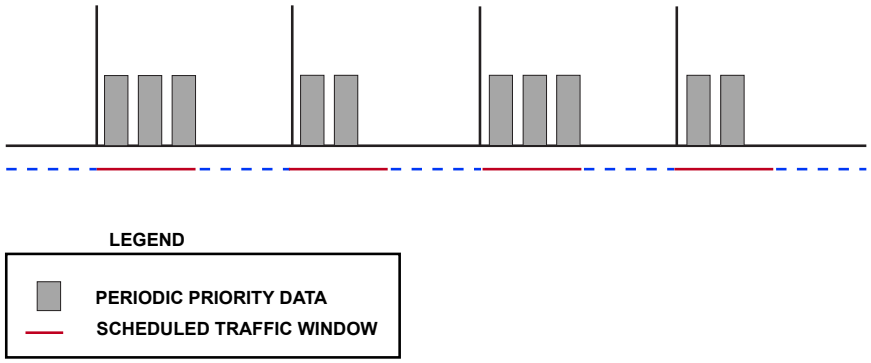

Figure 30-47: Time Aware Shaper Implementation

To achieve a low latency, ensure there are no interfering frames during the scheduled windows that are reserved for high priority traffic. The use of scheduled traffic imposes limitations while starting a transmission.

Refer to the ***Implementing a Guard Band*** figure. IWhenan interfering frame begins transmission just before the start of a reserved period, transmission can be extended into the reserved window, and potentially interfere with higher priority traffic. Therefore, a guard band whose size is equal to the largest possible interfering frame is required before the window starts.

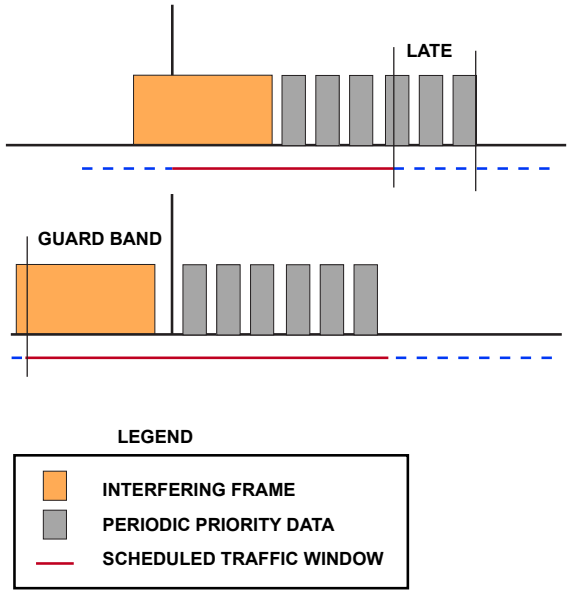

Figure 30-48: Implementing a Guard Band

A larger guard band equates to a less efficient use of the network bandwidth. However, the implementation of IEEE802.1Qbu (frame preemption) addresses this inefficiency. Frame preemption breaks the interfering frame into smaller fragments. Therefore, the guard band must only be as large as the largest possible interfering fragment (instead of the largest possible interfering frame).

During the guard band, only the frames that can complete the transmission of the entire frame before the next gate close event are permitted. This ensures that the high priority traffic can always start at the beginning of the specified window .

Definitions

The following terms are frequently used in the EST support:

- *Gate Control List* - The list in the hardware memory that holds the gate controls and the associated time intervals.
- *Gate Controls* – For a given schedule (row in gate control list), there is a gate open (O) and a gate close (C) state associated with each traffic control (TC). Gate controls are the set of O or C values, whose width is same as the configured TCs. For example, CCOCOOCO means TC7 = C, TC6 = C, TC5 = O and so forth.
- *Time Interval* – Time interval (in nano seconds). It is a 16-, 20-, or 24-bit configured field in the gate control list that indicates the time for which the associated gate controls are valid.
- *Base Time Register* – Each gate control list is associated with a 64-bit base time register that holds the start time (in PTP format) for the list.

Transmit Scheduling Updates

To support EST, the following updates are required for transmit scheduling:

- Implementation of the Gate Control List (GCL)
- Enforcing gate controls in the scheduler
- Accounting for gate open duty cycle in the computation of idleSlope (CBS)

Gate Control List (GCL) Implementation

The ***Gate Close and Open Events*** figure shows a block diagram based on the IEEE 802.1Qbv specification. It illustrates how the gate control list governs the gate close (C) and open (O) events based on the schedule provided for each event. GCL includes a time interval and gate control.

Time Interval – Defines the time in nano seconds for which the gate controls are valid. It should be applied before reading the next gate control from the list. It has a configurable width of 16, 20 or 24 to represent a maximum of 64 us, 1 ms, or 16 ms schedule intervals, respectively. The GLC implementation supports a left shift of a time interval up to 7 bits to apply a multiplication factor from 1 to 128 ns (in steps of 2^n). The maximum value (post shifting) of this field must be 999,999,999 ns.

Gate Control – Defines the open event (represented by a logic 1) or the close event (represented by logic 0) state for the gate of each TC.

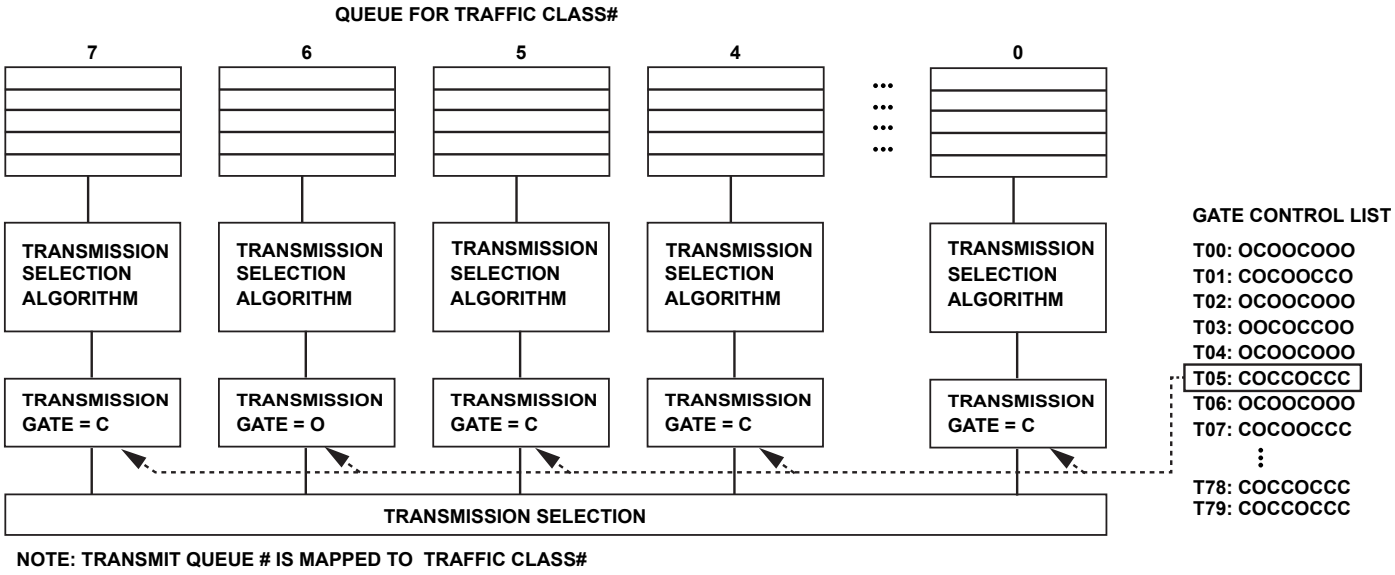

Figure 30-49: Gate Close and Open Events

The implementation of GCL consists of the following gate control lists:

- Hardware Owned List (HWOL) - a list for hardware access
- Software Owned List (SWOL) - a list for software access

The access to these lists is mutually exclusive. Hardware configures the ownership to the list in the `EMAC_EST_STAT` register. The ***External Memory Used for Holding the GCL*** table provides the implementation details of GCL.

Table 30-87: External Memory Used for Holding the GCL

Gate Control (up to 8 Bits)	Time Interval (ns) 16, 20 or 24 Bits	
OOCCCCCC	T0	HWOL or SWOL
OOOOCCCC	T1	
CCCCOOCC	T2	
CCCCCCOO	T3	
…	…	
…	…	
OCOCOCOO		
OOOOCCCC	T last	
OOOOCCCC	T0	SWOL or HWOL
OOOOCCCC	T1	
OOCCCCCC	T2	
OOOOCCCC	T3	
…	…	
…	…	
OCOCCCCC		
OOCCCCCC	T last	

GCL uses the following registers (one for each GCL). These registers are implemented through indirect addressing using the `EMAC_EST_GCL_CTL` and `EMAC_EST_GCL_DAT` registers.

Base Time Register (BTR) – A 64-bit register that holds the start time to execute the GCL. The format of the BTR is the same as the PTP format (the upper 32-bits holds time in seconds and the lower 32 bits hold time in nano seconds). Once the execution of a given list begins, the implementation can update the value in the BTR to indicate the next list execution time.

Cycle Time Register (CTR) – A 40-bit register that holds the time at which the execution of the GCL should be repeated. The cycle time register consists of an 8-bit value in seconds, and a 32-bit value in nano seconds (similar to the PTP time format with a truncated seconds register).

For a given gate control list:

Start time = Base Time + N * Cycle Time

where N is an integer value representing the iteration number starting with 0 for first iteration

If the gate control list execution takes longer than the cycle time, the list is truncated at the cycle time and the subsequent loop begins at cycle time.

Time Extension Register (TER) – An m-bit (where m = configured time interval width + 7) register that holds the amount of time (in nano seconds) that the current gate control list can be extended before switching to the new gate control list. This is useful to avoid small fragments of the current list before switching to a new list.

List Length Register (LLR) – An n-bit gate control register (when n is 7, 8, 9, 10, or 11 for a GCL configured depth of 64, 128, 256, 512, or 1024, respectively) that holds the integer value of the length of the GCL (the number of valid rows in each GCL). The processing of the GCL stops after the number of rows read equals the LLR value.

Transmission Gating Implementation

A bridge or an end station can be enhanced to allow transmission from each TC that is yet to be scheduled relative to a known timescale. To achieve this, a transmission gate is associated with each TC; the state of the transmission gate determines whether the queued frames can be selected for transmission.

For a TC, the transmission gate can be in one of the following states:

1. Open-queued frames are selected for transmission in accordance with the definition of the transmission selection algorithm associated with the TC
2. Closed-queued frames are not selected for transmission

A frame on a traffic class queue is not available for transmission when the transmission gate is in the closed state or when there is not enough time to transmit the entire frame before the next gate-close event associated with the queue.

The implementation has visibility into the current schedule of gate controls and the immediate next schedule of the gate controls. So, the maximum gate open period does not exceed the sum of the two time intervals. A frame is selected for transmission only when the gate is currently open and the duration of gate open interval is greater than the time taken to transfer the entire frame.

The implementation must have the frame size before the transmission to avoid transmission overruns and schedule only frames that can complete. To implement transmission gating:

- Program the `EMAC_EST_EXT_CTL.OVHD` bit field with a fixed overhead of the IPG or EIPG, preamble, and scheduler delay
- Enable the automatic prediction of variable overhead due to the offloads for a packet in the MAC transmitter. Consider the following while programming the EST-related fields for correct scheduling of packets:
    - Speeds: 1Gpbs/100 Mbps
    - PTOV in ns: 6 PTP clock cycles
    - CTOV in ns: 3 PTP + 3 transmit clock cycles
    - Per packet slot interval in ns: (packet size + overhead + IPG or EIPG + preamble) * (time to transmit 1 byte)
    - Overhead, scheduler delay in bytes is calculated as:

      17 Tx + (6 + X + Y + Z) CLKO7 clock cycles

where

- If Tx COE or TSO is selected, X = 4

  If TBS or OST is selected, Y = 4

  If VLAN tag insertion is enabled, Z = 2

The implementation compensates for the data transfer delays from the buffer to the line by offsetting the current time with all the relevant delays (provided by the `EMAC_EST_CTL.CTOV` field). This configuration ensures that the schedule provided is always accurately implemented at the line.

NOTE:
- An overhead is added to the packet size to account for the scheduler delay, IPG or EIPG, and preamble overheads on the line. Therefore, for a 128 byte frame to be transmitted, the gate open window must be able to accommodate at least 128 overhead bytes.
- In 100 Mbps mode of operation, the rounding down error is about 0.4%. For example, the gate open duration must be at least 1035 bytes for transmitting 1000 byte frames at a speed of 100 Mbps (31 bytes for scheduler delay, line overheads for two-port SRAM configurations, and 4 bytes for rounding down error)
- The minimum time interval for GCL entry must be equal to the time required to transmit fragment size + scheduler delay + IPG/EIPG + preamble overheads

Idle Slope Computation

When EST is enabled, credit is accumulated only when the gate is open; therefore, the effective data rate of the idle slope must be increased to reflect the duty cycle for the transmission gate associated with the queue.

The idle slope is computed based on GateOpenTime and OperCycleTime values. Program the idleSlope registers (implemented one per CBS-enabled TC) based on the following equation. The existing MTL register has sufficient bit width to accommodate the new values for idleSlope.

idleSlope = (operIdleSlope(N) * OperCycle/GateOpenTime)

Operational Details of GCL

Set (=1) the switch to the software list using the `EMAC_EST_CTL.SSWL` bit. Hardware can subsequently access the programmed gate control list. The first configuration of gate controls are applied when the current time is equal to the value in the BTR. It is held for the programmed time interval value.

To avoid transmission overruns, one additional gate control event is read ahead from the list. This operation permits the GCL to determine the next gate close events (if any) for the TCs that are open.

The scheduling is based on the gate open state and time interval of only the current and subsequent schedule. An internal accumulator is used to add the time intervals when gate controls are applied. The BTR and accumulator hold the time at which the next set of gate controls will be applied.

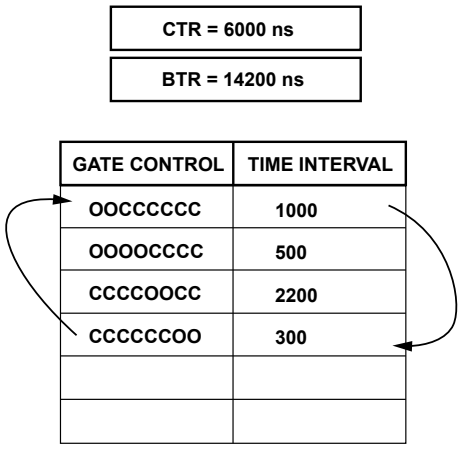

Figure 30-50: GCL Example - Base Time and Cycle Time

Refer to the ***GCL Example - Base Time and Cycle Time*** figure. The GCL is read progressively from the first row adhering to the schedule. The read operations continue until the list length (from LLR register) is reached and the execution of the list restarts at BTR + CTR time. At this point, the BTR is incremented by value in CTR to mark the beginning of a new cycle. In the absence of any gate controls, all gates are deemed to be in the open state during the execution of the list.

In cases where the execution time of the list is greater than the cycle time, the list is truncated and the next iteration starts when the current time equals BTR + CTR.

Table 30-88: GCL Execution Example - BTR and CTR

Current Time	Gate Control Applied	Accumulator Value (ns)	BTR (with updates)
14200	OOCCCCCC	1000	14200
15200	OOOOCCCC	1500	14200
15700	CCCCOOCC	3700	14200
17200	CCCCCCOO	4000	14200
18200	OOOOOOOO	0	20200
20200	OOCCCCCC	1000	20200
21200	OOOOCCCC	1500	20200

Refer to the ***GCL Execution Example - BTR and CTR*** table. The execution starts at 14200 and the first set of gate controls OOCCCCCC are applied immediately. When the time interval is 1000 ns, the next set of gate controls are applied at 14200 (BTR) + 1000 (Accumulator) = 15200 ns. Since there are no gate controls available after the execution of the last gate control and before the next iteration of the loop, the gates are deemed to be in open state during that period as depicted at time 18200.

Refer to the ***GCL Example - Base Time and Cycle Time, Execution Time > Cycle Time*** figure. Because the list execution takes longer than the allocated cycle time, the list is truncated.

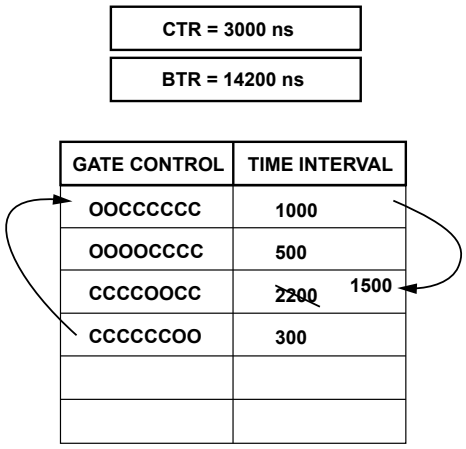

Figure 30-51: GCL Example - Base Time and Cycle Time, Execution Time > Cycle Time

Refer to the ***GCL Execution Example - BTR and CTR , Execution Time > Cycle Time*** table. The list is started from the BTR + CTR. While applying the third set of gate controls, the BTR + Cycle Time (17200) < BTR + Accumulator (17900). Therefore, the list is truncated and execution switches to a new iteration at 17200.

Table 30-89: GCL Execution Example - BTR and CTR, Execution Time > Cycle Time

Current Time	Gate Control Applied	Accumulator Value (ns)	BTR (with updates)
14200	OOCCCCCC	1000	14200
15200	OOOOCCCC	1500	14200
15700	CCCCOOCC	3700	14200
17200	OOCCCCCC	1000	17200
18200	OOOOCCCC	1500	17200
18700	CCCCOOCC	3700	17200

Installing a New GCL

When a new software programmed GCL is available and must be executed at the new BTR value, the switch to the new GCL can happen as a:

- New base time aligned with current schedule
- New base time unaligned with current schedule

New Base Time Aligned with Current Schedule

If the cycle time for the new gating cycle is the same as the cycle time for the current gating cycle, and if the BTR chosen for the new gating cycle is an integer multiple of the current cycle time (+ current BTR), the new and old gating cycle are aligned. This would be the ideal case; it allows the new gating cycle to be installed and executed with no timing issues. The implementation completes the execution of an iteration of the current list, and switches to the new list at the beginning of the base time listed in the new list.

When (New BaseTime ≥ Current Time), then ConfigChangeTime = New BaseTime, Else If (New BaseTime < Current Time):

1. Set the BTRError.
2. ConfigChangeTime = (New BaseTime + N* New CycleTime).

   where N is the smallest integer for which the relationship ConfigChangeTime ≥ CurrentTime and (N =< 8) = TRUE.

When N > 8, the hardware cannot auto recover and the loop count value in BTR error reporting is set to 1111. The software must reprogram the new base time.

The ***Switching to a New List Example - Aligned*** figure illustrates the installation of a new GCL that is aligned with the existing configuration. In the example, after the sixth iteration of the first GCL, the BTR values of the old and new GCL are equal. At that point, the new GCL is processed as a natural extension to the existing GCL.

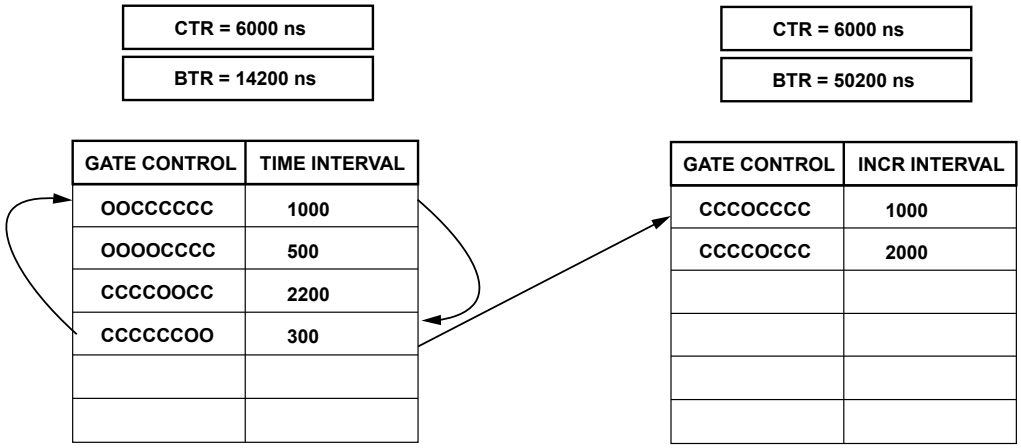

Figure 30-52: Switching to a New List Example - Aligned

Table 30-90: GCL Execution Example - BTR and CTR

Current Time	Gate Control Applied	Accumulator Value	BTR (with updates)
44200	OOCCCCCC	1000	44200
45200	OOOOCCCC	1500	44200
45700	CCCCOOCC	3700	44200
47900	CCCCCCOO	4000	44200
48200	OOOOOOOO	0	50200
50200	CCCOCCCC	1000	50200
51200	CCCCOCCC	3000	50200
53200	OOOOOOOO	0	56200

New Base Time Unaligned with Current Schedule

If a new cycle time differs from current cycle time or the new base time is in the future and not an integer multiple of the current cycle time, the old and new cycles are unaligned. When new base time is reached (when the new configuration is installed and starts to execute), the last old cycle is normally truncated to start the first new cycle. This could be undesirable if it results in a very short last old cycle. Arguably, it would be better to extend the old cycle by that small amount, rather than start a short cycle. The cycle time extension register (related to the current configuration list) allows this extension of the last old cycle. If the last complete old cycle ends normally in less than current Cycle Time Extension (TER) ns before the new base time, then the last complete cycle (before new base time is reached) is extended so that it ends at the new base time.

The ***Switching to a New List Example - Unaligned*** figure shows how the installation of a new GCL that is unaligned with the current schedule truncates the current list.

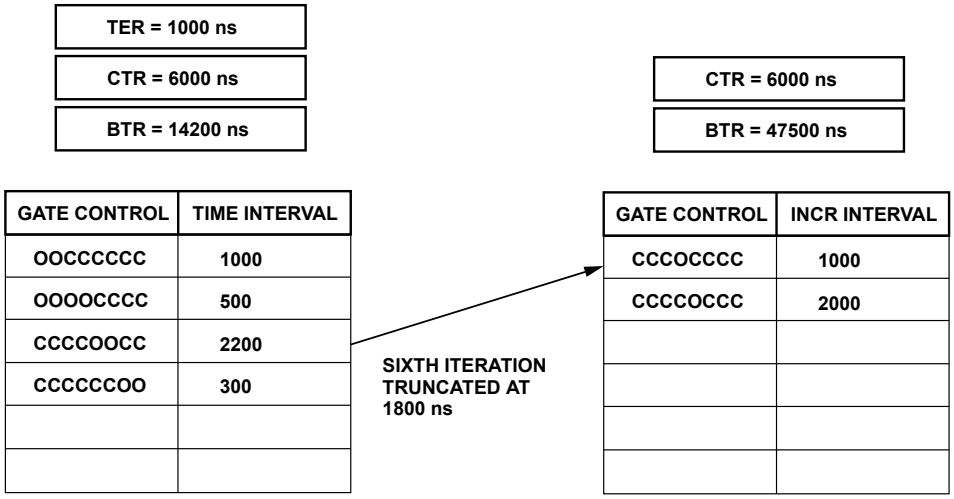

Figure 30-53: Switching to a New List Example - Unaligned

At the end of the fifth iteration the Current time + Cycle time extension (TER) < New BTR. So, the sixth iteration of current configuration is started. During the sixth iteration of the current list when the new BTR value is smaller than the next schedule in the current list, it switches to the new list.

Table 30-91: Extending to New List by Truncating the Current List

Current Time	Gate Control Applied	Accumulator Value	BTR (with updates)
44200	OOCCCCCC	1000	44200
45200	OOOOCCCC	1500	44200
45700	CCCCOOCC	3700	44200
47500	CCCOCCCC	4000	44200
48500	CCCCOCCC	0	50200
50500	OOOOOOOO	1000	50200

The *Switching to a New List Example - Extended* figure shows where the current configuration list is extended (instead of starting a new iteration). The extension time of 800 ns is less than the allowed cycle extension time (TER) of 1000 ns.

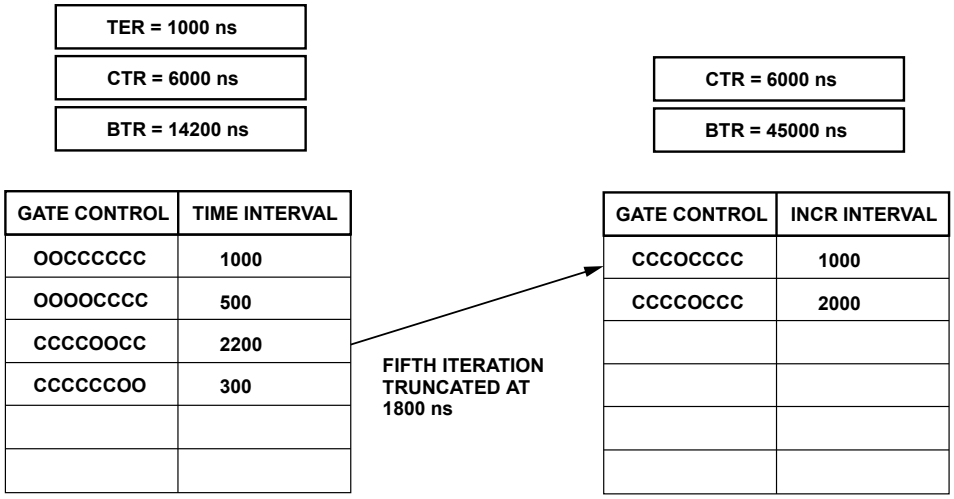

Figure 30-54: Switching to a New List Example - Extended

Table 30-92: Switching to New List by Extending the Current List

Current Time	Gate Control Applied	Accumulator Value	BTR (with updates)
38200	OOCCCCCC	1000	38200
39200	OOOOCCCC	1500	38200
39700	CCCCOOCC	3700	38200
41900	CCCCCCOO	4000	38200
42200	OOOOOOOO	0	44200
45000	CCCOCCCC	1000	45000
46000	CCCCOCCC	3000	45000
48000	OOOOOOOO	0	51000

Impact of Transmit Scheduling Algorithms on EST

When EST is used in isolation, the gate control list manages the final open/close state of the queues along with the checks carried out by the transmission selection algorithm in MTL. Because the gate controls operate on a predefined repetitive schedule, use the strict priority or Credit Based Shaper (CBS) scheduling algorithms.

Other algorithms such as the Weighted Round Robin (WRR), Deficit Weighted Round Robin (DWRR) and Weighted Fair Queuing (WFQ) implement masking of the queues based on the current winning queue. The algorithm is applied only among the group of queues that open simultaneously. To ensure queues whose gates are open get priority, these algorithms are modified to treat gate open queues and gate closed queues as separate groups giving priority to gate open queues.

For example, consider four queues (Q3, Q2, Q1, Q0) with weights 4:3:2:1; Q3 and Q2 are in open state in slot one slot, while Q1 and Q0 are in open state in another slot. In this case, the scheduler works as follows:

1. In the first slot, the Q3 and Q2 are serviced in the ratio of 4:3 for the duration that the slot is open.
2. In the second slot, the queues Q1 and Q0 are serviced in the ratio of 2:1.
3. Fresh arbitration is started every time a slot is opened.

The traffic does not get distributed in the intended ratio of 4:3:2:1, but rather as two groups with different ratios and only for the duration of the slot when the gates are open continuously.

Frame Preemption (FPE)

The IEEE 802.1Qbv-2015 specification defines the schedule for each queue on every egress port that makes the implementation aware of the traffic arrival schedule. This information can be used to block the lower priority traffic from transmission in this time window. Scheduled traffic is forwarded from the sender to the receiver through all the network nodes with a deterministic delay.

To achieve a low latency, ensure that there are no interfering frames during the scheduled windows that are reserved for high priority traffic. The use of scheduled traffic imposes limitations while starting a transmission.

If an interfering frame begins transmission just before the start of a reserved time period, it can extend transmission into the reserved window, and potentially interfere with higher priority traffic. Therefore, a guard band whose size is equal to the largest possible interfering frame is required before the window starts.

A larger guard band equates to a less efficient use of network bandwidth. However, with the implementation of IEEE802.1Qbu (frame preemption), this issue is addressed. Frame preemption breaks the interfering frame into smaller fragments. Therefore, the guard band needs to be only as large as the largest possible interfering fragment instead of the largest possible interfering frame.

During the guard band, only the frames that can complete the transmission of the entire frame before the next gate close event are permitted. This ensures that the high priority traffic can always start at the beginning of the window reserved for it.

NOTE: Internal loopback is not supported for preempted frames.

Preemption allows one or more higher priority (express) frames to interrupt the transmission of a lower priority (preemptable) frame; the preemptable frame transmission is resumed and completed after the express frame transmission is complete. To support frame preemption, the following abstractions of the MAC are used:

- A preemptable MAC, called pMAC, which carries the preemptable traffic
- An express MAC, called eMAC, which carries the express traffic

In the implementation, only the parts of the MAC that hold the state during preemption are replicated and represented as pMAC and eMAC. The MAC uses the following ways to halt the transmission of preemtable traffic in the presence of express traffic:

- The MTL scheduler interrupts the preemptable traffic that is currently being transmitted. When the preemption capability is active, the MAC interrupts the transmission and reception of preemptable frames. A preempted fragment can be followed by zero or more express frames before the continuation fragments. The preemptable frame can be fragmented any number of times. However, the minimum final and non-final fragment length criterion must be met.
    - Interleaving of more than one preemptable packet is not permitted. IWhen a preemptable packet is fragmented by an express packet, another preemptable packet cannot be transferred until all the remaining fragments of the first preempted packet are transferred.
- The MTL scheduler prevents starting the transmission of preemptable traffic. When the preemption capability is inactive, the pMAC entity is disabled and only express traffic is transmitted or received.

NOTE: Queue 0 can be an express queue when FPE is enabled, and EST is disabled.

Enabling Frame Preemption

Enable the frame preemption feature by setting the `EMAC_FPE_CTLSTAT.EFPE` bit.

GCL Modification to Support FPE

In the EST only configuration, the GCL entry has up to 24 bits of time interval, and up to 8 high order bits representing the gate open and close state requirements as shown in the ***Gate Control*** table.

Table 30-93: Gate Control - FPE Disabled

Gate Control (up to 8 Bits)	Time Interval (ns) 16, 20 or 24 Bits
OOCCCCCC	T0
OOOOCCCC	T1
CCCCOOCC	T2
CCCCCCOO	T3
…	…
…	…
OCOCOCOO	T126
OOOOCCCC	T127

EST only supports the *SetGate* operation, which implies that the gates are set to either open or close at a given time interval.

However, when both FPE and EST are enabled, the GCL also supports *Set-and-Hold-MAC* and *Set-and-Release-MAC* operations, in addition to the *SetGate* operation. To enable the support of hold and release operations, the format of the GCL is slightly changed while configuring and enabling the FPE. The first queue (Q0) is always programmed to carry preemption traffic. Therefore, it is always open. The bit corresponding to Q0 is renamed as hold and release MAC control.

The TX queues whose packets are preemptable are indicated by the EMAC_FPE_CTRLSTS.PEC field. The GCL bit of the corresponding queue is ignored and considered as always open. So, even if the software writes a 0 (C), it is ignored for such queues.

Table 30-94: Gate Control, FPE Enabled

Gate Control (up to 7 Bits)	Release/Hold Indication	Time Interval (ns) 16, 20 or 24 Bits
CCCOOOO	0	T0
CCCCOOO	0	T1
OCCCOOO	1	T2
COCCOOO	1	T3
CCOCOOO	1	T4
CCCOOOO	0	T5
CCCCOOO	0	T6

When the hold and release bit transitions from a 0 to 1, a *Set-and-Hold-MAC* operation is performed. This operation indicates the halting of the preemptable traffic. A hold request is sent to MTL in advance (the time interval is given in the EMAC_FPE_ADV.HADV field). When the hold and release bit transitions from a 1 to 0, a *Set-and-Release-MAC* operation is performed. This operation marks the resumption of the preemptable traffic. A release request is sent to MTL in advance (the time interval is given in the EMAC_FPE_ADV.RADV field). The preemptable traffic is blocked for the duration that the hold and release bit is set to a 1 in the GCL.

NOTE: The EMAC_FPE_ADV.HADV field is the advance time to initiate the hold state. Ideally, it should be programmed to a value of minimum fragment size. The size should be smaller than the time interval (minimum fragment size + IPG + preamble overheads in nanoseconds).

Impact of Preemption on CBS

In CBS, the definition of *transmit* is:

- True for the duration of frame transmission from the queue.
- False when frame transmission from the queue is complete.

When the CBS algorithm is used along with frame preemption, the value of *transmit* is true only while the MAC is transmitting the frame. If the frame transmission is delayed or interrupted, the value of *transmit* is false until transmission of the frame commences or is resumed. For example, a preemptable frame transmission is interrupted to allow the transmission of an express frame from a different queue. Or the start of express frame is delayed because a preemptable frame is being transmitted)

The value of *transmit* is false during the transmission of any overhead that is a consequence of frame preemption. For example, an additional frame overhead (mCRC, fragment count) that is added to the preemptable frame.

At any given time, if there are no frames in the queue, and the value of *transmit* is false, and credit is a positive value. The credit value is set to zero if there is no preemptable frame from the queue for which transmission is in-progress but has been interrupted.

mPacket Format

When the preemption capability is active, the MAC sends mPackets to the PHY. An mPacket can be one of the following:

1. An express packet
2. A preemptable packet
3. An initial fragment of a preemptable packet
4. A continuation fragment of a preemptable packet

The ***mPacket Format*** figure shows the format of the mPacket. It contains an express packet, a complete preemptable packet, or the initial fragment of a preemptable packet. Format B shows the format of an mPacket containing a continuation fragment of a packet.

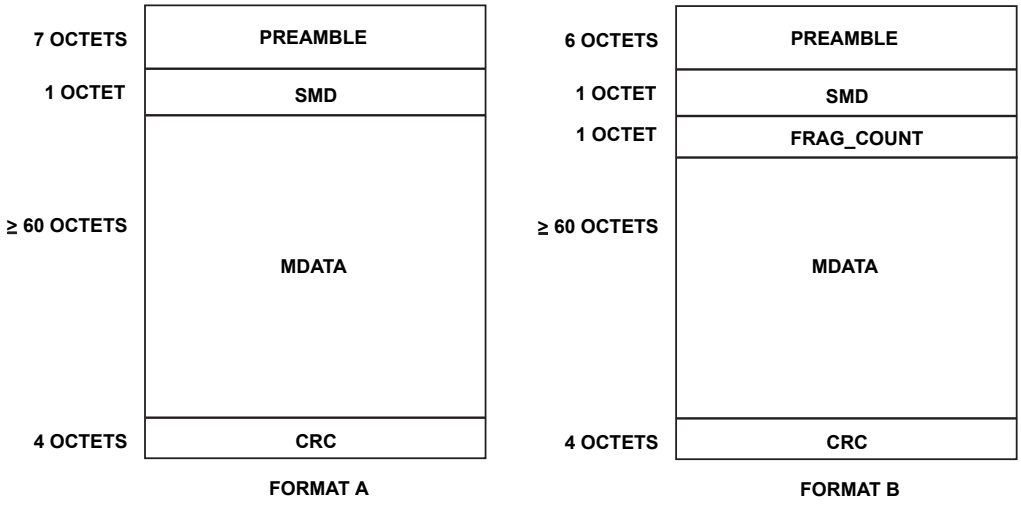

Figure 30-55: mPacket Format

Preamble

The preamble in the mPacket shown in ***mPacket Format*** contains seven octets. The preamble in the mPacket shown in ***mPacket Format*** (Format B) contains six octets. Each octet contains the value of 0x55 (transmitted in order from left to right 10101010).

Start mPacket Delimiter (SMD)

The value of the SMD indicates whether the mPacket contains an express packet, the start of a preemptable packet (initial fragment or complete packet), or any of continuation fragments of a preemptable packet. The ***SMD Values*** table shows the valid SMD values for different mPacket types.

Table 30-95: SMD Values

mPacket Type	Notation	Frame Count	Value
Verify packet	SMD-V	N/A	0x07
Respond packet	SMD-R	N/A	0x19
Express packet	SMD-E	N/A	0xD5
Preemptable packet start	SMD-S0	0	0xE6
	SMD-S1	1	0x4C
	SMD-S2	2	0x7F
	SMD-S3	3	0xB3
Continuation fragment	SMD-C0	0	0x61
	SMD-C1	1	0x52
	SMD-C2	2	0x9E
	SMD-C3	3	0x2A

frag_count

A frag_count is a modulo 4 counter that increments for each continuation fragment of the preemptable packet. The frag_count protects against mPacket reassembly errors by enabling the detection of the loss of up to three packet fragments.

The frag_count field is present only in mPackets with SMD-C notation (continuation fragment). The frag_count is zero in the first continuation fragment of each preemptable packet. The ***frag_count Values*** table shows value associated with the frag_count.

Table 30-96: frag_count Values

frag_count	Value
0	0xE6
1	0x4C
2	0x7F
3	0xB3

mData

The contents of the packet from the MAC. It includes the first byte after the SFD to the last byte before the FCS. The contents are sent in the mData fields of one or more mPackets for that frame. The minimum size of the mData field is 60 bytes.

CRC

The CRC field contains a Cyclic Redundancy Check (CRC) and has an indication of the final mPacket of a frame. In the final mPacket of a frame, the CRC field contains the last four octets of the MAC frame (the FCS field).

For other mPackets, the CRC field contains an mCRC value. The mCRC is calculated on the octets of the packet from the first octet of the frame (the octet following the SFD of preemption frames) to the last octet of the packet transmitted in that mPacket. The check by performing an XOR of the calculated 32 bit CRC value of the fragment and a value of 0x0000FFFF.

Summary of Packet Formats

- Express packet – 7 bytes of preamble, SMD-E, data, and CRC
- Complete preemptable packet – 7 bytes of preamble, current preemptable packet SMD, data, CRC
- Initial fragment (non-final) of preemptable packet– 7 bytes of preamble, current preemptable packet SMD, data, mCRC
- Continuation fragments (non-final) of preemptable packet – 6 bytes of preamble, current preemptable continuation fragment SMD, current preemptable continuation fragment FC, data, mCRC
- Final fragment of preemptable packet – 6 bytes of preamble, current preemptable continuation fragment SMD, current preemptable continuation fragment FC, data, CRC

When frame preemption is enabled, the MAC receiver communicates the exceptions related to received preempted fragments (incorrect fragment sequencing, missed fragment, and so on) to MTL layer by reporting it as a CRC error. Software should not set (=1) the `EMAC_MAC_EXT_CFG.DCRCC` bit. Otherwise, the MTL layer might forward the unintended preempted fragments to the application.

SMD-C3	FC3	SMD-C3	FC0

Transmit Preemption

To support preemption, the MAC should have more than one transmit queue with at least one queue designated as express queue (and one queue designated as preemption queue). When FPE is enabled (`EMAC_FPE_CTLSTAT.EFPE` =1), the MTL preempts a preemptable frame. When a hold request is asserted (EST/Qbv configured and enabled), express frames are available for transmission. The frame is present in the MTL FIFO and qualified for arbitration after ensuring that the minimum mPacket mData field size is met.

Therefore, preemption occurs only when at least 60 bytes of the preemptable frame have been transmitted and at least 64 bytes (including the frame CRC) remain.

The earliest starting position of preemption is controlled by the `EMAC_FPE_CTRLSTS.AFSZ` bit. Preemption does not occur until at least 64 x (1 + AFSZ) - 4 bytes of the preemptable frame have been sent.

When preemption occurs, all of the preemptable queues are blocked; only the express queues can arbitrate (if more than one express queue has traffic) and transmit.

The continuation fragment of the preempted frame is the first frame to be transmitted after the release request is asserted (EST/Qbv configured and enabled) and all the express traffic transmission completes.

NOTE: All the PTP packets should be transmitted as express packets.

MTL communicates the following frame-type information to the MAC using a 2-bit preemption control signal on the MTI interface (qualified with SoF and EoF). Refer to the ***MTI Preemption Control Values*** table.

- Express frame
- Preemption frame (full or fragment)
- Continuation fragment (non-final or final)

Table 30-99: MTI Preemption Control Values

Qualifier	Preemption Control Values	Frame Types
SoF	00	Start express
SoF	01	Start preemption
SoF	10	Continuation fragment
SoF	11	Reserved
EoF	00	End of frame
EoF	01	End of fragment

The MTL must wait for the previous fragment status to be received before resuming the continuation fragments of a preempted frame.

MAC Transmit Preemption

The MAC supports preemption by implementing the functionality needed to generate the mPackets. The functionality is based on the preemption control value received on the MTI interface (qualified with SoF and EoF). The MAC determines the frame type (see the ***MTI Preemption Control Values*** table) and generates mPackets accordingly. When the preemption capability is active, the MAC replaces the SFD of a preemption packet with an SMD-S value. A 2-bit rolling frame count is encoded in the SMD-S value. The SMD-E value is the same as the SFD value. So, the SFD of an express packet does not need to be replaced.

Transmit Fragment Status

The MAC sends the transmit fragment status to indicate a successful transmission of fragmented mPackets. To indicate a fragment status, bit 31 of the mti_txstatus_o field is set (=1) and all other values in the status field are zero.

For a transmission error (for example, an underflow or jabber), the frame status is sent (and not a fragment status) with an error indication along with all other relevant status fields. For a receiving an error status, the MTL drops the remaining fragments and does not send any more continuation fragments.

Receive Preemption

When FPE is enabled, the MAC receiver passes the incoming packets and differentiates between express packets and preemptable packets. An SMD containing an SMD-E indicates an express packet; an SMD containing an SMD-S indicates the first mPacket of a preemptable packet.

If an mPacket containing an SMD-S is received when the MAC has not completely received the previous preempted packet, MAC sets a CRC error status for the previously received partial packet.

When an SMD-S is detected, the MAC records the frame count indicated by the SMD and then begins sending data on the MRI interface.

The MAC checks the last four bytes of the mPacket. If the last four bytes of the mPacket do not match CRC, it indicates the end of the packet with or without a CRC error (CRC check result). If the last four octets of the mPacket match, it indicates that the packet was preempted.

An SMD containing an SMD-C indicates an mPacket that continues the data for a preempted packet. Upon receiving an SMD value of SMD-C, the MAC checks the following:

1. A preempted packet is in progress
2. The frame count indicated by the SMD matches the frame count of the packet in progress
3. The frag_count value indicates the next fragment count

If any of these checks fail, the mPacket is discarded and MAC sets a CRC error status for the partially received packet.

If all the checks pass, the next fragment count is incremented modulo 4.

When a packet is preempted, the MAC saves the state of the partially received packet (filter check status, time stamp, length fields and so on) and can process any received express packets before the continuation fragment is received.

The MAC receiver sends a dummy status for all of the mPacket fragments that are successfully received. It sends the Rx status with the final fragment. If an error is detected during any of the fragments, the Rx status is sent, and the fragment is marked as final fragment. All subsequent continuation fragments received for this packet are dropped in the MAC.

The MAC communicates the following frame type information to the MTL using a 2-bit preemption control signal on the MRI interface. Refer to the ***MRI Preemption Control Values*** table.

1. Express frame
2. Preemption frame (full or fragment)
3. Continuation fragment (non-final or final)

Table 30-100: MRI Preemption Control Values

Qualifier	Preemption Control Values	Frame Types
SoF	00	Start express
SoF	01	Start preemption
SoF	10	Continuation fragment
SoF	11	Reserved

Table 30-100: MRI Preemption Control Values (Continued)

Qualifier	Preemption Control Values	Frame Types
EoF	00	End of frame
EoF	01	End of fragment

Data Alignment

When a received frame cannot be fragmented on any byte boundary, the MAC retains the unaligned bytes of data in the previous fragment and resends them with the next fragment. See the ***MAC Data Alignment*** figure.

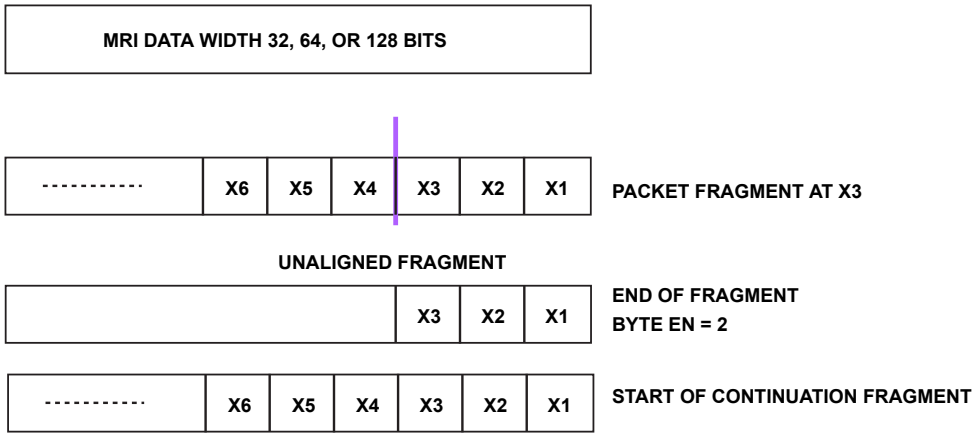

Figure 30-56: MAC Data Alignment

The MTL can choose to ignore the partial data (based on byte enable value) that comes with the end of the fragment and instead use the data width aligned data received in the first beat of the next continuation fragment.

MTL Receive Preemption

The MTL Rx must have at least two receive queues to support FPE function because the preemptable packets and the express packets must be routed to separate queues. The `EMAC_RXQ_CTL0` registers control the destination Rx queue of a received packet. Program these registers such that preemptable traffic and express traffic are not routed to the same receive queue. The queue mapping for tagged packets is based on VLAN user-priority field. So, the priority of preemptable and express packets are mutually exclusive. Packets of a certain priority (traffic class) are either express or preemptable, but not both.

For the preemptable frames, in addition to the Priority Selected in Rx Queue (PSRQ) routing, a programmable Frame Preemption Residue Queue (FPRQ) is supported. This feature routes all other preemption packets received (untagged, SA/ DA or VLAN filter fails forwarded due to RA being set or VTFE being reset). Refer to the ***MTI Preemption Routing*** table.

Table 30-101: MRI Preemption Routing

Preemption Packet Type	Queue Routing
AV tagged packets passing the SA/DA and VLAN filters	PSRQ*
DCB/generic tagged packets passing the SA/DA and VLAN filters	PSRQ**
Tagged packets failing the SA/DA and VLAN filters without setting the receive all (RA = 0) or setting VTFE =1	Dropped
All other packets or when RA = 1	FPRQ

The express frames use queue 0 as a default queue. In case of filter failures, queue 0 must not be used for receiving preemption frames.

When a fragment is received, it is pushed into its destination receive queue. When this packet is preempted, and is followed by an express packet, it is pushed/stored in a different receive queue. The MTL saves the context of the preempted frame, and processes one or more express frames. When the continuation fragment arrives, it restores the saved context and pushes the remainder of the fragmented frame into its receive queue.

MTL Receive Arbitration

On the ARI interface, data is fetched from the MTL receive FIFO based on the arbitration selected in the EMAC_MTL_OPMODE register. Frame-based arbitration can be used only when all the MTL preemption queues operate in store-and-forward mode. Otherwise, there is a loss of bandwidth on the ARI interface because all of the fragments of a preemptable packet are not available. Therefore, express packets received between the fragments are blocked until all of the fragments are received and transferred; this defeats the purpose of express traffic.

When operating in either threshold (cut through) or store-and-forward modes, PBL-based arbitration is recommended over frame-based arbitration. For PBL-based arbitration, the watermark check is always performed. The arbitration/transfer of data is in chunks of PBL size of data (similar to the concepts of fragments). Therefore, the express queue packets are blocked for less time and the ARI interface transfers the data without a loss of efficiency.

Frames Support in Offload Engines

When frame preemption is enabled, all the packets processed by the offload engines (ARP, PTO) and PTP, PAUSE, and PFC packets must be received as express/normal packets. These offload engine logic and functions do not recognize preemption frames.

Verify and Respond mPackets

When FPE function is present, the MAC can receive and detect the verify and respond mPackets, even when FPE is not enabled by software. When the MAC detects valid verify and respond mPackets, it notifies the software by configuring the EMAC_FPE_CTLSTAT.RVER and EMAC_FPE_CTLSTAT.RRSP fields, respectively. Optionally, an interrupt can be generated. These packets have empty (all-zero) data payload; they are dropped inside the MAC and not forwarded to the MRI.

Software can configure the EMAC_FPE_CTLSTAT.SRSP and EMAC_FPE_CTLSTAT.SVER fields to request the MAC to transmit verify and respond mPackets, respectively. Upon successful transmission of these frames, the MAC clears the EMAC_FPE_CTLSTAT.SRSP / EMAC_FPE_CTLSTAT.SVER bit and sets the EMAC_FPE_CTLSTAT.TVER/EMAC_FPE_CTLSTAT.TRSP bits. Optionally, an interrupt can be generated when these events occur.

NOTE: 1. For preemption frames received with a CRC error, ignore the following status fields:
   - Packet length
   - Dribble error indication
   - Runt frame indication
2. When FPE is configured, the EMAC_RQ0_OPMODE.FUP (RXQ(n)) bit should not be set.
3. When FPE is configured, do not disable CRC checking upon receive. Internally, FPE error fragments are identified using CRC checks. For details, see the EMAC_MAC_EXT_CFG.DCRCC field.
4. Express and preemption traffic must be routed to different DMAs.

MMC Counter and Interrupt Registers

The following MMC counters and associated interrupt registers are instantiated/present in the MAC when the frame preemption feature and any one of the existing MMC counters are selected during RTL configuration.

Table 30-102: MMC Counters and Interrupt Registers

Frame Assembly Error Counter	Description	Associated MMC Counter
Frame assembly error counter	A 32-bit counter that provides the number of MAC frames with reassembly errors on the receiver, due to a mismatch in the fragment count value	EMAC_RXPKT_ASERR_CNT
Frame SMD error counter	A 32-bit counter that provides the number of MAC frames rejected due to arriving with an SMD-C when there was no preceding preempted frame	EMAC_RXPKT_SMDERR_CNT
Frame assembly OK counter	A 32-bit counter that provides the number of MAC frames that were successfully reassembled	EMAC_RXPKT_ASOK_CNT
MAC Rx fragment counter	A 32-bit counter that provides the number of additional mPackets received due to preemption.	EMAC_RXFPE_FRGMNT_CNT
MAC Tx fragment counter	A 32-bit counter that provides the number of additional mPackets transmitted due to preemption.	EMAC_TXFPE_FRGMNT_CNT

Table 30-102: MMC Counters and Interrupt Registers (Continued)

Frame Assembly Error Counter	Description	Associated MMC Counter
Hold request counter	A 32-bit counter that maintains the count of the number of hold requests given to the MAC	EMAC_TXHLDRQ_CNT

Additional Registers Associated with MMC Interrupts

Following are the additional registers associated with MMC interrupts for the MMC error counters:

- EMAC_MMC_FPE_TXINT
- EMAC_MMC_FPE_TXIMSK
- EMAC_MMC_FPE_RXINT
- EMAC_MMC_FPE_RXIMSK

Time-Based Scheduling

The time-based scheduling feature is suitable for traffic whose periodicity and rate are predictable. This feature is optional. To improve the quality-of-service of such traffic:

- The transmit DMA fetches the packet from the host memory for transmission at designated time. This method helps the software to set up the transmit descriptors before the packet is ready/available. It reduces the overhead on the software and avoids constant monitoring of the time. It prepares the descriptors for the targeted transmission time of the packet.
- The MAC transmits the packet only at the designated/pre-determined time even when the packets are fetched in advance. This method helps in maintaining a constant transmission rate that can be consumed by the receiver station; therefore, it avoids congestion and excessive buffering in the network.

The time-based scheduling feature supports fetching and launching an Ethernet packet at (or after) a pre-determined time. The time-based scheduling is supported only in the following modes:

- Full duplex mode
- Link speed is 100 Mbps or higher

NOTE:
- Do not enable time-based scheduling for the channel for which TSO feature is enabled.
- In EST enabled configurations, the EMAC_TBS_CTRL.ESTM bit impacts the time-based scheduling feature only when the DUT processes the GCL list.
- Slot number is meaningful only after GCL is active. So, start the GCL list before enabling the TBS and EST features. If GCL is not started, all gates are deemed open. If packets do not make progress, the Tx queue creates back pressure.

TBS Definitions

The following definitions apply to time-based scheduling:

- Launch time - the time beyond which MTL can schedule the packet for transmission
- Fetch time - the time beyond which the Tx DMA can schedule a packet-fetch from the host memory
- Expiry time - the time beyond which the packet is dropped by MTL

Launch Time

The launch time is specified in the enhanced normal descriptor in the DMA configurations. For more details, see Enhanced Descriptor for Time-Based Scheduling. The launch time can also be specified as a control word for each packet. When the launch time is specified in the DMA configuration, it is valid only for the specific frame that is scheduled for transmission. The launch time is reset after the transmission of one frame.

The formats of the launch time include:

- Normal/absolute format
- EST/offset format

In normal/absolute format, the launch time is an absolute time value at which the packet is launched for transmission. The launch time is interpreted in the normal/absolute format when `EMAC_TBS_CTRL.ESTM` = 0.

The launch time is a 32-bit value, where the most-significant 8-bits represent the time in seconds and the rest 24 bits represent the time in 256 ns. The launch time is compared against the IEEE 1588 based system/PTP time (bits [39:8]) and rolls over after 256 seconds.

The maximum value of the lower 32-bits of system time is 999,999,999 decimal (0x3B9AC9FF). It wraps to zero when reaching this value (representing a full second). Therefore, the maximum value of the lower 24 bits of the launch time (after multiplying by 256) must be 0x3B9AC9.

Because the maximum value of launch time is 256 seconds:

- Launch time is greater than current system time when its value is between system time[39:8] and system time[39:8] + 128 s
- Launch time is less than current system time when its value is between system time[39:8] + 128 s and system time[39:8] + 256 s. This computation is modulo 256.

In EST/offset format, the launch time is an offset value relative to the time indicated by the BTR of the GCL list provided in the GCL Slot Number (GSN). The value in the BTR is always updated to the start time of the current loop of the GCL. For each packet, the GSN value and the launch time value are specified in the enhanced transmit descriptor.

The launch time offset is a 32-bit value; the upper 8-bits represent the time in seconds and the rest 24 bits represent the time in 256 ns, which is added to the BTR value corresponding to GSN. The value of the launch time offset must be smaller than the value of the cycle time (specified in the CTR register that is implemented when EST is enabled). If the CTR is greater than or equal to 1s, the maximum value of the lower-24 bits of launch time offset should be 999,999,999 decimal (0x3B9AC9FF).

In EST/offset format, the launch time is a 64-bit value, which is interpreted as:

Launch time = Launch GSN BTR[63:0] + (Launch time offset[31:0] << 8), which is compared with the system time [63:0].

where:

GSN BTR – the base time value at which the launch GSN loop started execution.

GSN – A modulo 16 count of the GCL loop count. The count is incremented for every new GCL loop; installation of new GCL list does not impact the count. The current GCL slot number can be obtained by reading the EMAC_EST_STAT.CGSN field. The maximum value of GSN is 15. Therefore, GSN values between the EMAC_EST_STAT.CGSN field and CGSN+8 represent current or future slots; all other GSN values are interpreted as elapsed slots or past slots. So, for the correct interpretation of time, GSN value must be between EMAC_EST_STAT.CGSN and CGSN+8 for the correct interpretation of time.

Launch Expiry Time

In the normal/absolute format, when EMAC_TBS_CTRL.LEOV = 1, the EMAC_TBS_CTRL.LEOS bit determines the maximum amount of time a frame is eligible for launch, starting from the time the frame becomes eligible for launch.

The launch expiry offset is a 24-bit value defined in 256 ns units, with a maximum possible value of 999,999,999 ns (0x3B9AC9FF).

Launch expiry time = (launch time[39:8] + EMAC_TBS_CTRL.LEOS [32:8]) * 256 ns

The packet with a specific launch time is considered eligible for transmission when the launch time is less than the system time and (if EMAC_TBS_CTRL.LEOV = 1) the system time is less than the launch expiry time.

When the system time is greater than the launch expiry time the frame is categorized as expired and is dropped from the MTL FIFO.

NOTE:
1. For correct interpretation and meaningful operation, the fetch, launch, and launch expiry time should never be set to a value larger than current system time + 128 s; such a value is interpreted as time that has already elapsed.
2. In full duplex mode, the frames dropped from the MTL FIFO have an error summary (bit 15) and Excessive Deferral (bit 3) of the TxStatus set.

In the EST/offset format, when EMAC_TBS_CTRL.LEOV = 1, the launch expiry GSN offset (EMAC_TBS_CTRL.LEGOS) and launch expiry offset (EMAC_TBS_CTRL.LEOS bits determine the maximum amount of time a frame remains eligible for launch, starting from the time the frame becomes eligible for launch.

The launch expiry offset is computed as:

Launch expiry offset = (EMAC_TBS_CTRL.LEGOS: EMAC_TBS_CTRL.LEOS)

The launch expiry offset is a 24-bit value defined in the units of 256 ns, with a maximum possible value of the smaller of 999,999,999 ns or CTR-1 ns. The EMAC_TBS_CTRL.LEGOS field holds the GSN offset (multiples of CTR time). The EMAC_TBS_CTRL.LEOS field holds maximum value of CTR (sub-CTR values) in ns.

The launch expiry GSN is computed as:

Launch expiry GSN = (launch GSN + EMAC_TBS_CTRL.LEGOS + CCMA)

where,

CCMA - the CTR carry due to modulo addition. This value is 1 if ((launch time offset + EMAC_TBS_CTRL.LEOS) << 8) ≥ CTR.

- When CCMA = 1, launch expiry offset = (launch time offset+ EMAC_TBS_CTRL.LEOS) - CTR
- When CCMA = 0, launch expiry offset = (launch time offset + EMAC_TBS_CTRL.LEOS).

Launch expiry time = launch expiry GSN BTR[63:0] + launch expiry time offset

- When EMAC_TBS_CTRL.LEOV = 0, the launch expiry time is not checked.
- When EMAC_TBS_CTRL.LEOV =1, and
  - The system time is greater than the launch expiry time, the frame is dropped from MTL FIFO. The frame is considered as expired.
  - The launch time is smaller than the system time and launch expiry time is greater than system time, the frame is considered eligible for launch.

NOTE:

1. The max value of EMAC_TBS_CTRL.LEGOS is 7. This implies that when EMAC_TBS_CTRL.LEOV = 1, the frame has a maximum lifetime of < 8 GCL loop iterations after it becomes eligible for launch.
2. The slot number of the first GCL list executed each time after EST is enabled, is zero.

Fetch Time

Software can indicate the fetch time for each packet (EMAC_DMA_TBS_CTL0.FTOV =1). When EMAC_DMA_TBS_CTL0.FTOV = 0, the fetch time offset is not valid and the DMA fetches packets without any time constraints. The fetch time accounts for all possible delays in the DMA fetch operation and ensures that the frame is present in the MTL FIFO before the launch time.

In normal/absolute mode, fetch time is derived/calculated by reducing the time specified in the EMAC_DMA_TBS_CTL0.FTOS field from the given launch time. In a normal mode of operation, the fetch launch time is computed as:

Fetch time[39:8] = (launch time[39:8] - EMAC_DMA_TBS_CTL0.FTOS[31:8])

The fetch time is 32 bits. It is compared against system time[39:8] to determine the eligible for fetching the frame:

- The fetch time is defined as greater than system time when the fetch time is in the range of system time[39:8] and system time[39:8] + 128 s. The frame is considered ineligible for fetch.
- The fetch time is defined as smaller than the system time when the fetch time is in the range of system time[39:8] + 128 s and system time[39:8] + 256 s. The frame is considered as eligible for fetch.

This computation is modulo 256 .

In the EST/offset mode, theEMAC_DMA_TBS_CTL0.FGOS field provides the slot number offset to be deducted from the launch GSN. In this case, the EMAC_DMA_TBS_CTL0.FTOS value should be the smaller of 999,999,999 ns or CTR-1 ns.

When (launch time offset ≥ EMAC_DMA_TBS_CTL0.FTOS):

- Fetch time offset = ((launch time offset - EMAC_DMA_TBS_CTL0.FTOS) x 256 ns)
- CBFS (CTR borrow for fetch subtraction) = 0

When (launch time offset < EMAC_DMA_TBS_CTL0.FTOS):

- Fetch time offset = CTR + ((launch time offset - EMAC_DMA_TBS_CTL0.FTOS) x 256 ns)
- CBFS = 1

The fetch GSN is computed as follows:

Fetch GSN = launch GSN - EMAC_DMA_TBS_CTL0.FGOS - CBFS

Fetch time = Fetch GSN BTR[63:0] + Fetch time offset

The frame is marked eligible for DMA fetch when the fetch time is smaller than the system time.

The max value of EMAC_DMA_TBS_CTL0.FGOS is 7. This implies that when EMAC_DMA_TBS_CTL0.FTOV =1, the frame can be fetched at a maximum of <8 GCL loop iterations before it becomes eligible for launch.

DMA Operations Sequence

When EMAC_DMA_TBS_CTL0.FTOV = 1, the following DMA operations sequence occurs:

1. Fetch the first enhanced normal descriptor. (FD is set).
2. If LTV is set and fetch enabled, compute the fetch time based on the launch time. Wait for the system time to be greater than fetch time.
3. Read the frame (data) from the host memory and transfer to MTL FIFO.
4. Close the normal descriptor.
5. Fetch the next normal descriptor (if the previous descriptor was not the last).
6. Repeat steps 4 to 6, until the last descriptor of the frame (LD is set).

After the last descriptor of a frame, the next enhanced normal descriptor should be programmed with a new launch time and with the LTV bit set. Otherwise, the subsequent frames are processed without any time restrictions.

Control Word

Time-based scheduling ensures that a packet is allowed to arbitrate for transmission only when the system time is greater than the launch time.

- Launch time and GSN use the same field that holds the 64-bit time stamp value for One Step Timestamping Correction (OSTC). When the LTV bit is set and OSTC bit is not set (bit 19 of the first control word), the time stamp field is interpreted as the launch time. Launch time uses the fields meant for OSTC time stamp[39:8]; GSN uses the OSTC time stamp[43:40] field.
- Bit 31 of control word 0 is the equivalent of the LTV field. The last two Control D words provide the launch time and GST.
- The last two control D words are the time stamp for OSTC when bit 19 of control word 0 (OSTC) is set.

When the MTL TxFIFO read controller reads the first control word, it checks bit 31 to determine if the frame has a valid launch time. If bit 31 is set, it reads the subsequent control words to get the launch time.

Impact on Transmission Selection Algorithm

The time-based scheduler does not directly influence the transmission selection algorithm. However, it has an indirect influence as it determines whether a queue is eligible to participate in the scheduling.

When a frame of a specific queue has a valid launch time, the time-based scheduler ensures that the frame participates in transmit scheduling (TRC scheduler) only after the launch time has elapsed.

The gating done by time-base scheduler is only for the scheduling (picking frame for transmission). It might not alter any other characteristics and behavior of the frame. For example, the frame waiting for the launch time to lapse continues to gain credits in CBS. The CBS credits are not lost because the frame is marked as available, but not ready. Strict priority or CBS are the recommended transmit scheduling algorithms for the TBS implementation. Scheduling for TBS-enabled queues is more predictable.

The ***Time-Based Scheduling Flow*** figure shows the time-based scheduling flow.

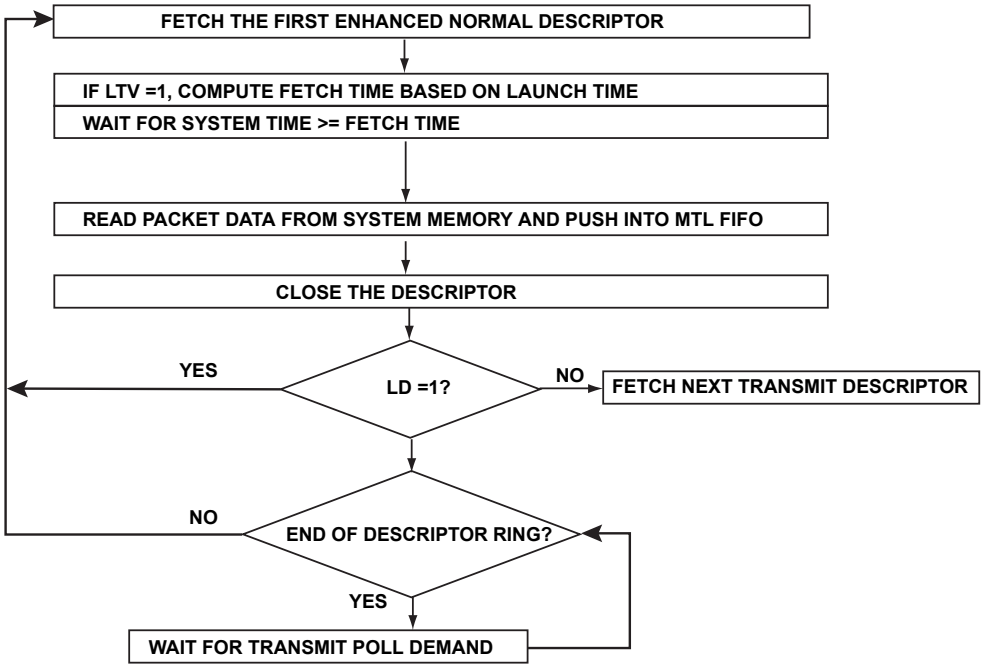

Figure 30-57: Time-Based Scheduling Flow

Flow Control

This section describes the flow control feature of EMAC for transmit and receive paths.

Transmit Flow Control

The transmit flow control involves transmitting pause packets in full-duplex mode and backpressure in half-duplex mode to control the flow of packets from the remote end.

Flow Control in Full-Duplex Mode

In full-duplex mode, the EMAC uses one of the following packet types for flow control:

- IEEE 802.3x pause packets
- Priority flow control (PFC) packets

The `EMAC_RXFLOW_CTL.PFCE` bit determines whether PFC packets or IEEE 802.3x pause control packets are used for flow control. If the PFCE bit is set, the MAC sends the PFC packets.

Pause Packet Structure

The *Pause Packet Fields* table describes the fields of a pause packet.

Table 30-103: Pause Packet Fields

Field	Description
DA	Contains the special multicast address
SA	Contains the MAC address 0
Type	Contains 8808
MAC Control Opcode	Contains 0001 for IEEE 802.3x Pause Control packets; 0101 for PFC packets
PT	Contains Pause time specified in the PT field of the MAC_Q#_Tx_Flow_Ctrl register

Pause Packet Control

When the EMAC_Q[i]_TXFLOW_CTL.FCB_BPA bit is set, the MAC generates and transmits a single pause packet. If the FCB bit is set again after the pause packet transmission is complete, the MAC sends another pause packet irrespective of whether the pause time is complete or not. To extend the pause or terminate the pause prior to the time specified in the previously transmitted pause packet, the application should program the pause time register with appropriate value and then again set the FCB_BPA bit.

Similarly, when the flow control signal from FIFO layer (mti_flowctrl_i) is asserted, the MAC generates and transmits a single pause packet. If the mti_flowctrl_i signal remains asserted at a configurable number of slot times before the pause time runs out, the MAC transmits a second pause packet. This process is repeated if the mti_flowctrl_i signal remains active. If the mti_flowctrl_i signal goes inactive prior to the sampling time, the MAC transmits a pause packet with zero pause time (if the bit is set to 0) to indicate to the remote end that the receive buffer is ready to receive new data packets. For PFC packets, the priority, pause time, and other controls can be specified for a queue in the EMAC_Q[i]_TXFLOW_CTL register. The MAC supports independent flow control for each receive queue. There is one trigger input for each receive queue. Therefore, when multiple triggers come simultaneously, the MAC sends one PFC packet for each trigger. Based on the hardware trigger or software trigger through respective queues, the MAC sends a PFC packet with programmed pause time and priority. If multiple priorities are programmed in same receive queue, multiple priorities are set for the PFC packet with same pause time values. A separate pause timer is available for each receive queue.

Flow Control in Half-Duplex Mode

In half-duplex mode, the MAC uses the deferral mechanism for the flow control (backpressure). When the application requests to stop receiving packets, the MAC sends a JAM pattern of 32 bytes when it senses a packet reception, provided the transmit flow control is enabled. This results in a collision and the remote station backs off. If the application requests a packet to be transmitted, it is scheduled and transmitted even when the backpressure is activated. If the backpressure is kept activated for a long time (and more than 16 consecutive collision events occur), the remote stations abort the transmission because of excessive collisions.

The *Transmit MAC Flow Control* table describes the flow control in the transmit path for queue 0 based on the setting of the following bits:

- EMAC_RQ0_OPMODE.EHFC

- EMAC_Q[i]_TXFLOW_CTL.TFE
- EMAC_MAC_CFG.DM

Flow control is similar for all queues.

Table 30-104: Transmit MAC Flow Control

EHFC	TFE	DM	Description
x	0	x	The MAC transmitter does not perform the flow control or backpressure operation.
0	1	0	The MAC transmitter performs back-pressure when bit 0 of the EMAC_Q[i]_TXFLOW_CTL register is set or the sideband signal sbd_flowctrl_i = 1.
1	1	0	The MAC transmitter performs back-pressure when bit 0 of the EMAC_Q[i]_TXFLOW_CTL register is set or the sideband signal sbd_flowctrl_i is 1. In addition, the MAC Tx performs back-pressure when the Rx queue level crosses the threshold set by bits[10:8] of the EMAC_RQ0_OPMODE register.
0	1	1	The MAC transmitter sends the pause packet when bit 0 of the EMAC_Q[i]_TXFLOW_CTL register is set or the sideband signal sbd_flowctrl_i = 1.
1	1	1	The MAC transmitter sends the pause packet when bit 0 of the EMAC_Q[i]_TXFLOW_CTL register is set or the sideband signal sbd_flowctrl_i = 1. In addition, the MAC Tx sends a pause packet when the Rx queue level crosses the threshold set by bits[10:8] of the EMAC_RQ0_OPMODE register.

Enabling Transmit Flow Control

To independently enable transmit flow control for each receive queue, set the EMAC_Q[i]_TXFLOW_CTL.TFE bit.

Triggering Transmit Flow Control

Transmit flow control involves transmitting pause packets in full-duplex mode and backpressure in half-duplex mode to control the flow of packets from the remote end. The application can request the MAC to send a pause packet or initiate back-pressure by using either of the following methods:

- Software Trigger: In this method, the application sets the EMAC_Q[i]_TXFLOW_CTL.FCB_BPA bit.
- Hardware Trigger: In this method, the application triggers the flow control by asserting the mti_flowctrl_i signal based on the receive queue threshold.
- Receive Queue Threshold: The flow control operation of the MAC is enabled when the EMAC_RQ0_OPMODE.EHFC bit is set. The flow control signal to the MAC is asserted when the fill level of the receive queue crosses the threshold configured in the EMAC_RQ0_OPMODE.RFA bit field. This flow control signal is de-asserted when the fill-level of the queue is lower than the threshold configured in the EMAC_RQ0_OPMODE.RFD field.

The hardware flow control generated based on the receive queue threshold crossing condition is applicable only when the receive queue size is 4,096 bytes or more.

NOTE: The RFA sets the threshold at which the flow control is triggered and the MAC schedules to send a PAUSE frame to be sent by the local transmitter.

The remote transmitter can continue to send packets until it receives this PAUSE packet. So, the RXQ needs space to take in this data even after the flow-control is triggered, to avoid overflow and loss of packets.

The max-space required that is calculated theoretically can be 2 max-sized packets + a little more when the read from the RXFIFO is not occurring during this whole time.

Theoretically, this makes RFA = 4 or more, which implies that RxQ must have at least a size of 4KB.

Practically, the system works with RFA = 2 (Full – 2KB, with little probability of overflow). When the application has a FIFO size of less than 4K, with RFA = 2, the flow control is triggered with 1000B in the RxQ, which is less than maximum packet size.

The `EMAC_RQ0_OPMODE.RFA` bit field is used for activating the flow control. These bits control the threshold (fill-level of Rx queue) at which the flow control is activated.

For example, if the RxQ size is 2K and the program sets the `EMAC_RQ0_OPMODE.RFA` bit field to 1K; as soon as 1K is received, flow control is activated. If the program sends a packet of 1500 bytes (which is allowed as per spec), flow-control is triggered even before a complete packet is received. This reduces the throughput considerably.

When the RxQ size is 4K, the program can set the RFA to 2K, and the whole packet can be received.

NOTE: Receive pause packets should have a frame size of 64 bytes.

Receive Flow Control

Receive flow control is implemented by the MAC based on the bit value of the respective register, and the destination address and different fields of the received packet.

The *Receive MAC Flow Control* table describes the flow control in the receive path based on the setting of the `EMAC_RXFLOW_CTL.RFE` and `EMAC_MAC_CFG.DM` bits.

Table 30-105: Receive MAC Flow Control

RFE	DM	Description
0	X	The MAC receiver does not detect the received pause packets
1	0	The MAC receiver does not detect the received pause packets but recognizes such packets as control packets.
1	1	The MAC receiver detects or processes the pause packets and responds to such packets by stopping the MAC transmitter.

For EMAC0, the program can enable the PFC packet detection by setting the EMAC_RXFLOW_CTL.PFCE bit. If PFC packet detection is enabled, the MTL transmit queue corresponding to the received priority is blocked when the PFC packet is received. If PFC packet detection is not enabled in configurations with multiple queues and the RFE bit is enabled, the MAC transmitter is blocked when the 802.3x pause packet is received.

The following list describes the receive flow control.

1. The MAC checks the destination address of the received pause packet for either of the following:
    - Multicast destination address: The DA matches the unique multicast address specified for the control packet (48'h0180C2000001).
    - Unicast destination address: The DA matches the content of the MAC address register 0 and the EMAC_RXFLOW_CTL.UP bit. If the UP bit is set, the MAC processes pause packets with a unicast destination address in addition to the unique multicast address.
2. The MAC decodes the following fields of the received packet:
    - Type field: This field is checked for 16'h8808.
    - Opcode field: This field is checked for 16'h0001 (pause packet) or 16'h0101 (PFC packet).
    - Pause Time or Pause Time Vector field: The pause time (for pause packet) is captured to determine the time for which the transmitter needs to be blocked. The Pause Time Vector field (for a PFC packet) is captured to determine the time for which the MTL transmit queue corresponding to the received priority needs to be blocked.
    - Priority Enable Vector field: This field is valid only for PFC packets. It is captured to determine the MTL transmit queue corresponding to the received priority.
3. If the byte count of the status indicates 64 bytes and there is no CRC error, the MAC transmitter does one of the following:
    - For 802.3x Pause packets, the MAC pauses the transmission of any data packet for the duration of the decoded pause time value multiplied by the slot time (64-byte times).
    - For PFC packets, the MAC blocks the transmit queues corresponding to the priority. Based on the priorities assigned to the transmit queues in the EMAC_TXQ_PRTY_MAP0 and EMAC_TXQ_PRTY_MAP1 registers, the MAC asserts the respective bit in the mti_disable_txq_o signal and loads the pause timer corresponding to the priority. The transmit queue corresponding to the priority is blocked until the pause timer expires.
    - In addition to the PFC-based flow control operation, when the PFCE bit is set, all bits of the mti_disable_txq_o signal are asserted while in LPI mode so that the ETS or CBS scheduler can start over after exiting the LPI mode.
4. The MAC transfers the received control packet to the application based on the setting of the EMAC_MACPKT_FILT.PCF bit field.

If subsequent pause or PFC packets are received before the earlier pause time expires, the MAC updates the pause timer with new value.

Loopback Mode

The MAC supports Loopback of transmitted packets to its receiver.

Guidelines for Using Loopback Mode

The following are some guidelines for using the loopback mode:

- Enable loopback only with the full-duplex mode. In half-duplex mode, the carrier sense signal (crs) or collision (col) signal inputs get sampled which may result in issues such as packet dropping.
- If the loopback mode is enabled without connecting a PHY chip (for example, in a FPGA setup), the program should externally generate the transmit and receive clocks and provide these clocks to the MAC.
- Do not loop back big packets. Big packets may get corrupted in the loopback FIFO.

The transmit and receive clocks can have an asynchronous timing relationship. Therefore, an asynchronous FIFO is used to make the loopback path of the `EMAC_TXD[n]` data to the receive path. The asynchronous FIFO is 10-bits (6-bits in 10/100 Mbps mode) wide to accommodate `EMAC_TXD[n]`, TXEN, and TX_ER. The depth of the FIFO is five in 1000 Mbps mode and nine in 10/100 Mbps mode. The FIFO is free running to write on the write clock TX_CLK and read on every read clock RX_CLK.

At the start of each packet read out of the FIFO, the write and read pointers are re-initialized to have an offset of 2 (4 in 10/100 Mbps mode). This avoids overflow or underflow during a packet transfer. This also ensures that the overflow or underflow occurs only during the IPG period between the packets. The FIFO depth of five or nine is sufficient to prevent data corruption for packet sizes up to 9,022 bytes with a difference of 200 ppm between MII/RMII/RGMII transmit and receive clock frequencies. Therefore, bigger packets should not be looped back because they may become corrupt in this loopback FIFO.

At the end of every received packet, the Receive Protocol Engine module generates received packet status and sends it to the Receive Packet Controller module. The control, missed packet, and filter fail status are added to the Receive status in the Receive Packet Controller module. The MAC does not process ARP packets that are looped back.

Enabling Loopback Mode

To enable this feature, program the `EMAC_MAC_CFG.LM` bit.

Programs can enable loopback for all PHY interfaces. The data is always looped back through an internal asynchronous FIFO on to the internal receive MII/RMII/RGMII interface, irrespective of which PHY interface is selected. The loopback data is also passed through the corresponding transmit PHY interface block, on to the Ethernet line.

NOTE:
- During loopback, the data/packet is reflected on TXD[n] signal.
- Preemption is not supported in loopback mode.

Endian Support

The EMAC DMA supports both little endian and big endian modes. The following table illustrates the order of bytes on 32-bit data bus for little endian and big endian modes, respectively.

Table 30-106: Endian Support

Transfer Size	Address OffsetA[1:0]	Data[31:24]	Data[23:16]	Data[15:8]	Data[7:0]
Little-Endian Mode					
Always word transfer	0	MSB	MSB - 1	LSB + 1	LSB
Big Endian Mode					
Always word transfer	0	LSB	LSB + 1	MSB - 1	MSB

The endian mode can be programmed using the `PADS_PCFG0.EMAC0_ENDIANNESS/ PADS_PCFG0.EMAC1_ENDIANNESS` registers. This bit should be set for big-endian mode and cleared for little endian mode. The reset value of this bit is '1' (big endian mode).

EMAC Event Control

The EMAC has registered with the system event controller (SEC) module. Various interrupt sources within the EMAC peripheral are shared through this interrupt line. Refer to the SEC chapter for details on how interrupts work in this product and how to configure them.

EMAC Interrupt Signals

Interrupts from the EMAC are triggered from the EMAC DMA layer MTL, or the EMAC CORE (MAC) layer. The following table shows the EMAC interrupt signals.

Table 30-107: EMAC Interrupt Signals

Interrupt Type	Description
`EMAC_STAT`	Combined interrupt signal includes MAC, MTL, and DMA interrupts.
`EMAC_MAC`	Interrupts from MAC and MTL
`EMAC_DMA[n]_TX`	DMA Transmit Per Channel Interrupts
`EMAC_DMA[n]_RX`	DMA Receive Per Channel Interrupts

Interrupts can be generated because of various events in the EMAC. These events are captured in status registers, and interrupt enables are provided for each source of an interrupt such that the interrupt signal (`EMAC_STAT`) is asserted for an event only when the corresponding interrupt enable is set.

On EMAC, the interrupt status and corresponding enable registers are organized in an hierarchical manner so that it is easier for software to traverse and identify the source of an interrupt event quickly. When `EMAC_STAT` is asserted, the `EMAC_DMA_ISTAT` register is the first level that indicates the major blocks for the interrupt event source.

This register is read-only, and it contains bits corresponding to each DMA channel (transmit and receive pair), the MTL, and the MAC. The software application must then read one (or more) of the following registers corresponding to the bits that are set:

- EMAC_MAC_ISTAT
- EMAC_MTL_ISTAT
- EMAC_DMA[n]_STAT

Interrupts from the MAC

Interrupts can be generated from the MAC because of various events in the MAC Receiver, Transmitter, or the modules/functions such as RMON counters, EEE and so on. The MAC interrupts are of level type, that is, the interrupt remains asserted (high) until it is cleared by the application or software. The EMAC_MAC_ISTAT register describes the events that can cause an interrupt from the MAC. The MAC interrupts are disabled by default. Each event can assert the interrupt on the EMAC_STAT or EMAC_MAC signals when the corresponding bit is set in the EMAC_MAC_IEN register.

The interrupt register bits only indicate the block from which the event is reported. The program must read the corresponding status registers and other registers to clear the interrupt. For example, when set high, bit 0 (EMAC_MAC_ISTAT.RGSMIIIS) indicates that the link status on the RGMII, SGMII, or SMII interface has changed. The program must read the EMAC_PHYIF_CTLSTAT register to clear this interrupt event.

NOTE: By default, the MAC interrupt status bits are cleared when the register that contains the source of the interrupt is read. If the EMAC_CSR_SW_CTL.RCWE bit is programmed to 1, the MAC interrupt status bits are cleared when the bit that contains the source of the interrupt is explicitly written to 1.

NOTE: Both the EMAC_STAT and the EMAC_MAC interrupt signals are generated for interrupts from the MAC. The EMAC_MAC interrupt is always generated one cycle ahead of the EMAC_STAT interrupt. If both the EMAC_STAT and EMAC_MAC interrupts are enabled:

- For GIC/ARM, only the EMAC_MAC interrupt service routine is called
- For SEC/SHARC, both the EMAC_STAT and EMAC_MAC interrupt services routines is called

Interrupts from the MTL

The EMAC can generate interrupts because of events in the MAC layer or in the MTL modules. The EMAC_STAT output is the interrupt signal, which is a level signal (asserted until the interrupt source is read and cleared). In the MTL, the interrupts are mainly related to exception events in the TxQ or RxQ in the transmit and receive paths, respectively. The interrupt status is captured and organized in a hierarchical manner to identify the root cause quickly.

The EMAC_MTL_ISTAT register identifies the top-level modules that can cause the interrupt to be asserted. Bits[7:0] identify 8 Queues (transmit or receive). They are read-only bits, and the application should read the corresponding EMAC_Q[n]_INT_CTLSTAT register to identify the exact cause and set the corresponding bits to 1'b1

to clear the interrupt event. The assertion of EMAC_MAC due to these events is enabled by the corresponding enable bits in the EMAC_Q[n]_INT_CTLSTAT register.

Interrupts from DMA

The EMAC_STAT interrupt is a level signal and gets de-asserted only when all the enabled interrupt events are cleared in their respective status registers and correspondingly all the bits in the EMAC_DMA_ISTAT register are cleared.

The EMAC_DMA[n]_STAT register captures all the interrupt events of that transmit DMA and receive DMA channel pair. The EMAC_DMA[n]_IEN register contains the corresponding enable bits for each interrupt event. There are two groups of interrupts in the DMA channel, normal and abnormal. They are indicated by the EMAC_DMA[n]_STAT.NIS and EMAC_DMA[n]_STAT.AIS bits. The normal group is for events that happen during the normal transfer of packets (EMAC_DMA[n]_STAT.TI, EMAC_DMA[n]_STAT.RI, EMAC_DMA[n]_STAT.TBU) while the abnormal interrupt events are for error events. Interrupt events are cleared by writing 1'b1 to the corresponding bit position. When all the enabled interrupt events are cleared (including the NIS and AIS), the interrupt source from the DMA channel is cleared and the corresponding bit in the EMAC_DMA_ISTAT register is also cleared.

Interrupts are not queued. If the same interrupt event occurs again before the driver responds to the previous one, no additional interrupts are generated. For example, the EMAC_DMA[n]_STAT.RI bit indicates that one or more packets were transferred to the application buffer. The driver must scan all descriptors, from the last recorded position to the first one, owned by the DMA to determine how many packets are received.

An interrupt is generated only once for multiple events. The driver must scan the EMAC_DMA_ISTAT register for the cause of the interrupt and clear the source in the respective status register. The EMAC_STAT is cleared only when all the bits of the EMAC_DMA_ISTAT register are cleared.

Periodic Scheduling of Transmit and Receive Interrupt

To improve the throughput and performance, EMAC supports interrupt timer and transmit descriptor to generate interrupts periodically, instead of every DMA transfer.

It is not preferable to generate interrupts for every packet transferred by DMA (EMAC_DMA[n]_STAT.RI and EMAC_DMA[n]_STAT.TI) for system throughput performance reasons. The EMAC gives the flexibility to schedule the interrupt at regular intervals using two methods:

- Set the interrupt on completion bit in transmit descriptor (TDES2[31]) once for every "required" number of packets to be transmitted.
- Similarly, set the IOC (see RDES3[30]) bit only at some specific intervals of receive descriptors. This way, whenever a received packet transfer to system memory is complete, and any of the descriptors used for that packet transfer has the IOC bit set, only then is the event is generated.

In addition, an interrupt timer (EMAC_DMA[n]_RXINTWDTMR) is given for flexible control and periodic scheduling of receive interrupts. When this interrupt timer is programmed with a nonzero value, it gets activated as soon as the receive DMA completes a transfer of a received packet to system memory without asserting the Receive Interrupt because the corresponding interrupt of completion IOC bit (see Table 30-26 Receive Descriptor Fields 3

(RDES3)) is not set. When this timer runs out as per the programmed value, the bit is set, and the interrupt is asserted when the corresponding EMAC_DMA[n]_IEN.RIE bit is enabled. The timer is stopped and cleared before it expires, iwhen the RI bit is set for a packet transfer whose descriptor's IOC was set. The timer is reactivated automatically after the next packet transfer is complete without the RI event being generated.

Per Channel Transfer Complete Interrupt

The transmit transfer complete interrupt (TI) and receive transfer complete interrupt (RI) are reflected in theEMAC_DMA[n]_STAT register. The EMAC_DMA[n]_STAT.TI bit is set whenever the transmit DMA channel closes the transmit descriptor in which the IOC (interrupt on completion - TDES2[31]) bit is set. Similarly, the EMAC_DMA[n]_STAT.RI bit is set whenever the receive DMA channel closes the receive descriptor with LD bit set and in any of the descriptors used for transferring that packet, IOC (interrupt enable on completion - RDES3[30]) bit is set.

The common EMAC_STAT output signal is asserted for the transfer complete interrupts only when the corresponding interrupts are enabled in the EMAC_DMA[n]_IEN register.

EMAC also supports the following per channel transfer complete interrupt signals.

- EMAC_DMA[n]_TX (transmit per channel interrupts)
- EMAC_DMA[n]_RX (receive per channel interrupts)

The behavior of the RI/TI/EMAC_DMA[n]_TX/EMAC_DMA[n]_RX changes depending on the settings of the EMAC_DMA_MODE.INTM bit field [17:16]. The following explains the transfer complete interrupt behavior.

Table 30-108: Transfer Complete Interrupt Behavior

S. No.	Interrupt Mode (INTM)	Behavior of EMAC_DMA[n]_TX and EMAC_DMA[n]_RX	Behavior of EMAC_STAT
1	0	A pulse is asserted on these output signals when corresponding TX/RX transfer complete event (for which IOC descriptor bits are enabled) is detected, irrespective of the corresponding interrupt status.	The TI/RI status signals are set whenever the "Transfer complete" event is detected. The bits get cleared whenever the software driver writes '1' to these bits. The EMAC_STAT is asserted whenever the corresponding interrupts are also enabled in the EMAC_DMA[n]_IEN register. The EMAC_DMA[n]_STAT.NIS status bit is asserted for RI/TI events.
2	1	These signals reflect the value of corresponding EMAC_DMA[n]_STAT.TI/ EMAC_DMA[n]_STAT.TI bits when the corresponding interrupt enable is set. Therefore, they are level signals and are cleared by the application by writing 1'b1 to the RI/TI status bits. This signal is not asserted when the corresponding interrupt enable bit is not set.	The EMAC_STAT signal and EMAC_DMA[n]_STAT.NIS status bit are not asserted for RI/TI events.

Table 30-108: Transfer Complete Interrupt Behavior (Continued)

S. No.	Interrupt Mode (INTM)	Behavior of EMAC_DMA[n]_TX and EMAC_DMA[n]_RX	Behavior of EMAC_STAT
3	2	In this mode, RI/TI interrupts are queued. These signals reflect the value of corresponding `EMAC_DMA[n]_STAT.TI`/ `EMAC_DMA[n]_STAT.TI` bits when the corresponding interrupt enable is set. They are level signals and cleared by software by writing 1'b1 to the RI/TI status bits. However, it is set again if another TI/RI event(s) is detected before the TI/RI bits are cleared for the previous event.	The RI/TI status bits are set whenever the Transfer Complete event is detected and gets reset whenever software driver clears those bits by writing 1. However, if another transfer complete event is detected before it is cleared (serviced) by the software, then EMAC automatically set these status bits again. However, the `EMAC_STAT` signal is not generated based on TI/RI. The `EMAC_DMA[n]_STAT.NIS` status bit is not asserted for RI/TI events.

EMAC Triggers

EMAC0 contains:

- 12 trigger requesters – 8 for receive DMA channels (`EMAC_DMA[n]_RX`) and 4 for MCGR DMA request (EMAC0_MCGR[n])
- 20 trigger completers – 8 for receive DMA channels (`EMAC_DMA[n]_RX_STOP`), 8 for transmit DMA channels (`EMAC_DMA[n]_TX`) and 4 for MCGR DMA Ack (EMAC0_MCGR[n]_ACK)

EMAC1 contains:

- 1 trigger requester – for Rx DMA (EMAC1_DMA0_RX)
- 2 trigger completers – 1 for Rx DMA (EMAC1_DMA0_RX_STOP) and 1 for Tx DMA (EMAC1_DMA0_TX)

NOTE:
- Each of the DMA trigger completers at EMAC interface is controller by 2 trigger signals from the TRU – 1 start trigger, 1 stop trigger. When the TRU gives a start trigger, the trigger completer at EMAC interface is asserted. When the TRU gives a stop trigger, the trigger completer at EMAC interface is de-asserted.
- An error condition occurs when the TRU generates a 2nd start trigger that occurs before a stop trigger or a 2nd stop trigger before a start trigger. This error condition does not affect the trigger signal at EMAC. It is just to check the status and is stored as a W1C status bit in ECO_REG9 of the MISC REG block.

EMAC Programming Model

This section provides the programming model and programming procedures for the Ethernet MAC peripheral.

Initializing DMA

Use the following procedure to initialize DMA.

1. Perform a software reset by setting the EMAC_DMA_MODE.SWR bit. This action resets all of the EMAC internal registers and logic.
2. Wait for the completion of the reset process by polling the EMAC_DMA_MODE.SWR bit which is only cleared (automatically) after the reset operation completes.
3. Program the following fields to initialize the EMAC_DMA_SYSBMODE register:
    a. EMAC_DMA_SYSBMODE.AAL
    b. Fixed burst or undefined burst (EMAC_DMA_SYSBMODE.FB)
    c. Maximum SCB outstanding request limit (EMAC_DMA_SYSBMODE.WR_OSR_LMT and EMAC_DMA_SYSBMODE.RD_OSR_LMT for both write and read)
    d. If fixed length value is enabled (EMAC_DMA_SYSBMODE.FB bit is set), select the maximum burst length possible on the SCB bus (EMAC_DMA_SYSBMODE.BLEN16, EMAC_DMA_SYSBMODE.BLEN8 and EMAC_DMA_SYSBMODE.BLEN4 bits).
4. Create a descriptor list for transmit and receive. In addition, ensure that the descriptors are owned by DMA (set bit 31 of descriptor TDES3/RDES3). For more information about descriptors, see DMA Descriptors.
5. Program the transmit and receive ring length registers (EMAC_DMA[n]_TXDSC_RLEN and EMAC_DMA[n]_RXCTL2.RDRL). The ring length programmed must be at least four.
6. Initialize the receive and transmit descriptor list address with the base address of the transmit and receive descriptor (EMAC_DMA[n]_TXDSC_ADDR and EMAC_DMA[n]_RXDSC_ADDR). Also, program transmit and receive tail pointer registers indicating to the DMA about the available descriptors (EMAC_DMA[n]_TXDSC_TLPTR and EMAC_DMA[n]_RXDSC_TLPTR).
7. Program the settings of the following registers for the parameters like maximum burst-length (PBL) initiated by DMA, descriptor skip lengths, OSP in case of TxDMA, RBSZ in case of RxDMA, and so on:
    a. EMAC_DMA[n]_CTL
    b. EMAC_DMA[n]_TXCTL
    c. EMAC_DMA[n]_RXCTL
8. Enable the interrupts by programming the EMAC_DMA[n]_IEN register.
9. Start the receive and transmit DMAs by setting the EMAC_DMA[n]_RXCTL.SR and the EMAC_DMA[n]_TXCTL.ST bits.
10. Repeat steps 4 to 9 for all the transmit DMA and receive DMA channels selected in the hardware.

Initializing the MTL Registers

The Transaction layer (MTL) registers must be initialized to establish the transmit and receive operating modes and commands. Use the following steps to initialize the MTL registers:

1. Program the transmit scheduling (EMAC_MTL_OPMODE.SCHALG) and receive arbitration algorithm (EMAC_MTL_OPMODE.RAA) fields to initialize the MTL operation in case of multiple transmit and receive queues.
2. Program the receive queue to DMA mapping in the EMAC_RXQ_DMA_MAP0 and EMAC_RXQ_DMA_MAP1 registers.
3. Program the following fields to initialize the mode of operation in the EMAC_TQ0_OPMODE register.
    a. Transmit store and forward (EMAC_TQ0_OPMODE.TSF) or transmit threshold control (EMAC_TQ0_OPMODE.TTC) in case of threshold mode.
    b. Transmit queue enable (EMAC_TQ0_OPMODE.TXQEN) to value 2‘b10 to enable transmit queue0.
    c. Transmit queue size (EMAC_TQ0_OPMODE.TQS).
4. Program the following fields to initialize the mode of operation in the EMAC_RQ0_OPMODE register:
    a. Receive store and forward (EMAC_RQ0_OPMODE.RSF) or EMAC_RQ0_OPMODE.RTC in case of threshold mode.
    b. Flow control activation and de-activation thresholds for MTL receive FIFO (EMAC_RQ0_OPMODE.RFA and EMAC_RQ0_OPMODE.RFD).
    c. Error Packet and undersized good packet forwarding enable (EMAC_RQ0_OPMODE.FEP and EMAC_RQ0_OPMODE.FUP).
    d. Receive queue size (EMAC_RQ0_OPMODE.RQS).
5. Repeat previous two steps for all MTL transmit and receive queues selected in the configuration.

Initializing the MAC

The MAC configuration registers establish the operating mode of the MAC. These registers must be initialized before initializing the DMA.

The following MAC initialization operations can be performed after DMA initialization. If the MAC initialization is completed before the DMA is configured, enable the MAC receiver (the last step in the following sequence) only after the DMA is active. Otherwise, received frames fill the receive FIFO and overflow.

1. Provide the required number of MAC address registers:EMAC_ADDR0_HI and EMAC_ADDR0_LO.
2. Program the following fields to set the appropriate filters for the incoming frames in the packet filter register:
    a. Receive all (EMAC_MACPKT_FILT.RA)

b. Promiscuous mode (EMAC_MACPKT_FILT.PR)

c. Hash or perfect filter (EMAC_MACPKT_FILT.HPF)

d. Unicast, multicast, broadcast, and control frames filter settings

3. Program the following fields for proper flow control in the flow control register:

a. Pause time and other pause frame control bits (EMAC_Q[i]_TXFLOW_CTL.PT, EMAC_Q[i]_TXFLOW_CTL.PLT)

b. Transmit flow control bits (EMAC_Q[i]_TXFLOW_CTL.TFE)

c. Flow control busy (EMAC_Q[i]_TXFLOW_CTL.FCB_BPA)

4. Program the EMAC_MAC_IEN register, as required, and if applicable, for the configuration.

5. Program the appropriate fields in the EMAC_MAC_CFG register. For example: Inter-packet gap (EMAC_MAC_CFG.IPG) while transmission and jabber disable (EMAC_MAC_CFG.JD).

6. Set bit 0 (EMAC_MAC_CFG.RE) and 1 (EMAC_MAC_CFG.TE) to start the MAC transmitter and receiver.

7. To support jumbo transmit/receive packets, configure the MAC configuration register as follows:

a. Set the EMAC_MAC_CFG.JE field to 1

b. Set the EMAC_MAC_CFG.JD and EMAC_MAC_CFG.WD fields to 1 to avoid giant packet error reporting

c. Set the EMAC_MAC_CFG.GPSLCE field to 1

d. Set the EMAC_MAC_EXT_CFG.GPSL field to a value > 9026

8. To support transmit/receive packets up to 16K, configure the MAC configuration register as follows:

a. Set the EMAC_MAC_CFG.JD and EMAC_MAC_CFG.WD fields to 1 to avoid giant packet error reporting

b. Set the EMAC_MAC_CFG.GPSLCE field to 1

c. Set the EMAC_MAC_EXT_CFG.GPSL field to 16383

Performing Normal Transmit and Receive Operations

During normal operation of the EMAC, normal and transmit interrupts are read, descriptors polled, the DMA is suspended (when it does not own descriptors), and the values of the current host transmitter or receiver descriptor pointers are read for debugging.

For normal operations, use the following steps:

1. For normal transmit and receive interrupts, read the interrupt status. Then, poll the descriptors, reading the status of the descriptor owned by the host (either transmit or receive).

2. Set appropriate values for the descriptors, ensuring that transmit and receive descriptors are owned by the DMA to resume the transmission and reception of data.

   ADDITIONAL INFORMATION: When the descriptors are not DMA (or no descriptor is available), the DMA goes into the SUSPEND state. The transmission or reception can be resumed by freeing the descriptors and writing the descriptor tail pointer to the transmit/receive tail pointer registers (EMAC_DMA[n]_TXDSC_TLPTR and EMAC_DMA[n]_RXDSC_TLPTR).

3. The values of the current host transmitter or receiver descriptor address pointer can be read for the debug process (EMAC_DMA[n]_TXDSC_CUR and EMAC_DMA[n]_RXDSC_CUR).

4. The values of the current host transmit buffer address pointer and receive buffer address pointer can be read for the debug process (EMAC_DMA[n]_TXBUF_CUR and EMAC_DMA[n]_RXBUF_CUR).

Stopping and Starting Transmission

Use the following procedure to stop and start EMAC transfers.

1. Disable the MAC transmitter and receiver by clearing the EMAC_MAC_CFG.RE and EMAC_MAC_CFG.TE bits.

2. Ensure that both the transmit and receive queues are empty (EMAC_TQ0_DBG.TXQSTS and EMAC_RQ0_DBG.RXQSTS is 0).

3. Disable the receive DMA (whenapplicable), after ensuring that the data in the Rx FIFO is transferred to the system memory (by reading the appropriate bits of EMAC_RQ0_DBG register, EMAC_RQ0_DBG.PRXQ = 0 and EMAC_RQ0_DBG.RXQSTS = 00).

4. To restart the operation, first start the DMAs, and then enable the MAC transmitter and receiver.

   ADDITIONAL INFORMATION: Do not change the configuration (such as duplex mode, speed, port, or loop back) when the MAC is actively transmitting or receiving. These parameters are changed by software only when the MAC transmitter and receiver are not active. Similarly, do not change the DMA-related configuration when transmit and receive DMA are active.

Switching to New Descriptor List in Receive DMA

Switching to a new descriptor list is different in the receive DMA compared to the transmit DMA. Switching to a new descriptor list is permitted when the receive DMA is in SUSPEND state, as clarified by the following points:

- Generally, receive DMA prepares the descriptors in advance.
- If the receive DMA goes to the SUSPEND state due to the descriptors not being available, a major failure occurs (software is not able to free the filled-up descriptors/buffers). If this issue is not rectified immediately, frames are lost because of a receive FIFO overflow. Therefore, the software is allowed to create a new descriptor list and program the receive DMA to start using it immediately, without going into the STOP state.

Multi-Channel Multi-Queuing

Transmit

Use the following procedure for a transmit operation.

1. Program the transmit queue size in the EMAC_TQ0_OPMODE.TQS bit field. Based on the value programmed in this bit field, the size of the queue is determined. In the transmit operation, the number of channels is equal to the number of the queues. Due to this reason, the channel-to-queue mapping is fixed.
2. For a queue to be used, enable the queue using the EMAC_TQ0_OPMODE.TXQEN bit. Enable the EMAC_DMA[n]_TXCTL.ST bit and the corresponding EMAC_TQ0_OPMODE.TXQEN bit.
3. Program the scheduling method in the EMAC_MTL_OPMODE.SCHALG bit field.
4. Program the EMAC_TQ0_QTMWGT register for DCB queues as per the selected algorithm. For CBS algorithms in AVB queues, the EMAC_TQ[n]_ETS_CTL, EMAC_TQ[n]_SSCRDT, EMAC_TQ[n]_HICRDT and EMAC_TQ[n]_LOCRDT registers also need to be programmed as required.
5. If DCB is enabled and the PFC function is required, program the EMAC_TXQ_PRTY_MAP0 register to assign a fixed priority to the queue. This priority is used for determining if the corresponding queue should stop transmitting a packet based on the received PFC packet.

Receive

Use the following procedure for the receive operation.

1. Program the receive queue size in the EMAC_RQ0_OPMODE.RQS bit field. Based on the value programmed in this bit field, the size of the queue is determined.
2. Enable the receive queues 0 to 7 in the EMAC_RXQ_CTL0.RXQ0EN to EMAC_RXQ_CTL0.RXQ7EN bit fields for AV or DCB. In DMA configurations, enable the EMAC_DMA[n]_RXCTL.SR bit of statically or dynamically mapped EMAC_DMA[n]_RXCTL register and the corresponding EMAC_RXQ_CTL0.RXQ0EN to EMAC_RXQ_CTL0.RXQ7EN bits.
3. The MAC routes the receive packets to the receive queues based on following packet types:
   - AV PTP packets – based on the programming of the EMAC_RXQ_CTL1.PTPQ bit.
   - AV untagged control packets – based on the programming of the EMAC_RXQ_CTL1.AVCPQ bit.
   - Data Center Bridging (DCB) related Link Layer Discovery Protocol (LLDP) packets. Program the EMAC_RXQ_CTL1.DCBCPQ bits to indicate to the MAC which queue receives the DCB packets.
   - VLAN Tag Priority field in VLAN tagged packets – program the PSRQ7-0 bits in the EMAC_RXQ_CTL2 and EMAC_RXQ_CTL3 registers for the routing of tagged packets based on the USP (user priority) field of the received packets to the receive queues 0 to 7.
   - The AV tagged control and data packets are also routed based on PSRQ field of the EMAC_RXQ_CTL2 and EMAC_RXQ_CTL3 registers. The priorities set in PSRQ7-0 should be unique.

4. If multiple receive DMA channels are enabled, the following programming is required for proper arbitration and mapping:
    a. Program the EMAC_MTL_OPMODE.RAA bit field to select the arbitration algorithm to decide which RxQ is read out from the RxFIFO memory.
    b. Program the EMAC_RQ0_CTL register to decide the weights and the packet arbitration for each RxQ.
    c. If static mapping is programmed in the EMAC_RXQ_DMA_MAP0/EMAC_RXQ_DMA_MAP1 registers (the DDMACH bits are reset to 0), the RXQx2DMA and others need to be programmed to select the channel for which each queue is mapped.
    d. Set the EMAC_RXQ_DMA_MAP0 DDMACH bits to select dynamic mapping of packets in each receive queue.
    e. In dynamic channel mapping, the routing of a packet to a specific receive DMA channel is decided by the value of the DCS field in the lowest MAC address register (for example EMAC_ADDR0_HI.DCS).

Recovering from DMA Channel Failure

When the DMA channel issues a bus error, follow these steps to recover from the failure.

Recovering from the Receive DMA Channel Failure

Follow these steps a bus error occurs in the receive DMA channel:

1. Set the EMAC_DMA[n]_RXCTL.RPF bit to 1. This flushes all the packets one after the other. This step is optional. However, setting this bit prevents HOL (head-of-line) blocking in the receive queues when packets sent to the receive DMA are stopped due to bus error.
2. Re-program the specific registers of the DMA channel.
3. Start the DMA channel.

Recovering from the Transmit DMA Channel Failure

Follow these steps if a bus error occurs in the transmit DMA channel:

1. Stop the specific DMA channel, even if it is in an active state.
2. Flush the corresponding MTL queue.
3. Re-program the specific registers of the DMA channel.
4. Start the DMA channel.

NOTE: Reprogramming the DMA channel registers might not always be successful in recovering from a bus error. If EMAC is not fully functional after reprogramming the DMA, as a workaround, issue a soft reset to recover from the bus error.

Disabling the Receive Queue

Follow these steps to disable specific receive queues

1. Disable the receiver by setting the EMAC_MAC_CFG.RE bit to 0.
2. Read the debug register (ensure that the EMAC_MAC_DBG.RPESTS and EMAC_MAC_DBG.RFCFCSTS fields are 0) and the EMAC_RQ0_DBG registers of all the receive queues.
3. When the EMAC_RQ0_DBG registers are read as 0, disable the intended receive queue by programming the corresponding fields in the EMAC_RXQ_CTL0 register.
4. Enable the receiver by setting the EMAC_MAC_CFG.RE bit to 1.

IEEE 1588 Time Stamping (PTP)

The following sections provide programming information for using for IEEE 1588 Time Stamping.

Initialization Guidelines for System Time Generation

Programs can enable the time stamp feature by setting the EMAC_TM_CTL.TSENA bit. However, it is essential that the time stamp counter be initialized after this bit is set. Complete the following steps during EMAC initialization:

1. Mask the time stamp trigger interrupt by clearing the EMAC_MAC_IEN.TSIE bit.
2. Set the EMAC_TM_CTL.TSENA bit 0 to enable time stamping.
3. Program the EMAC_TM_SUBSEC register based on the PTP clock frequency.
4. If the Fine Correction method is required, program the EMAC_TM_ADDEND register and set the EMAC_TM_CTL.TSADDREG bit.
5. Poll the EMAC_TM_CTL register until the EMAC_TM_CTL.TSADDREG bit is cleared.
6. Program the EMAC_TM_CTL.TSCFUPDT bit to select the Fine Update method (if required).
7. Program the EMAC_TM_SECUPDT and EMAC_TM_NSECUPDT registers with the appropriate time value.
8. Set the EMAC_TM_CTL.TSINIT bit.

   ADDITIONAL INFORMATION: The time stamp counter starts operation as soon as it is initialized with the value written in the time stamp update registers. If one-step time stamping is enabled:

   a. To enable one-step time stamping, program bit 27 of the TDES3 Context Descriptor.

   b. Program the EMAC_TM_INGASYM_CORR and EMAC_TM_EGASYM_CORR registers to update the correction field in PDelay_Req PTP messages.
9. Enable the MAC receiver and transmitter for proper time stamping.

If a time stamp operation is disabled by clearing the EMAC_TM_CTL.TSENA bit, repeat all these steps to restart the time stamp operation.

System Time Correction

The following sections provide programming information for system time correction.

Coarse Correction Method

To synchronize or update the system time in one process (coarse correction method), complete the following steps:

1. Set the offset (positive or negative) in the timestamp update registers (EMAC_TM_SECUPDT and EMAC_TM_NSECUPDT).
2. Set the EMAC_TM_CTL.TSUPDT bit. The value in the time stamp update registers is added to or subtracted from the system time when the TSUPDT bit is cleared.

Fine Correction Method

To synchronize or update the system time to reduce system-time jitter (fine correction method), complete the following steps:

1. With the help of the algorithm explained in Fine Correction Method, calculate the rate by which to make the system time increments slower or faster.
2. Update the EMAC_TM_ADDEND register with the new value and set the EMAC_TM_CTL.TSADDREG bit.
3. Wait for the time for the new value of the Addend register to be active. You can do this by enabling the Timestamp Trigger interrupt after the system time reaches the target value.
4. Program the required target time in the EMAC_PPS[n]_TGTM_SEC and EMAC_PPS[n]_TGTM_NSEC registers.
5. Enable the time stamp interrupt using the EMAC_MAC_IEN.TSIE bit.
6. Set bit 4 in the EMAC_TM_CTL register.
7. When this trigger causes an interrupt, read the EMAC_MAC_ISTAT register.
8. Reprogram the EMAC_MAC_ISTAT register with the old value and set the EMAC_TM_CTL.TSADDREG bit again.

PTP Offloading

The following sections provide programming information for using PTP offload.

Automatic Periodic Generation of PTP Sync Messages

Follow these steps to enable automatic periodic generation of PTP sync messages:

1. Program the EMAC_TM_CTL.SNAPTYPSEL, EMAC_TM_CTL.TSMSTRENA, and EMAC_TM_CTL.TSEVNTENA bit fields to zero, one, and one respectively, to configure the node as ordinary or boundary requester (one, one, and one for transparent requester).
2. Program the EMAC_PTO_CTL.PTOEN bit and EMAC_PTO_CTL.DN bit field to enable the PTP offload feature and domain number to send in egress PTP Sync message.
3. Program the EMAC_PTO_CTL.ASYNCEN bit to enable periodic generation of PTP Sync messages.
4. Program the 80-bit Source Port Identity in theEMAC_SRCPRT_IDNTY0 through EMAC_SRCPRT_IDNTY2 registers to send in egress PTP Sync message.
5. Program the EMAC_LOG_MSG_INTVL.LSI bit field to program the periodicity of the PTP Sync messages. For example, value of 1 corresponds to 21 which translates to PTP Sync message every 2 seconds and value of 0xFF (twos complement of -1) corresponds to 2-1 which translates to PTP Sync message every 0.536 seconds.
6. Program the EMAC_MAC_IEN.TSIE bit to enable generation of time stamp interrupt.
7. Wait for a EMAC_STAT or EMAC_MAC interrupt generated when the EMAC_TM_STAT.TXTSSIS bit is set, which indicates that the time stamp for PTP Sync message is captured in the EMAC_TXTMSTAT_SEC and EMAC_TXTMSTAT_NSEC registers.

Periodic Generation of PTP Pdelay_Req Messages

Follow these steps to enable automatic periodic generation of PTP Pdelay_Req messages.

1. Program the EMAC_TM_CTL.SNAPTYPSEL, EMAC_TM_CTL.TSMSTRENA, and EMAC_TM_CTL.TSEVNTENA bit fields to 1, 0, and 1 respectively to configure the node as transparent completer (1, 1, and 1 for transparent requester OR 3, X, and X for Peer-to-Peer Transparent).
2. Program the EMAC_PTO_CTL.PTOEN bit and EMAC_PTO_CTL.DN bit field to enable PTP Offload feature and domain Number to send in egress PTP Pdelay_Req message.
3. Program the EMAC_PTO_CTL.APDREQEN bit to enable periodic generation of PTP Pdelay_Req messages.
4. Program the 80-bit Source Port Identity in theEMAC_SRCPRT_IDNTY0 through EMAC_SRCPRT_IDNTY2 registers to send in egress PTP Pdelay_Req message.
5. Program the EMAC_LOG_MSG_INTVL.LMPDRI bit field to program the periodicity of the PTP Pdelay_Req messages. For example, value of 1 corresponds to 21 which translates to PTP Pdelay_Req message every 2 seconds and value of 0xFF (twos complement of -1) corresponds to 2-1 which translates to PTP Pdelay_Req message every 0.536 seconds.
6. Program the EMAC_MAC_IEN.TSIE bit to enable generation of Timestamp Interrupt.
7. Wait for EMAC_STAT or EMAC_MAC interrupt generated on setting of the EMAC_TM_STAT.TXTSSIS bit is set, which indicates that the time stamp for PTP Sync message is captured in the EMAC_TXTMSTAT_SEC and EMAC_TXTMSTAT_NSEC registers.

Response Generation - Ordinary or Boundary Requester Mode

Follow these steps to enable generation of PTP response messages for Ordinary or Boundary Requester mode (periodic PTP sync messages generated and PTP Delay_Resp message generated in response to PTP Delay_Req message).

1. Program the EMAC_TM_CTL.SNAPTYPSEL, EMAC_TM_CTL.TSMSTRENA and EMAC_TM_CTL.TSEVNTENA bit fields to zero, one, and one respectively.
2. Program the EMAC_PTO_CTL.PTOEN bit and EMAC_PTO_CTL.DN field to enable the PTP offload feature and domain number to match with ingress PTP Delay_Req message and send in egress PTP Delay_Resp message.
3. Program the 80-bit source port identity in the EMAC_SRCPRT_IDNTY0 through EMAC_SRCPRT_IDNTY2 registers to match with ingress PTP Delay_Req message and send in egress PTP Delay_Resp message.
4. Program the EMAC_LOG_MSG_INTVL.DRSYNCR and EMAC_LOG_MSG_INTVL.LSI bit fields. The sum of both these fields is updated in the logMinDelayReqInterval field of the PTP Delay_Resp message.

Response Generation - Ordinary or Boundary Completer Mode

Follow these steps to enable generation of PTP response messages for Ordinary or Boundary completer mode (PTP Delay_Req message generated in response to PTP Sync message).

1. Program the EMAC_TM_CTL.SNAPTYPSEL, EMAC_TM_CTL.TSMSTRENA and EMAC_TM_CTL.TSEVNTENA bit fields to zero, zero, and one respectively.
2. Program the EMAC_PTO_CTL.PTOEN bit and EMAC_PTO_CTL.DN bit field to enable PTP Offload feature and domain Number to match with ingress PTP Sync message and send in egress PTP Delay_Req message.
3. Program the 80-bit source port identity in the EMAC_SRCPRT_IDNTY0 through EMAC_SRCPRT_IDNTY2 registers to match with ingress PTP Sync message and send in egress PTP Delay_Req message.
4. Program the EMAC_LOG_MSG_INTVL.DRSYNCR bit field to indicate one PTP Delay_Req message is generated in response to how many received PTP Sync messages.

Response Generation - Transparent Completer Mode

Follow these steps to enable generation of PTP response messages for transparent completer mode (PTP Delay_Req message generated in response to PTP Sync message, PTP Pdelay_Resp message generated in response to PTP Pdelay_Req message and Periodic PTP Pdelay_Req messages generated).

1. Program the EMAC_TM_CTL.SNAPTYPSEL, EMAC_TM_CTL.TSMSTRENA and EMAC_TM_CTL.TSEVNTENA bit fields to one, zero, and one respectively.

2. Program the EMAC_PTO_CTL.PTOEN bit and EMAC_PTO_CTL.DN bit field to enable the PTP offload feature and domain number to match with ingress PTP Sync or Pdelay_Req message and send in egress PTP Delay_Req or Pdelay_Resp or Pdelay_Req message.
3. Program the 80-bit source port identity in the EMAC_SRCPRT_IDNTY0 through EMAC_SRCPRT_IDNTY2 registers to match with ingress PTP Sync or Pdelay_Req message and send in egress PTP Delay_Req or Pdelay_Resp or Pdelay_Req message.
4. Program the EMAC_LOG_MSG_INTVL.DRSYNCR bit field and EMAC_LOG_MSG_INTVL.LMPDRI bit fields to indicate one PTP Delay_Req message is generated in response to how many received PTP Sync messages and periodicity of the PTP Pdelay_Req messages.
5. Program the EMAC_MAC_IEN.TSIE bit to enable generation of the timestamp interrupt.
6. Wait for the EMAC_STAT or EMAC_MAC interrupt that is generated when the EMAC_TM_STAT.TXTSSIS bit is set. This indicates that the timestamp for PTP Sync message is captured in the EMAC_TXTMSTAT_SEC and EMAC_TXTMSTAT_NSEC registers for egress PTP Pdelay_Req and Pdelay_Resp messages.

Response Generation - Transparent Requester Mode

Follow these steps to enable generation of PTP response messages for transparent requester mode (PTP Delay_Resp message generated in response to PTP Delay_Req message, PTP Pdelay_Resp message generated in response to PTP Pdelay_Req message and Periodic PTP Pdelay_Req or Sync messages generated).

1. Program the EMAC_TM_CTL.SNAPTYPSEL, EMAC_TM_CTL.TSMSTRENA and EMAC_TM_CTL.TSEVNTENA bit fields to one, one, and 1one respectively.
2. Program the EMAC_PTO_CTL.PTOEN bit and EMAC_PTO_CTL.DN bit field to enable the PTP offload feature and domain number to match with ingress PTP Delay_Req or Pdelay_Req message and send in egress PTP Delay_Resp or Pdelay_Resp or Pdelay_Req or Sync message.
3. Program the 80-bit source port identity in the EMAC_SRCPRT_IDNTY0 through EMAC_SRCPRT_IDNTY2 registers to match with ingress PTP Delay_Req or Pdelay_Req message and send in egress PTP Delay_Resp or Pdelay_Resp or Pdelay_Req or Sync message.
4. Program the EMAC_LOG_MSG_INTVL.DRSYNCR, EMAC_LOG_MSG_INTVL.LSI and EMAC_LOG_MSG_INTVL.LMPDRI bit fields. The sum of EMAC_LOG_MSG_INTVL.DRSYNCR and EMAC_LOG_MSG_INTVL.LSI is updated in logMinDelayReqInterval field of PTP Delay_Resp message and periodicity of the PTP Sync or Pdelay_Req messages.
5. Program the EMAC_MAC_IEN.TSIE bit to enable generation of the timestamp interrupt.
6. Wait for the EMAC_STAT or EMAC_MAC interrupt that is generated when the EMAC_TM_STAT.TXTSSIS bit is set. This indicates that the timestamp for PTP Sync message is captured in the EMAC_TXTMSTAT_SEC and EMAC_TXTMSTAT_NSEC registers for egress PTP Sync, Pdelay_Req and Pdelay_Resp messages.

Response Generation - Peer-to-Peer Transparent Mode

Follow these steps to enable generation of PTP response messages for Peer-to-Peer Transparent mode (PTP Pdelay_Resp message generated in response to PTP Pdelay_Req message and Periodic PTP Pdelay_Req messages generated).

1. Program the EMAC_TM_CTL.SNAPTYPSEL, EMAC_TM_CTL.TSMSTRENA and EMAC_TM_CTL.TSEVNTENA bit fields to 3, X, and X respectively.
2. Program the EMAC_PTO_CTL.PTOEN bit and EMAC_PTO_CTL.DN bit field to enable the PTP offload feature and domain number to match with ingress PTP Pdelay_Req message and send in egress PTP Pdelay_Resp message.
3. Program the 80-bit source port identity in the EMAC_SRCPRT_IDNTY0 through EMAC_SRCPRT_IDNTY2 registers to match with ingress PTP Pdelay_Req message and send in egress PTP Pdelay_Resp message.
4. Program the EMAC_LOG_MSG_INTVL.LMPDRI bit field to indicate periodicity of the PTP Pdelay_Req messages.
5. Program the EMAC_MAC_IEN.TSIE bit to enable generation of the timestamp interrupt.
6. Wait for the EMAC_STAT or EMAC_MAC interrupt that is generated when the EMAC_TM_STAT.TXTSSIS bit is set. This indicates that the timestamp for PTP Sync message is captured in the EMAC_TXTMSTAT_SEC and EMAC_TXTMSTAT_NSEC registers for egress PTP Pdelay_Req and Pdelay_Resp messages.

Using the Audio Video Feature

The following sections provide procedures to program audio video features.

Initializing the DMA in Audio Video Feature

1. Provide a software reset to reset all internal registers and logic (EMAC_DMA_MODE.SWR bit).
2. Wait for the completion of the reset process. Poll the EMAC_DMA_MODE.SWR bit, which is cleared only after the reset operation is completed.
3. Program the fields to initialize the DMA register by setting the values in the EMAC_DMA_MODE register.
4. Create a proper descriptor list for transmit and receive. In addition, ensure that the DMA owns the transmit and receive descriptors.

   ADDITIONAL INFORMATION: When OSF mode is used, at least two transmit descriptors are required. For more information about descriptors, see the DMA Descriptors section.
5. Ensure that the software creates three or more different transmit or receive descriptors in the list before reusing any of the descriptors.

6. Program the transmit and receive ring length registers (EMAC_DMA[n]_TXDSC_RLEN and EMAC_DMA[n]_RXCTL2.RDRL). The programmed ring length must be at least 4.
7. Initialize receive and transmit descriptor list address with the base address of the transmit and receive descriptor (EMAC_DMA[n]_TXDSC_ADDR and EMAC_DMA[n]_RXDSC_ADDR). In addition, program the transmit and receive tail pointer registers that indicate to the DMA the available descriptors (EMAC_DMA[n]_TXDSC_TLPTR and EMAC_DMA[n]_RXDSC_TLPTR).
8. Program the following fields to initialize the mode of operation in the EMAC_TQ0_OPMODE register:
    a. Transmit store and forward (EMAC_TQ0_OPMODE.TSF)
    b. Transmit threshold control (EMAC_TQ0_OPMODE.TTC)
    c. Transmit queue enable (EMAC_TQ0_OPMODE.TXQEN) to value 2‘b10 to enable transmit queue0
    d. Transmit queue size (EMAC_TQ0_OPMODE.TQS)
9. Enable the interrupts by programming the EMAC_DMA[n]_IEN register.
10. Repeat steps 4 through 9 for all additional channels of AV feature.
11. Program the EMAC_TQ[n]_ETS_CTL register, idleSlope (EMAC_TQ0_QTMWGT), sendSlope (EMAC_TQ[n]_SSCRDT, hiCredit (EMAC_TQ[n]_HICRDT), and loCredit (EMAC_TQ[n]_LOCRDT) registers of the AVQueues.
12. Start the receive and transmit DMA by setting the EMAC_DMA[n]_TXCTL.ST bit and the EMAC_DMA[n]_RXCTL.SR bit.

Enabling Slot Number Checking

The program enables the ability to report the average bits that are transmitted in a slot. The EMAC_TQ0_ETS_STAT register of the additional AV channels provides information about the average bits that are transmitted in a slot. The software can asynchronously read this register to retrieve information about the average bits transmitted per slot. Complete the following steps to enable average bits per slot reporting.

1. Enable time stamping by following the steps described in the “Initialization Guidelines for System Time Generation."
2. Program the EMAC_TQ[n]_ETS_CTL.SLC bits [6:4] of a channel with the number of slots over which the average transmitted bits per slot need to be computed.

    ADDITIONAL INFORMATION: The frequency of this interrupt depends on the value programmed in this step. For example, when the value 0 is used in the EMAC_TQ[n]_ETS_CTL.SLC field, the interrupt is generated at every 125 microseconds. When not required, disable this interrupt to stop the interrupt flooding.
3. Enable the EMAC_Q0_INT_CTLSTAT.ABPSIE bit of a channel to generate the average bits per slot interrupt.
4. Read the EMAC_TQ0_ETS_STAT.ABS bits [16:0] of a channel on each interrupt.

ADDITIONAL INFORMATION: The software can read the EMAC_TQ0_ETS_STAT.ABS bits in polling mode even if the EMAC_Q0_INT_CTLSTAT.ABPSIE bit is not enabled. When high, bit 1 (EMAC_Q0_INT_CTLSTAT.ABPSIS) indicates that a new value is updated in the ABS field.

Disabling Flow Control for AV Enabled Queues

Receive Flow

Program the EMAC_RQ0_OPMODE.EHFC (enable hardware flow control) bit of the corresponding receive queue's operation mode register to 0.

Transmit Flow

Program the EMAC_TXQ_PRTY_MAP0.PSTQ0 through EMAC_TXQ_PRTY_MAP1.PSTQ7 bit fields corresponding to the AV enabled transmit queue (using the EMAC_TXQ_PRTY_MAP0 and EMAC_TXQ_PRTY_MAP1 registers) to 0.

Programming Energy Efficient Ethernet

The following sections provide procedures to program energy efficient Ethernet.

Entering and Exiting the Transmit LPI Mode

EEE enables the IEEE 802.3 Media Access Control (MAC) sub layer along with a family of Physical layers to operate in the Low-Power Idle (LPI) mode. In the transmit path, the software must set the EMAC_LPI_CTLSTAT.LPIEN bit to indicate to the MAC to stop transmission and initiate the LPI protocol. Follow these steps for entering/existing the transmit LPI Mode:

1. Read the PHY register through the MDIO interface, check if the remote end has the EEE capability, and then negotiate the timer values.
2. Program the PHY registers through the MDIO interface (including the RX_CLK_stoppable bit that indicates to the PHY whether to stop receive clock in LPI mode.)
3. Program the EMAC_LPI_TMRSCTL.LST and EMAC_LPI_TMRSCTL.TWT bit fields.
4. Read the link status of the PHY chip by using the MDIO interface and update the EMAC_LPI_CTLSTAT.PLS bit accordingly. This update should be done whenever the link status in the PHY chip changes.
5. Program the EMAC_ONEUS_TIC_CNT register as per the frequency of SCLK0.
6. Program the EMAC_LPI_ENTR_TMR.LPIET bit field with the IDLE time for which the MAC should wait before entering the LPI state on its own.
7. Set the EMAC_LPI_CTLSTAT.LPIATE and EMAC_LPI_CTLSTAT.LPITXA to enable the auto-entry into LPI and auto-exit of MAC from LPI state.
8. Set the EMAC_LPI_CTLSTAT.LPIEN bit to make the MAC transmitter enter the LPI state.

The MAC enters the LPI mode after completing all scheduled packets and remains IDLE for the time indicated by the EMAC_LPI_ENTR_TMR.LPIET bit field. It sets the EMAC_LPI_ENTR_TMR.LPIET bit [0] after entry to the LPI state.

When a packet is scheduled for transmission (when the transmit DMA comes out of the IDLE state), the MAC transmitter exits the LPI state automatically. It waits for TWT time before setting the EMAC_LPI_CTLSTAT.TLPIEX interrupt status bit and then resumes the packet transmission.

9. The MAC transmitter re-enters the LPI state if it remains IDLE for EMAC_LPI_ENTR_TMR.LPIET time and sets the EMAC_LPI_CTLSTAT.LPIEN bit and the entry-exit cycle continues.
10. Reset the EMAC_LPI_CTLSTAT.TLPIEX bit in case the application wants to over-ride the auto-entry/exit modes and make the MAC transmitter exit the LPI state directly.

To ensure MAC enter the LPI state only after completion of transmission of all the queued frames in the Tx FIFO, set the EMAC_LPI_CTLSTAT.LPITXA bit [19].

Programming Flexible Pulse-Per-Second Output

The following sections provide procedures to program Flexible Pulse-Per-Second Output.

Generating Single Pulse on PPS

To program single pulse on PPS, use the following procedure.

1. Program 11 or 10 (for interrupt) using the EMAC_PPS_CTL.TRGTMODSEL0 bits [6:5]. This instructs the MAC to use the target time registers (EMAC_PPS[n]_TGTM_SEC and EMAC_PPS[n]_TGTM_NSEC) for the start time of PPS signal output.
2. Program the start time value in the target time registers (EMAC_PPS[n]_TGTM_SEC and EMAC_PPS[n]_TGTM_NSEC).
3. Program the width of the PPS signal output in the EMAC_PPS[n]_WID register.
4. Program the EMAC_PPS_CTL.PPSCMD1 bits [3:0] to 0001. This instructs the MAC to generate a single pulse on the PPS signal output at the time programmed in the target time registers.

Generating Next Pulse on PPS

When the PPSCMD is executed (PPSCMD bits = 0), the program can cancel the pulse generation by giving the cancel start command (PPSCMD = 0011) before the programmed start time elapses. The behavior of the next pulse can be programmed in advance. To program the next pulse, follow this procedure.

1. Program the start time for the next pulse in the target yime registers. This time should be more than the time at which the falling edge occurs for the previous pulse.
2. Program the width of the next PPS signal output in the EMAC_PPS[n]_WID register.

3. Program the EMAC_PPS_CTL.PPSCTRL_PPSCMD bits [3:0], PPSCMD to generate a single pulse after the time at which the previous pulse is de-asserted. This instructs the MAC to generate single pulse on the PPS signal output, at the time programmed in target time registers. When this command executes before the previous pulse becomes low, then the new command overwrites the previous command and the EMAC may generate only one extended pulse.

Generating a Pulse Train on PPS

The EMAC_PPS_CTL.TRGTMODSEL0 bits program the target time registers to do any one of the following:

- Generate only interrupts.
- Generate interrupts and the PPS start and stop time.
- Generate only PPS start and stop time.

Complete the following steps to program the target time registers to generate only interrupt event.

1. Program the EMAC_PPS_CTL.TRGTMODSEL0 bits = 00 (for interrupt). This instructs the MAC to use the target time registers for target time interrupt.
2. Program a target time value in the target time registers. This instructs the MAC to generate an interrupt when the target time elapses. If the mode select bits [6:5] are changed (for example, to control the PPS), then the interrupt generation is over-written with the new mode and new programmed target time register value.

The TSTARGTERR[n] interrupt is generated when the programmed target time is smaller (that is, time in the past) compared to system time in the EMAC_TM_SEC and EMAC_TM_NSEC registers. Therefore, to avoid unwanted TSTARGTERR[n] interrupt, the correct writing order is as follows:

1. EMAC_PPS[n]_TGTM_NSEC
2. EMAC_PPS[n]_TGTM_SEC
3. EMAC_PPS[n]_INTVL
4. EMAC_PPS[n]_WID
5. EMAC_PPS_CTL.PPSCTRL_PPSCMD and EMAC_PPS_CTL.PPSEN0

Programming TSO

The TCP Segmentation Offload (TSO) engine is used to offload the TCP segmentation functions to the hardware. To program the TSO, set the TSE bit to enable TCP packet segmentation, and program descriptor fields to enable TSO for the current packet. Use the following steps to program TSO.

1. Program the EMAC_DMA[n]_TXCTL.TSE bit to enable TCP packet segmentation in that DMA channel.
2. In addition to the normal transfer descriptor setting, the following descriptor fields must be programmed to enable TSO for the current packet:

a. Enable the TSE in bit 18 of the TDES3 register

b. Program the length of the un-segmented TCP/IP packet payload in bits [17:0] of the TDES3 register and the TCP header in bits [22:19] of TDES3.

c. Program the maximum size of the segment using the `EMAC_DMA[n]_CTL.MSS` bits or MSS in the context descriptor. If the MSS field is programmed in both the DMA channel control register and in the context descriptor, the latest software programmed sequence is considered.

3. The header of the unsegmented TCP/IP packet should be in buffer 1 of the first descriptor and this buffer must not hold any payload bytes. The payload is allocated to buffer 2 and the buffers of the subsequent descriptors.

   ADDITIONAL INFORMATION: If the TSE bit is enabled in the TDES3 register for a non-TCP-IP packet, the result is unpredictable.

Programming UFO

EMAC supports fragmentation of UDP packets into smaller IPv4 fragments. Enable the IP fragmentation by programming the `EMAC_DMA[n]_TXCTL.TSE_MODE` bits [14:13] as follows:

- Set to 2'b01 to enable fragmentation of UDP over IPv4 with checksum
- Set to 2'b10 to enable fragmentation of UDP over IPv4 without checksum

NOTE: In both the cases, if the `EMAC_DMA[n]_TXCTL.TSE` bit [12] is set to 1 for a TCP packet, DMA enables TCP segmentation; fragmentation is not enabled, because fragmentation is supported only for UDP packets.

Software Guidelines

When the software creates Transmit Descriptor of the UDP/IPv4 packet that is to be fragmented, the software must:

1. Set the desired fragment size (MFS) in the MSS field of TDES2 of the Context Descriptor. The MFS must be set only once, unless the MFS needs to be changed (for TCP packet targeted for segmentation). The MFS must be a multiple of 8 bytes for IP fragmentation.
2. Set the TSE bit of TDES3 of normal descriptor.
3. Program the THL = 2 in TDES3 of normal descriptor.
4. Program the correct value in the TPL field of TDES3 of normal descriptor. This value should be equal to length of UDP Header + UDP payload.

NOTE:
- Enable fragmentation only for IPv4; not for IPv6.
- Set the DF flag (do not fragment) in the IPv4 header packet to 0.
- Set the fragmentation offset in the IPv4 header packet to 0.

When the input packet is UDP over IPv6, do not enable IP fragmentation. Set the TSE bit to 0 in the TDES3 of normal descriptor and let the software perform the fragmentation.

Programming Header Payload Split Receive

The Header-Payload Split support can be enabled by

1. Setting the EMAC_DMA[n]_CTL.SPH bit field.
2. Selecting the Header-Payload split option by setting the EMAC_SPLM_OFST_CFG.SPLM bit field.

The DMA can process the header and payload of the received packets separately.

NOTE:
- In case of L3/L4 header-payload split, if the IPv4 header length or IPv6 payload length fields are corrupt, the split might not always happen at the correct boundary.
- When the EMAC_DMA[n]_CTL.SPH bit field is set to 1, buffer 1 of only the first descriptor is used with buffer size indicated by the EMAC_MAC_EXT_CFG.HDSMS bit field.
- Buffer 2 of the first descriptor and subsequent descriptors are used with buffer size indicated by the EMAC_DMA[n]_RXCTL.RBSZ_13_Y/EMAC_DMA[n]_RXCTL.RBSZ_X_0 bit fields.
- When the HL field of the first descriptor (RDES2) is zero, it indicates packet is not split into header and payload.
- When the HL field of the first descriptor (RDES2) is non-zero, it indicates that the packet is split into header and payload.

Programming VLAN Filtering on Receive

Use the following steps to program VLAN filtering on receive:

1. Program the EMAC_VLANTAG_CTL register as follows to select the filtering method.
   a. EMAC_VLANTAG_CTL.ETV – Enable 12-bit VLAN tag comparison or 16-bit VLAN tag comparison.
   b. EMAC_VLANTAG_CTL.VTHM – VLAN tag hash table match enable.
   c. EMAC_VLANTAG_CTL.ERIVLT – Enable inner VLAN tag or outer VLAN tag (to enable the inner or outer VLAN tag filtering, enable double VLAN processing by setting the EMAC_VLANTAG_CTL.EDVLP bit)
   d. EMAC_VLANTAG_CTL.ERSVLM – Enable receive S-VLAN Match or C-VLAN match (for S-VLAN processing to be enabled, set EMAC_VLANTAG_CTL.ESVL ESVL)
   e. EMAC_VLANTAG_CTL.DOVLTC – Ignores VLAN type for tag match
   f. EMAC_VLANTAG_CTL.VTIM – Enable VLAN tag inverse match instead of the normal VLAN tag matching

2. Program the EMAC_VLANTAG_CTL.ETV bit field to select 12-bit or 16-bit VLAN tag.
3. If hash filtering of VLAN tag is enabled, program the EMAC_VLAN_HASHTBL register.

   ADDITIONAL INFORMATION: When the EMAC_VLANTAG_CTL.ETV bit is reset, upper 4 bits of the calculated CRC-32 of VLAN tag are inverted and used to index the content of the EMAC_VLAN_HASHTBL register. When the ETV bit is set, upper 4 bits of calculated CRC-32 of VLAN tag are used to index the content of the EMAC_VLAN_HASHTBL register. For example, when the EMAC_VLANTAG_CTL.ETV bit is set, a hash value of 4b'1000 selects Bit 8 of the VLAN hash table. When the ETV bit is reset a hash value of 4'b1000 selects bit 7 of the VLAN hash table.

Programming Extended VLAN Filtering and Routing on Receive

For the indirect access of the per VLAN tag registers, follow these steps:

Write

1. Write the required data into the EMAC_VLANTAG_DAT register.
2. Program the EMAC_VLANTAG_CTL.OFS bit field with the required filter register's offset and command type to the EMAC_VLANTAG_CTL.CT bit field. For a write command, set this bit to 0.
3. Write 1 to the EMAC_VLANTAG_CTL.OB bit field and wait until the bit is reset before performing the next write. This is to ensure that the appropriate VLAN tag filter register has been programmed.

Read

1. Program the EMAC_VLANTAG_CTL.OFS bit field with the required register's offset and command type to the EMAC_VLANTAG_CTL.CT bit field. For a read command, set this bit to 1.
2. Write 1 to the EMAC_VLANTAG_CTL.OB bit field and wait until the bit is reset. The appropriate VLAN tag filter register's value is available in the EMAC_VLANTAG_DAT register.

Programming Queue/Channel Based VLAN Inclusion Registers

The following sections provide the procedures for reading and writing the Queue/Channel based VLAN inclusion register.

Writing to the Indirect Registers

To write to the queue/channel based VLAN inclusion register, use the following steps.

1. Set the EMAC_VLAN_INCL.CBTI bit to 1, to enable queue/channel based VLAN tag insertion on all transmitted packets.

   ADDITIONAL INFORMATION: This bit must be set before any indirect access to the queue/channel specific MAC_VLAN_INCL[n] register.
2. Set the EMAC_VLAN_INCL.RDWR bit field to 1, to indicate a write access.

3. Program the VLAN tag and VLAN type to be inserted in packets from a particular queue/channel using the EMAC_VLAN_INCL.VLT and EMAC_VLAN_INCL.CSVL bit fields. The corresponding offset address in the EMAC_VLAN_INCL.ADDR field (0 for queue/channel 0, 1 for queue/channel 1, and so on) must be set.
4. Set the EMAC_VLAN_INCL.RDWR bit to 1 to indicate write access.

   ADDITIONAL INFORMATION: The write to byte 0 (byte 3 in Big Endian mode) of the EMAC_VLAN_INCL register initiates access to indirect access MAC_VLAN_INCL[n] register.
5. The EMAC_VLAN_INCL.BUSY bit is set by EMAC to indicate the progress of access to indirect access MAC_VLAN_INCL[n] register. On completion of the access, the EMAC_VLAN_INCL.BUSY bit is cleared. The application must not attempt subsequent accesses to the MAC_VLAN_INCL[n] register when this bit is one.
6. Repeat step 3 through 5 to insert VLAN tag and VLAN type in packets from the remaining queues/channels. The application must ensure that the required VLAN tag and VLAN type for all the queues/channels are programmed; otherwise unintended VLAN tag and VLAN type might be inserted.

Reading the Indirect Registers

To read the queue/channel based VLAN inclusion register, complete the following steps:

1. Set the EMAC_VLAN_INCL.CBTI bit to 1, to enable queue/channel based VLAN tag insertion on all the transmitted packets. This bit must be set before indirect access to the queue/channel specific MAC_VLAN_INCL[n] register.
2. Program the read offset address in the EMAC_VLAN_INCL.ADDR ADDR field (0 for queue/channel 0, 1 for queue/channel 1, and so on). Set the EMAC_VLAN_INCL.RDWR bit to 0, to indicate read access.
3. The EMAC_VLAN_INCL.BUSY field is set by EMAC to indicate the progress of access to the indirect access MAC_VLAN_INCL[n] register. On completion of the access, the BUSY field is cleared. The bits [15:0] and bit [19] of the EMAC_VLAN_INCL register contains the VLAN tag and VLAN type respectively, from the corresponding queue/channel/offset address.
4. Repeat step 2 and step 3 to read VLAN tag and VLAN type from the remaining queues/channels.

Programming EST

Program the gate control values and time intervals in the Software Owned Gate Control List (SWOL) along with the other EST related registers to appropriate values. The following sub-sections provide step by step details for programming the GCL and the other EST related registers.

GCL and GCL Linked Registers

Follow these steps to program the Gate Control List (GCL) and the four other registers implemented per GCL.

The GCL and the four other GCL-linked registers are accessed through indirect addressing using the EMAC_EST_GCL_CTL and EMAC_EST_GCL_DAT registers. The EMAC_EST_STAT.SWOL bit field indicates if GCL0 or GCL1 is owned by software.

1. Write the 32-bit write data to EMAC_EST_GCL_DAT register. Then program the EMAC_EST_GCL_CTL register to write the write address and other control information.

   ADDITIONAL INFORMATION: In the EMAC_EST_GCL_DAT register, write data consists of up to 8 bits (configurable) of gate controls and up to 24 bits (configurable) of time interval. Gate close is indicated by programming a 0 and gate open is indicated by programming a 1. For a 4-TC and 20-bit time interval configuration, the data width is 24 bits and the remaining 8 bits are reserved/read-only. Write the data in the following format: {8'h0, TC3, TC2, TC1, TC0, 20-bit Time Interval} where TCx = 0 or 1.

2. Program the EMAC_EST_GCL_CTL.SRWO bit to 1 (to start a write op) and program the address and R/W fields appropriately.

3. Poll and check for the EMAC_EST_GCL_CTL.SRWO bit to be cleared by hardware to indicate the completion of the previous operation before initiating a new R/W operation using the same indirect addressing mode.

4. Repeat steps 3, 4, 5 until the programming of the GCL is completed.

5. Using the indirect addressing method, program the BTR, CTR, TER and LLR registers. Set the EMAC_EST_GCL_CTL.GCRR bit appropriately. This bit interprets the address field as belonging to these registers (instead of the GCL).

6. After programming of the GCL and the related registers, program the EMAC_EST_CTL register to allow hardware to own and process the GCL.

   ADDITIONAL INFORMATION: When the list length (as indicated in LLR) is 1, the associated time interval should be smaller than the value of the cycle time register. Otherwise, an error is reported (as detailed in the Error handling section) as a single set of gate controls add no value in the TSN context.

   ADDITIONAL INFORMATION: The time unit in all the GCL related registers is seconds and nanoseconds. In cases where internally generated PTP System Time is used, the nano-seconds field must be programmed to use the digital rollover mode (EMAC_TM_CTL.TSCTRLSSR bit field must be set to 1).

EST Registers

After completing the steps described in GCL and GCL Linked Registers, program the EMAC_EST_CTL register.

1. Set the current time offset value (EMAC_EST_CTL.CTOV and time internal left shift fields (EMAC_EST_CTL.TILS appropriately. Also, set the enable EST (EMAC_EST_CTL.EEST) and switch to SWOL (EMAC_EST_CTL.SSWL) bits.

   This enables EMAC to own and process the new GCL and switch to the new GCL at the BTR value. If enabled, EMAC generates an interrupt when the switch to the new list occurs.

   Software must address any other interrupts received during the hardware execution of the GCL

2. Set the EMAC_EST_CTL.SSWL bit field to handoff to the controller.

   The EMAC_EST_CTL.SSWL is reset/cleared by the controller when it successfully switches to the new list. The controller also flips the EMAC_EST_CTL.SSWL bit to indicate the new GCL that the software owns. To

install a new GCL, program the GCL it owns (indicated by SSWL bit) as described in GCL and GCL Linked Registers.

3. Program the EMAC_EST_CTL register as described. Ensure that the new BTR is set to an appropriate value to avoid BTR error that might need software intervention in some cases.

   ADDITIONAL INFORMATION: To avoid transmission overruns, the packet length (frame size) information should always be available. Therefore, in the DMA configurations, program the packet length in the first descriptor of every transmit frame. Similarly, in the MTL configuration, provide the packet length in the control word.

Programming Launch Time in Time-Based Scheduling

The launch time is programmed in the enhanced normal transmit descriptors in DMA configurations and is driven as a control word in MTL configurations as follows.

The OSTC and launch time features are mutually exclusive and should not be used together. If a context descriptor is received with a valid OSTC value immediately before receiving a first normal descriptor with the LTV bit set, then the LTV is ignored.

Programming Media Clock Generation and Recovery

The following sections provide procedures for programming the media clock.

Media Clock Generation

1. Program the appropriate presentation time control (supported generation modes "1001-1011") to the EMAC_PPS_CTL.PPSCTRL_PPSCMD (for 0th instance) and EMAC_PPS_CTL.PPSCMD1 through EMAC_PPS_CTL.PPSCMD3 bits. Program all the EMAC_PPS_CTL.MCGREN0 through EMAC_PPS_CTL.MCGREN3 bits to enable MCGR mode.

   ADDITIONAL INFORMATION: The application must drive the appropriate trigger signal to the corresponding EMAC_PTPAUX_MCG_IN[n] pin, for the instances enabled for media clock generation.

2. Based on the programmed mode, MCGR instance[n] captures the time stamp and programs it in the EMAC_PPS[n]_TGTM_SEC register. Then, the trigger requester event EMAC_MCGR[n] is generated.

   For every request generated by the MCGR instance n, EMAC reads the corresponding EMAC_PPS[n]_TGTM_SEC register and acknowledges the read request by accepting the corresponding completer trigger request.

Media Clock Recovery

1. Enable the Current Presentation Time (CPT) counter by setting the EMAC_TM_CTL.PTGE bit field. In addition to programming the initialization values for the system time, update the EMAC_PRSNTM_UPDT bits with the equivalent presentation time initial value. This is a requirement for the EMAC_TM_CTL.TSINIT bit field to be set.

ADDITIONAL INFORMATION: The increment values used for the system time is also used for the current presentation time. This is because, the increment value is in Sub-seconds and Sub-nanoseconds.

2. Along with programming the update values for the system time, update the EMAC_PRSNTM_UPDT register with the equivalent presentation time update value (32-bit ns) when an update is needed. Finally, set the EMAC_TM_CTL.TSUPDT bit field ensure update is completed.
3. Program the appropriate presentation time control (supported recovery modes "0001 - 0011") to the EMAC_PPS_CTL.PPSCTRL_PPSCMD bit field (for 0th instance) and EMAC_PPS_CTL.PPSCMD1 through EMAC_PPS_CTL.PPSCMD3 bits. Program all the EMAC_PPS_CTL.MCGREN0 through EMAC_PPS_CTL.MCGREN3 bits to enable MCGR mode.
4. For instances enabled for media clock recovery, the corresponding EMAC_MCGR[n] trigger signal is set by the EMAC. For every request generated by EMAC, program the target presentation time into the EMAC_PPS[n]_TGTM_SEC register and acknowledge the request by asserting the corresponding trigger completer signal. Acknowledgment can be given before/after programming the target presentation time.
5. Observe the recovered media clock on the corresponding EMAC_PTPPPS[n] pin.

EMAC Programming Concepts

The following sections provide basic information and guidelines to help with programming the EMAC module.

IEEE 802.3 Ethernet Packet Structure

The ***IEEE 802.3 Frame Structure*** table provides typical frame format of an Ethernet packet. Refer to the IEEE standards for detailed information on Ethernet packets and their format.

Table 30-109: IEEE 802.3 Frame Structure

Parameter	Description	Position in Ethernet Packet	Total Bytes
PREAMBLE	This parameter is a 56-bit (7-byte) pattern of alternating 1 and 0 bits (#10101010), which allows devices on the network to detect a new incoming frame for synchronization.	1	7
SFD	The SFD (#10101011) is a 1-byte pattern designed to break the preamble pattern, and signal the start of the actual frame.	2	1
DA	48-bit destination address. This parameter can be a unicast, multicast, or broadcast address.	3	6
SA	48-bit long source address, typically a unicast, multicast, or broadcast address.	4	6
LT	Typically this field is the length, in terms of the number of bytes, and can be anywhere between 0–1500. When the value is greater than or equal to 0x0600, this field also indicates the type of special payload carried by the frame. Examples include 0x8808 for flow control and 0x0800 for IPv4.	5	2
DATA	Actual application data payload, usually between 0–1500.	6	0–1500

Table 30-109: IEEE 802.3 Frame Structure (Continued)

Parameter	Description	Position in Ethernet Packet	Total Bytes
PAD	This field compensates for data frames that are shorter than 64 bytes long, not including the preamble.	7	0–46
FCS	The frame check sequence is a 32-bit cyclic redundancy check that detects corrupted data within the entire frame. This parameter is generated from a CRC-32 polynomial code (CRC-32-IEEE): G (x) = x32 + x26 + x23 + x22 + x16 + x12 + x11 + x10 + x8 + x7 + x5 + x4 + x2 + x + 1.	8	4

Frame Size Statistics for Application Software

Table 30-110: Ethernet Frame Size Statistics

Frame size statistics	VLAN-specific change Comments	
Information bytes/Header	4 byte 802.1Q header inserted after source address and before Type/LAN in 802.3 packets = 22 bytes.	6 x 2 + 2 + 4 = 18 bytes (DA+SA+LT+FCS)
Minimum Frame Size (typical)	If DATA is NULL, 42-byte padding makes 64 bytes (42 +22)	64 bytes. If DATA is NULL, 46-byte padding makes 64 bytes (46 +18)
Maximum Frame Size (typical)	1522 bytes	1518 bytes (1500 bytes DATA and 18-bytes header)
Jumbo Frame Size	9022 bytes	Typical industry standard. Ethernet jumbo frame size treated as 9018 bytes.

Software Visualization of Programmable Packet Size

The ***Visualization of Programmable Packet Size*** table provides the byte sizes of packets with various configurations.

Table 30-111: Visualization of Programmable Packet Size

Size in Bytes	Comments
16384	Receive watchdog and transmit jabber disabled, jumbo frames enabled.
10240	Receive watchdog and transmit jabber disabled, jumbo frames disabled.
2048	Receive watchdog and transmit jabber enabled.
1518	Typical max size of Ethernet frame. Receive watchdog and transmit jabber enabled.
64	Typical minimum size of Ethernet frame.
< 64	Runt frames requiring Zero-PAD.

Ethernet Packet Structure in C

The following is an example for Ethernet packet structure in the C language.

```
typedef struct ETHER_PACKET
{
    char  dst_addr[6];              //destination address
    char  src_addr[6];              //source address
    char  length[2];                //length of actual data
    char  data[DATA_SIZE];          //application data
    char  fdlimit[DELIMIT_SIZE];    //32-bit delimit (if manual appending)
    char  fcs[4];                   //crc frame checksum, used by RX buffer.
} ETHER_PACKET;
```

PTP Header Structure in C

The following code is an example of the PTP message format.

```
/* PTP Message Format (Refer to PTP Frame Over IPv4)*/
    typedef struct EMAC_PTP_HEADER
    {
    unsigned char    messageType:4,    //PTP Version 2 message type
    transportSpecific:4;
    unsigned char    versionPTP;       //PTP Version (1 or 2)
    unsigned short    messageLength;
    unsigned char    domainNumber;
    unsigned char    RESERVED1;
    unsigned short    flagField;
    unsigned char    correctionField[8];
    unsigned char    RESERVED2[4];
    unsigned char    sourcePortIdentity[10];
    unsigned short    sequenceid;
    unsigned char    controlField;     //PTP Version 1 message type
    unsigned char    logMessageInterval;
    }EMAC_PTP_HEADER;
```

ADSP-SC59x EMAC Register Descriptions

RGMII, RMII, MII Ethernet Controller (EMAC) contains the following registers.

Table 30-112: ADSP-SC59x EMAC Register List

Name	Description
EMAC_DMA[n]_CTL	DMA Channel n Control Register
EMAC_DMA[n]_RXBUF_CUR	DMA Channel n Current Application Receive Buffer Address Register
EMAC_DMA[n]_RXDSC_CUR	DMA Channel n Current Application Receive Descriptor Register
EMAC_DMA[n]_TXBUF_CUR	DMA Channel n Current Application Transmit Buffer Address Register
EMAC_DMA[n]_TXDSC_CUR	DMA Channel n Current Application Transmit Descriptor Register
EMAC_DMA[n]_IEN	DMA Channel n Interrupt Enable Register

Table 30-112: ADSP-SC59x EMAC Register List (Continued)

Name	Description
EMAC_DMA[n]_MISSFRM_CNT	DMA Channel n Missed Frame Counter Register
EMAC_DMA[n]_RXDSC_ADDR	DMA Channel n Receive Descriptor List Address Register
EMAC_DMA[n]_RXDSC_TLPTR	DMA Channel n Receive Descriptor Tail Pointer Register
EMAC_DMA[n]_RXCTL	DMA Channel n Receive Control Register
EMAC_DMA[n]_RXCTL2	DMA Channel n Extended Receive Control Register
EMAC_DMA[n]_RXINTWDTMR	DMA Channel n Receive Interrupt Watchdog Timer Register
EMAC_DMA[n]_SFN_CTLSTAT	DMA Channel n Slot Function Control and Status register
EMAC_DMA[n]_STAT	DMA Channel n Status Register
EMAC_DMA[n]_TXDSC_ADDR	DMA Channel n Transmit Descriptor List Address Register
EMAC_DMA[n]_TXDSC_RLEN	DMA Channel n Transmit Descriptor Ring Length Register
EMAC_DMA[n]_TXDSC_TLPTR	DMA Channel n Transmit Descriptor Tail Pointer Register
EMAC_DMA[n]_TXCTL	DMA Channel n Transmit Control Register
EMAC_DMA_DBG_STAT0	DMA Debug Status 0 Register
EMAC_DMA_DBG_STAT1	DMA Debug Status 1 Register
EMAC_DMA_DBG_STAT2	DMA Debug Status 2 Register
EMAC_DMA_ISTAT	DMA Interrupt Status Register
EMAC_DMA_MODE	DMA Mode Register
EMAC_DMA_SYSBMODE	DMA System Bus Mode Register
EMAC_DMA_TBS_CTL0	DMA TBS Control 0 Register
EMAC_DMA_TBS_CTL1	DMA TBS Control 1 Register
EMAC_DMA_TBS_CTL2	DMA TBS Control 2 Register
EMAC_DMA_TBS_CTL3	DMA TBS Control 3 Register
EMAC_ONEUS_TIC_CNT	LPI One Microsecond Tic Counter Register
EMAC_ARP_ADDR	Address Resolution Protocol (ARP) Register
EMAC_ADDR0_HI	MAC Address 0 High Register
EMAC_ADDR0_LO	MAC Address 0 Low Register
EMAC_ADDR[i]_HI	MAC Address n High Register
EMAC_ADDR[i]_LO	MAC Address n Low Register
EMAC_TM_AUX_CTL	Auxiliary Time Stamp Control Register
EMAC_TM_AUXTS_NSEC	Auxiliary Time Stamp Nanoseconds Register
EMAC_TM_AUXTS_SEC	Auxiliary Time Stamp Seconds Register

Table 30-112: ADSP-SC59x EMAC Register List (Continued)

Name	Description
EMAC_CSR_SW_CTL	CSR Software Control Register
EMAC_MAC_CFG	MAC Configuration Register
EMAC_MAC_DBG	Debug Register
EMAC_SPLM_OFST_CFG	MAC Split Mode and Offset Configuration Register
EMAC_MAC_EXT_CFG	MAC Extended Configuration Register
EMAC_FPE_CTLSTAT	Frame Preemption Control and Status Register
EMAC_HW_FTR_PSNT0	Hardware Feature Presence Register 0
EMAC_HW_FTR_PSNT1	Hardware Feature Presence Register 1
EMAC_HW_FTR_PSNT2	Hardware Feature Presence Register 2
EMAC_HW_FTR_PSNT3	Hardware Feature Presence Register 3
EMAC_HASHTBL_REG0	Hash Table Register 0
EMAC_HASHTBL_REG1	Hash Table Register 1
EMAC_HASHTBL_REG2	Hash Table Register 2
EMAC_HASHTBL_REG3	Hash Table Register 3
EMAC_HASHTBL_REG4	Hash Table Register 4
EMAC_HASHTBL_REG5	Hash Table Register 5
EMAC_HASHTBL_REG6	Hash Table Register 6
EMAC_HASHTBL_REG7	Hash Table Register 7
EMAC_INDR_ACC_CTL	Indirect Access Control Register
EMAC_INDR_ACC_DAT	Indirect Access Data Register
EMAC_INVLAN_INCL	Inner VLAN Tag Inclusion or Replacement Register
EMAC_MAC_IEN	MAC Interrupt Enable Register
EMAC_MAC_ISTAT	MAC Interrupt Status Register
EMAC_L3L4_CTL7	Layer 3 and Layer 4 Control Register
EMAC_L3L4_CTL[i]	Layer 3 and Layer 4 Control Register
EMAC_LPI_CTLSTAT	LPI Control and Status Register
EMAC_LPI_ENTR_TMR	Transmit LPI Entry Timer Register
EMAC_LPI_TMRSCTL	LPI Timers Control Register
EMAC_L3_ADDR0_REG7	Layer 3 Address 0 Register 7
EMAC_L3_ADDR0_REG[i]	Layer 3 Address 0 Register [i]
EMAC_L3_ADDR1_REG7	Layer 3 Address 1 Register 7

Table 30-112: ADSP-SC59x EMAC Register List (Continued)

Name	Description
EMAC_L3_ADDR1_REG[i]	Layer 3 Address 1 Register [i]
EMAC_L3_ADDR2_REG7	Layer 3 Address 2 Register 7
EMAC_L3_ADDR2_REG[i]	Layer 3 Address 2 Register [i]
EMAC_L3_ADDR3_REG7	Layer 3 Address 3 Register 7
EMAC_L3_ADDR3_REG[i]	Layer 3 Address 3 Register [i]
EMAC_L4_ADDR7	Layer 4 Address Register [i]
EMAC_L4_ADDR[i]	Layer 4 Address Register [i]
EMAC_LOG_MSG_INTVL	PTP Log Message Interval Register
EMAC_MDIO_ADDR	MDIO Address Register
EMAC_MDIO_DATA	MDIO Data Register
EMAC_PHYIF_CTLSTAT	PHY Interface Control and Status Register
EMAC_PPS[n]_INTVL	PPS n Interval Register
EMAC_PPS[n]_TGTM_NSEC	PPS n Target Time Nanoseconds Register
EMAC_PPS[n]_TGTM_SEC	PPS n Target Time Seconds Register
EMAC_PPS[n]_WID	PPS n Width Register
EMAC_PPS_CTL	PPS Control Register
EMAC_PTO_CTL	PTP Time Stamp Offload Control Register
EMAC_MACPKT_FILT	MAC Packet Filter Register
EMAC_PRSNTM_UPDT	Presentation Time Update Register
EMAC_PRSNTM_NSEC	Presentation Time Nanosecond Register
EMAC_Q0_TXFLOW_CTL	Queue 0 Transmit Flow Control Register
EMAC_Q[i]_TXFLOW_CTL	Queue [i] Transmit Flow Control Register
EMAC_RXQ_CTL0	Receive Queue Control 0 Register
EMAC_RXQ_CTL1	Receive Queue Control 1 Register
EMAC_RXQ_CTL2	Receive Queue Control 2 Register
EMAC_RXQ_CTL3	Receive Queue Control 3 Register
EMAC_RXQ_CTL4	Receive Queue Control 4 Register
EMAC_RXFLOW_CTL	Receive Flow Control Register
EMAC_RXTX_STAT	Receive Transmit Status Register
EMAC_SRCPRT_IDNTY0	Source Port Identity 0 Register
EMAC_SRCPRT_IDNTY1	Source Port Identity 1 Register

Table 30-112: ADSP-SC59x EMAC Register List (Continued)

Name	Description
EMAC_SRCPRT_IDNTY2	Source Port Identity 2 Register
EMAC_TM_SUBSEC	Subsecond Increment Register
EMAC_TM_HISEC	System Time Higher Word Seconds Register
EMAC_TM_NSEC	System Time Nanoseconds Register
EMAC_TM_NSECUPDT	System Time Nanoseconds Update Register
EMAC_TM_SEC	System Time Seconds Register
EMAC_TM_SECUPDT	System Time Seconds Update Register
EMAC_TM_ADDEND	Time Stamp Addend Register
EMAC_TM_CTL	Time Stamp Control Register
EMAC_TM_EGASYM_CORR	Time Stamp Egress Asymmetry Correction Register
EMAC_TM_EGCORR_NSEC	Time Stamp Egress Correction Nanosecond Register
EMAC_TM_EGCORR_SNSEC	Time Stamp Egress Correction Sub Nanosecond Register
EMAC_TM_EG_LTNCY	Time Stamp Egress Latency Register
EMAC_TM_INGASYM_CORR	Time Stamp Ingress Asymmetry Correction Register

EMAC_TX_VLAN_PCNT_G	Transmit VLAN Packets Good Counter Register

DMA Channel n Control Register

The EMAC_DMA[n]_CTL register specifies the MSS value for segmentation, length to skip between two descriptors, and also the features such as header splitting and 8xPBL mode.

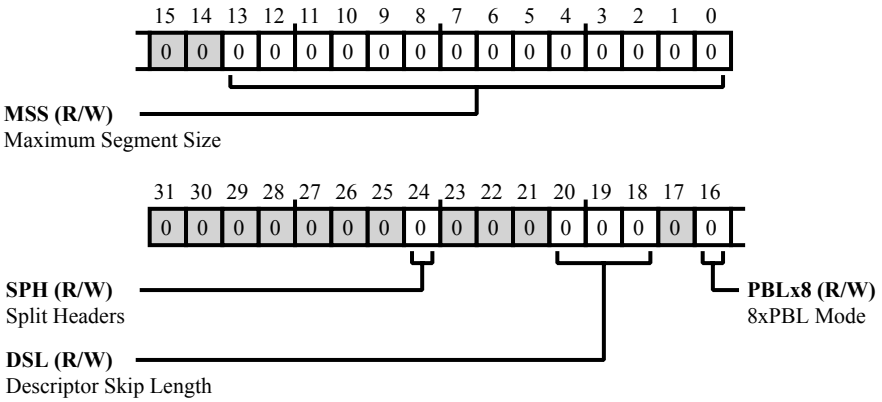

Figure 30-58: EMAC_DMA[n]_CTL Register Diagram

Table 30-113: EMAC_DMA[n]_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
24 (R/W)	SPH	Split Headers. When the EMAC_DMA[n]_CTL.SPH bit is set (=1), the DMA splits the header and payload in the receive path. The DMA writes the header to Buffer Address1 of RDES0. The DMA writes the payload to the buffer to which the Buffer Address2 is pointing. The software must ensure that the header fits into the receive buffers. If the header length exceeds the receive buffer size, the DMA does not split the header and payload. The EMAC_DMA[n]_CTL.SPH bit is available only when the split header feature is enabled (EMAC_HW_FTR_PSNT1.SPHEN =1).	
		0	Split Headers Feature is Disabled
		1	Split Headers Feature is Enabled
20:18 (R/W)	DSL	Descriptor Skip Length. The EMAC_DMA[n]_CTL.DSL bit specifies the number of 32-bit words to skip between two unchained descriptors. The address skipping starts from the end of the current descriptor to the start of the next descriptor. When EMAC_DMA[n]_CTL.DSL = 0, the DMA takes the descriptor table as contiguous.	

Table 30-113: EMAC_DMA[n]_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/W)	PBLX8	8xPBL Mode. When the EMAC_DMA[n]_CTL.PBLX8 bit is set, the PBL value programmed in bits[21:16] in EMAC_DMA[n]_TXCTL and bits[21:16] in EMAC_DMA[n]_RXCTL is multiplied by eight times. Therefore, the DMA transfers the data in 8, 16, 32, 64, 128, and 256 beats depending on the PBL value.	
		0	8xPBL Mode is Disabled
		1	8xPBL Mode is Enabled
13:0 (R/W)	MSS	Maximum Segment Size. The EMAC_DMA[n]_CTL.MSS field specifies the maximum segment size to be used while segmenting the packet. The EMAC_DMA[n]_CTL.MSS field is valid only when EMAC_DMA[n]_TXCTL.TSE =1. The value programmed in this field must be more than the configured data width in bytes. Use a EMAC_DMA[n]_CTL.MSS value of 64 bytes or more.	

DMA Channel n Current Application Receive Buffer Address Register

The EMAC_DMA[n]_RXBUF_CUR register points to the current Rx buffer address read by the DMA.

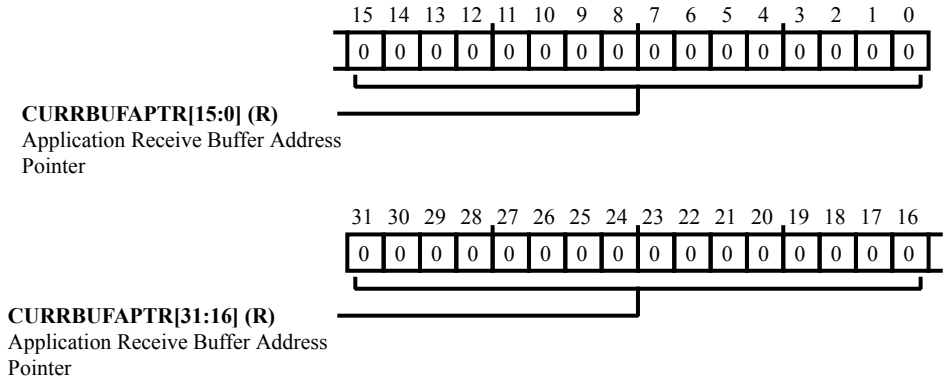

Figure 30-59: EMAC_DMA[n]_RXBUF_CUR Register Diagram

Table 30-114: EMAC_DMA[n]_RXBUF_CUR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CURRBUFAPTR	Application Receive Buffer Address Pointer. The DMA updates the EMAC_DMA[n]_RXBUF_CUR.CURRBUFAPTR field during the Rx operation. This pointer is cleared on reset.

DMA Channel n Current Application Receive Descriptor Register

The EMAC_DMA[n]_RXDSC_CUR register points to the current receive descriptor read by the DMA.

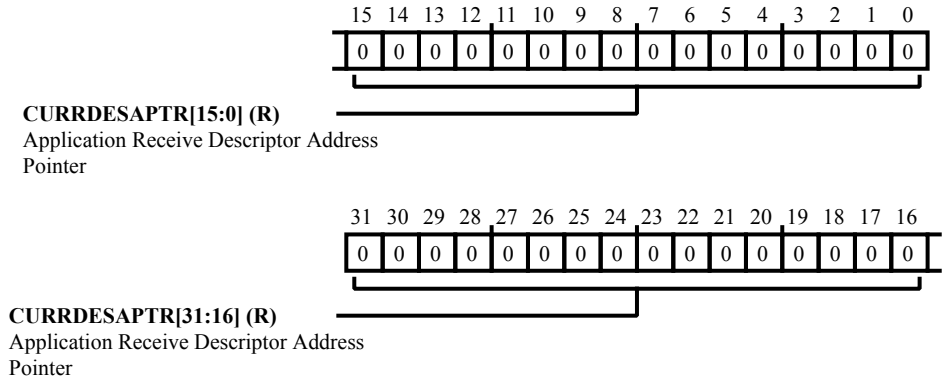

Figure 30-60: EMAC_DMA[n]_RXDSC_CUR Register Diagram

Table 30-115: EMAC_DMA[n]_RXDSC_CUR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CURRDESAPTR	Application Receive Descriptor Address Pointer. The DMA updates the EMAC_DMA[n]_RXDSC_CUR.CURRDESAPTR field during the Rx operation. This pointer is cleared on reset.

DMA Channel n Current Application Transmit Buffer Address Register

The EMAC_DMA[n]_TXBUF_CUR register points to the current Tx buffer address read by the DMA.

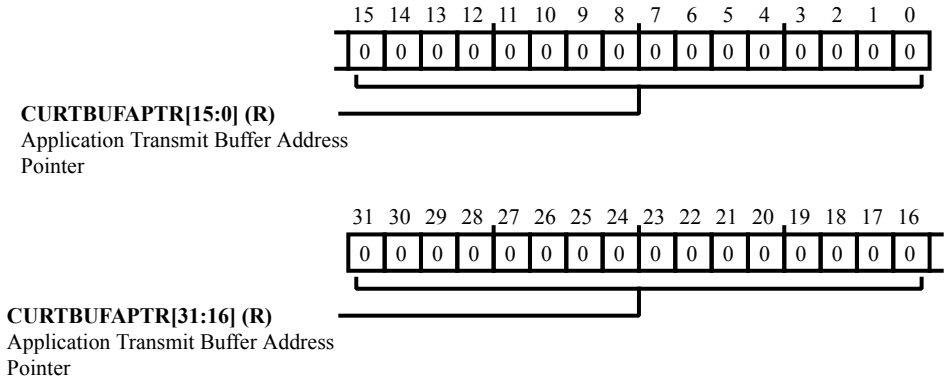

Figure 30-61: EMAC_DMA[n]_TXBUF_CUR Register Diagram

Table 30-116: EMAC_DMA[n]_TXBUF_CUR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CURTBUFAPTR	Application Transmit Buffer Address Pointer. The DMA updates the EMAC_DMA[n]_TXBUF_CUR.CURTBUFAPTR field during the Tx operation. This pointer is cleared on reset.

DMA Channel n Current Application Transmit Descriptor Register

The EMAC_DMA[n]_TXDSC_CUR register points to the current transmit descriptor read by the DMA.

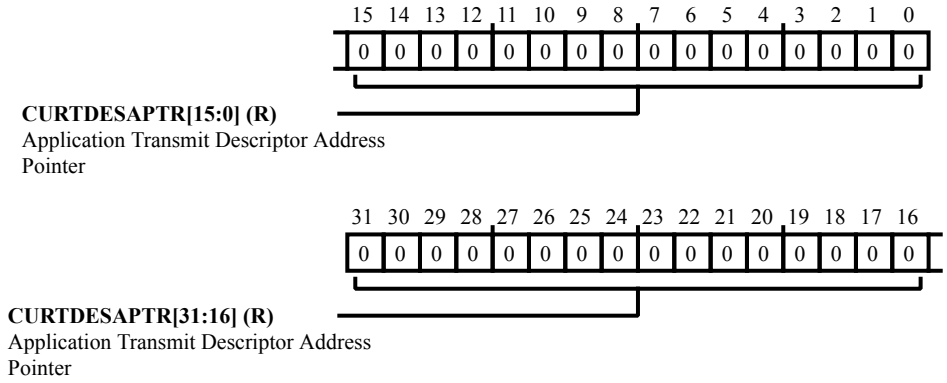

Figure 30-62: EMAC_DMA[n]_TXDSC_CUR Register Diagram

Table 30-117: EMAC_DMA[n]_TXDSC_CUR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CURTDESAPTR	Application Transmit Descriptor Address Pointer. The DMA updates the EMAC_DMA[n]_TXDSC_CUR.CURTDESAPTR field during the Tx operation. This pointer is cleared on reset.

DMA Channel n Interrupt Enable Register

The EMAC_DMA[n]_IEN register enables the interrupts reported by the status register.

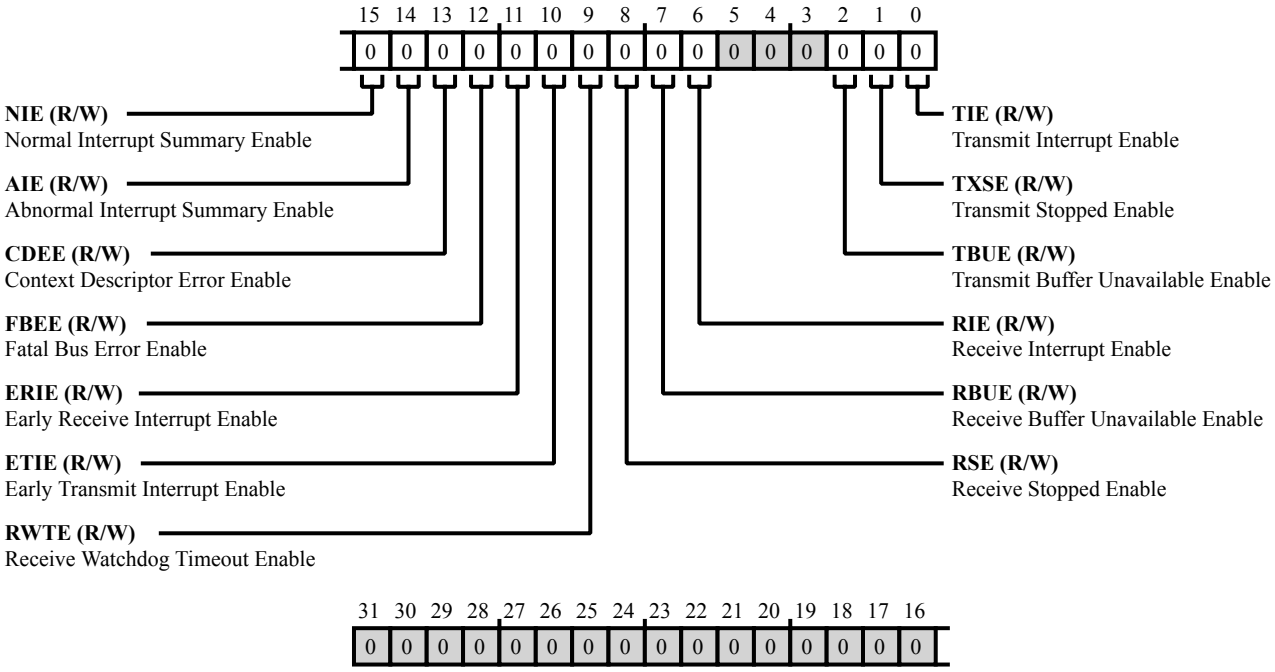

Figure 30-63: EMAC_DMA[n]_IEN Register Diagram

Table 30-118: EMAC_DMA[n]_IEN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	NIE	Normal Interrupt Summary Enable. When the EMAC_DMA[n]_IEN.NIE bit is set (=1), the normal interrupt summary is enabled. The EMAC_DMA[n]_IEN.NIE bit enables the following interrupts in the EMAC_DMA[n]_STAT register: - Bit 0: Transmit Interrupt - Bit 2: Transmit Buffer Unavailable - Bit 6: Receive Interrupt - Bit 11: Early Receive Interrupt When EMAC_DMA[n]_IEN.NIE = 0, the normal interrupt summary is disabled.	
		0	Disable
		1	Enable

Table 30-118: EMAC_DMA[n]_IEN Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
14 (R/W)	AIE	Abnormal Interrupt Summary Enable. When the EMAC_DMA[n]_IEN.AIE bit is set, the abnormal interrupt summary is enabled. The EMAC_DMA[n]_IEN.AIE bit enables the following interrupts in the EMAC_DMA[n]_STAT register: - Bit 1: Transmit Process Stopped - Bit 7: Rx Buffer Unavailable - Bit 8: Receive Process Stopped - Bit 9: Receive Watchdog Timeout - Bit 10: Early Transmit Interrupt - Bit 12: Fatal Bus Error - Bit 13: Context Descriptor Error When EMAC_DMA[n]_IEN.AIE = 0, the abnormal interrupt summary is disabled.	
		0	Disable
		1	Enable
13 (R/W)	CDEE	Context Descriptor Error Enable. When EMAC_DMA[n]_IEN.CDEE =1 and EMAC_DMA[n]_IEN.AIE =1, the descriptor error interrupt is enabled. When EMAC_DMA[n]_IEN.CDEE = 0, the descriptor error interrupt is disabled.	
		0	Disable
		1	Enable
12 (R/W)	FBEE	Fatal Bus Error Enable. When EMAC_DMA[n]_IEN.FBEE =1 and EMAC_DMA[n]_IEN.AIE =1, the fatal bus error interrupt is enabled. When EMAC_DMA[n]_IEN.FBEE = 0, the fatal bus error interrupt is disabled.	
		0	Disable
		1	Enable
11 (R/W)	ERIE	Early Receive Interrupt Enable. When EMAC_DMA[n]_IEN.ERIE =1 and EMAC_DMA[n]_IEN.NIE =1, the early receive interrupt is enabled. When EMAC_DMA[n]_IEN.ERIE = 0, the early receive interrupt is disabled.	
		0	Disable
		1	Enable

Table 30-118: EMAC_DMA[n]_IEN Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
10 (R/W)	ETIE	Early Transmit Interrupt Enable. When EMAC_DMA[n]_IEN.ETIE =1 and EMAC_DMA[n]_IEN.AIE =1, the early transmit interrupt is enabled. When EMAC_DMA[n]_IEN.ETIE = 0, the early transmit interrupt is disabled.	
		0	Disable
		1	Enable
9 (R/W)	RWTE	Receive Watchdog Timeout Enable. When EMAC_DMA[n]_IEN.RWTE =1 and EMAC_DMA[n]_IEN.AIE =1, the receive watchdog timeout interrupt is enabled. When EMAC_DMA[n]_IEN.RWTE = 0, the receive watchdog timeout interrupt is disabled.	
		0	Disable
		1	Enable
8 (R/W)	RSE	Receive Stopped Enable. When EMAC_DMA[n]_IEN.RSE =1 and EMAC_DMA[n]_IEN.AIE =1, the receive stopped interrupt is enabled. When EMAC_DMA[n]_IEN.RSE = 0, the receive stopped interrupt is disabled.	
		0	Disable
		1	Enable
7 (R/W)	RBUE	Receive Buffer Unavailable Enable. When EMAC_DMA[n]_IEN.RBUE =1 and EMAC_DMA[n]_IEN.AIE =1, the receive buffer unavailable interrupt is enabled. When EMAC_DMA[n]_IEN.RBUE = 0, the receive buffer unavailable interrupt is disabled.	
		0	Disable
		1	Enable
6 (R/W)	RIE	Receive Interrupt Enable. When EMAC_DMA[n]_IEN.RIE =1 and EMAC_DMA[n]_IEN.NIE =1, the receive interrupt is enabled. When EMAC_DMA[n]_IEN.RIE = 0, the receive interrupt is disabled.	
		0	Disable
		1	Enable

Table 30-118: EMAC_DMA[n]_IEN Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W)	TBUE	Transmit Buffer Unavailable Enable. When `EMAC_DMA[n]_IEN.TBUE` =1 and EMAC_DMA[n]_IEN.NIE =1, the transmit buffer unavailable interrupt is enabled. When `EMAC_DMA[n]_IEN.TBUE` = 0, the transmit buffer unavailable interrupt is disabled.	
		0	Disable
		1	Enable
1 (R/W)	TXSE	Transmit Stopped Enable. When `EMAC_DMA[n]_IEN.TXSE` =1 and EMAC_DMA[n]_IEN.AIE =1, the transmission stopped interrupt is enabled. When `EMAC_DMA[n]_IEN.TXSE` = 0, the transmission stopped interrupt is disabled.	
		0	Disable
		1	Enable
0 (R/W)	TIE	Transmit Interrupt Enable. When `EMAC_DMA[n]_IEN.TIE` =1 and EMAC_DMA[n]_IEN.NIE =1, the transmit interrupt is enabled. When `EMAC_DMA[n]_IEN.TIE` = 0, the transmit interrupt is disabled.	
		0	Disable
		1	Enable

DMA Channel n Missed Frame Counter Register

The EMAC_DMA[n]_MISSFRM_CNT register indicates the number of frames that the DMA dropped due to a bus error or due to programming the EMAC_DMA[n]_RXCTL.RPF bit.

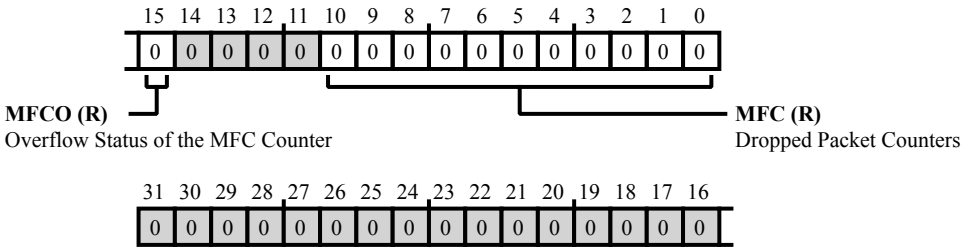

Figure 30-64: EMAC_DMA[n]_MISSFRM_CNT Register Diagram

Table 30-119: EMAC_DMA[n]_MISSFRM_CNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/NW)	MFCO	Overflow Status of the MFC Counter. When EMAC_DMA[n]_MISSFRM_CNT.MFCO bit is set (=1), the MFC counter does not get incremented further. The bit is cleared (=0) when this register is read. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	Miss Frame Counter Overflow Not Occurred
		1	Miss Frame Counter Overflow Occurred
10:0 (R/NW)	MFC	Dropped Packet Counters. The EMAC_DMA[n]_MISSFRM_CNT.MFC field indicates the number of frames that are dropped by the DMA either because of a bus error or because of programing the EMAC_DMA[n]_RXCTL.RPF bit. The counter is cleared when this register is read. Access restriction applies. Clears on read. Self-set to 1 on internal event.	

DMA Channel n Receive Descriptor List Address Register

The EMAC_DMA[n]_RXDSC_ADDR register points the DMA to the start of the receive descriptor list.

The descriptor lists reside in the physical memory space of the application. It must be 32-bit aligned. The DMA internally converts it to bus width aligned address by making the corresponding least significant bits low.

Writing to the EMAC_DMA[n]_RXDSC_ADDR register is permitted only when reception is stopped. When stopped, this register must be written to before the receive start command is given.

Write to this register only when Rx DMA has stopped (EMAC_DMA[n]_RXCTL.SR = 0). When stopped, this register can be written with a new descriptor list address.

When EMAC_DMA[n]_RXCTL.SR = 1, the DMA takes the newly programmed descriptor base address.

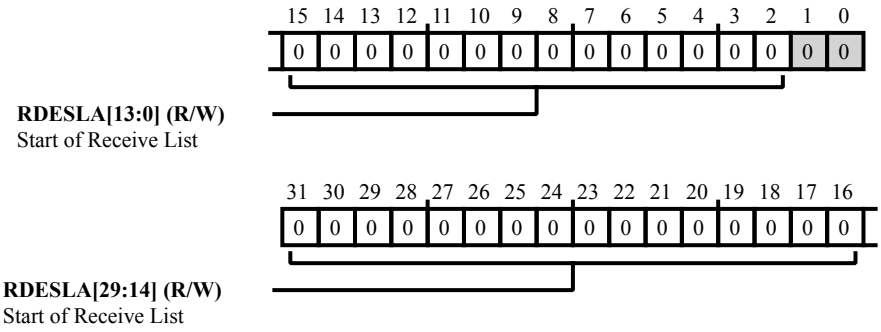

Figure 30-65: EMAC_DMA[n]_RXDSC_ADDR Register Diagram

Table 30-120: EMAC_DMA[n]_RXDSC_ADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:2 (R/W)	RDESLA	Start of Receive List. The EMAC_DMA[n]_RXDSC_ADDR.RDESLA field contains the base address of the first descriptor in the Rx descriptor list. The DMA ignores the last two bits (1:0) and internally takes these bits as all-zero. Therefore, these LSB bits are read-only (RO).

DMA Channel n Receive Descriptor Tail Pointer Register

The EMAC_DMA[n]_RXDSC_TLPTR register indicates an offset from the base and indicates the location of the last valid descriptor.

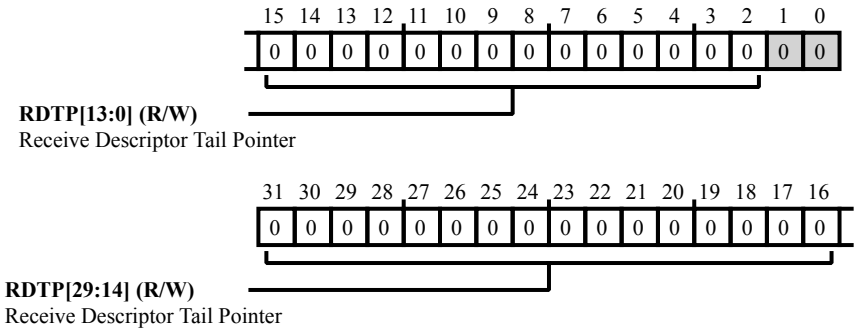

Figure 30-66: EMAC_DMA[n]_RXDSC_TLPTR Register Diagram

Table 30-121: EMAC_DMA[n]_RXDSC_TLPTR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:2 (R/W)	RDTP	Receive Descriptor Tail Pointer. The EMAC_DMA[n]_RXDSC_TLPTR.RDTP field contains the tail pointer for the Rx descriptor ring. The software writes the tail pointer to add more descriptors to the Rx channel. The hardware tries to write all received packets to the descriptors referenced between the head and the tail pointer registers.

DMA Channel n Receive Control Register

The EMAC_DMA[n]_RXCTL register controls the Rx features such as PBL, buffer size, and extended status.

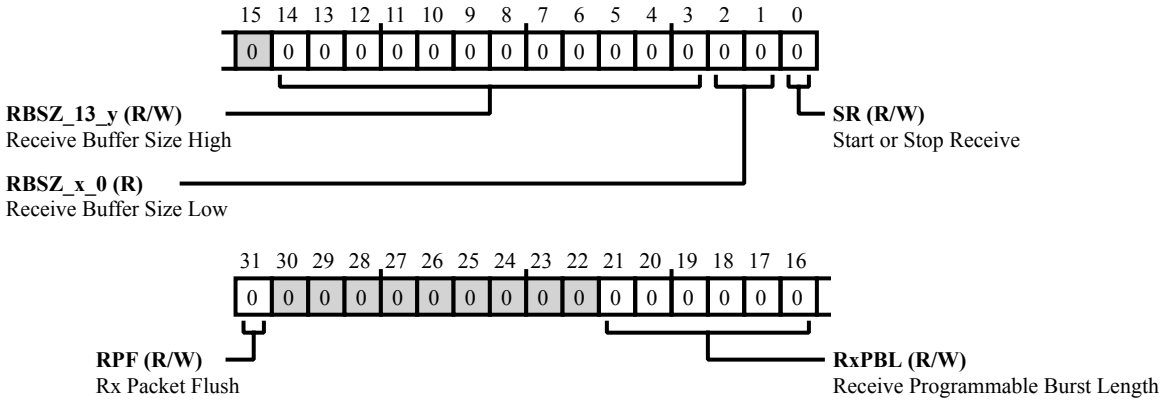

Figure 30-67: EMAC_DMA[n]_RXCTL Register Diagram

Table 30-122: EMAC_DMA[n]_RXCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	RPF	Rx Packet Flush. The EMAC_DMA[n]_RXCTL.RPF bit enables the Rx packet flush feature. When set (= 1), the EMAC module automatically flushes the packet from the Rx queues designated to this DMA Rx channel, when it is stopped. When the EMAC_DMA[n]_RXCTL.RPF bit remains set and the DMA is restarted by the software driver, the packets residing in the Rx queues that were received when this RxDMA was stopped, are flushed out. The packets that are received by the MAC after the RxDMA is restarted are routed to the RxDMA. The flushing is done on the read side of the Rx queue. When the EMAC_DMA[n]_RXCTL.RPF bit is cleared (= 0), the EMAC module does not flush the packet in the Rx queue destined to this RxDMA channel when it is in STOP state. This operation can cause head-of-line blocking in the corresponding Rx queue. Note: The stopping of packet flow from a Rx DMA channel to the application by setting RPF works only when there is one-to-one mapping of Rx queue to Rx DMA channels. In dynamic mapping mode, setting this bit can flush packets from unintended Rx queues which are destined to the stopped Rx DMA channel.	
		0	Rx Packet Flush is Disabled
		1	Rx Packet Flush is Enabled

Table 30-122: EMAC_DMA[n]_RXCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
21:16 (R/W)	RXPBL	Receive Programmable Burst Length. The EMAC_DMA[n]_RXCTL.RXPBL field indicates the maximum number of beats to be transferred in one DMA block data transfer. The DMA always attempts max burst as specified in PBL each time it starts a burst transfer on the application bus. Program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior. To transfer more than 32 beats, perform the following steps: 1. Set the 8xPBL mode in the EMAC_DMA[n]_CTL register. 2. Set the RxPBL. Note: The maximum value of RxPBL must be less than or equal to half the Rx queue size (EMAC_RQ[n]_OPMODE.RQS) in terms of beats. This is required so that the Rx queue has space to store at least another Rx PBL worth of data while the Rx DMA is transferring a block of data. For example, in the total locations in Rx queue of size 512 bytes is 128, so RxPBL and 8xPBL needs to be programmed to less than or equal to 64.
14:3 (R/W)	RBSZ_13_Y	Receive Buffer Size High. RBSZ[13:0] is split into two fields: higher EMAC_DMA[n]_RXCTL.RBSZ_13_Y and lower RBSZ_x_0. The RBSZ[13:0] field indicates the size of the Rx buffers specified in bytes. The maximum buffer size is limited to 16K bytes. The buffer size is applicable to payload buffers when split headers are enabled. Note: The buffer size must be a multiple of 4 bytes. This is required even if the value of buffer address pointer is not aligned to data bus width. Hence, the lower RBSZ_x_0 bits are read-only and the value is considered as all-zero. Thus, the EMAC_DMA[n]_RXCTL.RBSZ_13_Y indicates the buffer size in terms of locations (with the width same as bus width).
2:1 (R/NW)	RBSZ_X_0	Receive Buffer Size Low. RBSZ[13:0] is split into two fields RBSZ_13_y and RBSZ_x_0. The EMAC_DMA[n]_RXCTL.RBSZ_X_0 field is the lower field whose width is based on data bus width of the configuration. The EMAC_DMA[n]_RXCTL.RBSZ_X_0 field is 2 bits wide. The EMAC_DMA[n]_RXCTL.RBSZ_X_0 field is read-only (RO).

Table 30-122: EMAC_DMA[n]_RXCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	SR	Start or Stop Receive. When the `EMAC_DMA[n]_RXCTL.SR` bit is set (=1), the DMA tries to acquire the descriptor from the receive list and processes the incoming packets. The DMA tries to acquire descriptor from either of the following positions: The current position in the list - This is the address set by the EMAC_DMA[n]_RXDSC_ADDR register. The position at which the Rx process was previously stopped - If the DMA does not own the current descriptor, the reception is suspended and the EMAC_DMA[n]_STAT.RBU bit is set (=1). The start receive command is effective only when the reception is stopped. If the command is issued before configuring the EMAC_DMA[n]_RXDSC_ADDR register, the DMA behavior is unpredictable. When `EMAC_DMA[n]_RXCTL.SR` bit = 0, the Rx DMA operation is stopped after the transfer of the current packet. The next descriptor position in the receive list is saved, and it becomes the current position after the Rx process is restarted. The stop receive command is effective only when the Rx process is in the running (waiting for Rx packet) or suspended state.	
		0	Stop Receive
		1	Start Receive

DMA Channel n Extended Receive Control Register

The EMAC_DMA[n]_RXCTL2 register controls the Rx features such as Rx descriptor ring length and alternate Rx buffer size.

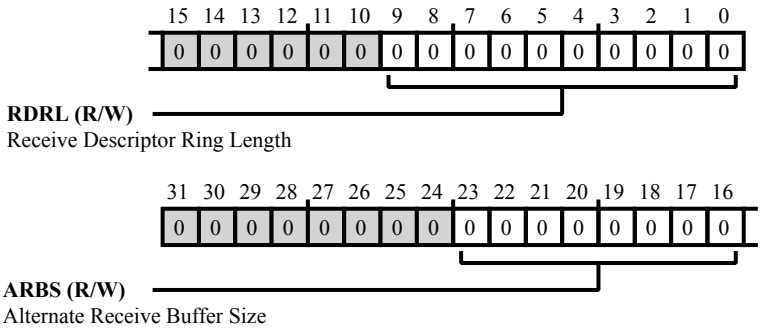

Figure 30-68: EMAC_DMA[n]_RXCTL2 Register Diagram

Table 30-123: EMAC_DMA[n]_RXCTL2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
23:16 (R/W)	ARBS	Alternate Receive Buffer Size. The EMAC_DMA[n]_RXCTL2.ARBS field indicates the size in bytes for buffer 1, when programmed to a non-zero value (when the split header feature is not enabled). When the split header feature is enabled, the EMAC_DMA[n]_RXCTL2.ARBS field indicates the buffer size for header data. The maximum alternate buffer is limited to 1020 bytes for the 32-bit data bus width. When EMAC_DMA[n]_RXCTL2.ARBS= 0, the Rx Buffer1 and Rx Buffer2 sizes are based on EMAC_DMA[n]_RXCTL.RBSZ.
9:0 (R/W)	RDRL	Receive Descriptor Ring Length. The EMAC_DMA[n]_RXCTL2 register sets the maximum number of Rx descriptors in the circular descriptor ring. The maximum number of descriptors is limited to 1K descriptors. For example, program any value up to 0x3FF in this field. The EMAC_DMA[n]_RXCTL2.RDRL field is 10 bits wide. When programming 0x3FF, there are 1024 descriptors. For 10 descriptors, program it to a value of 0x9.

DMA Channel n Receive Interrupt Watchdog Timer Register

The EMAC_DMA[n]_RXINTWDTMR register indicates the watchdog timeout for Receive Interrupt (RI) from the DMA. When this register is written with a non-zero value, it enables the watchdog timer for the EMAC_DMA[n]_STAT.RI bit.

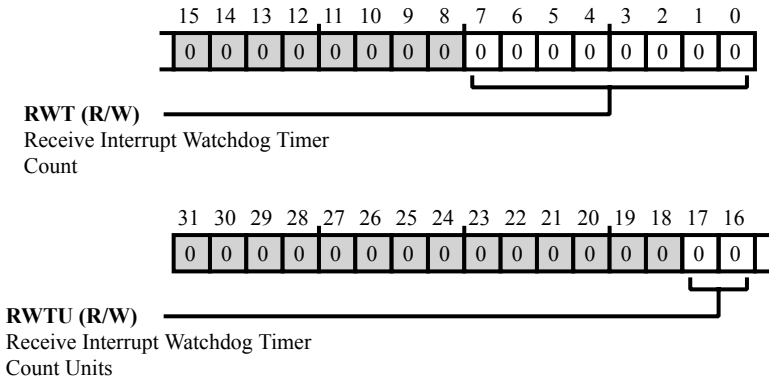

Figure 30-69: EMAC_DMA[n]_RXINTWDTMR Register Diagram

Table 30-124: EMAC_DMA[n]_RXINTWDTMR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
17:16 (R/W)	RWTU	Receive Interrupt Watchdog Timer Count Units. The EMAC_DMA[n]_RXINTWDTMR.RWTU field indicates the number of SCLK0 cycles corresponding to one unit in the EMAC_DMA[n]_RXINTWDTMR.RWT field. For example, when EMAC_DMA[n]_RXINTWDTMR.RWT=2 and EMAC_DMA[n]_RXINTWDTMR.RWTU = 1, the watchdog timer is configured for 2 * 512 = 1024 SCLK0 cycles.	
		0	256
		1	512
		2	1024
		3	2048

Table 30-124: EMAC_DMA[n]_RXINTWDTMR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	RWT	Receive Interrupt Watchdog Timer Count. The `EMAC_DMA[n]_RXINTWDTMR.RWT` field indicates the number of SCLK0 cycles, multiplied by factor indicated in `EMAC_DMA[n]_RXINTWDTMR.RWTU` field, for which the watchdog timer is set. The watchdog timer is triggered with the programmed value after the Rx DMA completes the transfer of a packet for which EMAC_DMA[n]_STAT.RI = 0 register, because of the setting of Interrupt Enable bit in the corresponding descriptor RDES3[30]. When the watchdog timer runs out, the RI bit is set and the timer is stopped. The watchdog timer is reset when the RI bit is set (=1) because of automatic setting of RI as per the Interrupt Enable bit RDES3[30] of any received packet.

DMA Channel n Slot Function Control and Status register

The EMAC_DMA[n]_SFN_CTLSTAT register contains the control bits for slot function and the status for transmit path.

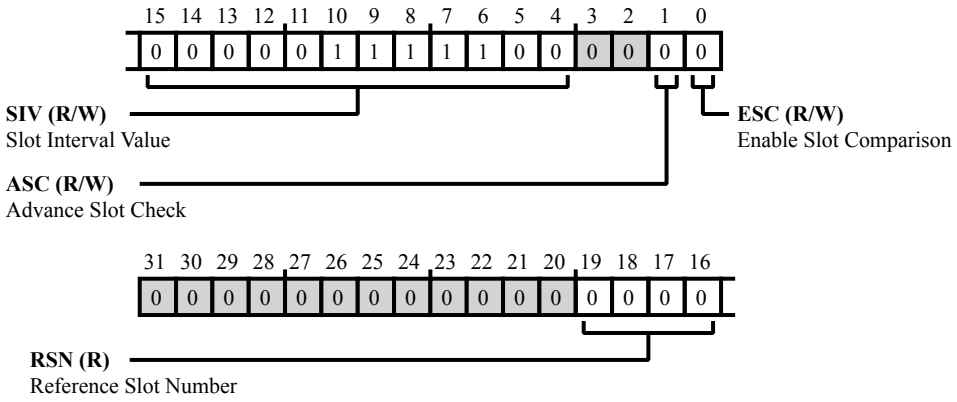

Figure 30-70: EMAC_DMA[n]_SFN_CTLSTAT Register Diagram

Table 30-125: EMAC_DMA[n]_SFN_CTLSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
19:16 (R/NW)	RSN	Reference Slot Number. The EMAC_DMA[n]_SFN_CTLSTAT.RSN field gives the current value of the reference slot number in the DMA. It is used for slot comparison.	
15:4 (R/W)	SIV	Slot Interval Value. The EMAC_DMA[n]_SFN_CTLSTAT.SIV field controls the period of the slot interval in which the TxDMA fetches the scheduled packets. A value of 0 specifies the slot interval of 1 us while the maximum value 4095 specifies the slot interval of 4096us. The default/reset value is 0x07C which corresponds to a slot interval of 125 us.	
1 (R/W)	ASC	Advance Slot Check. When set, the EMAC_DMA[n]_SFN_CTLSTAT.ASC bit enables the DMA to fetch the data from the buffer when the slot number (SLOTNUM) programmed in the Tx descriptor is: - equal to the reference slot number given in the RSN field or - ahead of the reference slot number by up to two slots. The EMAC_DMA[n]_SFN_CTLSTAT.ASC bit is applicable only when the ESC bit is set.	
		0	Advance Slot Check is Disabled
		1	Advance Slot Check is Enabled

Table 30-125: EMAC_DMA[n]_SFN_CTLSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	ESC	Enable Slot Comparison. When set (=1), the `EMAC_DMA[n]_SFN_CTLSTAT.ESC` bit enables the checking of the slot numbers programmed in the Tx descriptor with the current reference given in the RSN field. The DMA fetches the data from the corresponding buffer only when the slot number is: - equal to the reference slot number or - ahead of the reference slot number by one slot. When cleared (=0), the `EMAC_DMA[n]_SFN_CTLSTAT.ESC` bit disables the checking of the slot numbers. The DMA fetches the data immediately after the descriptor is processed. Note: The UFO (UDP Fragmentation over IPv4)/TSO/USO must not be enabled with the TBS/AVB slot number check. The UFO/TSO/USO involves multiple packets/segments/fragments transmission for single packet received from application, and the slot number checks are applicable for the fetching of only the first segment/fragment. As a result, it can be difficult for software to specify a slot number for subsequent packets.	
		0	Slot Comparison is Disabled
		1	Slot Comparison is Enabled

DMA Channel n Status Register

The software driver (application) reads the EMAC_DMA[n]_STAT register during interrupt service routine or polling to determine the status of the DMA.

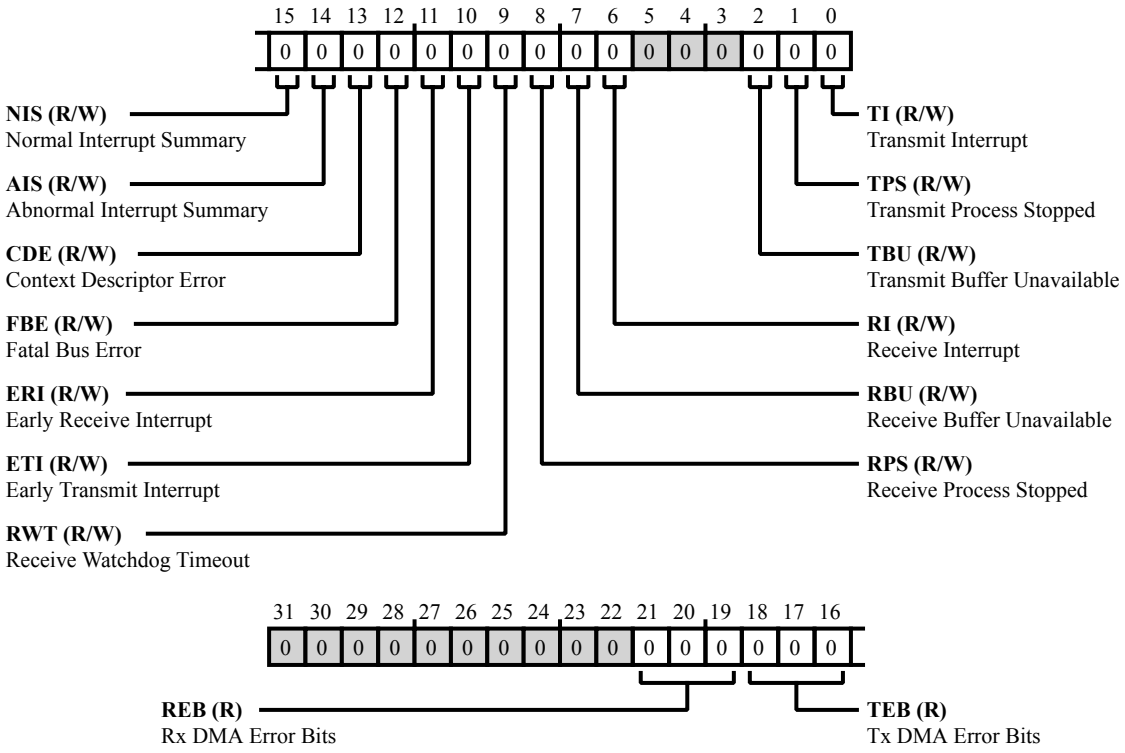

Figure 30-71: EMAC_DMA[n]_STAT Register Diagram

Table 30-126: EMAC_DMA[n]_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
21:19 (R/NW)	REB	Rx DMA Error Bits. The EMAC_DMA[n]_STAT.REB field indicates the type of error that caused a bus error. For example, an error response on the SPB or SCB interface. Bit 21 -- 1'b1: Error during data transfer by Rx DMA -- 1'b0: No Error during data transfer by Rx DMA Bit 20 -- 1'b1: Error during descriptor access -- 1'b0: Error during data buffer access Bit 19 -- 1'b1: Error during read transfer -- 1'b0: Error during write transfer The EMAC_DMA[n]_STAT.REB field is valid only when the FBE bit is set. It does not generate an interrupt.
18:16 (R/NW)	TEB	Tx DMA Error Bits. The EMAC_DMA[n]_STAT.TEB field indicates the type of error that caused a bus error. For example, error response on the SPB or SCB interface. Bit 18 -- 1'b1: Error during data transfer by Tx DMA -- 1'b0: No Error during data transfer by Tx DMA Bit 17 -- 1'b1: Error during descriptor access -- 1'b0: Error during data buffer access Bit 16 -- 1'b1: Error during read transfer -- 1'b0: Error during write transfer The EMAC_DMA[n]_STAT.TEB field is valid only when the FBE bit is set. It does not generate an interrupt.

Table 30-126: EMAC_DMA[n]_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	NIS	Normal Interrupt Summary. The EMAC_DMA[n]_STAT.NIS bit value is the logical OR of the following bits when the corresponding interrupt bits are enabled in the EMAC_DMA[n]_IEN register: Bit 0: Transmit Interrupt Bit 2: Transmit Buffer Unavailable Bit 6: Receive Interrupt Bit 11: Early Receive Interrupt Only unmasked bits (interrupts for which interrupt enable is set in EMAC_DMA[n]_IEN register) affect the Normal Interrupt Summary bit. This is a sticky bit; the EMAC_DMA[n]_STAT.NIS bit must be cleared (by writing 1) each time a corresponding bit that causes NIS to be set is cleared. Access restriction applies. Self-set to 1 on internal event. Write 1 to clear. Writing 0 has no effect.	
		0	Normal Interrupt Summary Status Not Detected
		1	Normal Interrupt Summary Status Detected
14 (R/W)	AIS	Abnormal Interrupt Summary. The EMAC_DMA[n]_STAT.AIS bit value is the logical OR of the following when the corresponding interrupt bits are enabled in the EMAC_DMA[n]_IEN register: Bit 1: Transmit Process Stopped Bit 7: Receive Buffer Unavailable Bit 8: Receive Process Stopped Bit 10: Early Transmit Interrupt Bit 12: Fatal Bus Error Bit 13: Context Descriptor Error Only unmasked bits affect the Abnormal Interrupt Summary bit. This is a sticky bit. Clear the EMAC_DMA[n]_STAT.AIS bit (by writing 1 to the EMAC_DMA[n]_STAT.AIS bit) each time a corresponding bit, which causes AIS to be set, is cleared. Access restriction applies. Self-set to 1 on internal event. Write 1 to clear. Writing 0 has no effect.	
		0	Abnormal Interrupt Summary Status Not Detected
		1	Abnormal Interrupt Summary Status Detected

Table 30-126: EMAC_DMA[n]_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
13 (R/W)	CDE	Context Descriptor Error. The EMAC_DMA[n]_STAT.CDE bit indicates that the DMA Tx/Rx engine received a descriptor error, which indicates invalid context in the middle of packet flow (intermediate descriptor) or all one's descriptor in Tx case and on Rx side it indicates DMA has read a descriptor with either of the buffer address as ones which is considered to be invalid. Access restriction applies. Self-set to 1 on internal event. Write 1 to clear. Writing 0 has no effect.	
		0	Context Descriptor Error Status Not Detected
		1	Context Descriptor Error Status Detected
12 (R/W)	FBE	Fatal Bus Error. The EMAC_DMA[n]_STAT.FBE bit indicates that a bus error occurred (as described in the EB field). When the EMAC_DMA[n]_STAT.FBE bit is set, the corresponding DMA channel engine disables all bus accesses. Access restriction applies. Self-set to 1 on internal event. Write 1 to clear. Writing 0 has no effect.	
		0	Fatal Bus Error Status Not Detected
		1	Fatal Bus Error Status Detected
11 (R/W)	ERI	Early Receive Interrupt. The EMAC_DMA[n]_STAT.ERI bit when set indicates that the RxDMA has completed the transfer of packet data to the memory. In configurations supporting ERIC, ERIC = 0: The EMAC_DMA[n]_STAT.ERI bit is set only after the Rx DMA has completely filled up a receive buffer with packet data. ERIC = 1: The EMAC_DMA[n]_STAT.ERI bit is set after every burst transfer of data from the Rx DMA to the buffer. The setting of RI bit automatically clears the EMAC_DMA[n]_STAT.ERI bit. Access restriction applies. Self-set to 1 on internal event. Write 1 to clear. Writing 0 has no effect.	
		0	Early Receive Interrupt Status Not Detected
		1	Early Receive Interrupt Status Detected

Table 30-126: EMAC_DMA[n]_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
10 (R/W)	ETI	Early Transmit Interrupt. The EMAC_DMA[n]_STAT.ETI bit when set indicates that the TxDMA has completed the transfer of packet data to the MTL TXFIFO memory. In configurations supporting ETIC: ETIC = 0: The EMAC_DMA[n]_STAT.ETI bit is set only after the Tx DMA has transferred a complete packet to MTL. ETIC = 1: The EMAC_DMA[n]_STAT.ETI bit is set after completion of (partial) packet data transfer from buffers in the transmit descriptor in which IOC = 1. Access restriction applies. Self-set to 1 on internal event. Write 1 to clear. Writing 0 has no effect.	
		0	Early Transmit Interrupt Status Not Detected
		1	Early Transmit Interrupt Status Detected
9 (R/W)	RWT	Receive Watchdog Timeout. The EMAC_DMA[n]_STAT.RWT bit is asserted when a packet with length greater than 2,048 bytes (10,240 bytes when jumbo packet mode is enabled (EMAC_MAC_CFG.JE = 1) is received.	
		0	Receive Watchdog Timeout Status Not Detected
		1	Receive Watchdog Timeout Status Detected
8 (R/W)	RPS	Receive Process Stopped. The EMAC_DMA[n]_STAT.RPS bit is asserted when the Rx process enters the STOP state. Access restriction applies. Self-set to 1 on internal event. Write 1 to clear. Writing 0 has no effect.	
		0	Receive Process Stopped Status Not Detected
		1	Receive Process Stopped Status Detected

Table 30-126: EMAC_DMA[n]_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	RBU	Receive Buffer Unavailable. The EMAC_DMA[n]_STAT.RBU bit indicates that the application owns the next descriptor in the receive list, and the DMA cannot acquire it. The Rx process is suspended. To resume processing Rx descriptors, the application should change the ownership of the descriptor and issue a Receive Poll Demand command. If this command is not issued, the Rx process resumes when the next recognized incoming packet is received. In ring mode, the application should advance the EMAC_DMA[n]_RXDSC_TLPTR register of a channel. The EMAC_DMA[n]_STAT.RBU bit is set only when the DMA owns the previous Rx descriptor. Access restriction applies. Self-set to 1 on internal event. Write 1 to clear. Writing 0 has no effect.	
		0	Receive Buffer Unavailable Status Not Detected
		1	Receive Buffer Unavailable Status Detected
6 (R/W)	RI	Receive Interrupt. The EMAC_DMA[n]_STAT.RI bit indicates that the packet reception is complete. When packet reception is complete, bit 31 of RDES3 is reset in the last descriptor, and the specific packet status information is updated in the descriptor. The reception remains in the running state. Access restriction applies. Self-set to 1 on internal event. Write 1 to clear. Writing 0 has no effect.	
		0	Receive Interrupt Status Not Detected
		1	Receive Interrupt Status Detected
2 (R/W)	TBU	Transmit Buffer Unavailable. The EMAC_DMA[n]_STAT.TBU bit indicates that the application owns the next descriptor in the transmit list, and the DMA cannot acquire it. Transmission is suspended. The EMAC_DMA_DBG_STAT0.TPS0 field indicates the transmit process state transitions. To resume processing the transmit descriptors, the application must: 1. Change the ownership of the descriptor by setting bit 31 of TDES3. 2. Issue a Transmit Poll Demand command. 3. For ring mode, the application should advance the EMAC_DMA[n]_TXDSC_TLPTR register of a channel. Access restriction applies. Self-set to 1 on internal event. Write 1 to clear. Writing 0 has no effect.	
		0	Transmit Buffer Unavailable Status Not Detected
		1	Transmit Buffer Unavailable Status Detected

Table 30-126: EMAC_DMA[n]_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W)	TPS	Transmit Process Stopped. The `EMAC_DMA[n]_STAT.TPS` bit is set when the transmission is stopped. Access restriction applies. Self-set to 1 on internal event. Write 1 to clear. Writing 0 has no effect.	
		0	Transmit Process Stopped Status Not Detected
		1	Transmit Process Stopped Status Detected
0 (R/W)	TI	Transmit Interrupt. The `EMAC_DMA[n]_STAT.TI` bit indicates that the packet transmission is complete. When transmission is complete, bit 31 of TDES3 is reset in the last descriptor, and the specific packet status information is updated in the descriptor. Access restriction applies. Self-set to 1 on internal event. Write 1 to clear. Writing 0 has no effect.	
		0	Transmit Interrupt Status Not Detected
		1	Transmit Interrupt Status Detected

DMA Channel n Transmit Descriptor List Address Register

The EMAC_DMA[n]_TXDSC_ADDR register points the DMA to the start of transmit descriptor list. The descriptor lists reside in the physical memory space of the application and must be 32-bit aligned. The DMA internally converts it to bus width aligned address by making the corresponding LSB to low.

Write to the EMAC_DMA[n]_TXDSC_ADDR register only when the Tx DMA has stopped (EMAC_DMA[n]_TXCTL.ST = 0). When stopped, this register can be written with a new descriptor list address. When EMAC_DMA[n]_TXCTL.ST = 1, the DMA takes the newly-programmed descriptor base address. If this register is not changed when EMAC_DMA[n]_TXCTL.ST = 0, the DMA takes the descriptor address where it was stopped earlier.

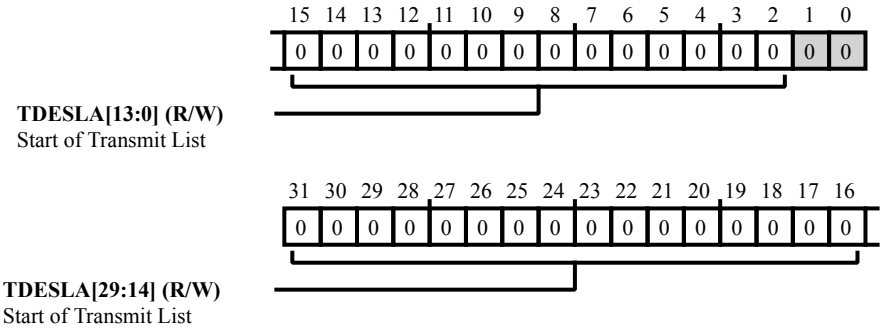

Figure 30-72: EMAC_DMA[n]_TXDSC_ADDR Register Diagram

Table 30-127: EMAC_DMA[n]_TXDSC_ADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:2 (R/W)	TDESLA	Start of Transmit List. The EMAC_DMA[n]_TXDSC_ADDR.TDESLA field contains the base address of the first descriptor in the transmit descriptor list. The DMA ignores the LSB bits (1:0) and internally takes these bits as all-zero. Therefore, these LSB bits are read-only (RO).

DMA Channel n Transmit Descriptor Ring Length Register

The EMAC_DMA[n]_TXDSC_RLEN register contains the length of the transmit descriptor ring.

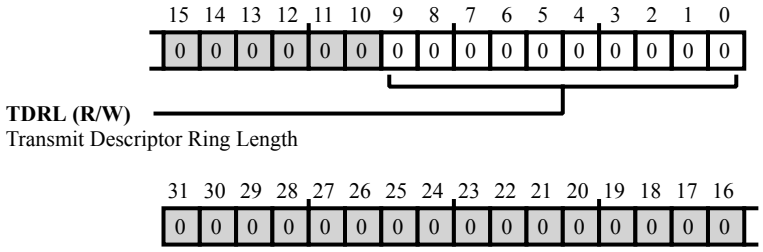

Figure 30-73: EMAC_DMA[n]_TXDSC_RLEN Register Diagram

Table 30-128: EMAC_DMA[n]_TXDSC_RLEN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
9:0 (R/W)	TDRL	Transmit Descriptor Ring Length. The EMAC_DMA[n]_TXDSC_RLEN.TDRL field sets the maximum number of Tx descriptors in the circular descriptor ring. The maximum number of descriptors is limited to 1K descriptors. A minimum ring descriptor length of 4 is recommended. For example, program any value up to 0x3FF in this field. The EMAC_DMA[n]_TXDSC_RLEN.TDRL field is 10 bits wide. To program 0x3FF, 1024 descriptors are available. For 10 descriptors, program it to a value of 0x9.

DMA Channel n Transmit Descriptor Tail Pointer Register

The EMAC_DMA[n]_TXDSC_TLPTR register points to an offset from the base and indicates the location of the last valid descriptor.

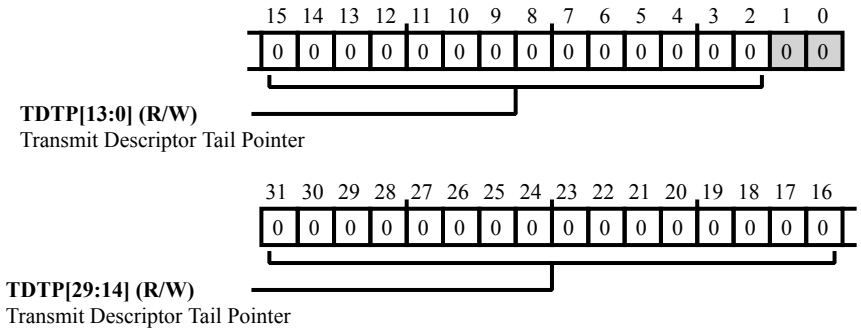

Figure 30-74: EMAC_DMA[n]_TXDSC_TLPTR Register Diagram

Table 30-129: EMAC_DMA[n]_TXDSC_TLPTR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:2 (R/W)	TDTP	Transmit Descriptor Tail Pointer. The EMAC_DMA[n]_TXDSC_TLPTR.TDTP field contains the tail pointer for the Tx descriptor ring. The software writes the tail pointer to add more descriptors to the Tx channel. The hardware tries to transmit all packets referenced by the descriptors between the head and the tail pointer registers.

DMA Channel n Transmit Control Register

The EMAC_DMA[n]_TXCTL register controls the Tx features such as PBL, TCP segmentation, and Tx channel weights.

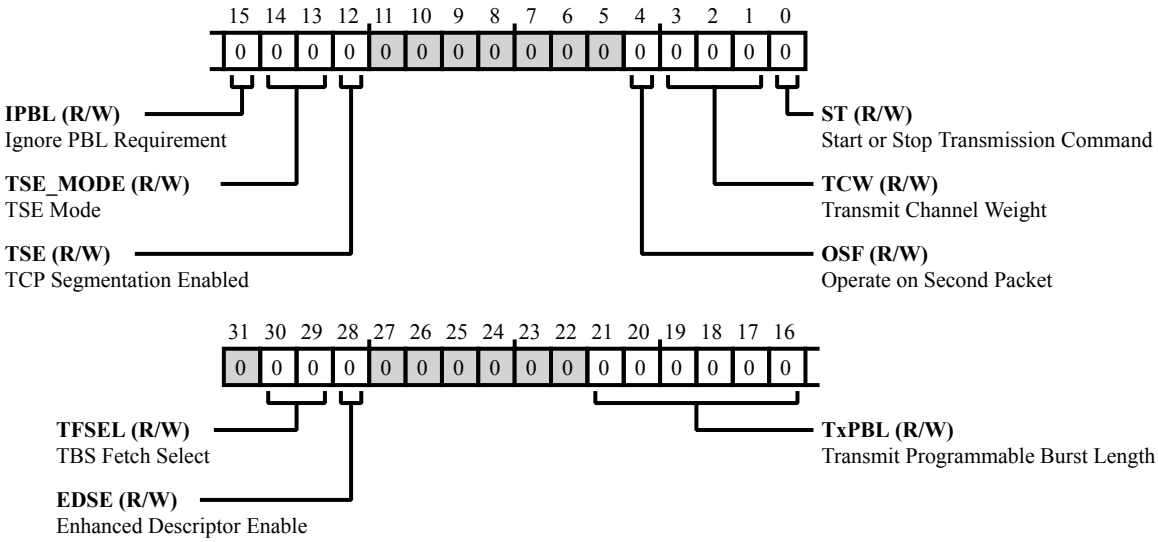

Figure 30-75: EMAC_DMA[n]_TXCTL Register Diagram

Table 30-130: EMAC_DMA[n]_TXCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
30:29 (R/W)	TFSEL	TBS Fetch Select. The EMAC_DMA[n]_TXCTL.TFSEL field select the EMAC_DMA_TBS_CTRL0 - EMAC_DMA_TBS_CTRL3 register fields (FTOS, FGSN, FTOV) for the channel.	
		0	EMAC_DMA_TBS_CTL0
		1	EMAC_DMA_TBS_CTL1
		2	EMAC_DMA_TBS_CTL2
		3	EMAC_DMA_TBS_CTL3
28 (R/W)	EDSE	Enhanced Descriptor Enable. When EMAC_DMA[n]_TXCTL.EDSE = 1, the corresponding channel uses enhanced descriptors that are 32 bytes for both normal and context descriptors. When cleared (=0), the corresponding channel uses the descriptors that are 16 bytes.	
		0	Enhanced Descriptor is Disabled
		1	Enhanced Descriptor is Enabled

Table 30-130: EMAC_DMA[n]_TXCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
21:16 (R/W)	TXPBL	Transmit Programmable Burst Length. The `EMAC_DMA[n]_TXCTL.TXPBL` field indicates the maximum number of beats to be transferred in one DMA block data transfer. The DMA always attempts max burst as specified in PBL each time it starts a burst transfer on the application bus. Program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior. To transfer more than 32 beats, perform the following steps: 1. Set the 8xPBL mode in EMAC_DMA[n]_CTL register. 2. Set the TxPBL. Note: The maximum value of TxPBL must be less than or equal to half the Tx queue size (EMAC_TQ[n]_OPMODE.TQS) in terms of beats. This is required so that the Tx queue has space to store at least another Tx PBL worth of data while the MTL Tx queue controller is transferring data to MAC. For example, in 64-bit data width configurations the total locations in Tx queue of size 512 bytes is 64, TxPBL and 8xPBL must be programmed to less than or equal to 32.	
15 (R/W)	IPBL	Ignore PBL Requirement. When `EMAC_DMA[n]_TXCTL.IPBL` = 1, the DMA does not check for PBL number of locations in the MTL before initiating a transfer. If space is not available, the MTL can use handshaking to slow the DMA. Note: The `EMAC_DMA[n]_TXCTL.IPBL` bit/mode must not be used when multiple transmit DMA channels are enabled as it might block other transmit and receive DMA channels from accessing the read data channel of SCB bus until space is available in transmit queue for the current transfer.	
		0	Ignore PBL Requirement is Disabled
		1	Ignore PBL Requirement is Enabled
14:13 (R/W)	TSE_MODE	TSE Mode. The `EMAC_DMA[n]_TXCTL.TSE_MODE` field indicates the TSE mode.	
		0	TSO/USO. Segmentation functionality is enabled.
		1	UFO with Checksum. Enables the UDP fragmentation functionality with checksum for all the UDP packets.
		2	UFO Without Checksum. Enables the UDP fragmentation functionality without Checksum for all the UDP packets.
		3	Reserved

Table 30-130: EMAC_DMA[n]_TXCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W)	TSE	TCP Segmentation Enabled. When EMAC_DMA[n]_TXCTL.TSE = 1, the DMA performs the TCP segmentation or UDP segmentation/fragmentation for packets in this channel. The TCP segmentation or UDP packet's segmentation/fragmentation is done only for those packets for which the TSE bit (TDES0[19]) is set in the Tx Normal descriptor. When EMAC_DMA[n]_TXCTL.TSE = 1, the TxPBL value must be greater than 4.	
		0	TCP Segmentation is Disabled
		1	TCP Segmentation is Enabled
4 (R/W)	OSF	Operate on Second Packet. When EMAC_DMA[n]_TXCTL.OSF = 1, the DMA processes the second packet of the transmit data, even before the status for the first packet is obtained.	
		0	Operate on Second Packet Disabled
		1	Operate on Second Packet Enabled
3:1 (R/W)	TCW	Transmit Channel Weight. The EMAC_DMA[n]_TXCTL.TCW field indicates the weight assigned to the corresponding transmit channel. When reset is complete, EMAC_DMA[n]_TXCTL.TCW = 0 for all channels by default, resulting in equal weights to all channels.	

Table 30-130: EMAC_DMA[n]_TXCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	ST	Start or Stop Transmission Command. When the EMAC_DMA[n]_TXCTL.ST bit is set, transmission is placed in the running state. The DMA checks the transmit list at the current position for a packet to be transmitted. The DMA tries to acquire descriptor from either of the following positions: The current position in the list - This is the base address of the transmit list configured by the EMAC_DMA[n]_TXDSC_ADDR register. The position at which the transmission was previously stopped - If the DMA does not own the current descriptor, the transmission enters the suspended state and the EMAC_DMA[n]_STAT.TBU =1. The start transmission command is effective only when the transmission is stopped. If the command is issued before configuring the EMAC_DMA[n]_TXDSC_ADDR register, the DMA behavior is unpredictable. When EMAC_DMA[n]_TXCTL.ST = 0, the transmission process is placed in the stopped state after completing the transmission of the current packet. The Next Descriptor position in the transmit list is saved, and it becomes the current position when the transmission is restarted. To change the list address, program EMAC_DMA[n]_TXDSC_ADDR register with a new value when EMAC_DMA[n]_TXCTL.ST = 0. The new value is considered when EMAC_DMA[n]_TXCTL.ST =1 again. The stop transmission command is effective only when the transmission of the current packet is complete or the transmission is in the suspended state.	
		0	Stop Transmission Command
		1	Start Transmission Command

DMA Debug Status 0 Register

The EMAC_DMA_DBG_STAT0 register gives the receive and transmit process status for DMA channels 0-2 for debugging purpose.

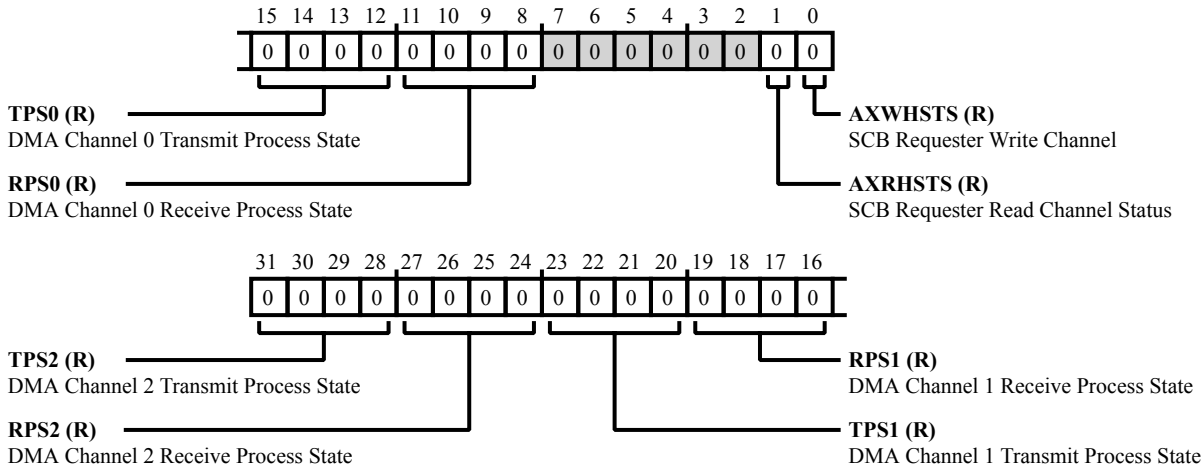

Figure 30-76: EMAC_DMA_DBG_STAT0 Register Diagram

Table 30-131: EMAC_DMA_DBG_STAT0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:28 (R/NW)	TPS2	DMA Channel 2 Transmit Process State. The EMAC_DMA_DBG_STAT0.TPS2 field indicates the Tx DMA FSM state for channel 2. The MSB of this field always returns 0. The EMAC_DMA_DBG_STAT0.TPS2 field does not generate an interrupt.	
		0	Stopped (Reset or Stop Transmit Command Issued)
		1	Running (Fetching Tx Transfer Descriptor)
		2	Running (Waiting for Status)
		3	Running (Reading Data from System Memory Buffer and Queuing It to the Tx Buffer (Tx FIFO))
		4	Time Stamp Write State
		5	Reserved
		6	Suspended (Tx Descriptor Unavailable or Tx Buffer Underflow)
		7	Running (Closing Tx Descriptor)
27:24 (R/NW)	RPS2	DMA Channel 2 Receive Process State. The EMAC_DMA_DBG_STAT0.RPS2 field indicates the Rx DMA FSM state for channel 2. The MSB of this field always returns 0. The EMAC_DMA_DBG_STAT0.RPS2 field does not generate an interrupt.	

Table 30-131: EMAC_DMA_DBG_STAT0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		0	Stopped (Reset or Stop Receive Command Issued)
		1	Running (Fetching Rx Transfer Descriptor)
		2	Reserved
		3	Running (Waiting for Rx Packet)
		4	Suspended (Rx Descriptor Unavailable)
		5	Running (Closing the Rx Descriptor)
		6	Time Stamp Write State
		7	Running (Transferring the Received Packet Data from the Rx Buffer to the System Memory)
23:20 (R/NW)	TPS1	DMA Channel 1 Transmit Process State. The `EMAC_DMA_DBG_STAT0.TPS1` field indicates the Tx DMA FSM state for channel 1. The MSB of this field always returns 0. The `EMAC_DMA_DBG_STAT0.TPS1` field does not generate an interrupt.	
		0	Stopped (Reset or Stop Transmit Command Issued)
		1	Running (Fetching Tx Transfer Descriptor)
		2	Running (Waiting for Status)
		3	Running (Reading Data from System Memory Buffer and Queuing It to the Tx Buffer (Tx FIFO))
		4	Time Stamp Write State
		5	Reserved
		6	Suspended (Tx Descriptor Unavailable or Tx Buffer Underflow)
		7	Running (Closing Tx Descriptor)
19:16 (R/NW)	RPS1	DMA Channel 1 Receive Process State. The `EMAC_DMA_DBG_STAT0.RPS1` field indicates the Rx DMA FSM state for channel 1. The MSB of this field always returns 0. The `EMAC_DMA_DBG_STAT0.RPS1` field does not generate an interrupt.	
		0	Stopped (Reset or Stop Receive Command Issued)
		1	Running (Fetching Rx Transfer Descriptor)
		2	Reserved
		3	Running (Waiting for Rx Packet)
		4	Suspended (Rx Descriptor Unavailable)
		5	Running (Closing the Rx Descriptor)

Bit No. (Access)	Bit Name	Description/Enumeration	
		6	Time Stamp Write State
		7	Running (Transferring the Received Packet Data from the Rx Buffer to the System Memory)
15:12 (R/NW)	TPS0	DMA Channel 0 Transmit Process State. The `EMAC_DMA_DBG_STAT0.TPS0` field indicates the Tx DMA FSM state for channel 0. The MSB of this field always returns 0. The `EMAC_DMA_DBG_STAT0.TPS0` field does not generate an interrupt.	
		0	Stopped (Reset or Stop Transmit Command Issued)
		1	Running (Fetching Tx Transfer Descriptor)
		2	Running (Waiting for Status)
		3	Running (Reading Data from System Memory Buffer and Queuing It to the Tx Buffer (Tx FIFO))
		4	Time Stamp Write State
		5	Reserved
		6	Suspended (Tx Descriptor Unavailable or Tx Buffer Underflow)
		7	Running (Closing Tx Descriptor)
11:8 (R/NW)	RPS0	DMA Channel 0 Receive Process State. The `EMAC_DMA_DBG_STAT0.RPS0` field indicates the Rx DMA FSM state for channel 0. The MSB of this field always returns 0. The `EMAC_DMA_DBG_STAT0.RPS0` field does not generate an interrupt.	
		0	Stopped (Reset or Stop Receive Command Issued)
		1	Running (Fetching Rx Transfer Descriptor)
		2	Reserved
		3	Running (Waiting for Rx Packet)
		4	Suspended (Rx Descriptor Unavailable)
		5	Running (Closing the Rx Descriptor)
		6	Time Stamp Write State
		7	Running (Transferring the Received Packet Data from the Rx Buffer to the System Memory)

Table 30-131: EMAC_DMA_DBG_STAT0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/NW)	AXRHSTS	SCB Requester Read Channel Status. When high, the `EMAC_DMA_DBG_STAT0.AXRHSTS` bit indicates that the read channel of the SCB requester is active, and it is transferring the data.	
		0	Status Not Detected
		1	Status Detected
0 (R/NW)	AXWHSTS	SCB Requester Write Channel. When high, the `EMAC_DMA_DBG_STAT0.AXWHSTS` bit indicates that the write channel of the SCB requester is active, and it is transferring data.	
		0	Status Not Detected
		1	Status Detected

DMA Debug Status 1 Register

The EMAC_DMA_DBG_STAT1 register gives the receive and transmit process status for DMA channels 3-6.

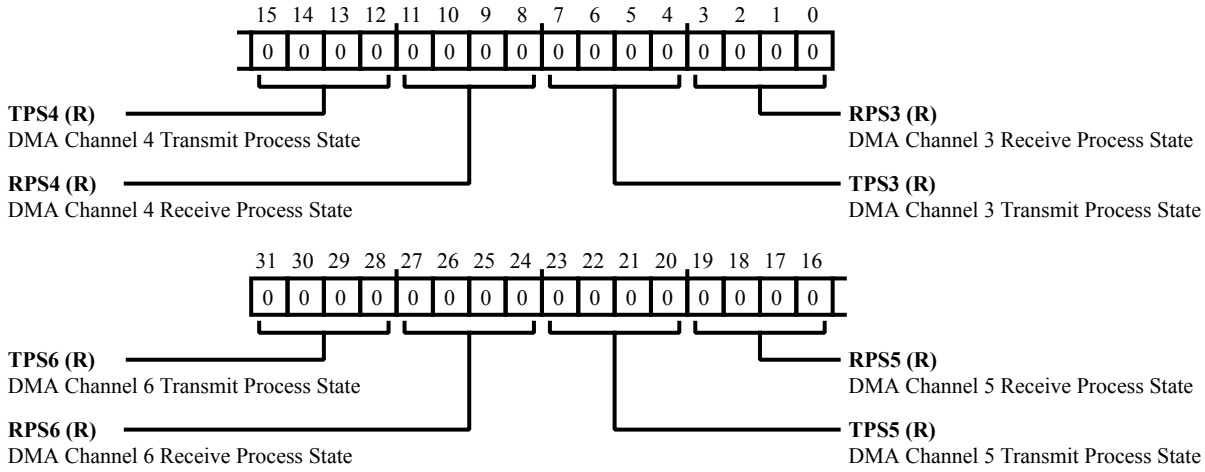

Figure 30-77: EMAC_DMA_DBG_STAT1 Register Diagram

Table 30-132: EMAC_DMA_DBG_STAT1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:28 (R/NW)	TPS6	DMA Channel 6 Transmit Process State. The EMAC_DMA_DBG_STAT1.TPS6 field indicates the Tx DMA FSM state for channel 6. The MSB of this field always returns 0. The EMAC_DMA_DBG_STAT1.TPS6 field does not generate an interrupt.	
		0	Stopped (Reset or Stop Transmit Command Issued)
		1	Running (Fetching Tx Transfer Descriptor)
		2	Running (Waiting for Status)
		3	Running (Reading Data from System Memory Buffer and Queuing It to the Tx Buffer (Tx FIFO))
		4	Time Stamp Write State
		5	Reserved
		6	Suspended (Tx Descriptor Unavailable or Tx Buffer Underflow)
		7	Running (Closing Tx Descriptor)
27:24 (R/NW)	RPS6	DMA Channel 6 Receive Process State. The EMAC_DMA_DBG_STAT1.RPS6 field indicates the Rx DMA FSM state for channel 6. The MSB of this field always returns 0. The EMAC_DMA_DBG_STAT1.RPS6 field does not generate an interrupt.	

Table 30-132: EMAC_DMA_DBG_STAT1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		0	Stopped (Reset or Stop Receive Command Issued)
		1	Running (Fetching Rx Transfer Descriptor)
		2	Reserved
		3	Running (Waiting for Rx Packet)
		4	Suspended (Rx Descriptor Unavailable)
		5	Running (Closing the Rx Descriptor)
		6	Time Stamp Write State
		7	Running (Transferring the Received Packet Data from the Rx Buffer to the System Memory)
23:20 (R/NW)	TPS5	DMA Channel 5 Transmit Process State. The `EMAC_DMA_DBG_STAT1.TPS5` field indicates the Tx DMA FSM state for channel 5. The MSB of this field always returns 0. The `EMAC_DMA_DBG_STAT1.TPS5` field does not generate an interrupt.	
		0	Stopped (Reset or Stop Transmit Command Issued)
		1	Running (Fetching Tx Transfer Descriptor)
		2	Running (Waiting for Status)
		3	Running (Reading Data from System Memory Buffer and Queuing It to the Tx Buffer (Tx FIFO))
		4	Time Stamp Write State
		5	Reserved
		6	Suspended (Tx Descriptor Unavailable or Tx Buffer Underflow)
		7	Running (Closing Tx Descriptor)
19:16 (R/NW)	RPS5	DMA Channel 5 Receive Process State. The `EMAC_DMA_DBG_STAT1.RPS5` field indicates the Rx DMA FSM state for channel 5. The MSB of this field always returns 0. The `EMAC_DMA_DBG_STAT1.RPS5` field does not generate an interrupt.	
		0	Stopped (Reset or Stop Receive Command Issued)
		1	Running (Fetching Rx Transfer Descriptor)
		2	Reserved
		3	Running (Waiting for Rx Packet)
		4	Suspended (Rx Descriptor Unavailable)
		5	Running (Closing the Rx Descriptor)

Table 30-132: EMAC_DMA_DBG_STAT1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		6	Time Stamp Write State
		7	Running (Transferring the Received Packet Data from the Rx Buffer to the System Memory)
15:12 (R/NW)	TPS4	DMA Channel 4 Transmit Process State. The `EMAC_DMA_DBG_STAT1.TPS4` field indicates the Tx DMA FSM state for channel 4. The MSB of this field always returns 0. The `EMAC_DMA_DBG_STAT1.TPS4` field does not generate an interrupt.	
		0	Stopped (Reset or Stop Transmit Command Issued)
		1	Running (Fetching Tx Transfer Descriptor)
		2	Running (Waiting for Status)
		3	Running (Reading Data from System Memory Buffer and Queuing It to the Tx Buffer (Tx FIFO))
		4	Time Stamp Write State
		5	Reserved
		6	Suspended (Tx Descriptor Unavailable or Tx Buffer Underflow)
		7	Running (Closing Tx Descriptor)
11:8 (R/NW)	RPS4	DMA Channel 4 Receive Process State. The `EMAC_DMA_DBG_STAT1.RPS4` field indicates the Rx DMA FSM state for channel 4. The MSB of this field always returns 0. The `EMAC_DMA_DBG_STAT1.RPS4` field does not generate an interrupt.	
		0	Stopped (Reset or Stop Receive Command Issued)
		1	Running (Fetching Rx Transfer Descriptor)
		2	Reserved
		3	Running (Waiting for Rx Packet)
		4	Suspended (Rx Descriptor Unavailable)
		5	Running (Closing the Rx Descriptor)
		6	Time Stamp Write State
		7	Running (Transferring the Received Packet Data from the Rx Buffer to the System Memory)
7:4 (R/NW)	TPS3	DMA Channel 3 Transmit Process State. The `EMAC_DMA_DBG_STAT1.TPS3` field indicates the Tx DMA FSM state for channel 3. The MSB of this field always returns 0. The `EMAC_DMA_DBG_STAT1.TPS3` field does not generate an interrupt.	

Table 30-132: EMAC_DMA_DBG_STAT1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		0	Stopped (Reset or Stop Transmit Command Issued)
		1	Running (Fetching Tx Transfer Descriptor)
		2	Running (Waiting for Status)
		3	Running (Reading Data from System Memory Buffer and Queuing It to the Tx Buffer (Tx FIFO))
		4	Time Stamp Write State
		5	Reserved
		6	Suspended (Tx Descriptor Unavailable or Tx Buffer Underflow)
		7	Running (Closing Tx Descriptor)
3:0 (R/NW)	RPS3	DMA Channel 3 Receive Process State. The `EMAC_DMA_DBG_STAT1.RPS3` field indicates the Rx DMA FSM state for channel 3. The MSB of this field always returns 0. The `EMAC_DMA_DBG_STAT1.RPS3` field does not generate an interrupt.	
		0	Stopped (Reset or Stop Receive Command Issued)
		1	Running (Fetching Rx Transfer Descriptor)
		2	Reserved
		3	Running (Waiting for Rx Packet)
		4	Suspended (Rx Descriptor Unavailable)
		5	Running (Closing the Rx Descriptor)
		6	Time Stamp Write State
		7	Running (Transferring the Received Packet Data from the Rx Buffer to the System Memory)

DMA Debug Status 2 Register

The EMAC_DMA_DBG_STAT2 register gives the receive and transmit process status for DMA channel 7.

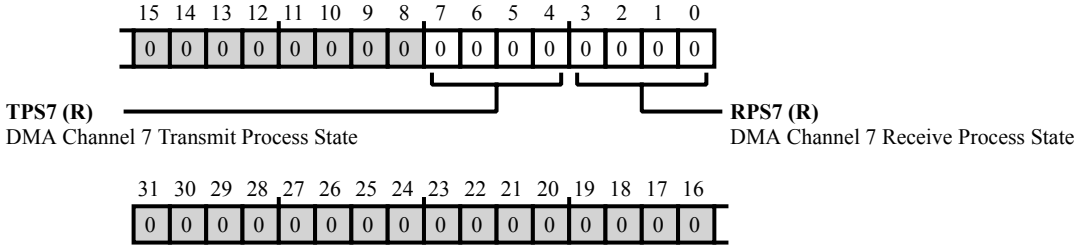

Figure 30-78: EMAC_DMA_DBG_STAT2 Register Diagram

Table 30-133: EMAC_DMA_DBG_STAT2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
7:4 (R/NW)	TPS7	DMA Channel 7 Transmit Process State. The EMAC_DMA_DBG_STAT2.TPS7 field indicates the Tx DMA FSM state for channel 7. The MSB of this field always returns 0. The EMAC_DMA_DBG_STAT2.TPS7 field does not generate an interrupt.	
		0	Stopped (Reset or Stop Transmit Command Issued)
		1	Running (Fetching Tx Transfer Descriptor)
		2	Running (Waiting for Status)
		3	Running (Reading Data from System Memory Buffer and Queuing It to the Tx Buffer (Tx FIFO))
		4	Time Stamp Write State
		5	Reserved
		6	Suspended (Tx Descriptor Unavailable or Tx Buffer Underflow)
		7	Running (Closing Tx Descriptor)
3:0 (R/NW)	RPS7	DMA Channel 7 Receive Process State. The EMAC_DMA_DBG_STAT2.RPS7 field indicates the Rx DMA FSM state for channel 7. The MSB of this field always returns 0. The EMAC_DMA_DBG_STAT2.RPS7 field does not generate an interrupt.	
		0	Stopped (Reset or Stop Receive Command Issued)
		1	Running (Fetching Rx Transfer Descriptor)
		2	Reserved
		3	Running (Waiting for Rx Packet)
		4	Suspended (Rx Descriptor Unavailable)

Table 30-133: EMAC_DMA_DBG_STAT2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		5	Running (Closing the Rx Descriptor)
		6	Time Stamp Write State
		7	Running (Transferring the Received Packet Data from the Rx Buffer to the System Memory)

DMA Interrupt Status Register

The application reads the EMAC_DMA_ISTAT register during interrupt service routine or polling to determine the interrupt status of DMA channels, MTL queues, and the MAC.

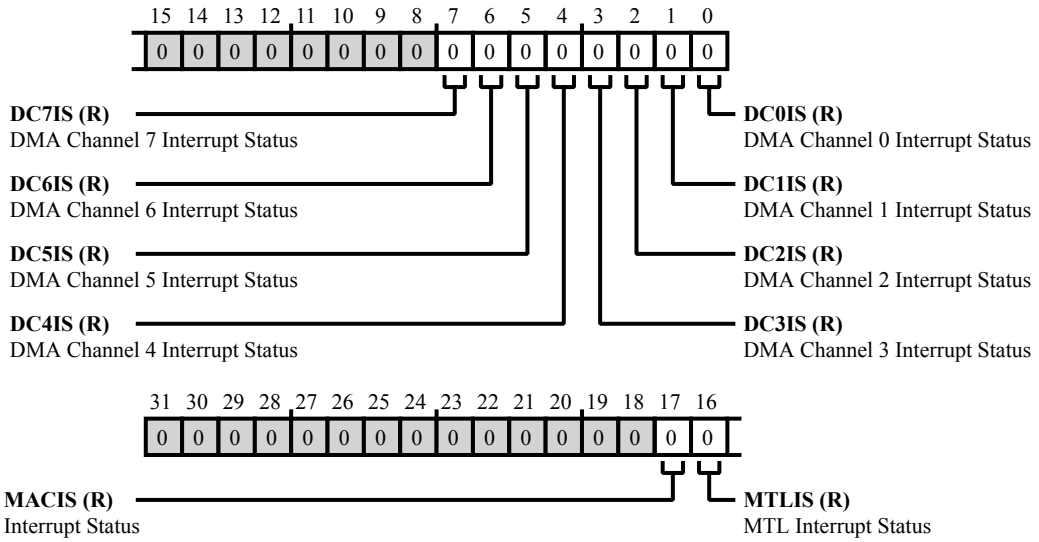

Figure 30-79: EMAC_DMA_ISTAT Register Diagram

Table 30-134: EMAC_DMA_ISTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/NW)	MACIS	Interrupt Status. The EMAC_DMA_ISTAT.MACIS bit indicates an interrupt event in the MAC. To clear the EMAC_DMA_ISTAT.MACIS bit (=0), the software must read the corresponding register in the MAC to get the exact cause of the interrupt and clear its source.	
		0	MAC Interrupt Status Not Detected
		1	MAC Interrupt Status Detected
16 (R/NW)	MTLIS	MTL Interrupt Status. The EMAC_DMA_ISTAT.MTLIS bit indicates an interrupt event in the MTL. To clear the EMAC_DMA_ISTAT.MTLIS bit (=0), the software must read the corresponding register in the MTL to get the exact cause of the interrupt and clear its source.	
		0	MTL Interrupt Status Not Detected
		1	MTL Interrupt Status Detected

Table 30-134: EMAC_DMA_ISTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/NW)	DC7IS	DMA Channel 7 Interrupt Status. The EMAC_DMA_ISTAT.DC7IS bit indicates an interrupt event in DMA channel 7. To clear the EMAC_DMA_ISTAT.DC7IS bit (=0), the software must read the corresponding register in DMA channel 7 to get the exact cause of the interrupt and clear its source.	
		0	DMA Channel 7 Interrupt Status Not Detected
		1	DMA Channel 7 Interrupt Status Detected
6 (R/NW)	DC6IS	DMA Channel 6 Interrupt Status. The EMAC_DMA_ISTAT.DC6IS bit indicates an interrupt event in DMA channel 6. To clear the EMAC_DMA_ISTAT.DC6IS bit (=0), the software must read the corresponding register in DMA channel 6 to get the exact cause of the interrupt and clear its source.	
		0	DMA Channel 6 Interrupt Status Not Detected
		1	DMA Channel 6 Interrupt Status Detected
5 (R/NW)	DC5IS	DMA Channel 5 Interrupt Status. The EMAC_DMA_ISTAT.DC5IS bit indicates an interrupt event in DMA channel 5. To clear the EMAC_DMA_ISTAT.DC5IS bit (=0), the software must read the corresponding register in DMA channel 5 to get the exact cause of the interrupt and clear its source.	
		0	DMA Channel 5 Interrupt Status Not Detected
		1	DMA Channel 5 Interrupt Status Detected
4 (R/NW)	DC4IS	DMA Channel 4 Interrupt Status. The EMAC_DMA_ISTAT.DC4IS bit indicates an interrupt event in DMA channel 4. To clear the EMAC_DMA_ISTAT.DC4IS bit (=0), the software must read the corresponding register in DMA channel 4 to get the exact cause of the interrupt and clear its source.	
		0	DMA Channel 4 Interrupt Status Not Detected
		1	DMA Channel 4 Interrupt Status Detected
3 (R/NW)	DC3IS	DMA Channel 3 Interrupt Status. The EMAC_DMA_ISTAT.DC3IS bit indicates an interrupt event in DMA channel 3. To clear the EMAC_DMA_ISTAT.DC3IS bit (=0), the software must read the corresponding register in DMA channel 3 to get the exact cause of the interrupt and clear its source.	
		0	DMA Channel 3 Interrupt Status Not Detected
		1	DMA Channel 3 Interrupt Status Detected

Table 30-134: EMAC_DMA_ISTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/NW)	DC2IS	DMA Channel 2 Interrupt Status. The EMAC_DMA_ISTAT.DC2IS bit indicates an interrupt event in DMA channel 2. To clear the EMAC_DMA_ISTAT.DC2IS bit (=0), the software must read the corresponding register in DMA channel 2 to get the exact cause of the interrupt and clear its source.	
		0	DMA Channel 2 Interrupt Status Not Detected
		1	DMA Channel 2 Interrupt Status Detected
1 (R/NW)	DC1IS	DMA Channel 1 Interrupt Status. The EMAC_DMA_ISTAT.DC1IS bit indicates an interrupt event in DMA channel 1. To clear the EMAC_DMA_ISTAT.DC1IS bit (=0), the software must read the corresponding register in DMA channel 1 to get the exact cause of the interrupt and clear its source.	
		0	DMA Channel 1 Interrupt Status Not Detected
		1	DMA Channel 1 Interrupt Status Detected
0 (R/NW)	DC0IS	DMA Channel 0 Interrupt Status. The EMAC_DMA_ISTAT.DC0IS bit indicates an interrupt event in DMA channel 0. To clear the EMAC_DMA_ISTAT.DC0IS bit (=0), the software must read the corresponding register in DMA channel 0 to get the exact cause of the interrupt and clear its source.	
		0	DMA Channel 0 Interrupt Status Not Detected
		1	DMA Channel 0 Interrupt Status Detected

DMA Mode Register

The EMAC_DMA_MODE register establishes the bus operating modes for the DMA.

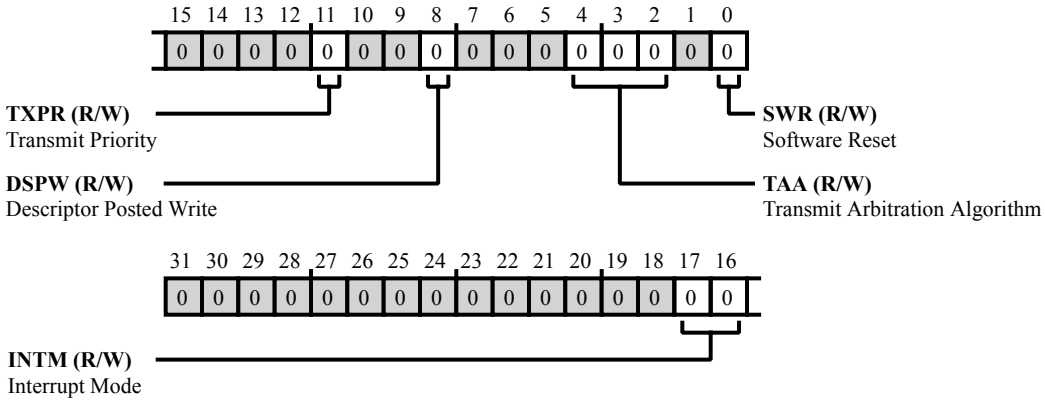

Figure 30-80: EMAC_DMA_MODE Register Diagram

Table 30-135: EMAC_DMA_MODE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
17:16 (R/W)	INTM	Interrupt Mode. The `EMAC_DMA_MODE.INTM` field defines the interrupt mode of the EMAC module. The behavior of the following outputs change depending on the following settings: - EMAC_DMA[n]_TX (Transmit Per Channel Interrupt) - EMAC_DMA[n]_RX (Receive Per Channel Interrupt) - EMAC_STAT (Common Interrupt) It also changes the behavior of the EMAC_DMA[n]_STAT.RI and EMAC_DMA[n]_STAT.TI bits. - 00: EMAC_DMA[n]_TX/RX are pulse signals for each TX/RX packet transfer completion events (irrespective of whether corresponding interrupts are enabled) for which IOC bits are enabled in descriptor. EMAC_STAT is also asserted when corresponding interrupts are enabled and cleared only when software clears the corresponding RI/TI status bits. - 01: EMAC_DMA[n]_TX/RX are level signals asserted on TX/RX packet transfer completion event when corresponding interrupts are enabled and deasserted when the software clears the corresponding RI/TI status bits. The EMAC_STAT is not asserted for these TX/RX packet transfer completion events. - 10: EMAC_DMA[n]_TX/RX are level signals asserted on TX/RX packet transfer completion event when corresponding interrupts are enabled and deasserted when the software clears the corresponding RI/TI status bits. However, the signal is asserted again if the same event occurred again before it was cleared. The EMAC_STAT is not asserted for these TX/RX packet transfer completion events. - 11: Reserved For more details, see Transfer Complete Interrupt Behavior.	
		0	See Above Description
		1	See Above Description
		2	See Above Description
		3	Reserved
11 (R/W)	TXPR	Transmit Priority. When set, the `EMAC_DMA_MODE.TXPR` bit indicates that the Tx DMA has higher priority than the Rx DMA during arbitration for the system-side bus.	
		0	Transmit Priority is Disabled
		1	Transmit Priority is Enabled

Table 30-135: EMAC_DMA_MODE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W)	DSPW	Descriptor Posted Write. When the EMAC_DMA_MODE.DSPW bit is cleared (=0), it indicates that the descriptor writes are always non-posted. When set (=1), the EMAC_DMA_MODE.DSPW bit indicates that the descriptor is non-posted only when the IOC (Interrupt on Completion) is set in last descriptor. Otherwise, the descriptor writes are always posted.	
		0	Disable
		1	Enable
4:2 (R/W)	TAA	Transmit Arbitration Algorithm. The EMAC_DMA_MODE.TAA field is used to select the arbitration algorithm for the transmit side when multiple Tx DMAs are selected.	
		0	Fixed Priority (Channel 0 Has the Lowest Priority and the Last Channel Has the Highest Priority)
		1	Weighted Strict Priority (WSP)
		2	Weighted Round-Robin (WRR)
		3	Reserved
0 (R/W)	SWR	Software Reset. When the EMAC_DMA_MODE.SWR bit is set, the MAC and the DMA controller reset the logic and all internal registers of the DMA, MTL, and MAC. The EMAC_DMA_MODE.SWR bit is automatically cleared after the reset operation is complete in all the EMAC clock domains. Before reprogramming any the EMAC register, a value of zero should be read in the EMAC_DMA_MODE.SWR bit. The EMAC_DMA_MODE.SWR bit must be read at least 4 SCLK0 clock cycles after it is written to 1. Note: The reset operation is complete only when all resets in all active clock domains are deasserted. Therefore, it is essential that all PHY inputs clocks (applicable for the selected PHY interface) are present for software reset completion. The time to complete the software reset operation depends on the frequency of the slowest active clock. Access restriction applies. Write 1 to set. Self-cleared. Writing 0 has no effect.	
		0	Software Reset is Disabled
		1	Software Reset is Enabled

DMA System Bus Mode Register

The EMAC_DMA_SYSBMODE register controls the behavior of the SPB or SCB requester. It mainly controls burst splitting and number of outstanding requests.

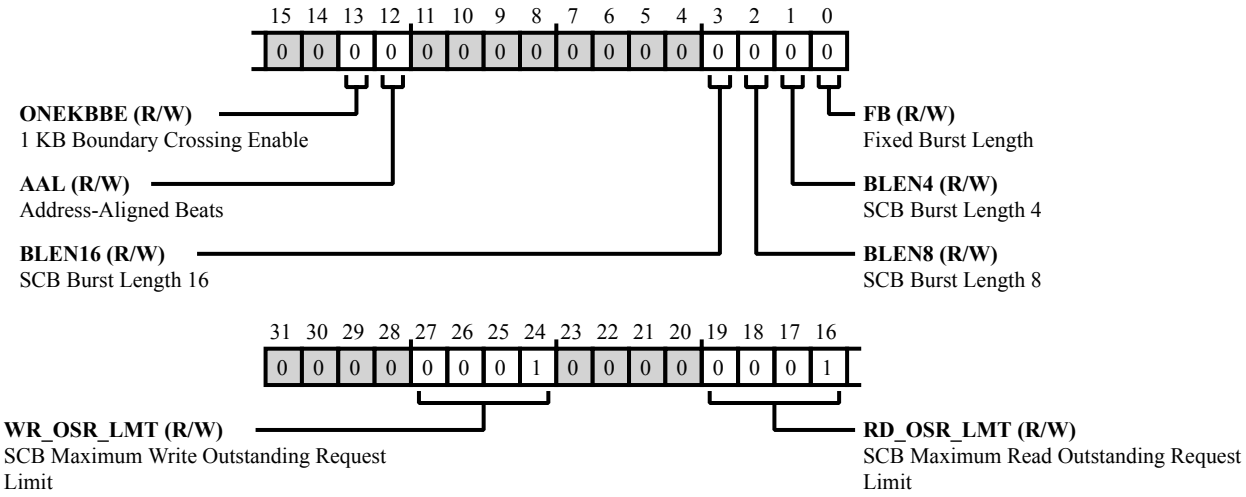

Figure 30-81: EMAC_DMA_SYSBMODE Register Diagram

Table 30-136: EMAC_DMA_SYSBMODE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
27:24 (R/W)	WR_OSR_LMT	SCB Maximum Write Outstanding Request Limit. This value limits the maximum outstanding request on the SCB write interface. Maximum outstanding requests = EMAC_DMA_SYSBMODE.WR_OSR_LMT + 1	
19:16 (R/W)	RD_OSR_LMT	SCB Maximum Read Outstanding Request Limit. This value limits the maximum outstanding request on the SCB read interface. Maximum outstanding requests = EMAC_DMA_SYSBMODE.RD_OSR_LMT + 1.	
13 (R/W)	ONEKBBE	1 KB Boundary Crossing Enable. The EMAC_DMA_SYSBMODE.ONEKBBE bit indicates whether the burst transfers performed by the SCB requester do not cross a 1 KB or (the default) 4 KB boundary.	
		0	Disable
		1	Enable

Table 30-136: EMAC_DMA_SYSBMODE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W)	AAL	Address-Aligned Beats. When the EMAC_DMA_SYSBMODE.AAL = 1, the SCB or SPB requester performs address-aligned burst transfers on read and write channels. When the EMAC_DMA_SYSBMODE.AAL = 0, the SCB or SPB requester performs burst transfers on read and write channels without aligning to address boundaries.	
		0	Address-Aligned Beats is Disabled
		1	Address-Aligned Beats is Enabled
3 (R/W)	BLEN16	SCB Burst Length 16. When EMAC_DMA_SYSBMODE.BLEN16 = 1 or EMAC_DMA_SYSBMODE.FB = 1, the SCB requester can select a burst length of 16 on the SCB interface. When EMAC_DMA_SYSBMODE.FB = 0, writing to the EMAC_DMA_SYSBMODE.BLEN16 bit has no effect.	
		0	Disable
		1	Enable
2 (R/W)	BLEN8	SCB Burst Length 8. When EMAC_DMA_SYSBMODE.BLEN8 = 1 or EMAC_DMA_SYSBMODE.FB = 1, the SCB requester can select a burst length of 8 on the SCB interface. When EMAC_DMA_SYSBMODE.FB = 0, writing to the EMAC_DMA_SYSBMODE.BLEN8 bit has no effect.	
		0	Disable
		1	Enable
1 (R/W)	BLEN4	SCB Burst Length 4. When EMAC_DMA_SYSBMODE.BLEN4 = 1 or EMAC_DMA_SYSBMODE.FB = 1, the SCB requester can select a burst length of 4 on the SCB interface. When EMAC_DMA_SYSBMODE.FB = 0, writing to the EMAC_DMA_SYSBMODE.BLEN4 bit has no effect.	
		0	Disable
		1	Enable

Table 30-136: EMAC_DMA_SYSBMODE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	FB	Fixed Burst Length. The EMAC_DMA_SYSBMODE.FB bit enables a fixed burst length. When EMAC_DMA_SYSBMODE.FB= 1, the SCB requester initiates burst lengths as indicated by the BLEN16, BLEN8, or BLEN4 field -- Burst transfers of length 1. When EMAC_DMA_SYSBMODE.FB = 0, the SCB requester initiates burst transfers that are equal to or less than the maximum allowed burst length programmed in bits[7:4].	
		0	Fixed Burst Length is Disabled
		1	Fixed Burst Length is Enabled

DMA TBS Control 0 Register

The EMAC_DMA_TBS_CTL0 register is used to control the Time Based Scheduling (TBS) attributes.

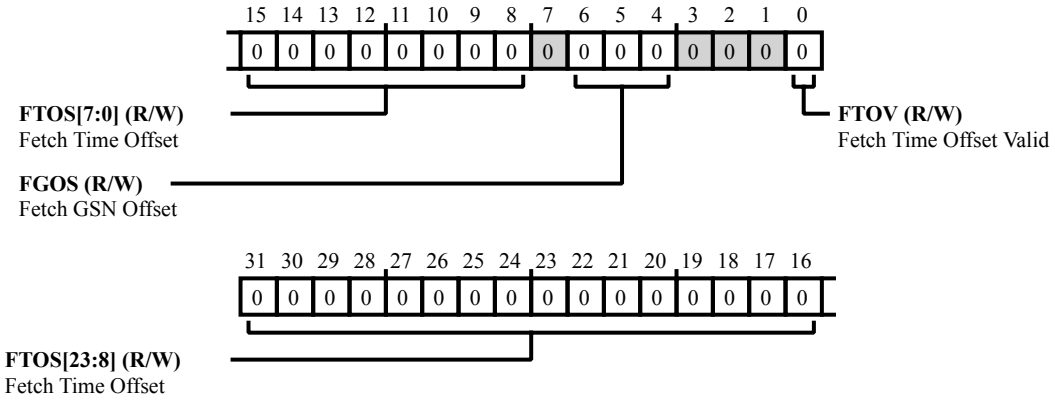

Figure 30-82: EMAC_DMA_TBS_CTL0 Register Diagram

Table 30-137: EMAC_DMA_TBS_CTL0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:8 (R/W)	FTOS	Fetch Time Offset. The EMAC_DMA_TBS_CTL0.FTOS field indicates the value in units of 256 nanoseconds, that has to be deducted from the launch time to compute the fetch Time. Max value: 999,999,999 ns, additionally should be smaller than CTR-1 value when ESTM mode is enabled since this value is a modulo CTR value.	
6:4 (R/W)	FGOS	Fetch GSN Offset. The EMAC_DMA_TBS_CTL0.FGOS field indicates the number of GSN slots that must be deducted from the Launch GSN to compute the Fetch GSN. Value valid only when EMAC_DMA_TBS_CTL0.FTOV is set.	
0 (R/W)	FTOV	Fetch Time Offset Valid. When set (=1), the EMAC_DMA_TBS_CTL0.FTOV bit indicates that the EMAC_DMA_TBS_CTL0.FTOS field is valid. When cleared (=0), the EMAC_DMA_TBS_CTL0.FTOV bit indicates that the Fetch Offset is not valid and the DMA engine can fetch the frames from host memory without any time restrictions.	
		0	Fetch Time Offset is Invalid
		1	Fetch Time Offset is Valid

DMA TBS Control 1 Register

The EMAC_DMA_TBS_CTL1 register is used to control the Time Based Scheduling (TBS) attributes.

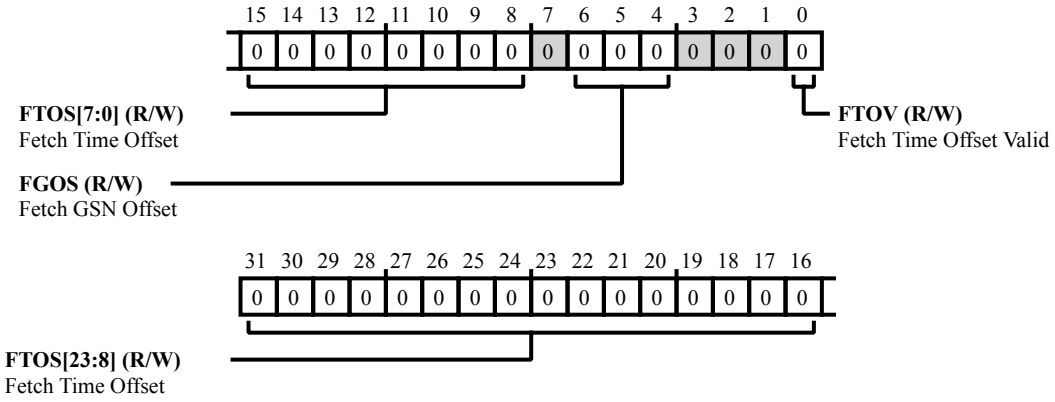

Figure 30-83: EMAC_DMA_TBS_CTL1 Register Diagram

Table 30-138: EMAC_DMA_TBS_CTL1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:8 (R/W)	FTOS	Fetch Time Offset. The value in units of 256 nanoseconds, that has to be deducted from the Launch time to compute the Fetch Time. Max value: 999,999,999 ns, additionally should be smaller than CTR-1 value when ESTM mode is enabled since this value is a modulo CTR value.	
6:4 (R/W)	FGOS	Fetch GSN Offset. The number GSN slots that must be deducted from the Launch GSN to compute the Fetch GSN. Value valid only when EMAC_DMA_TBS_CTL1.FTOV= 1.	
0 (R/W)	FTOV	Fetch Time Offset Valid. When set (=1), the EMAC_DMA_TBS_CTL1.FTOV bit indicates that the EMAC_DMA_TBS_CTL1.FTOS field is valid. When not set, indicates the Fetch Offset is not valid and the DMA engine can fetch the frames from host memory without any time restrictions.	
		0	Fetch Time Offset is Invalid
		1	Fetch Time Offset is Valid

DMA TBS Control 2 Register

The EMAC_DMA_TBS_CTL2 register is used to control the Time Based Scheduling (TBS) attributes.

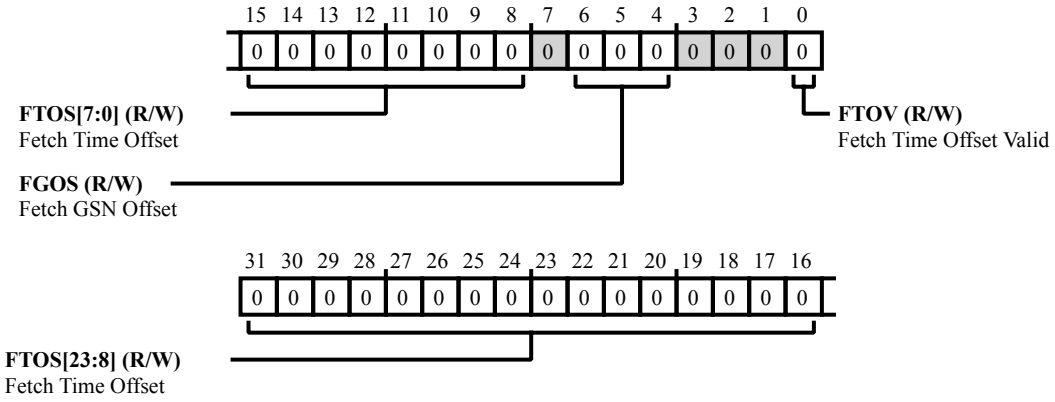

Figure 30-84: EMAC_DMA_TBS_CTL2 Register Diagram

Table 30-139: EMAC_DMA_TBS_CTL2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:8 (R/W)	FTOS	Fetch Time Offset. The value in units of 256 nanoseconds, that has to be deducted from the Launch time to compute the Fetch Time. Max value: 999,999,999 ns, additionally should be smaller than CTR-1 value when ESTM mode is enabled since this value is a modulo CTR value.	
6:4 (R/W)	FGOS	Fetch GSN Offset. The EMAC_DMA_TBS_CTL2.FGOS field indicates the number GSN slots that must be deducted from the Launch GSN to compute the Fetch GSN. Value valid only when EMAC_DMA_TBS_CTL2.FTOV= 1.	
0 (R/W)	FTOV	Fetch Time Offset Valid. When set (=1), the EMAC_DMA_TBS_CTL2.FTOV bit indicates that the EMAC_DMA_TBS_CTL2.FTOS field is valid. When not set, indicates the Fetch Offset is not valid and the DMA engine can fetch the frames from host memory without any time restrictions.	
		0	Fetch Time Offset is Invalid
		1	Fetch Time Offset is Valid

DMA TBS Control 3 Register

The EMAC_DMA_TBS_CTL3 register is used to control the TBS attributes.

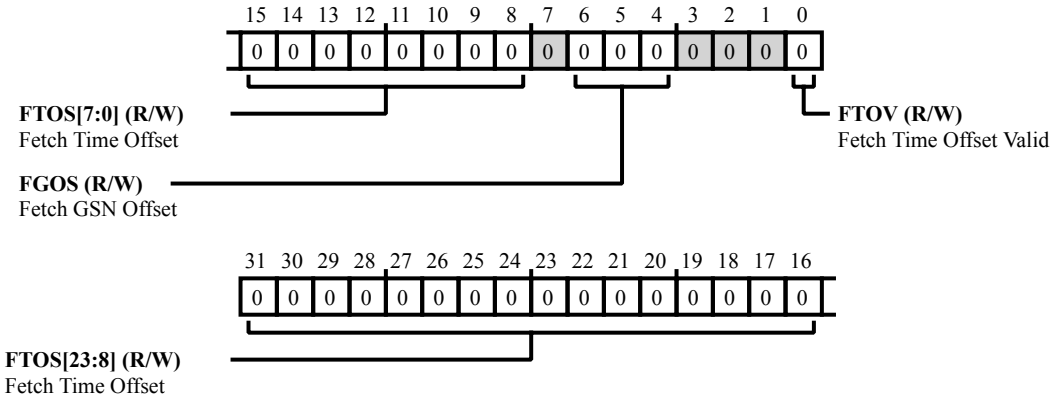

Figure 30-85: EMAC_DMA_TBS_CTL3 Register Diagram

Table 30-140: EMAC_DMA_TBS_CTL3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:8 (R/W)	FTOS	Fetch Time Offset. The value in units of 256 nanoseconds, that has to be deducted from the Launch time to compute the Fetch Time. Max value: 999,999,999 ns, additionally should be smaller than CTR-1 value when ESTM mode is enabled since this value is a modulo CTR value.	
6:4 (R/W)	FGOS	Fetch GSN Offset. The EMAC_DMA_TBS_CTL3.FGOS field indicates the number of GSN slots that must be deducted from the Launch GSN to compute the Fetch GSN. Value valid only when EMAC_DMA_TBS_CTL3.FTOV is set.	
0 (R/W)	FTOV	Fetch Time Offset Valid. When set (=1), the EMAC_DMA_TBS_CTL3.FTOV bit indicates that the EMAC_DMA_TBS_CTL3.FTOS field is valid. When cleared (=0), the EMAC_DMA_TBS_CTL3.FTOV bit indicates that the Fetch Offset is not valid and the DMA engine can fetch the frames from host memory without any time restrictions.	
		0	Fetch Time Offset is Invalid
		1	Fetch Time Offset is Valid

LPI One Microsecond Tic Counter Register

The EMAC_ONEUS_TIC_CNT register controls the generation of the reference time (1 microsecond tic) for all of the LPI timers. This timer has to be programmed by the software initially.

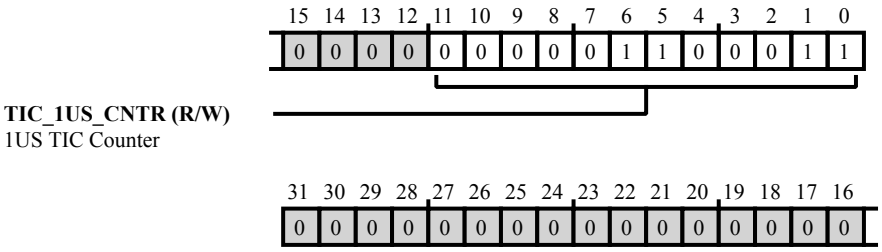

Figure 30-86: EMAC_ONEUS_TIC_CNT Register Diagram

Table 30-141: EMAC_ONEUS_TIC_CNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
11:0 (R/W)	TIC_1US_CNTR	1US TIC Counter. The application must program the EMAC_ONEUS_TIC_CNT.TIC_1US_CNTR field so that the number of clock cycles of SCLK0 is 1us. (Subtract 1 from the value before programming). For example, if the SCLK0 is 100MHz, this field must be programmed to value 100 - 1 = 99 (which is 0x63). This is required to generate the 1 us events that are used to update some of the EEE-related counters.

Address Resolution Protocol (ARP) Register

The EMAC_ARP_ADDR register contains the IPv4 destination address of the MAC.

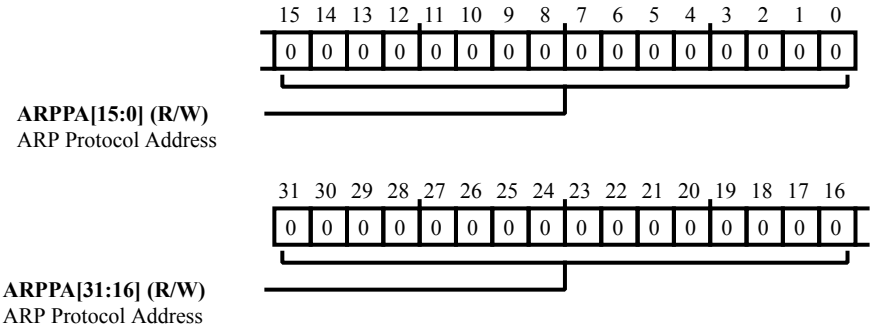

Figure 30-87: EMAC_ARP_ADDR Register Diagram

Table 30-142: EMAC_ARP_ADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	ARPPA	ARP Protocol Address. The EMAC_ARP_ADDR.ARPPA field contains the IPv4 destination address of the MAC. This address is used for perfect match with the protocol address of the target field in the received ARP packet.

MAC Address 0 High Register

The EMAC_ADDR0_HI register holds the upper 16 bits of the first 6-byte MAC address of the station. The first DA byte that is received on the (G)MII interface corresponds to the LS byte (Bits [7:0]) of the EMAC_ADDR0_LO register. For example, if 0x112233445566 is received (0x11 in lane 0 of the first column) on the (G)MII as the destination address, then the MAC Address 0 Register [47:0] is compared with 0x665544332211.

The MAC address registers are configured to be double-synchronized to the (G)MII clock domains. Hence, the synchronization is triggered only when bits[31:24] (in little endian mode) or bits[7:0] (in big endian mode) of the EMAC_ADDR0_LO register are written. For proper synchronization updates, the consecutive writes to this register should be performed only after at least four clock cycles in the (G)MII clock domain.

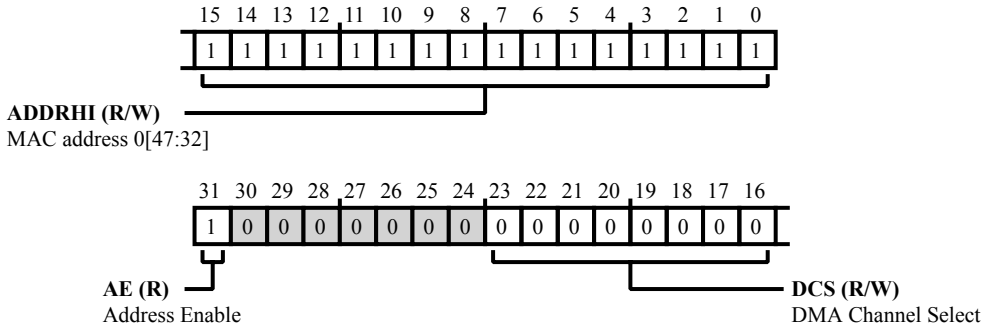

Figure 30-88: EMAC_ADDR0_HI Register Diagram

Table 30-143: EMAC_ADDR0_HI Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/NW)	AE	Address Enable. The EMAC_ADDR0_HI.AE bit is always set (=1).	
		0	Invalid
		1	The bit is always set
23:16 (R/W)	DCS	DMA Channel Select. When EMAC_MAC_EXT_CFG.PDC = 0, the EMAC_ADDR0_HI.DCS field contains the binary representation of the DMA channel number to which an Rx packet whose DA matches the MAC Address 0 content is routed. When EMAC_MAC_EXT_CFG.PDC = 1, the EMAC_ADDR0_HI.DCS field contains the one-hot representation of one or more DMA channel numbers to which an Rx packet whose DA matches the MAC Address 0 content is routed.	
15:0 (R/W)	ADDRHI	MAC address 0[47:32]. The EMAC_ADDR0_HI.ADDRHI field contains the upper 16 bits [47:32] of the first 6-byte MAC address. The MAC uses this field for filtering the received packets and inserting the MAC address in the Transmit Flow Control (Pause) Packets.	

MAC Address 0 Low Register

The EMAC_ADDR0_LO register holds the lower 32 bits of the 6-byte first MAC address of the station.

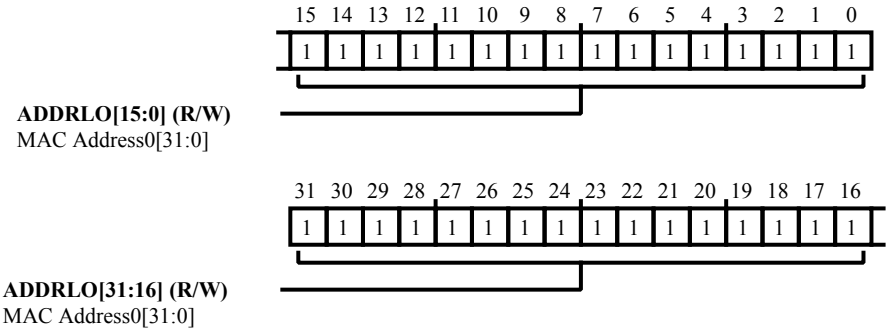

Figure 30-89: EMAC_ADDR0_LO Register Diagram

Table 30-144: EMAC_ADDR0_LO Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	ADDRLO	MAC Address0[31:0]. The EMAC_ADDR0_LO.ADDRLO field contains the lower 32 bits of the first 6-byte MAC address. The MAC uses this field for filtering the received packets and inserting the MAC address in the Transmit Flow Control (Pause) Packets.

MAC Address n High Register

The EMAC_ADDR[i]_HI register holds the upper 16 bits of the second 6-byte MAC address of the station.

If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or bits[7:0] (in big-endian mode) of the EMAC_ADDR0_LO register are written. For proper synchronization updates, the consecutive writes to this EMAC_ADDR0_LO register should be performed after at least four clock cycles in the destination clock domain.

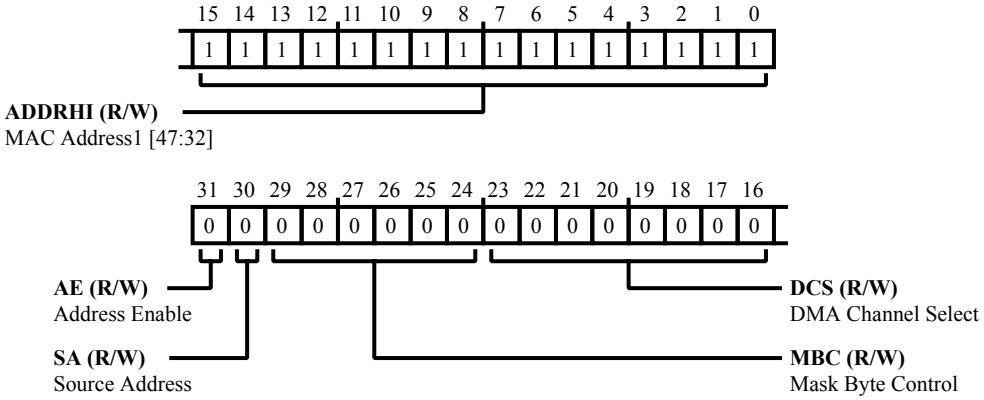

Figure 30-90: EMAC_ADDR[i]_HI Register Diagram

Table 30-145: EMAC_ADDR[i]_HI Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	AE	Address Enable. When the EMAC_ADDR[i]_HI.AE bit is set (=1), the address filter module uses the second MAC address for perfect filtering. When EMAC_ADDR[i]_HI.AE = 0, the address filter module ignores the address for filtering.	
		0	Address is Ignored
		1	Address is Enabled
30 (R/W)	SA	Source Address. When the EMAC_ADDR[i]_HI.SA bit is set (=1), MAC address 1 [47:0] is used to compare with the SA fields of the received packet. When EMAC_ADDR[i]_HI.SA = 0, MAC address 1 [47:0] is used to compare with the DA fields of the received packet.	
		0	Compare with Destination Address
		1	Compare with Source Address

Table 30-145: EMAC_ADDR[i]_HI Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
29:24 (R/W)	MBC	Mask Byte Control. These bits are mask control bits for comparing each of the MAC address bytes. When set (=1), the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC address 1 registers. Each bit controls the masking of the bytes as follows: Bit 29: EMAC_ADDR[i]_HI[15:8] Bit 28: EMAC_ADDR[i]_HI[7:0] Bit 27: EMAC_ADDR[i]_HI[31:24] .. Bit 24: EMAC_ADDR[i]_HI[7:0] Filter a group of addresses (known as group address filtering) by masking one or more bytes of the address.
23:16 (R/W)	DCS	DMA Channel Select. When EMAC_MAC_EXT_CFG.PDC = 0, the EMAC_ADDR[i]_HI.DCS field contains the binary representation of the DMA channel number to which an Rx packet whose DA matches the MAC Address(n) content is routed. When EMAC_MAC_EXT_CFG.PDC = 1, the EMAC_ADDR[i]_HI.DCS field contains the one-hot representation of one or more DMA channel numbers to which an Rx packet whose DA matches the MAC address(n) content is routed.
15:0 (R/W)	ADDRHI	MAC Address1 [47:32]. The EMAC_ADDR[i]_HI.ADDRHI field contains the upper 16 bits[47:32] of the second 6-byte MAC address.

MAC Address n Low Register

The EMAC_ADDR[i]_LO register holds the lower 32 bits of the second 6-byte MAC address of the station.

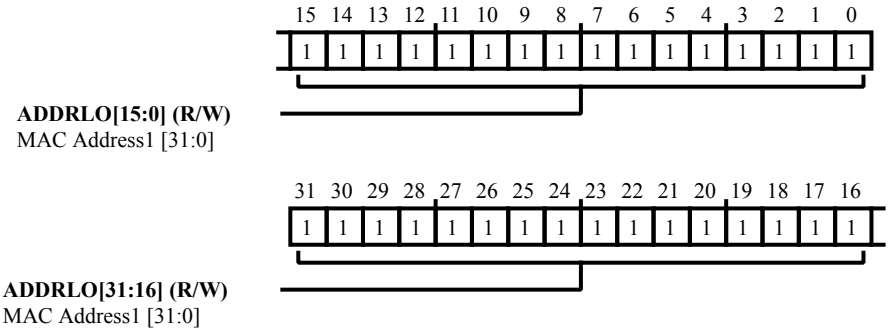

Figure 30-91: EMAC_ADDR[i]_LO Register Diagram

Table 30-146: EMAC_ADDR[i]_LO Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	ADDRLO	MAC Address1 [31:0]. The EMAC_ADDR[i]_LO.ADDRLO field contains the lower 32 bits of second 6-byte MAC address. The content of this field is undefined until loaded by the application after the initialization process.

Auxiliary Time Stamp Control Register

The EMAC_TM_AUX_CTL register controls the auxiliary time stamp snapshot.

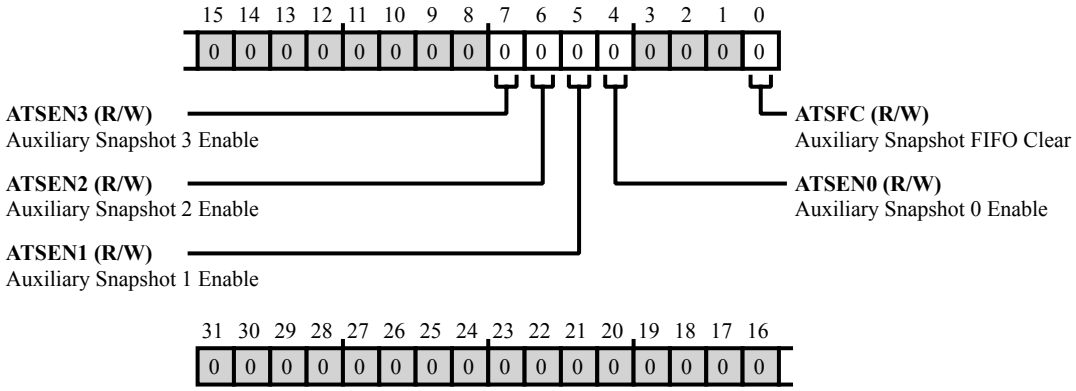

Figure 30-92: EMAC_TM_AUX_CTL Register Diagram

Table 30-147: EMAC_TM_AUX_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	ATSEN3	Auxiliary Snapshot 3 Enable. The EMAC_TM_AUX_CTL.ATSEN3 bit controls the capturing of auxiliary snapshot trigger 3. When the EMAC_TM_AUX_CTL.ATSEN3 bit is set, the auxiliary snapshot of the event on ETH0_PTPAUX_MCG_IN3 input is enabled. When EMAC_TM_AUX_CTL.ATSEN3 = 0, the events on this input are ignored.	
		0	Disable
		1	Enable
6 (R/W)	ATSEN2	Auxiliary Snapshot 2 Enable. The EMAC_TM_AUX_CTL.ATSEN2 bit controls the capturing of auxiliary snapshot trigger 2. When the EMAC_TM_AUX_CTL.ATSEN2 bit is set, the auxiliary snapshot of the event on ETH0_PTPAUX_MCG_IN2 input is enabled. When EMAC_TM_AUX_CTL.ATSEN2 = 0, the events on this input are ignored.	
		0	Disable
		1	Enable
5 (R/W)	ATSEN1	Auxiliary Snapshot 1 Enable. The EMAC_TM_AUX_CTL.ATSEN1 bit controls the capturing of auxiliary snapshot trigger 1. When the EMAC_TM_AUX_CTL.ATSEN1 bit is set, the auxiliary snapshot of the event on ETH0_PTPAUX_MCG_IN1 input is enabled. When EMAC_TM_AUX_CTL.ATSEN1 = 0, the events on this input are ignored.	
		0	Disable
		1	Enable

Table 30-147: EMAC_TM_AUX_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/W)	ATSEN0	Auxiliary Snapshot 0 Enable. The EMAC_TM_AUX_CTL.ATSEN0 bit controls the capturing of auxiliary snapshot trigger 0. When the EMAC_TM_AUX_CTL.ATSEN0 bit is set, the auxiliary snapshot of the event on ETH0_PTPAUX_MCG_IN0 input is enabled. When EMAC_TM_AUX_CTL.ATSEN0 = 0, the events on this input are ignored.	
		0	Disable
		1	Enable
0 (R/W)	ATSFC	Auxiliary Snapshot FIFO Clear. When set, the EMAC_TM_AUX_CTL.ATSFC bit resets the pointers of the Auxiliary Snapshot FIFO. The EMAC_TM_AUX_CTL.ATSFC bit is cleared when the pointers are reset and the FIFO is empty. When the EMAC_TM_AUX_CTL.ATSFC bit is high, the auxiliary snapshots are stored in the FIFO. Access restriction applies. Write 1 to set. Self-cleared. Writing 0 has no effect.	
		0	Disable
		1	Enable

Auxiliary Time Stamp Nanoseconds Register

The EMAC_TM_AUXTS_NSEC register, along with EMAC_TM_AUXTS_SEC register, gives the 64-bit time stamp stored as auxiliary snapshot. These two registers form the read port of a 64-bit wide FIFO with a depth of 4, 8, or 16 as selected while configuring the IP.

Multiple snapshots can be stored in this FIFO. Bits[29:25] in EMAC_TM_STAT register indicate the fill-level of the FIFO. The top of the FIFO is removed only when the last byte of EMAC_TM_AUXTS_SEC register is read. In the Little Endian mode, this means when bits[31:24] are read and in Big Endian mode, bits[7:0] are read.

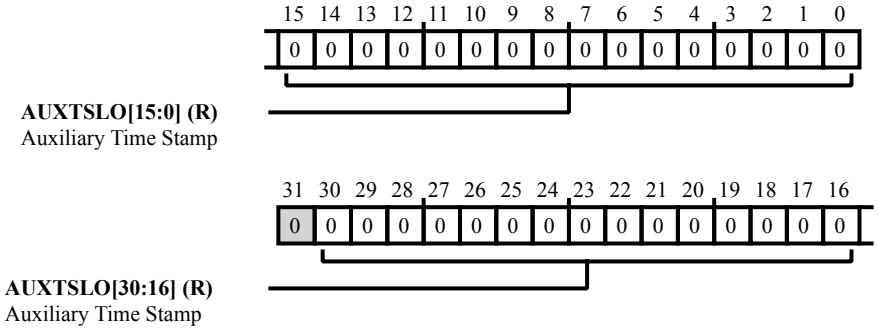

Figure 30-93: EMAC_TM_AUXTS_NSEC Register Diagram

Table 30-148: EMAC_TM_AUXTS_NSEC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
30:0 (R/NW)	AUXTSLO	Auxiliary Time Stamp. The EMAC_TM_AUXTS_NSEC.AUXTSLO field contains the lower 31 bits (nanoseconds field) of the auxiliary time stamp.

Auxiliary Time Stamp Seconds Register

The EMAC_TM_AUXTS_SEC register contains the lower 32 bits of the seconds field of the auxiliary time stamp register.

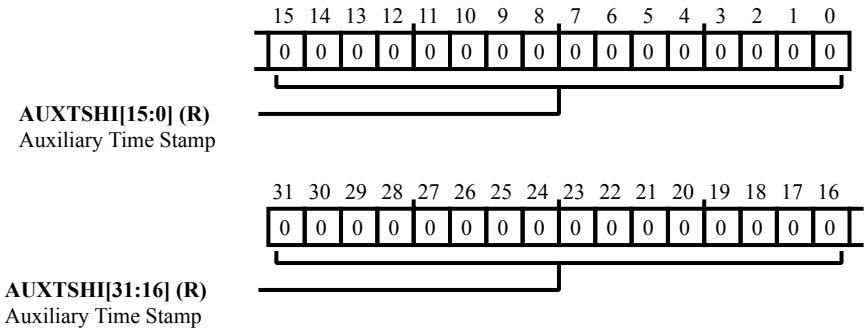

Figure 30-94: EMAC_TM_AUXTS_SEC Register Diagram

Table 30-149: EMAC_TM_AUXTS_SEC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	AUXTSHI	Auxiliary Time Stamp. Contains the lower 32 bits of the seconds field of the auxiliary time stamp.

CSR Software Control Register

The EMAC_CSR_SW_CTL register contains software programmable controls for changing the Control and Status Registers (CSR) access response and status bits clearing.

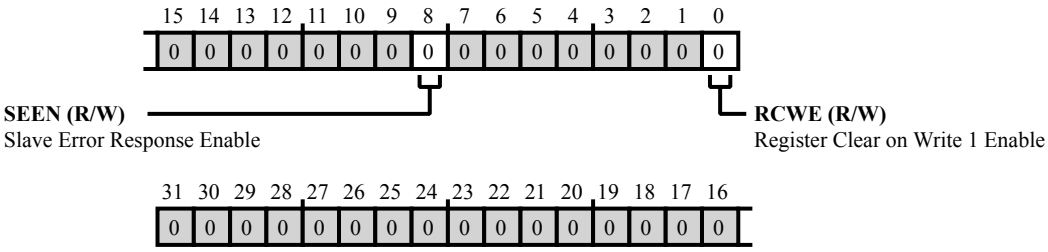

Figure 30-95: EMAC_CSR_SW_CTL Register Diagram

Table 30-150: EMAC_CSR_SW_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W)	SEEN	Slave Error Response Enable. When the EMAC_CSR_SW_CTL.SEEN bit is set, the MAC responds with a target error for accesses to reserved registers in CSR space. When EMAC_CSR_SW_CTL.SEEN = 0, the MAC responds with an okay response to any register accessed from CSR space.	
		0	Disable
		1	Enable
0 (R/W)	RCWE	Register Clear on Write 1 Enable. When the EMAC_CSR_SW_CTL.RCWE bit is set, the access mode of some register fields changes to (W1C) write one to clear; the application must set that respective bit to 1 to clear it. When EMAC_CSR_SW_CTL.RCWE = 0, the access mode of these register fields remain as Clear on read.	
		0	Disable
		1	Enable

MAC Configuration Register

The EMAC_MAC_CFG register establishes the operating mode of the MAC.

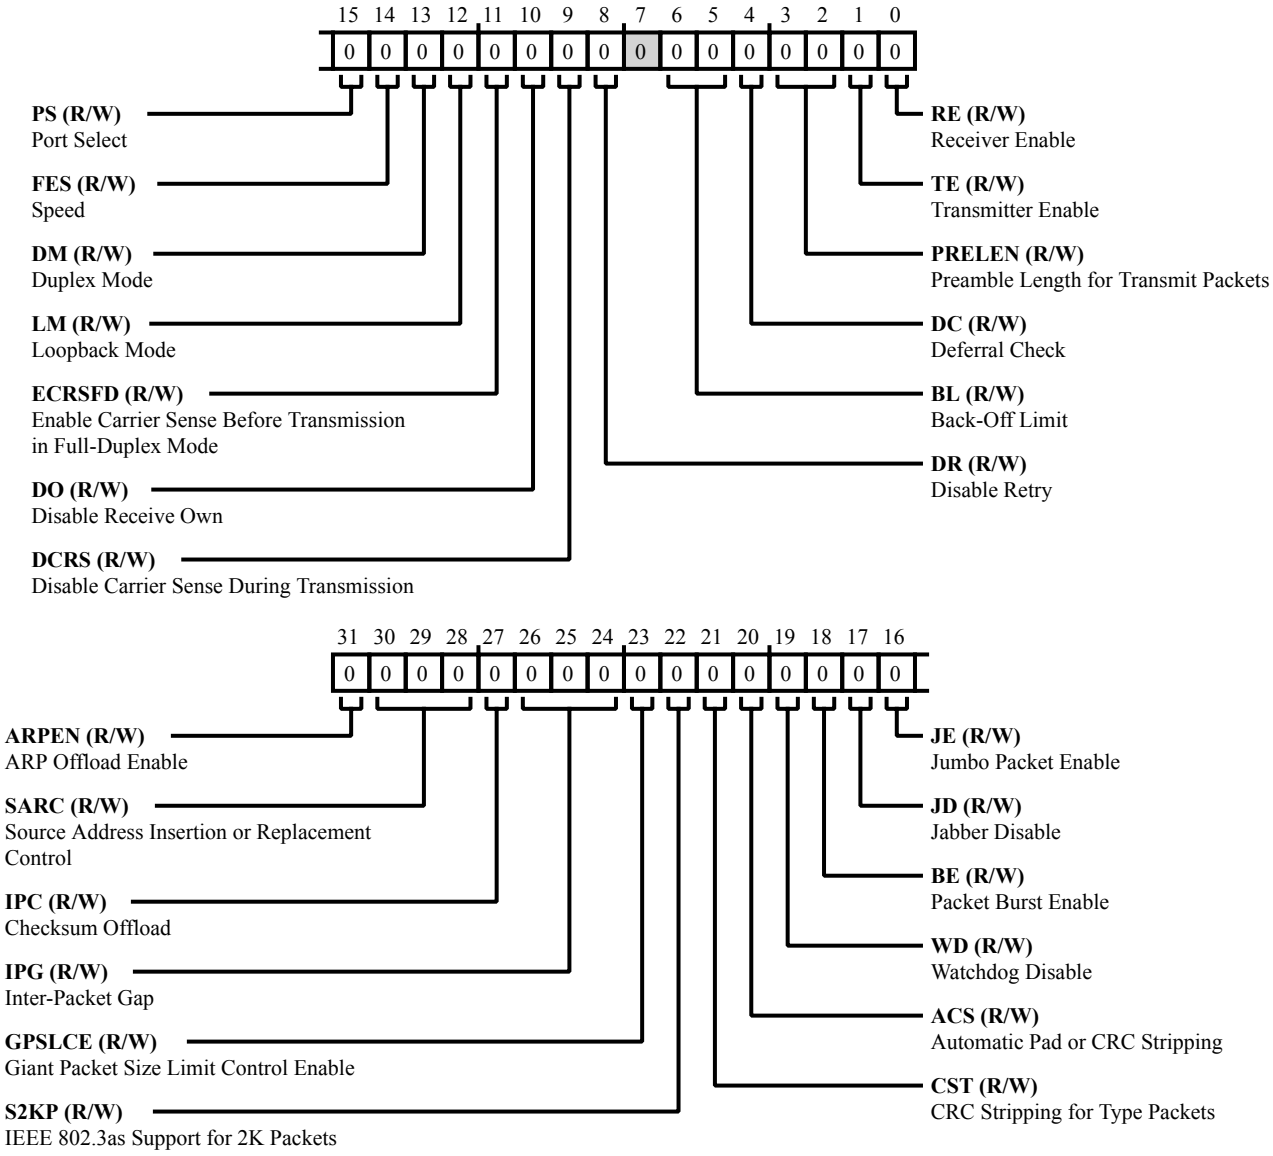

Figure 30-96: EMAC_MAC_CFG Register Diagram

Table 30-151: EMAC_MAC_CFG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	ARPEN	ARP Offload Enable. When the EMAC_MAC_CFG.ARPEN bit is set, the MAC can recognize an incoming ARP request packet and schedules the ARP packet for transmission. It forwards the ARP packet to the application and also indicate the events in the RxStatus. When EMAC_MAC_CFG.ARPEN = 0, the MAC receiver does not recognize any ARP packet and indicates them as type frame in the RxStatus. The EMAC_MAC_CFG.ARPEN bit is available only when enable IPv4 ARP offload is selected.	
		0	ARP Offload is Disabled
		1	ARP Offload is Enabled
30:28 (R/W)	SARC	Source Address Insertion or Replacement Control. The EMAC_MAC_CFG.SARC field controls the source address insertion or replacement for all transmitted packets. Bit 30 specifies which MAC Address register (0 or 1) is used for source address insertion or replacement based on the values of bits[29:28]: 2'b0x: - Reserved 2'b10: - If Bit 30 = 0, the MAC inserts the content of the MAC Address 0 registers in the SA field of all transmitted packets. - If Bit 30 = 1 and the Enable MAC Address Register 1 option is selected while configuring the IP, the MAC inserts the content of the MAC Address 1 registers in the SA field of all transmitted packets. 2'b11: - If Bit 30 = 0, the MAC replaces the content of the MAC Address 0 registers in the SA field of all transmitted packets. - If Bit 30 = 1 and the MAC Address Register 1 is enabled, the MAC replaces the content of the MAC Address 1 registers in the SA field of all transmitted packets. Note: Changes to this field take effect only on the start of a packet. A write to this register field when a packet is being transmitted, only the subsequent packet can use the updated value, that is, the current packet does not use the updated value.	
		0	Reserved
		2	Contents of MAC Address 0 Inserted in SA Field
		3	Contents of MAC Address 0 Replaces SA Field
		6	Contents of MAC Address 1 Inserted in SA Field
		7	Contents of MAC Address 1 Replaces SA Field

Table 30-151: EMAC_MAC_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
27 (R/W)	IPC	Checksum Offload. When set, the EMAC_MAC_CFG.IPC bit enables the IPv4 header checksum checking and IPv4 or IPv6 TCP, UDP, or ICMP payload checksum checking. When EMAC_MAC_CFG.IPC = 0, the COE function in the receiver is disabled. The layer 3 and layer 4 packet filter and enable split header features automatically select the IPC full checksum offload engine on the receive side. When any of these features are enabled, the EMAC_MAC_CFG.IPC bit must be set.	
		0	IP Header/payload Checksum Checking is Disabled
		1	IP Header/payload Checksum Checking is Enabled
26:24 (R/W)	IPG	Inter-Packet Gap. The EMAC_MAC_CFG.IPG field control the minimum IPG between packets during transmission. This range of minimum IPG is valid in full-duplex mode. In the half-duplex mode, the minimum IPG can be configured only for 64-bit times (IPG = 100). Lower values are not considered. When a JAM pattern is being transmitted because of back pressure activation, the MAC does not consider the minimum IPG. This function (IPG less than 96 bit times) is valid only when EMAC_MAC_EXT_CFG.EIPGEN = 0. When EMAC_MAC_EXT_CFG.EIPGEN = 1, the minimum IPG (greater than 96 bit times) is controlled as per the description given in the EMAC_MAC_EXT_CFG.EIPG field register.	
		0	96 Bit Times IPG
		1	88 Bit Times IPG
		2	80 Bit Times IPG
		3	72 Bit Times IPG
		4	64 Bit Times IPG
		5	56 Bit Times IPG
		6	48 Bit Times IPG
		7	40 Bit Times IPG

Table 30-151: EMAC_MAC_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
23 (R/W)	GPSLCE	Giant Packet Size Limit Control Enable. When the EMAC_MAC_CFG.GPSLCE bit is set, the MAC considers the value in EMAC_MAC_EXT_CFG.GPSL to declare a received packet as giant packet. The EMAC_MAC_CFG.GPSLCE field must be programmed to more than 1,518 bytes. Otherwise, the MAC considers 1,518 bytes as giant packet limit. When EMAC_MAC_CFG.GPSLCE = 0, the MAC considers a received packet as giant packet when its size is greater than 1,518 bytes (1522 bytes for tagged packet). The watchdog timeout limit, jumbo packet enable and 2K packet enable have higher precedence over the EMAC_MAC_CFG.GPSLCE bit, that is the MAC considers a received packet as giant packet when its size is greater than 9,018 bytes (9,022 bytes for tagged packet) with jumbo packet enabled and greater than 2,000 bytes with 2K packet enabled. The watchdog timeout, if enabled, terminates the received packet when watchdog limit is reached. Therefore, the programmed giant packet limit should be less than the watchdog limit to get the giant packet status.	
		0	Giant Packet Size Limit Control is Disabled
		1	Giant Packet Size Limit Control is Enabled
22 (R/W)	S2KP	IEEE 802.3as Support for 2K Packets. When the EMAC_MAC_CFG.S2KP bit is set (=1), the MAC considers all packets with up to 2,000 bytes length as normal packets. When EMAC_MAC_CFG.JE = 0, the MAC considers all received packets of size more than 2K bytes as giant packets. When EMAC_MAC_CFG.S2KP = 0 and EMAC_MAC_CFG.JE = 0, the MAC considers all received packets of size more than 1,518 bytes (1,522 bytes for tagged) as giant packets. Note: When EMAC_MAC_CFG.JE = 1, setting the EMAC_MAC_CFG.S2KP bit has no effect on the giant packet status.	
		0	Support Upto 2K Packet is Disabled
		1	Support Upto 2K Packet is Enabled
21 (R/W)	CST	CRC Stripping for Type Packets. When the EMAC_MAC_CFG.CST bit is set (=1), the last four bytes (FCS) of all packets of Ether type (type field greater than 1,536) are stripped and dropped before forwarding the packet to the application.	
		0	CRC Stripping for Type Packets is Disabled
		1	CRC Stripping for Type Packets is Enabled

Table 30-151: EMAC_MAC_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
20 (R/W)	ACS	Automatic Pad or CRC Stripping. When the EMAC_MAC_CFG.ACS bit is set, the MAC strips the pad or FCS field on the incoming packets only if the value of the length field is less than 1,536 bytes. All received packets with length field greater than or equal to 1,536 bytes are passed to the application without stripping the Pad or FCS field. When EMAC_MAC_CFG.ACS = 0, the MAC passes all incoming packets to the application, without any modification.	
		0	Automatic Pad or CRC Stripping is Disabled
		1	Automatic Pad or CRC Stripping is Enabled
19 (R/W)	WD	Watchdog Disable. When the EMAC_MAC_CFG.WD bit is set, the MAC disables the watchdog timer on the receiver. The MAC can receive packets of up to 16,383 bytes. When EMAC_MAC_CFG.WD = 0, the MAC does not allow more than 2,048 bytes (10,240 if EMAC_MAC_CFG.JE=1) of the packet being received. The MAC cuts off any bytes received after 2,048 bytes.	
		0	Watchdog is Enabled
		1	Watchdog is Disabled
18 (R/W)	BE	Packet Burst Enable. When the EMAC_MAC_CFG.BE bit is set, the MAC allows packet bursting during transmission in the RGMII half-duplex mode.	
		0	Packet Burst is Disabled
		1	Packet Burst is Enabled
17 (R/W)	JD	Jabber Disable. When the EMAC_MAC_CFG.JD bit is set, the MAC disables the jabber timer on the transmitter. The MAC can transfer packets of up to 16,383 bytes. When EMAC_MAC_CFG.JD = 0, if the application sends more than 2,048 bytes of data (10,240 if EMAC_MAC_CFG.JE is set (=1)) during transmission, the MAC does not send rest of the bytes in that packet.	
		0	Jabber is Enabled
		1	Jabber is Disabled

Table 30-151: EMAC_MAC_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/W)	JE	Jumbo Packet Enable. When the EMAC_MAC_CFG.JE bit is set, the MAC allows jumbo packets of 9,018 bytes (9,022 bytes for VLAN tagged packets) without reporting a giant packet error in the Rx packet status.	
		0	Jumbo Packet is Disabled
		1	Jumbo Packet is Enabled
15 (R/W)	PS	Port Select. The EMAC_MAC_CFG.PS bit selects the Ethernet line speed. The EMAC_MAC_CFG.PS bit, along with bit 14, selects the exact line speed. In the 10/100 Mbps only (always 1) or 1000 Mbps only (always 0) configurations, the EMAC_MAC_CFG.PS bit is read-only (RO) with appropriate value. In the default 10/100/1000 Mbps configurations, the EMAC_MAC_CFG.PS bit is read-write (R/W).	
		0	1000 Mbps Operation
		1	10 or 100 Mbps Operation
14 (R/W)	FES	Speed. The EMAC_MAC_CFG.FES bit selects the speed mode.	
		0	10 Mbps when PS = 1; 1 Gbps when PS = 0
		1	100 Mbps when PS = 1; reserved when PS = 0
13 (R/W)	DM	Duplex Mode. When the EMAC_MAC_CFG.DM bit is set, the MAC operates in the full-duplex mode in which it can transmit and receive simultaneously. The EMAC_MAC_CFG.DM bit is RO with default value of 1'b1 in the full-duplex-only configurations.	
		0	Half-duplex Mode
		1	Full-duplex Mode
12 (R/W)	LM	Loopback Mode. When the EMAC_MAC_CFG.LM bit is set, the MAC operates in the loopback mode at GMII or MII. The (G)MII Rx clock input (clk_rx_i) is required for the loopback to work properly. This is because the Tx clock is not internally looped back.	
		0	Loopback is Disabled
		1	Loopback is Enabled

Table 30-151: EMAC_MAC_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W)	ECRSFD	Enable Carrier Sense Before Transmission in Full-Duplex Mode. When the EMAC_MAC_CFG.ECRSFD bit is set, the MAC transmitter checks the CRS signal before packet transmission in the full-duplex mode. The MAC starts the transmission only when the CRS signal is low. When EMAC_MAC_CFG.ECRSFD = 0, the MAC transmitter ignores the status of the CRS signal.	
		0	ECRSFD is Disabled
		1	ECRSFD is Enabled
10 (R/W)	DO	Disable Receive Own. When the EMAC_MAC_CFG.DO bit is set, the MAC disables the reception of packets when the gmii_txen_o is asserted in the half-duplex mode. When EMAC_MAC_CFG.DO = 0, the MAC receives all packets given by the PHY. The EMAC_MAC_CFG.DO bit is not applicable in the full-duplex mode.	
		0	Enable Receive Own
		1	Disable Receive Own
9 (R/W)	DCRS	Disable Carrier Sense During Transmission. When the EMAC_MAC_CFG.DCRS bit is set, the MAC transmitter ignores the (G)MII CRS signal during packet transmission in the half-duplex mode. As a result, no errors are generated because of loss of carrier or no carrier during transmission. When EMAC_MAC_CFG.DCRS = 0, the MAC transmitter generates errors because of carrier sense. The MAC can even abort the transmission.	
		0	Enable Carrier Sense During Transmission
		1	Disable Carrier Sense During Transmission
8 (R/W)	DR	Disable Retry. When the EMAC_MAC_CFG.DR bit is set, the MAC attempts only one transmission. When a collision occurs on the GMII or MII interface, the MAC ignores the current packet transmission and reports a packet abort error with excessive collision error in the Tx packet status. When EMAC_MAC_CFG.DR = 0, the MAC retries based on the settings of the BL field. The EMAC_MAC_CFG.DR bit is applicable only in the half-duplex mode.	
		0	Enable Retry
		1	Disable Retry

Table 30-151: EMAC_MAC_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6:5 (R/W)	BL	Back-Off Limit. The EMAC_MAC_CFG.BL field determines the random integer number (r) of slot time delays (4,096 bit times for 1000/2500 Mbps; 512 bit times for 10/100 Mbps) for which the MAC waits before rescheduling a transmission attempt during retries after a collision. n = retransmission attempt. The random integer r takes the value in the range 0 <= r < 2^k The EMAC_MAC_CFG.BL bit is applicable only in the half-duplex mode.	
		0	k is Minimum of Retransmission Attempt and 10
		1	k is Minimum of Retransmission Attempt and 8
		2	k is Minimum of Retransmission Attempt and 4
		3	k is Minimum of Retransmission Attempt and 1
4 (R/W)	DC	Deferral Check. When the EMAC_MAC_CFG.DC bit is set, the deferral check function is enabled in the MAC. The MAC issues a packet abort status, along with the excessive deferral error bit set in the Tx packet status, when the Tx state machine is deferred for more than 24,288 bit times in 10 or 100 Mbps mode. If the MAC is configured for 1000 Mbps operation, the threshold for deferral is 155,680 bits times. Deferral begins when the transmitter is ready to transmit, but it is prevented because of an active carrier sense signal (CRS) on GMII or MII. The defer time is not cumulative. For example, if the transmitter defers for 10,000 bit times because the CRS signal is active and the CRS signal becomes inactive, the transmitter transmits and collision happens. Because of collision, the transmitter needs to back off and then defer again after back off completion. In such a scenario, the deferral timer is reset (=0), and it is restarted. When EMAC_MAC_CFG.DC = 0, the deferral check function is disabled and the MAC defers until the CRS signal goes inactive. The EMAC_MAC_CFG.DC bit is applicable only in the half-duplex mode.	
		0	Deferral Check Function is Disabled
		1	Deferral Check Function is Enabled

Table 30-151: EMAC_MAC_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3:2 (R/W)	PRELEN	Preamble Length for Transmit Packets. The EMAC_MAC_CFG.PRELEN field control the number of preamble bytes that are added to the beginning of every Tx packet. The preamble reduction occurs only when the MAC is operating in the full-duplex mode.	
		0	7 Bytes of Preamble
		1	5 Bytes of Preamble
		2	3 Bytes of Preamble
		3	Reserved
1 (R/W)	TE	Transmitter Enable. When the EMAC_MAC_CFG.TE bit is set, the Tx state machine of the MAC is enabled for transmission on the GMII or MII interface. When EMAC_MAC_CFG.TE = 0, the MAC Tx state machine is disabled after it completes the transmission of the current packet. The Tx state machine does not transmit any more packets.	
		0	Transmitter is Disabled
		1	Transmitter is Enabled
0 (R/W)	RE	Receiver Enable. When the EMAC_MAC_CFG.RE bit is set, the Rx state machine of the MAC is enabled for receiving packets from the GMII or MII interface. When the EMAC_MAC_CFG.RE = 0, the MAC Rx state machine is disabled after it completes the reception of the current packet. The Rx state machine does not receive any more packets from the GMII or MII interface.	
		0	Receiver is Disabled
		1	Receiver is Enabled

Debug Register

The EMAC_MAC_DBG register provides the debug status of various MAC blocks.

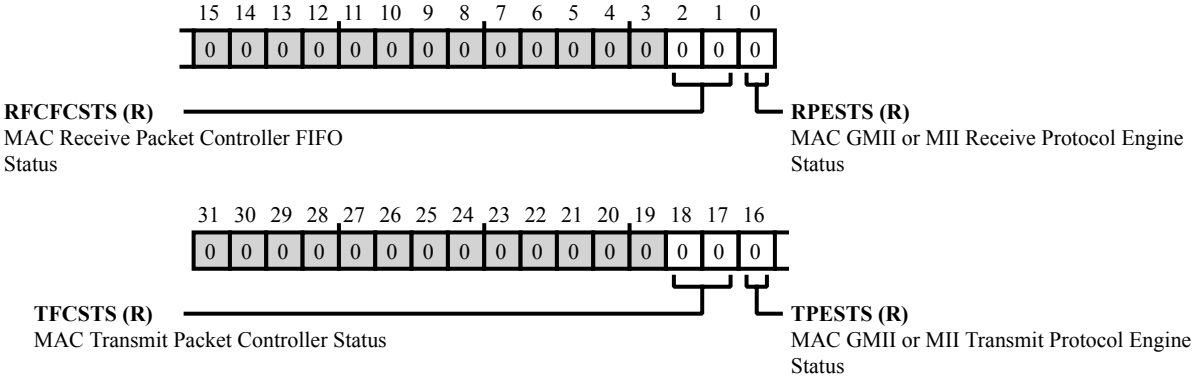

Figure 30-97: EMAC_MAC_DBG Register Diagram

Table 30-152: EMAC_MAC_DBG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
18:17 (R/NW)	TFCSTS	MAC Transmit Packet Controller Status. The EMAC_MAC_DBG.TFCSTS field indicates the state of the MAC Transmit Packet Controller module.	
		0	Idle State
		1	Waiting for One of the Following: Status of the Previous Packet OR IPG or Back off Period to Be Over
		2	Generating and Transmitting a Pause Control Packet (in Full-Duplex Mode)
		3	Transferring Input Packet for Transmission
16 (R/NW)	TPESTS	MAC GMII or MII Transmit Protocol Engine Status. When the EMAC_MAC_DBG.TPESTS bit is set, it indicates that the MAC GMII or MII transmit protocol engine is actively transmitting data, and it is not in the Idle state.	
		0	MAC GMII or MII Transmit Protocol Engine Status Not Detected
		1	MAC GMII or MII Transmit Protocol Engine Status Detected
2:1 (R/NW)	RFCFCSTS	MAC Receive Packet Controller FIFO Status. The EMAC_MAC_DBG.RFCFCSTS field indicates the active state of the small FIFO read and write controllers of the MAC Receive Packet Controller module.	

Table 30-152: EMAC_MAC_DBG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/NW)	RPESTS	MAC GMII or MII Receive Protocol Engine Status. When the `EMAC_MAC_DBG.RPESTS` bit is set, it indicates that the MAC GMII or MII receive protocol engine is actively receiving data, and it is not in the Idle state.	
		0	MAC GMII or MII Receive Protocol Engine Status Not Detected
		1	MAC GMII or MII Receive Protocol Engine Status Detected

MAC Split Mode and Offset Configuration Register

The EMAC_SPLM_OFST_CFG register contains the split mode control field and offset field for the split header feature.

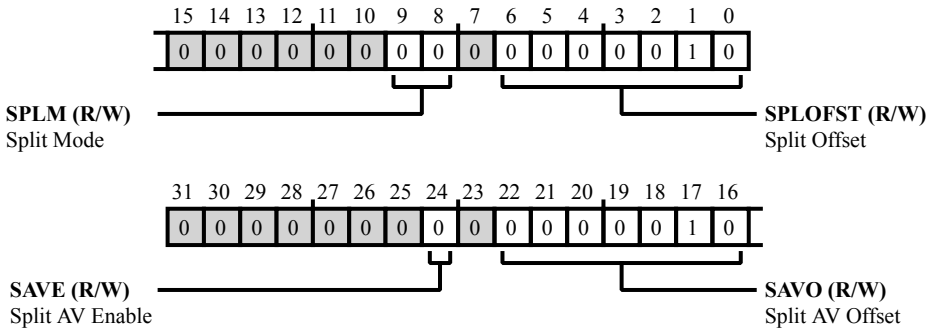

Figure 30-98: EMAC_SPLM_OFST_CFG Register Diagram

Table 30-153: EMAC_SPLM_OFST_CFG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
24 (R/W)	SAVE	Split AV Enable. When EMAC_SPLM_OFST_CFG.SAVE = 1, and the received packet is an AV Type packet, the header is split at SAVO bytes from the beginning of Length/Type field of the packet, for L2 Split. When EMAC_SPLM_OFST_CFG.SAVE = 0, header is split at SPLOFST bytes from the beginning of Length/Type field of the frame, for L2 Split.	
22:16 (R/W)	SAVO	Split AV Offset. When SAVE bit is set (=1), and the received packet is an AV Type packet, the EMAC_SPLM_OFST_CFG.SAVO field indicates the value of the offset from the beginning of Length/Type field at which header should be split, when appropriate SPLM is selected. The reset value of this field is 2 bytes, indicating a split at L2 header. Value is in terms of bytes.	
9:8 (R/W)	SPLM	Split Mode. The EMAC_SPLM_OFST_CFG.SPLM field indicates the mode of splitting the incoming Rx packets.	
		0	Split at L3/L4 Header
		1	Split at L2 Header with an Offset. Always Split at SPLOFST Bytes from the Beginning of Length/Type Field of the Frame
		2	Combination Mode: Split Similar to SPLM=00 for IP Packets That are Untagged or Tagged and VLAN Stripped
		3	Reserved

Table 30-153: EMAC_SPLM_OFST_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
6:0 (R/W)	SPLOFST	Split Offset. The `EMAC_SPLM_OFST_CFG.SPLOFST` field indicates the value of offset from the beginning of Length/Type field at which header split should take place when the appropriate SPLM is selected. The reset value of this field is 2 bytes indicating a split at L2 header. Value is in terms of bytes.

MAC Extended Configuration Register

The EMAC_MAC_EXT_CFG register establishes the operating mode of the MAC.

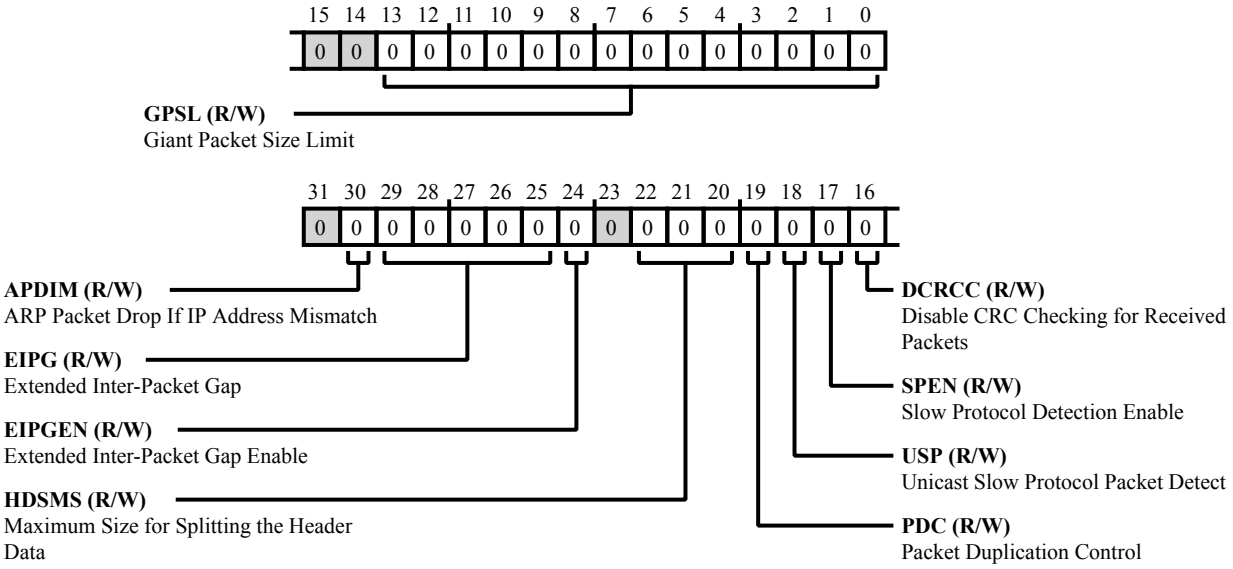

Figure 30-99: EMAC_MAC_EXT_CFG Register Diagram

Table 30-154: EMAC_MAC_EXT_CFG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
30 (R/W)	APDIM	ARP Packet Drop If IP Address Mismatch. When the EMAC_MAC_EXT_CFG.APDIM bit is set, packet for which target protocol address does not match IPv4 address is dropped in the MTL layer. When EMAC_MAC_EXT_CFG.APDIM = 0, when target protocol address does not match, packet is forwarded to MTL maintaining backward compatibility	
		0	Mux Select to Drop the Arp Packet If Target Protocol Address Mismatches IPv4 Address Disabled
		1	Mux Select to Drop the Arp Packet If Target Protocol Address Mismatches IPv4 Address Enabled

Table 30-154: EMAC_MAC_EXT_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
29:25 (R/W)	EIPG	Extended Inter-Packet Gap. The value in the EMAC_MAC_EXT_CFG.EIPG field is applicable when EMAC_MAC_EXT_CFG.EIPGEN = 1. The EMAC_MAC_EXT_CFG.EIPG field (as most significant bits), along with IPG, gives the minimum IPG greater than 96 bit times in steps of 8 bit times: {EIPG, IPG} 8'h00 - 104 bit times 8'h01 - 112 bit times 8'h02 - 120 bit times ---------- 8'hFF - 2144 bit times	
24 (R/W)	EIPGEN	Extended Inter-Packet Gap Enable. When the EMAC_MAC_EXT_CFG.EIPGEN bit is set, the MAC interprets EMAC_MAC_CFG.IPG and EMAC_MAC_CFG.EIPG together as minimum IPG greater than 96 bit times in steps of 8 bit times. When EMAC_MAC_EXT_CFG.EIPGEN = 0, the MAC ignores EMAC_MAC_CFG.EIPG and interprets EMAC_MAC_CFG.IPGas minimum IPG less than or equal to 96 bit times in steps of 8 bit times. Note: Enable the extended inter-packet gap feature only when operating in full-duplex mode. There might be undesirable effects on back-pressure function and frame transmission if it is enabled in half-duplex mode.	
		0	Extended Inter-Packet Gap is Disabled
		1	Extended Inter-Packet Gap is Enabled
22:20 (R/W)	HDSMS	Maximum Size for Splitting the Header Data. The EMAC_MAC_EXT_CFG.HDSMS field indicates the maximum header size allowed for splitting the header data in the received packet.	
		0	Maximum Size for Splitting the Header Data is 64 Bytes
		1	Maximum Size for Splitting the Header Data is 128 Bytes
		2	Maximum Size for Splitting the Header Data is 256 Bytes
		3	Maximum Size for Splitting the Header Data is 512 Bytes
		4	Maximum Size for Splitting the Header Data is 1024 Bytes
		5	Reserved

Table 30-154: EMAC_MAC_EXT_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
19 (R/W)	PDC	Packet Duplication Control. When the `EMAC_MAC_EXT_CFG.PDC` bit is set, the received packet with multicast/broadcast destination address is routed to multiple receive DMA channels. The receive DMA channels is identified by the DCS field of EMAC_ADDR[n]_HI register corresponding to the MAC Address register that matches the multicast/broadcast destination address in the received packet. The DCS field is interpreted to be a one-hot value, each bit corresponding to the receive DMA channel. When `EMAC_MAC_EXT_CFG.PDC` = 0, the received packet is routed to single receive DMA channel. The receive DMA channel is identified by EMAC_ADDR[n]_HI.DCS corresponding to the MAC Address register that matches the Destination address in the received packet. The DCS field is interpreted as a binary value.	
		0	Packet Duplication Control is Disabled
		1	Packet Duplication Control is Enabled
18 (R/W)	USP	Unicast Slow Protocol Packet Detect. When the `EMAC_MAC_EXT_CFG.USP` bit is set, the MAC detects the slow protocol packets with unicast address of the station specified in the EMAC_ADDR0_HI and EMAC_ADDR0_LO registers. The MAC also detects the slow protocol packets with the slow protocols multicast address (01-80-C2-00-00-02). When `EMAC_MAC_EXT_CFG.USP` = 0, the MAC detects only slow protocol packets with the slow protocol multicast address specified in the IEEE 802.3-2015, Section 5.	
		0	Unicast Slow Protocol Packet Detection is Disabled
		1	Unicast Slow Protocol Packet Detection is Enabled
17 (R/W)	SPEN	Slow Protocol Detection Enable. When the `EMAC_MAC_EXT_CFG.SPEN` bit is set, MAC processes the slow protocol packets (Ether Type 0x8809) and provides the slow protocol subtype and code fields in Rx status. When `EMAC_MAC_EXT_CFG.SPEN` = 0, the MAC forwards all error-free slow protocol packets to the application. The MAC considers such packets as normal type packets.	
		0	Slow Protocol Detection is Disabled
		1	Slow Protocol Detection is Enabled

Table 30-154: EMAC_MAC_EXT_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/W)	DCRCC	Disable CRC Checking for Received Packets. When the EMAC_MAC_EXT_CFG.DCRCC bit is set, the MAC receiver does not check the CRC field in the received packets. When EMAC_MAC_EXT_CFG.DCRCC = 0, the MAC receiver always checks the CRC field in the received packets.	
		0	CRC Checking is Enabled
		1	CRC Checking is Disabled
13:0 (R/W)	GPSL	Giant Packet Size Limit. If the received packet size is greater than the value programmed in the EMAC_MAC_EXT_CFG.GPSL field in units of bytes, the MAC declares the received packet as giant packet. The value programmed in this field must be greater than or equal to 1,518 bytes. Any other programmed value is considered as 1,518 bytes. For VLAN tagged packets, the MAC adds 4 bytes to the programmed value. When the enable double VLAN processing option is selected, the MAC adds 8 bytes to the programmed value for double VLAN tagged packets. The value in this field is applicable when EMAC_MAC_CFG.GPSLCE = 1.	

Frame Preemption Control and Status Register

The EMAC_FPE_CTLSTAT register controls the operation of frame preemption.

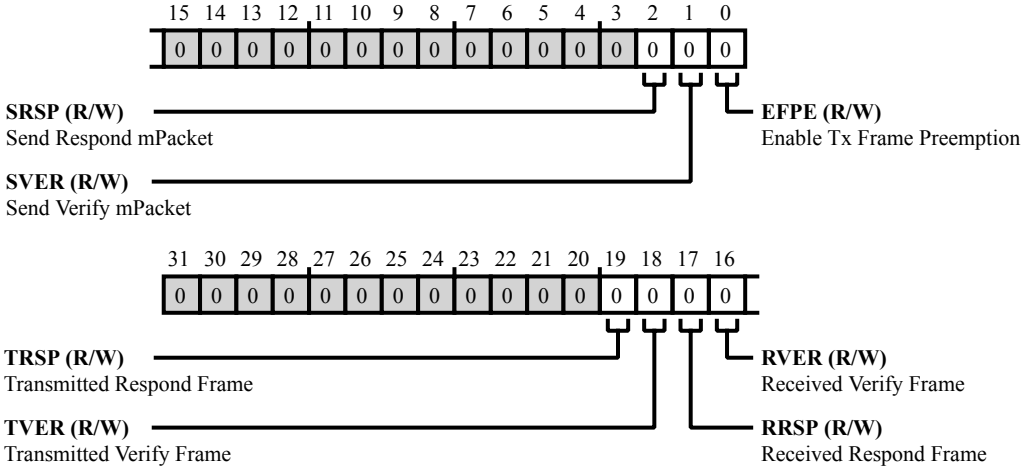

Figure 30-100: EMAC_FPE_CTLSTAT Register Diagram

Table 30-155: EMAC_FPE_CTLSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
19 (R/W)	TRSP	Transmitted Respond Frame. The EMAC_FPE_CTLSTAT.TRSP bit is set when a Respond mPacket is transmitted (triggered by EMAC_FPE_CTLSTAT.SRSP = 1). An interrupt can be generated for this event if EMAC_MAC_IEN.FPEIE = 1. Access restriction applies. Clears on read (or write of 1 when EMAC_CSR_SW_CTL.RCWE = 1). Self-set to 1 on internal event.	
		0	Not Transmitted Respond Frame
		1	Transmitted Respond Frame
18 (R/W)	TVER	Transmitted Verify Frame. The EMAC_FPE_CTLSTAT.TVER bit is set when a Verify mPacket is transmitted (triggered by EMAC_FPE_CTLSTAT.SVER = 1). An interrupt can be generated for this event if EMAC_MAC_IEN.FPEIE = 1. Access restriction applies. Clears on read (or write of 1 when EMAC_CSR_SW_CTL.RCWE = 1). Self-set to 1 on internal event.	
		0	Not Transmitted Verify Frame
		1	Transmitted Verify Frame

Table 30-155: EMAC_FPE_CTLSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/W)	RRSP	Received Respond Frame. The `EMAC_FPE_CTLSTAT.RRSP` bit is set when a Respond mPacket is received. An interrupt can be generated for this event if EMAC_MAC_IEN.FPEIE = 1. Access restriction applies. Clears on read (or write of 1 when EMAC_CSR_SW_CTL.RCWE = 1). Self-set to 1 on internal event.	
		0	Not Received Respond Frame
		1	Received Respond Frame
16 (R/W)	RVER	Received Verify Frame. The `EMAC_FPE_CTLSTAT.RVER` bit is set when a Verify mPacket is received. An interrupt can be generated for this event if EMAC_MAC_IEN.FPEIE = 1. Access restriction applies. Clears on read (or write of 1 when EMAC_CSR_SW_CTL.RCWE = 1). Self-set to 1 on internal event.	
		0	Not Received Verify Frame
		1	Received Verify Frame
2 (R/W)	SRSP	Send Respond mPacket. When set (=1), the `EMAC_FPE_CTLSTAT.SRSP` bit indicates to hardware to send a Respond mPacket. Reset by hardware after sending the Respond mPacket. Access restriction applies. Write 1 to set. Self-cleared. Writing 0 has no effect.	
		0	Send Respond MPacket is Disabled
		1	Send Respond MPacket is Enabled
1 (R/W)	SVER	Send Verify mPacket. When set (=1), the `EMAC_FPE_CTLSTAT.SVER` bit indicates to hardware to send a verify mPacket. Reset by hardware after sending the Verify mPacket. Access restriction applies. Write 1 to set. Self-cleared. Writing 0 has no effect.	
		0	Send Verify MPacket is Disabled
		1	Send Verify MPacket is Enabled
0 (R/W)	EFPE	Enable Tx Frame Preemption. When set (=1), the `EMAC_FPE_CTLSTAT.EFPE` bit enables Tx Frame Preemption.	
		0	Tx Frame Preemption is Disabled
		1	Tx Frame Preemption is Enabled

Hardware Feature Presence Register 0

The EMAC_HW_FTR_PSNT0 register indicates the presence of first set of the optional features or functions of the EMAC module. The software driver can use this register to dynamically enable or disable the programs related to the optional blocks.

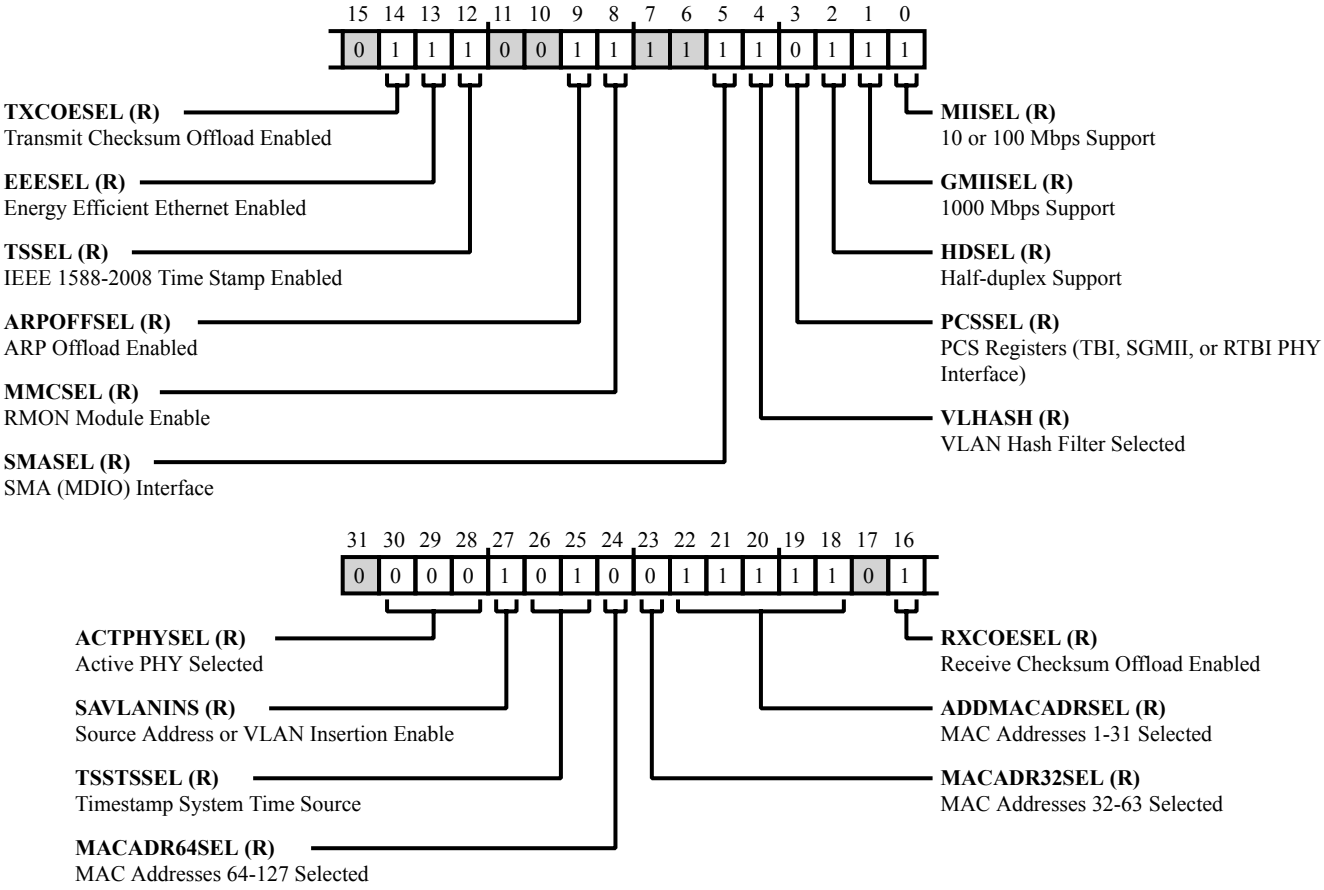

Figure 30-101: EMAC_HW_FTR_PSNT0 Register Diagram

Table 30-156: EMAC_HW_FTR_PSNT0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
30:28 (R/NW)	ACTPHYSEL	Active PHY Selected. When there are multiple PHY interfaces in the configuration, the EMAC_HW_FTR_PSNT0.ACTPHYSEL field indicates the sampled value of PADS_PCFG0.EMACPHYISEL during reset deassertion.	
		0	GMII or MII
		1	RGMII
		2	SGMII

Table 30-156: EMAC_HW_FTR_PSNT0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		3	TBI
		4	RMII
		5	RTBI
		6	SMII
		7	RevMII
27 (R/NW)	SAVLANINS	Source Address or VLAN Insertion Enable. The EMAC_HW_FTR_PSNT0.SAVLANINS bit is set (=1) when the Enable SA and VLAN Insertion on Tx option is selected.	
		0	Source Address or VLAN Insertion Enable Option is Not Selected
		1	Source Address or VLAN Insertion Enable Option is Selected
26:25 (R/NW)	TSSTSSEL	Timestamp System Time Source. The EMAC_HW_FTR_PSNT0.TSSTSSEL bit indicates the source of the time stamp system time. The EMAC_HW_FTR_PSNT0.TSSTSSEL bit is set (=1) when the Enable IEEE 1588 time stamp Support option is selected.	
		0	Internal
		1	External
		2	Both
		3	Reserved
24 (R/NW)	MACADR64SEL	MAC Addresses 64-127 Selected. The EMAC_HW_FTR_PSNT0.MACADR64SEL bit is set (=1) when the Enable Additional 64 MAC Address Registers (64-127) option is selected.	
		0	MAC Addresses 64-127 Select Option is Not Selected
		1	MAC Addresses 64-127 Select Option is Selected
23 (R/NW)	MACADR32SEL	MAC Addresses 32-63 Selected. The EMAC_HW_FTR_PSNT0.MACADR32SEL bit is set (=1) when the Enable Additional 32 MAC Address Registers (32-63) option is selected.	
		0	MAC Addresses 32-63 Select Option is Not Selected
		1	MAC Addresses 32-63 Select Option is Selected
22:18 (R/NW)	ADDMACADRSEL	MAC Addresses 1-31 Selected. The EMAC_HW_FTR_PSNT0.ADDMACADRSEL bit is set (=1) when the non-zero value is selected for Enable Additional 1-31 MAC Address Registers option.	

Table 30-156: EMAC_HW_FTR_PSNT0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/NW)	RXCOESEL	Receive Checksum Offload Enabled. The EMAC_HW_FTR_PSNT0.RXCOESEL bit is set (=1) when the Enable Receive TCP/IP Checksum Check option is selected.	
		0	Receive Checksum Offload Enable Option is Not Selected
		1	Receive Checksum Offload Enable Option is Selected
14 (R/NW)	TXCOESEL	Transmit Checksum Offload Enabled. The EMAC_HW_FTR_PSNT0.TXCOESEL bit is set (=1) when the Enable Transmit TCP/IP Checksum Insertion option is selected.	
		0	Transmit Checksum Offload Enable Option is Not Selected
		1	Transmit Checksum Offload Enable Option is Selected
13 (R/NW)	EEESEL	Energy Efficient Ethernet Enabled. The EMAC_HW_FTR_PSNT0.EEESEL bit is set (=1) when the Enable Energy Efficient Ethernet (EEE) option is selected.	
		0	Energy Efficient Ethernet Enable Option is Not Selected
		1	Energy Efficient Ethernet Enable Option is Selected
12 (R/NW)	TSSEL	IEEE 1588-2008 Time Stamp Enabled. The EMAC_HW_FTR_PSNT0.TSSEL bit is set (=1) when the Enable IEEE 1588 Time Stamp Support Option is selected.	
		0	Option is Not Selected
		1	Option is Selected
9 (R/NW)	ARPOFFSEL	ARP Offload Enabled. The EMAC_HW_FTR_PSNT0.ARPOFFSEL bit is set (=1) when the Enable IPv4 ARP Offload option is selected.	
		0	ARP Offload Enable Option is Not Selected
		1	ARP Offload Enable Option is Selected
8 (R/NW)	MMCSEL	RMON Module Enable. The EMAC_HW_FTR_PSNT0.MMCSEL bit is set (=1) when the Enable MAC Management Counters (MMC) option is selected.	
		0	RMON Module Enable Option is Not Selected
		1	RMON Module Enable Option is Selected

Table 30-156: EMAC_HW_FTR_PSNT0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (R/NW)	SMASEL	SMA (MDIO) Interface. The `EMAC_HW_FTR_PSNT0.SMASEL` bit is set (=1) when the Enable Station Management (MDIO Interface) option is selected.	
		0	SMA (MDIO) Interface Not Selected
		1	SMA (MDIO) Interface Selected
4 (R/NW)	VLHASH	VLAN Hash Filter Selected. The `EMAC_HW_FTR_PSNT0.VLHASH` bit is set (=1) when the Enable VLAN Hash Table Based Filtering option is selected.	
		0	VLAN Hash Filter Not Selected
		1	VLAN Hash Filter Selected
3 (R/NW)	PCSSEL	PCS Registers (TBI, SGMII, or RTBI PHY Interface). The `EMAC_HW_FTR_PSNT0.PCSSEL` bit is set (=1) when the TBI, SGMII, or RTBI PHY interface option is selected.	
		0	No PCS Registers (TBI, SGMII, or RTBI PHY Interface)
		1	PCS Registers (TBI, SGMII, or RTBI PHY Interface)
2 (R/NW)	HDSEL	Half-duplex Support. The `EMAC_HW_FTR_PSNT0.HDSEL` bit is set (=1) when the half-duplex mode is selected,	
		0	No Half-duplex Support
		1	Half-duplex Support
1 (R/NW)	GMIISEL	1000 Mbps Support. The `EMAC_HW_FTR_PSNT0.GMIISEL` bit is set (=1) when 1000 Mbps is selected as the mode of operation.	
		0	No 1000 Mbps Support
		1	1000 Mbps Support
0 (R/NW)	MIISEL	10 or 100 Mbps Support. The `EMAC_HW_FTR_PSNT0.MIISEL` bit is set (=1) when 10/100 Mbps is selected as the mode of operation.	
		0	No 10 or 100 Mbps Support
		1	10 or 100 Mbps Support

Hardware Feature Presence Register 1

The EMAC_HW_FTR_PSNT1 register indicates the presence of second set of the optional features or functions of the EMAC module. The software driver can use this register to dynamically enable or disable the programs related to the optional blocks.

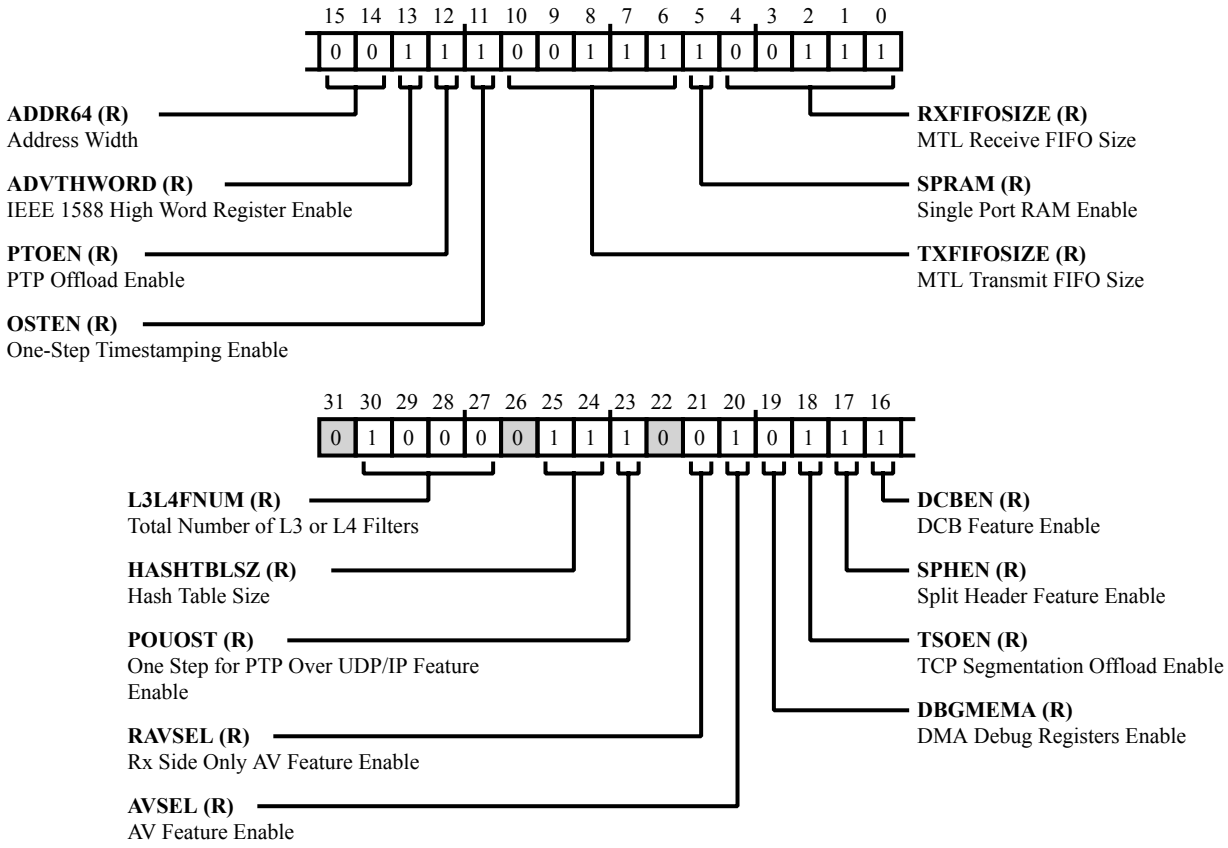

Figure 30-102: EMAC_HW_FTR_PSNT1 Register Diagram

Table 30-157: EMAC_HW_FTR_PSNT1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
30:27 (R/NW)	L3L4FNUM	Total Number of L3 or L4 Filters. The EMAC_HW_FTR_PSNT1.L3L4FNUM field indicates the total number of L3 or L4 filters.	
		0	No L3 or L4 Filter
		1	1 L3 or L4 Filter
		2	2 L3 or L4 Filters
		3	3 L3 or L4 Filters

Table 30-157: EMAC_HW_FTR_PSNT1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		4	4 L3 or L4 Filters
		5	5 L3 or L4 Filters
		6	6 L3 or L4 Filters
		7	7 L3 or L4 Filters
		8	8 L3 or L4 Filters
25:24 (R/NW)	HASHTBLSZ	Hash Table Size. The `EMAC_HW_FTR_PSNT1.HASHTBLSZ` field indicates the size of the hash table.	
		0	No Hash Table
		1	64
		2	128
		3	256
23 (R/NW)	POUOST	One Step for PTP Over UDP/IP Feature Enable. The `EMAC_HW_FTR_PSNT1.POUOST` bit is set (=1) when the Enable One Step Time Stamp for PTP over UDP/IP feature is selected.	
		0	One Step for PTP Over UDP/IP Feature is Not Selected
		1	One Step for PTP Over UDP/IP Feature is Selected
21 (R/NW)	RAVSEL	Rx Side Only AV Feature Enable. The `EMAC_HW_FTR_PSNT1.RAVSEL` bit is set (=1) when the Enable Audio Video Bridging option on Rx Side Only is selected.	
		0	Rx Side Only AV Feature is Not Selected
		1	Rx Side Only AV Feature is Selected
20 (R/NW)	AVSEL	AV Feature Enable. The `EMAC_HW_FTR_PSNT1.AVSEL` bit is set (=1) when the Enable Audio Video Bridging option is selected.	
		0	AV Feature is Not Selected
		1	AV Feature is Selected
19 (R/NW)	DBGMEMA	DMA Debug Registers Enable. The `EMAC_HW_FTR_PSNT1.DBGMEMA` bit is set (=1) when the Debug Mode Enable option is selected	
		0	DMA Debug Registers Option is Not Selected
		1	DMA Debug Registers Option is Selected

Table 30-157: EMAC_HW_FTR_PSNT1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
18 (R/NW)	TSOEN	TCP Segmentation Offload Enable. The `EMAC_HW_FTR_PSNT1.TSOEN` bit is set (=1) when the Enable TCP Segmentation Offloading for TCP/IP Packets option is selected	
		0	TCP Segmentation Offload Feature is Not Selected
		1	TCP Segmentation Offload Feature is Selected
17 (R/NW)	SPHEN	Split Header Feature Enable. The `EMAC_HW_FTR_PSNT1.SPHEN` bit is set (=1) when the Enable Split Header Structure option is selected	
		0	Split Header Feature is Not Selected
		1	Split Header Feature is Selected
16 (R/NW)	DCBEN	DCB Feature Enable. The `EMAC_HW_FTR_PSNT1.DCBEN` bit is set (=1) when the Enable Data Center Bridging option is selected	
		0	DCB Feature is Not Selected
		1	DCB Feature is Selected
15:14 (R/NW)	ADDR64	Address Width. The `EMAC_HW_FTR_PSNT1.ADDR64` field indicates the configured address width:	
		0	32
		1	40
		2	48
		3	Reserved
13 (R/NW)	ADVTHWORD	IEEE 1588 High Word Register Enable. The `EMAC_HW_FTR_PSNT1.ADVTHWORD` bit is set (=1) when the Add IEEE 1588 Higher Word Register option is selected	
		0	IEEE 1588 High Word Register Option is Not Selected
		1	IEEE 1588 High Word Register Option is Selected
12 (R/NW)	PTOEN	PTP Offload Enable. The `EMAC_HW_FTR_PSNT1.PTOEN` bit is set (=1) when the Enable PTP time stamp Offload Feature is selected.	
		0	PTP Offload Feature is Not Selected
		1	PTP Offload Feature is Selected

Table 30-157: EMAC_HW_FTR_PSNT1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/NW)	OSTEN	One-Step Timestamping Enable. The `EMAC_HW_FTR_PSNT1.OSTEN` bit is set (=1) when the Enable One-Step time stamp Feature is selected.	
		0	Feature is Not Selected
		1	Feature is Selected
10:6 (R/NW)	TXFIFOSIZE	MTL Transmit FIFO Size. The `EMAC_HW_FTR_PSNT1.TXFIFOSIZE` field contains the configured value of MTL Tx FIFO in bytes expressed as Log to base 2 minus 7, that is, Log2(TXFIFO_SIZE) -7:	
		0	128 Bytes
		1	256 Bytes
		2	512 Bytes
		3	1024 Bytes
		4	2048 Bytes
		5	4096 Bytes
		6	8192 Bytes
		7	16384 Bytes
		8	32 KB
		9	64 KB
		10	128 KB
		11	Reserved
5 (R/NW)	SPRAM	Single Port RAM Enable. The `EMAC_HW_FTR_PSNT1.SPRAM` bit is set (=1) when the Use single port RAM Feature is selected.	
		0	Single Port RAM Feature is Not Selected
		1	Single Port RAM Feature is Selected
4:0 (R/NW)	RXFIFOSIZE	MTL Receive FIFO Size. The `EMAC_HW_FTR_PSNT1.RXFIFOSIZE` field contains the configured value of MTL Rx FIFO in bytes expressed as Log to base 2 minus 7, that is, Log2(RXFIFO_SIZE) -7:	
		0	128 Bytes
		1	256 Bytes
		2	512 Bytes

Table 30-157: EMAC_HW_FTR_PSNT1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		3	1024 Bytes
		4	2048 Bytes
		5	4096 Bytes
		6	8192 Bytes
		7	16384 Bytes
		8	32 KB
		9	64 KB
		10	128 KB
		11	256 KB
		12	Reserved

Hardware Feature Presence Register 2

The EMAC_HW_FTR_PSNT2 register indicates the presence of third set of the optional features or functions of the EMAC module. The software driver can use this register to dynamically enable or disable the programs related to the optional blocks.

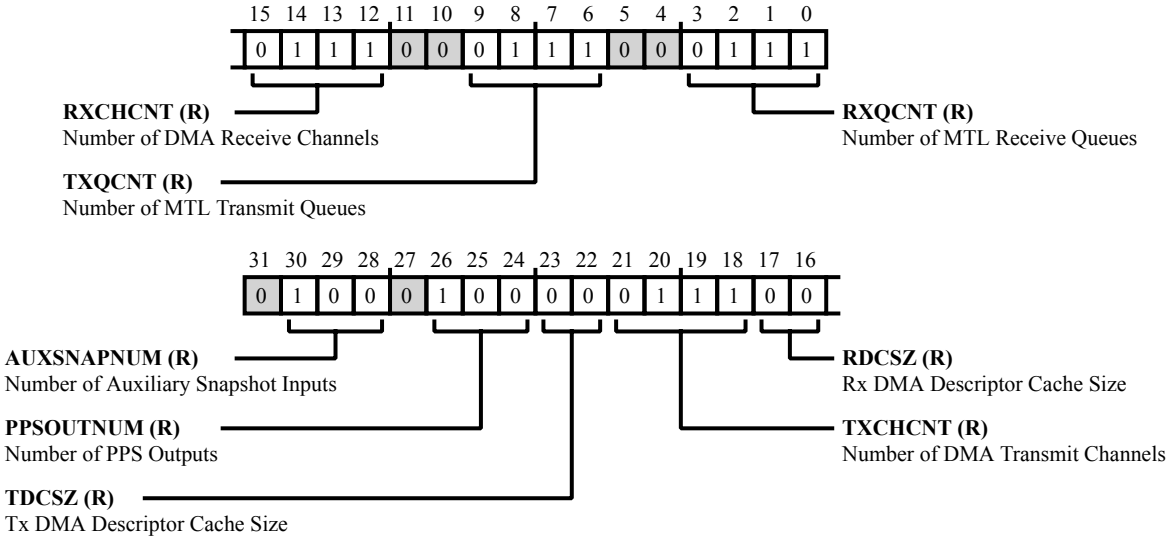

Figure 30-103: EMAC_HW_FTR_PSNT2 Register Diagram

Table 30-158: EMAC_HW_FTR_PSNT2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
30:28 (R/NW)	AUXSNAPNUM	Number of Auxiliary Snapshot Inputs. The EMAC_HW_FTR_PSNT2.AUXSNAPNUM field indicates the number of auxiliary snapshot inputs.	
		0	No Auxiliary Input
		1	1 Auxiliary Input
		2	2 Auxiliary Input
		3	3 Auxiliary Input
		4	4 Auxiliary Input
		5	Reserved
26:24 (R/NW)	PPSOUTNUM	Number of PPS Outputs. The EMAC_HW_FTR_PSNT2.PPSOUTNUM field indicates the number of PPS outputs.	
		0	No PPS Output
		1	1 PPS Output

Table 30-158: EMAC_HW_FTR_PSNT2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		2	2 PPS Output
		3	3 PPS Output
		4	4 PPS Output
		5	Reserved
23:22 (R/NW)	TDCSZ	Tx DMA Descriptor Cache Size. The `EMAC_HW_FTR_PSNT2.TDCSZ` field indicates the size of the Tx DMA descriptor cache in terms of 16 byte descriptors. 00 - Cache not configured 01 - Four 16 bytes descriptor 10 - Eight 16 bytes descriptor 11 - Sixteen 16 bytes descriptor	
21:18 (R/NW)	TXCHCNT	Number of DMA Transmit Channels. The `EMAC_HW_FTR_PSNT2.TXCHCNT` field indicates the number of DMA transmit channels.	
		0	1 MTL Tx Channel
		1	2 MTL Tx Channels
		2	3 MTL Tx Channels
		3	4 MTL Tx Channels
		4	5 MTL Tx Channels
		5	6 MTL Tx Channels
		6	7 MTL Tx Channels
		7	8 MTL Tx Channels
17:16 (R/NW)	RDCSZ	Rx DMA Descriptor Cache Size. The `EMAC_HW_FTR_PSNT2.RDCSZ` field indicates the size of the Rx DMA descriptor cache in terms of 16 byte descriptors. 00 - Cache not configured 01 - Four 16 bytes descriptor 10 - Eight 16 bytes descriptor 11 - Sixteen 16 bytes descriptor	
15:12 (R/NW)	RXCHCNT	Number of DMA Receive Channels. The `EMAC_HW_FTR_PSNT2.RXCHCNT` field indicates the number of DMA receive channels.	
		0	1 MTL Rx Channel

Table 30-158: EMAC_HW_FTR_PSNT2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		1	2 MTL Rx Channels
		2	3 MTL Rx Channels
		3	4 MTL Rx Channels
		4	5 MTL Rx Channels
		5	6 MTL Rx Channels
		6	7 MTL Rx Channels
		7	8 MTL Rx Channels
9:6 (R/NW)	TXQCNT	Number of MTL Transmit Queues. The `EMAC_HW_FTR_PSNT2.TXQCNT` field indicates the number of MTL transmit queues.	
		0	1 MTL Tx Queue
		1	2 MTL Tx Queues
		2	3 MTL Tx Queues
		3	4 MTL Tx Queues
		4	5 MTL Tx Queues
		5	6 MTL Tx Queues
		6	7 MTL Tx Queues
		7	8 MTL Tx Queues
3:0 (R/NW)	RXQCNT	Number of MTL Receive Queues. The `EMAC_HW_FTR_PSNT2.RXQCNT` field indicates the number of MTL receive queues.	
		0	1 MTL Rx Queue
		1	2 MTL Rx Queues
		2	3 MTL Rx Queues
		3	4 MTL Rx Queues
		4	5 MTL Rx Queues
		5	6 MTL Rx Queues
		6	7 MTL Rx Queues
		7	8 MTL Rx Queues

Hardware Feature Presence Register 3

The EMAC_HW_FTR_PSNT3 register indicates the presence of fourth set the optional features or functions of the EMAC module. The software driver can use this register to dynamically enable or disable the programs related to the optional blocks.

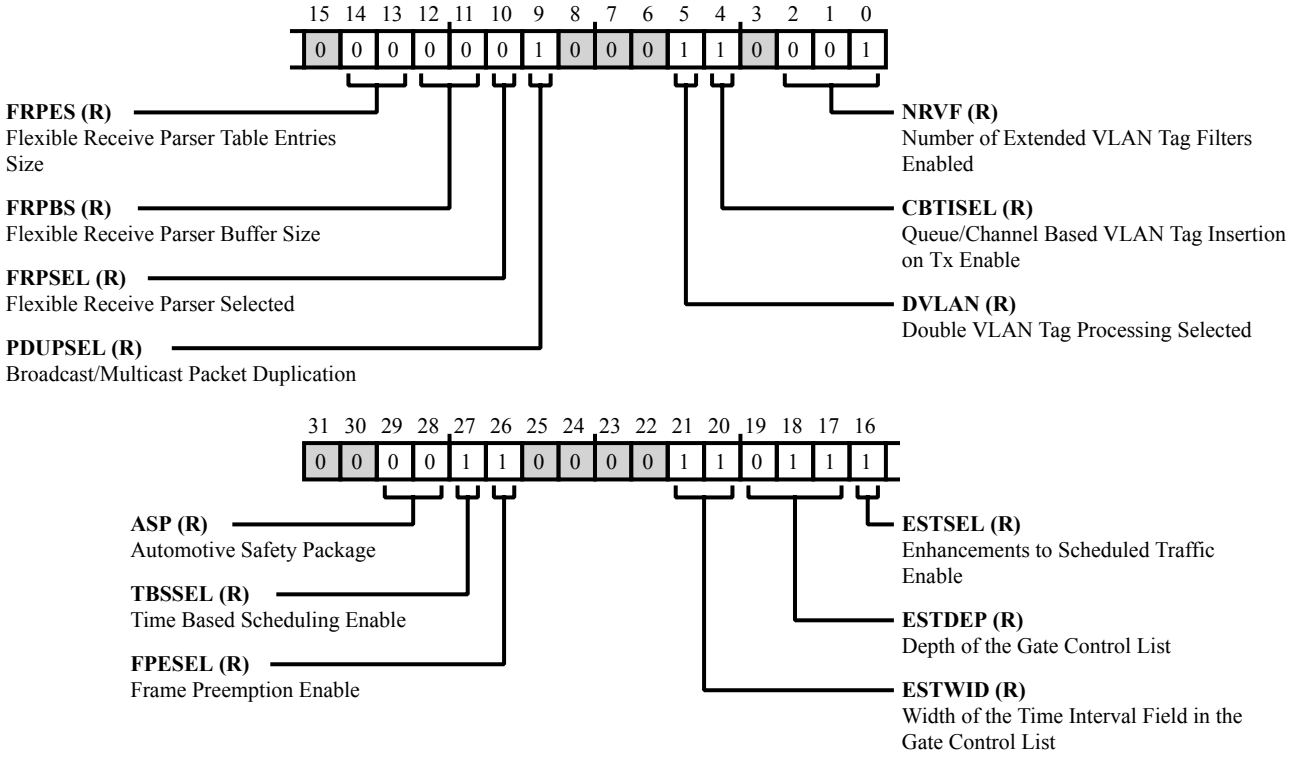

Figure 30-104: EMAC_HW_FTR_PSNT3 Register Diagram

Table 30-159: EMAC_HW_FTR_PSNT3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
29:28 (R/NW)	ASP	Automotive Safety Package. The EMAC_HW_FTR_PSNT3.ASP field indicates the different safety features.	
		0	No Safety Features Selected
		1	Only "ECC Protection for External Memory" Feature is Selected
		2	All the Automotive Safety Features are Selected Without the "Parity Port Enable for External Interface" Feature
		3	All the Automotive Safety Features are Selected with the "Parity Port Enable for External Interface" Feature

Table 30-159: EMAC_HW_FTR_PSNT3 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
27 (R/NW)	TBSSEL	Time Based Scheduling Enable. The `EMAC_HW_FTR_PSNT3.TBSSEL` bit is set (=1) when the Time Based Scheduling feature is selected.	
		0	Time Based Scheduling Enable Feature is Not Selected
		1	Time Based Scheduling Enable Feature is Selected
26 (R/NW)	FPESEL	Frame Preemption Enable. The `EMAC_HW_FTR_PSNT3.FPESEL` bit is set (=1) when the enable frame preemption feature is selected.	
		0	Frame Preemption Enable Feature is Not Selected
		1	Frame Preemption Enable Feature is Selected
21:20 (R/NW)	ESTWID	Width of the Time Interval Field in the Gate Control List. The `EMAC_HW_FTR_PSNT3.ESTWID` field indicates the width of the configured time interval field.	
		0	Width Not Configured
		1	16
		2	20
		3	24
19:17 (R/NW)	ESTDEP	Depth of the Gate Control List. The `EMAC_HW_FTR_PSNT3.ESTDEP` field indicates the depth of the GCL expressed as Log2(DWC_EQOS_EST_DEP)-5	
		0	No Depth Configured
		1	64
		2	128
		3	256
		4	512
		5	1024
		6	Reserved

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/NW)	ESTSEL	Enhancements to Scheduled Traffic Enable. The `EMAC_HW_FTR_PSNT3.ESTSEL` bit is set (=1) when the Enable Enhancements to Scheduling Traffic feature is selected.	
		0	Enable Enhancements to Scheduling Traffic Feature is Not Selected
		1	Enable Enhancements to Scheduling Traffic Feature is Selected
14:13 (R/NW)	FRPES	Flexible Receive Parser Table Entries Size. The `EMAC_HW_FTR_PSNT3.FRPES` field indicates the maximum number of parser entries supported the flexible receive parser.	
		0	64 Entries
		1	128 Entries
		2	256 Entries
		3	Reserved
12:11 (R/NW)	FRPBS	Flexible Receive Parser Buffer Size. The `EMAC_HW_FTR_PSNT3.FRPBS` field indicates the supported max number of bytes of the packet data to be parsed by the flexible receive parser.	
		0	64 Bytes
		1	128 Bytes
		2	256 Bytes
		3	Reserved
10 (R/NW)	FRPSEL	Flexible Receive Parser Selected. The `EMAC_HW_FTR_PSNT3.FRPSEL` bit is set (=1) when the enable flexible programmable receive parser option is selected.	
		0	Flexible Receive Parser Feature is Not Selected
		1	Flexible Receive Parser Feature is Selected
9 (R/NW)	PDUPSEL	Broadcast/Multicast Packet Duplication. The `EMAC_HW_FTR_PSNT3.PDUPSEL` bit is set (=1) when the broadcast/multicast packet duplication feature is selected.	
		0	Broadcast/Multicast Packet Duplication Feature is Not Selected
		1	Broadcast/Multicast Packet Duplication Feature is Selected

Table 30-159: EMAC_HW_FTR_PSNT3 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (R/NW)	DVLAN	Double VLAN Tag Processing Selected. The `EMAC_HW_FTR_PSNT3.DVLAN` bit is set (=1) when the enable double VLAN processing feature is selected.	
		0	Double VLAN Option is Not Selected
		1	Double VLAN Option is Selected
4 (R/NW)	CBTISEL	Queue/Channel Based VLAN Tag Insertion on Tx Enable. The `EMAC_HW_FTR_PSNT3.CBTISEL` bit is set (=1) when the enable queue/channel-based VLAN tag insertion on Tx feature is selected.	
		0	Enable Queue/Channel Based VLAN Tag Insertion on Tx Feature is Not Selected
		1	Enable Queue/Channel Based VLAN Tag Insertion on Tx Feature is Selected
2:0 (R/NW)	NRVF	Number of Extended VLAN Tag Filters Enabled. The `EMAC_HW_FTR_PSNT3.NRVF` field indicates the number of extended VLAN tag filters selected.	
		0	No Extended Rx VLAN Filters
		1	4 Extended Rx VLAN Filters
		2	8 Extended Rx VLAN Filters
		3	16 Extended Rx VLAN Filters
		4	24 Extended Rx VLAN Filters
		5	32 Extended Rx VLAN Filters
		6	Reserved

Hash Table Register 0

The EMAC_HASHTBL_REG0 register contains the first 32 bits of the hash table.

The hash table is used for group address filtering. For hash filtering, the content of the destination address in the incoming packet is passed through the CRC logic and the upper six bits of 64-bit hash (eight in 256-bit hash) bits of the CRC register are used to index the content of the hash table. The most significant bits determines the register to be used (Hash Table Register n), and the least significant five bits determine the bit within the register. For example, a hash value of 6'b100000 (in 64-bit Hash) selects bit 0 of the Hash Table Register 1, a value of 8b'10111111 (in 256-bit hash) selects bit 31 of the Hash Table Register 5.

The hash value of the destination address is calculated in the following way:

1. Calculate the 32-bit CRC for the DA (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32).

2. Perform bitwise reversal for the value obtained in Step 1.

3. Take the upper 6 (or 7 or 8) bits from the value obtained in step 2.

If the corresponding bit value of the register is 1'b1, the packet is accepted. Otherwise, it is rejected. If EMAC_MACPKT_FILT.PM = 1, all multicast packets are accepted regardless of the multicast hash values.

The hash table register is configured to be double-synchronized to the (G)MII clock domain; the synchronization is triggered only when bits[31:24] (in little-endian mode) or bits[7:0] (in big-endian mode) of the Hash Table Register n registers are written.

Hence, consecutive writes to this register should be performed only after at least four clock cycles in the (G)MII clock domain.

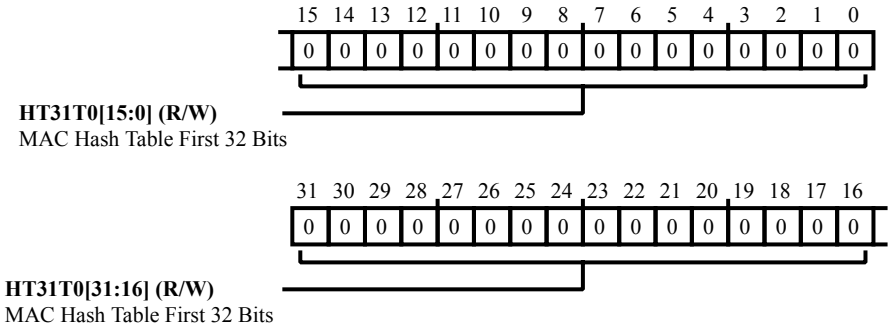

Figure 30-105: EMAC_HASHTBL_REG0 Register Diagram

Table 30-160: EMAC_HASHTBL_REG0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	HT31T0	MAC Hash Table First 32 Bits. The EMAC_HASHTBL_REG0.HT31T0 field contains the first 32 bits [31:0] of the hash table.

Hash Table Register 1

The EMAC_HASHTBL_REG1 register contains the second 32 bits of the hash table.

The hash table is used for group address filtering. For hash filtering, the content of the destination address in the incoming packet is passed through the CRC logic and the upper six bits of 64-bit hash (eight in 256-bit hash) bits of the CRC register are used to index the content of the hash table. The most significant bits determines the register to be used (Hash Table Register n), and the least significant five bits determine the bit within the register. For example, a hash value of 6'b100000 (in 64-bit Hash) selects bit 0 of the Hash Table Register 1, a value of 8b'10111111 (in 256-bit hash) selects bit 31 of the Hash Table Register 5.

The hash value of the destination address is calculated in the following way:

1. Calculate the 32-bit CRC for the DA (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32).

2. Perform bitwise reversal for the value obtained in Step 1.

3. Take the upper 6 (or 7 or 8) bits from the value obtained in step 2.

If the corresponding bit value of the register is 1'b1, the packet is accepted. Otherwise, it is rejected. If EMAC_MACPKT_FILT.PM = 1, all multicast packets are accepted regardless of the multicast hash values. The hash table register is configured to be double-synchronized to the (G)MII clock domain; the synchronization is triggered only when bits[31:24] (in little-endian mode) or bits[7:0] (in big-endian mode) of the Hash Table Register n registers are written.

Hence, consecutive writes to this register should be performed only after at least four clock cycles in the (G)MII clock domain.

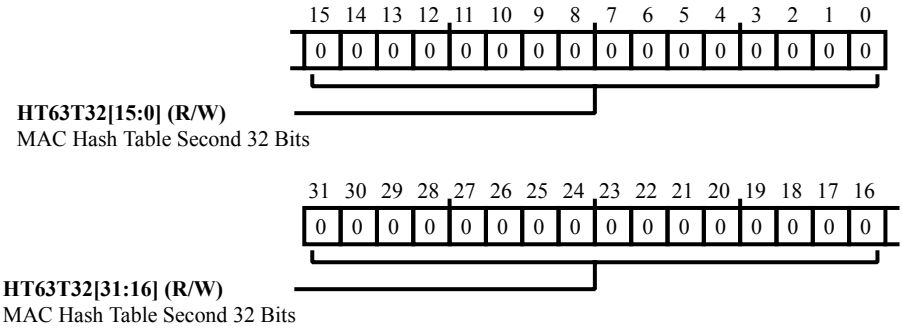

Figure 30-106: EMAC_HASHTBL_REG1 Register Diagram

Table 30-161: EMAC_HASHTBL_REG1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	HT63T32	MAC Hash Table Second 32 Bits. The EMAC_HASHTBL_REG1.HT63T32 field contains the second 32 bits [63:32] of the hash table.

Hash Table Register 2

The EMAC_HASHTBL_REG2 register contains the third 32 bits of the hash table.

The hash table is used for group address filtering. For hash filtering, the content of the destination address in the incoming packet is passed through the CRC logic and the upper six bits of 64-bit hash (eight in 256-bit hash) bits of the CRC register are used to index the content of the hash table. The most significant bits determines the register to be used (Hash Table Register n), and the least significant five bits determine the bit within the register. For example, a hash value of 6'b100000 (in 64-bit Hash) selects bit 0 of the Hash Table Register 1, a value of 8b'10111111 (in 256-bit hash) selects bit 31 of the Hash Table Register 5.

The hash value of the destination address is calculated in the following way:

1. Calculate the 32-bit CRC for the DA (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32).

2. Perform bitwise reversal for the value obtained in Step 1.

3. Take the upper 6 (or 7 or 8) bits from the value obtained in step 2.

If the corresponding bit value of the register is 1'b1, the packet is accepted. Otherwise, it is rejected. If EMAC_MACPKT_FILT.PM = 1, all multicast packets are accepted regardless of the multicast hash values. The hash table register is configured to be double-synchronized to the (G)MII clock domain; the synchronization is triggered only when bits[31:24] (in little-endian mode) or bits[7:0] (in big-endian mode) of the Hash Table Register n registers are written.

Hence, consecutive writes to this register should be performed only after at least four clock cycles in the (G)MII clock domain.

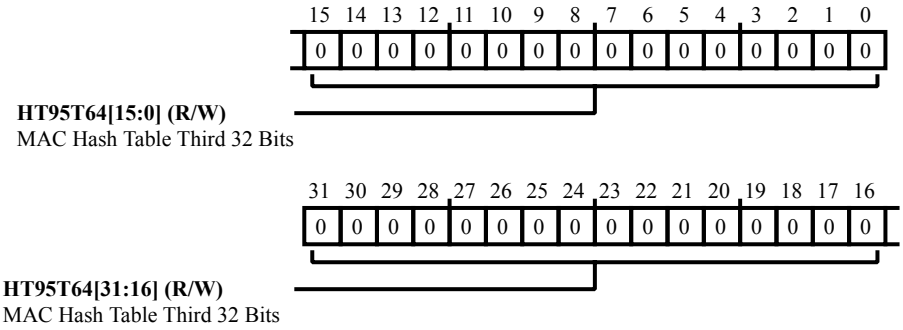

Figure 30-107: EMAC_HASHTBL_REG2 Register Diagram

Table 30-162: EMAC_HASHTBL_REG2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	HT95T64	MAC Hash Table Third 32 Bits. The EMAC_HASHTBL_REG2.HT95T64 field contains the third 32 bits [95:64] of the hash table.

Hash Table Register 3

The EMAC_HASHTBL_REG3 register contains the fourth 32 bits of the hash table.

The hash table is used for group address filtering. For hash filtering, the content of the destination address in the incoming packet is passed through the CRC logic and the upper six bits of 64-bit hash (eight in 256-bit hash) bits of the CRC register are used to index the content of the hash table. The most significant bits determines the register to be used (Hash Table Register n), and the least significant five bits determine the bit within the register. For example, a hash value of 6'b100000 (in 64-bit Hash) selects bit 0 of the Hash Table Register 1, a value of 8b'10111111 (in 256-bit hash) selects bit 31 of the Hash Table Register 5.

The hash value of the destination address is calculated in the following way:

1. Calculate the 32-bit CRC for the DA (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32).

2. Perform bitwise reversal for the value obtained in Step 1.

3. Take the upper 6 (or 7 or 8) bits from the value obtained in step 2.

If the corresponding bit value of the register is 1'b1, the packet is accepted. Otherwise, it is rejected. If EMAC_MACPKT_FILT.PM = 1, all multicast packets are accepted regardless of the multicast hash values. The hash table register is configured to be double-synchronized to the (G)MII clock domain; the synchronization is triggered only when bits[31:24] (in little-endian mode) or bits[7:0] (in big-endian mode) of the Hash Table Register n registers are written.

Hence, consecutive writes to this register should be performed only after at least four clock cycles in the (G)MII clock domain.

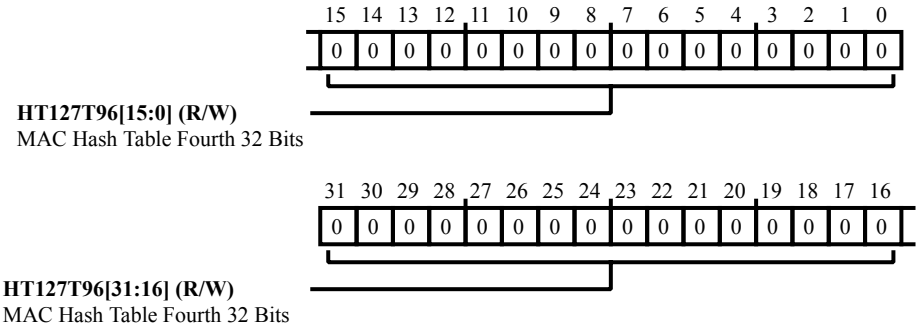

Figure 30-108: EMAC_HASHTBL_REG3 Register Diagram

Table 30-163: EMAC_HASHTBL_REG3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	HT127T96	MAC Hash Table Fourth 32 Bits. The EMAC_HASHTBL_REG3.HT127T96 field contains the fourth 32 bits [127:96] of the hash table.

Hash Table Register 4

The EMAC_HASHTBL_REG4 register contains the fifth 32 bits of the hash table.

The hash table is used for group address filtering. For hash filtering, the content of the destination address in the incoming packet is passed through the CRC logic and the upper six bits of 64-bit hash (eight in 256-bit hash) bits of the CRC register are used to index the content of the hash table. The most significant bits determines the register to be used (Hash Table Register n), and the least significant five bits determine the bit within the register. For example, a hash value of 6'b100000 (in 64-bit Hash) selects bit 0 of the Hash Table Register 1, a value of 8b'10111111 (in 256-bit hash) selects bit 31 of the Hash Table Register 5.

The hash value of the destination address is calculated in the following way:

1. Calculate the 32-bit CRC for the DA (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32).

2. Perform bitwise reversal for the value obtained in Step 1.

3. Take the upper 6 (or 7 or 8) bits from the value obtained in step 2.

If the corresponding bit value of the register is 1'b1, the packet is accepted. Otherwise, it is rejected. If EMAC_MACPKT_FILT.PM = 1, all multicast packets are accepted regardless of the multicast hash values.

The hash table register is configured to be double-synchronized to the (G)MII clock domain; the synchronization is triggered only when bits[31:24] (in little-endian mode) or bits[7:0] (in big-endian mode) of the Hash Table Register n registers are written.

Hence, consecutive writes to this register should be performed only after at least four clock cycles in the (G)MII clock domain.

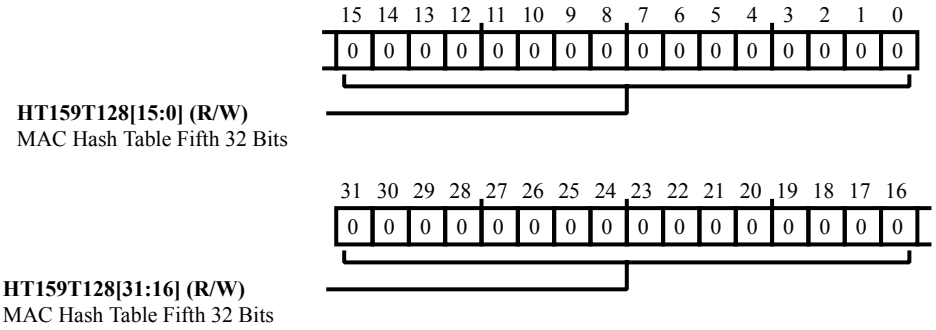

Figure 30-109: EMAC_HASHTBL_REG4 Register Diagram

Table 30-164: EMAC_HASHTBL_REG4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	HT159T128	MAC Hash Table Fifth 32 Bits. The EMAC_HASHTBL_REG4.HT159T128 field contains the fifth 32 bits [159:128] of the hash table.

Hash Table Register 5

The EMAC_HASHTBL_REG5 register contains the sixth 32 bits of the hash table.

The hash table is used for group address filtering. For hash filtering, the content of the destination address in the incoming packet is passed through the CRC logic and the upper six bits of 64-bit hash (eight in 256-bit hash) bits of the CRC register are used to index the content of the hash table. The most significant bits determines the register to be used (Hash Table Register n), and the least significant five bits determine the bit within the register. For example, a hash value of 6'b100000 (in 64-bit Hash) selects bit 0 of the Hash Table Register 1, a value of 8b'10111111 (in 256-bit hash) selects bit 31 of the Hash Table Register 5.

The hash value of the destination address is calculated in the following way:

1. Calculate the 32-bit CRC for the DA (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32).

2. Perform bitwise reversal for the value obtained in Step 1.

3. Take the upper 6 (or 7 or 8) bits from the value obtained in step 2.

If the corresponding bit value of the register is 1'b1, the packet is accepted. Otherwise, it is rejected. If EMAC_MACPKT_FILT.PM = 1, all multicast packets are accepted regardless of the multicast hash values.

The hash table register is configured to be double-synchronized to the (G)MII clock domain; the synchronization is triggered only when bits[31:24] (in little-endian mode) or bits[7:0] (in big-endian mode) of the Hash Table Register n registers are written.

Hence, consecutive writes to this register should be performed only after at least four clock cycles in the (G)MII clock domain.

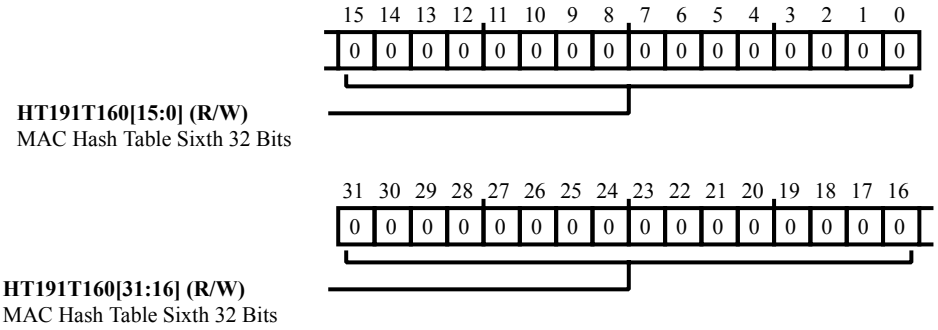

Figure 30-110: EMAC_HASHTBL_REG5 Register Diagram

Table 30-165: EMAC_HASHTBL_REG5 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	HT191T160	MAC Hash Table Sixth 32 Bits. The EMAC_HASHTBL_REG5.HT191T160 field contains the sixth 32 bits [191:160] of the hash table.

Hash Table Register 6

The EMAC_HASHTBL_REG6 register contains the seventh 32 bits of the hash table.

The hash table is used for group address filtering. For hash filtering, the content of the destination address in the incoming packet is passed through the CRC logic and the upper six bits of 64-bit hash (eight in 256-bit hash) bits of the CRC register are used to index the content of the hash table. The most significant bits determines the register to be used (Hash Table Register n), and the least significant five bits determine the bit within the register. For example, a hash value of 6'b100000 (in 64-bit Hash) selects bit 0 of the Hash Table Register 1, a value of 8b'10111111 (in 256-bit hash) selects bit 31 of the Hash Table Register 5.

The hash value of the destination address is calculated in the following way:

1. Calculate the 32-bit CRC for the DA (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32).

2. Perform bitwise reversal for the value obtained in Step 1.

3. Take the upper 6 (or 7 or 8) bits from the value obtained in step 2.

If the corresponding bit value of the register is 1'b1, the packet is accepted. Otherwise, it is rejected. If EMAC_MACPKT_FILT.PM = 1, all multicast packets are accepted regardless of the multicast hash values.

The hash table register is configured to be double-synchronized to the (G)MII clock domain; the synchronization is triggered only when bits[31:24] (in little-endian mode) or bits[7:0] (in big-endian mode) of the Hash Table Register n registers are written.

Hence, consecutive writes to this register should be performed only after at least four clock cycles in the (G)MII clock domain.

Table 30-166: EMAC_HASHTBL_REG6 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	HT223T192	MAC Hash Table Seventh 32 Bits. The EMAC_HASHTBL_REG6.HT223T192 field contains the seventh 32 bits [223:192] of the hash table.

Hash Table Register 7

The EMAC_HASHTBL_REG7 register contains the eighth 32 bits of the hash table.

The hash table is used for group address filtering. For hash filtering, the content of the destination address in the incoming packet is passed through the CRC logic and the upper six bits of 64-bit hash (eight in 256-bit hash) bits of the CRC register are used to index the content of the hash table. The most significant bits determines the register to be used (Hash Table Register n), and the least significant five bits determine the bit within the register. For example, a hash value of 6'b100000 (in 64-bit Hash) selects bit 0 of the Hash Table Register 1, a value of 8b'10111111 (in 256-bit hash) selects bit 31 of the Hash Table Register 5.

The hash value of the destination address is calculated in the following way:

1. Calculate the 32-bit CRC for the DA (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32).

2. Perform bitwise reversal for the value obtained in Step 1.

3. Take the upper 6 (or 7 or 8) bits from the value obtained in step 2.

If the corresponding bit value of the register is 1'b1, the packet is accepted. Otherwise, it is rejected. If EMAC_MACPKT_FILT.PM = 1, all multicast packets are accepted regardless of the multicast hash values. The hash table register is configured to be double-synchronized to the (G)MII clock domain; the synchronization is triggered only when bits[31:24] (in little-endian mode) or bits[7:0] (in big-endian mode) of the Hash Table Register n registers are written.

Hence, consecutive writes to this register should be performed only after at least four clock cycles in the (G)MII clock domain.

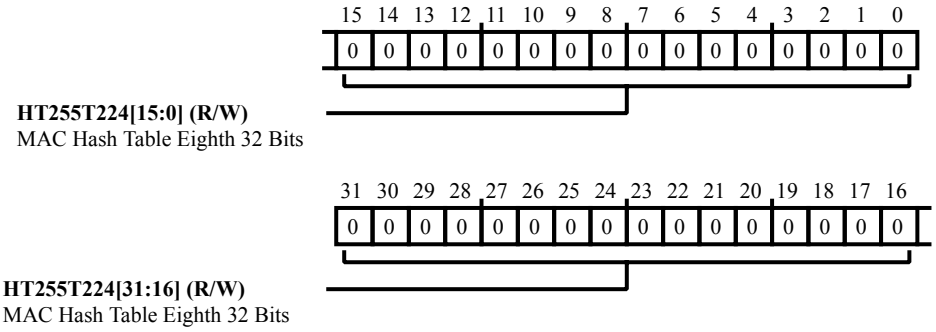

Figure 30-112: EMAC_HASHTBL_REG7 Register Diagram

Table 30-167: EMAC_HASHTBL_REG7 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	HT255T224	MAC Hash Table Eighth 32 Bits. The EMAC_HASHTBL_REG7.HT255T224 field contains the eighth 32 bits [255:224] of the hash table.

Indirect Access Control Register

The EMAC_INDR_ACC_CTL register provides the indirect access control and status for MAC_<MSEl>_<AOFF> registers.

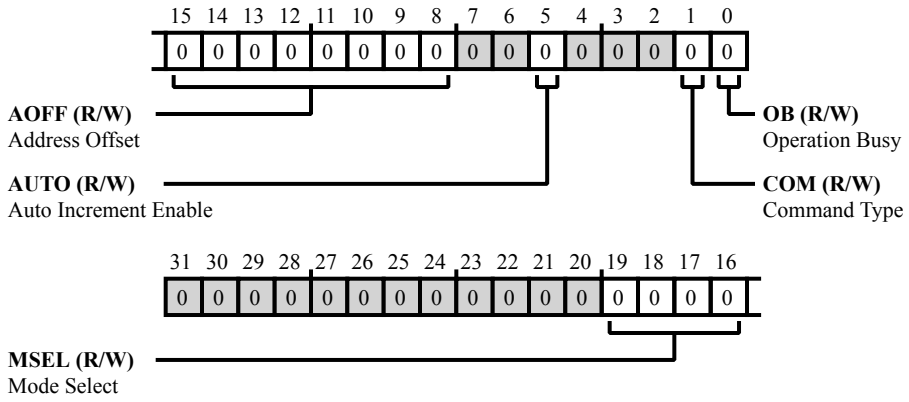

Figure 30-113: EMAC_INDR_ACC_CTL Register Diagram

Table 30-168: EMAC_INDR_ACC_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
19:16 (R/W)	MSEL	Mode Select. The EMAC_INDR_ACC_CTL.MSEL field is used in indirect access of MAC_<MSEL>_<AOFF>. The EMAC_INDR_ACC_CTL.MSEL field must be set along with initiation of read/write to MAC_<MSEL>_<AOFF> and should not be changed until the OB is cleared. Values: - 0000:Typ_RXQ_ (Type based RXQ mapping) - 0001-1111: Reserved
15:8 (R/W)	AOFF	Address Offset. The EMAC_INDR_ACC_CTL.AOFF field is used in indirect access of MAC_<MSEL>_<AOFF>. The EMAC_INDR_ACC_CTL.AOFF field must be configured along with initiation of read/write to MAC_<MSEL>_<AOFF> and should not be changed until the OB is cleared. Values: - 00000000: IndReg0(Indirect register 0) - 00000001: IndReg1(Indirect register 1) - ... - 00000111: IndReg7(Indirect register 7) - 00001000-11111111: Reserved

Table 30-168: EMAC_INDR_ACC_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (R/W)	AUTO	Auto Increment Enable. The EMAC_INDR_ACC_CTL.AUTO bit enables the address offset auto increment feature. When set (=1), AOFF is incremented by 1. Software should ensure not to cause a wrap condition. Byte wise read/write is not supported when auto increment is enabled. When the EMAC_INDR_ACC_CTL.AUTO bit is cleared (=0), AOFF is not incremented automatically. Software should program the correct Address Offset for each access.	
1 (R/W)	COM	Command Type. The EMAC_INDR_ACC_CTL.COM bit indicates the register access type. - 1: Indicates a read operation. - 0: Indicates a write operation.	
		0	Write Operation
		1	Read Operation
0 (R/W)	OB	Operation Busy. The EMAC_INDR_ACC_CTL.OB bit is set along with a read or write command for initiating the indirect access to MAC_<MSEL>_<AOFF> register. The EMAC_INDR_ACC_CTL.OB bit is cleared (=0) when the read or write command to MAC_<MSEL>_<AOFF> register is complete. The next indirect register access can be initiated only after EMAC_INDR_ACC_CTL.OB = 0. During a write operation, the bit is cleared (=0) only after the data has been written into MAC_<MSEL>_<AOFF> register. During a read operation, the data should be read from the EMAC_INDR_ACC_DAT register only after EMAC_INDR_ACC_CTL.OB = 0.	

Indirect Access Data Register

The EMAC_INDR_ACC_DAT register holds the read/write data for indirect access of MAC_<MSEL_<AOFF> registers.

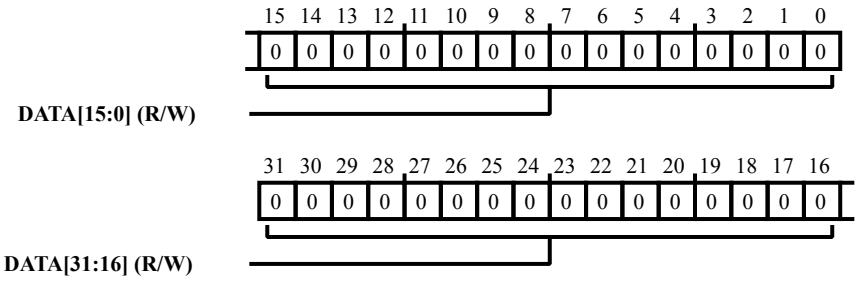

Figure 30-114: EMAC_INDR_ACC_DAT Register Diagram

Table 30-169: EMAC_INDR_ACC_DAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	DATA	. The EMAC_INDR_ACC_DAT.DATA field contains data to read/write for indirect address access associated with EMAC_INDR_ACC_CTL register.

Inner VLAN Tag Inclusion or Replacement Register

The EMAC_INVLAN_INCL register contains the inner VLAN tag to be inserted or replaced in the transmit packet. It also contains the inner VLAN tag insertion controls.

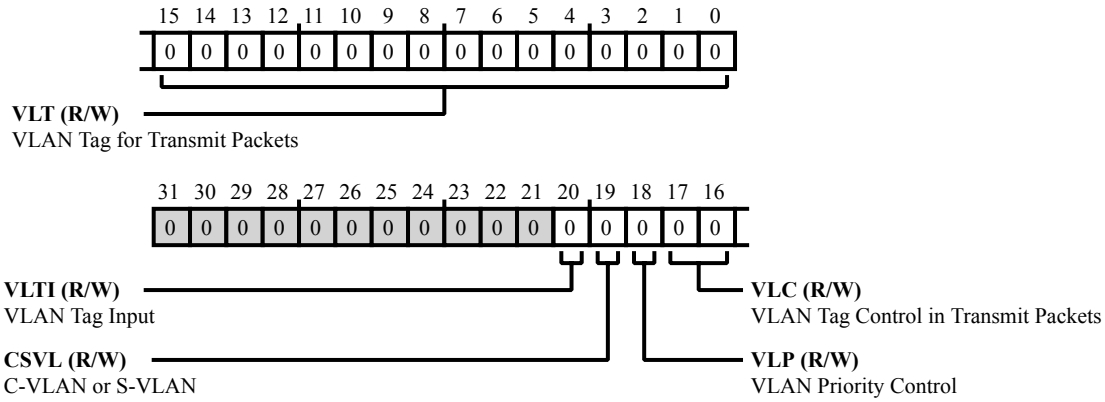

Figure 30-115: EMAC_INVLAN_INCL Register Diagram

Table 30-170: EMAC_INVLAN_INCL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
20 (R/W)	VLTI	VLAN Tag Input. When the EMAC_INVLAN_INCL.VLTI bit is set, it indicates that the VLAN tag to be inserted or replaced in Tx packet should be taken from the Tx descriptor.	
		0	VLAN Tag Input is Disabled
		1	VLAN Tag Input is Enabled
19 (R/W)	CSVL	C-VLAN or S-VLAN. When the EMAC_INVLAN_INCL.CSVL bit is set, S-VLAN type (0x88A8) is inserted or replaced in the 17th and 18th bytes of transmitted packets. When EMAC_INVLAN_INCL.CSVL = 0, C-VLAN type (0x8100) is inserted or replaced in the 17th and 18th bytes of transmitted packets.	
		0	C-VLAN Type (0x8100) is Inserted
		1	S-VLAN Type (0x88A8) is Inserted
18 (R/W)	VLP	VLAN Priority Control. When the EMAC_INVLAN_INCL.VLP bit is set, the VLC field is used for VLAN deletion, insertion, or replacement. When EMAC_INVLAN_INCL.VLP = 0, the TDES2.VTIR descriptor control is used and the VLC field is ignored.	
		0	VLAN Priority Control is Disabled
		1	VLAN Priority Control is Enabled

Table 30-170: EMAC_INVLAN_INCL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
17:16 (R/W)	VLC	VLAN Tag Control in Transmit Packets. The EMAC_INVLAN_INCL.VLC field indicates the VLAN tag control in transmit packets. 2'b00: No VLAN tag deletion, insertion, or replacement 2'b01: VLAN tag deletion. The MAC removes the VLAN type (bytes 17 and 18) and VLAN tag (bytes 19 and 20) of all transmitted packets with VLAN tags. 2'b10: VLAN tag insertion. The MAC inserts VLT in bytes 19 and 20 of the packet after inserting the Type value (0x8100 or 0x88a8) in bytes 17 and 18. This operation is performed on all transmitted packets, irrespective of whether they already have a VLAN tag. 2'b11: VLAN tag replacement. The MAC replaces VLT in bytes 19 and 20 of all VLAN-type transmitted packets (Bytes 17 and 18 are 0x8100 or 0x88a8). Note: Changes to this field take effect only on the start of a packet. If this register field is written to when a packet is being transmitted, only the subsequent packet can use the updated value; the current packet does not use the updated value.	
		0	No VLAN Tag Deletion, Insertion, or Replacement
		1	VLAN Tag Deletion
		2	VLAN Tag Insertion
		3	VLAN Tag Replacement
15:0 (R/W)	VLT	VLAN Tag for Transmit Packets. The EMAC_INVLAN_INCL.VLT field contains the value of the VLAN tag to be inserted or replaced. The value must only be changed when the transmit lines are inactive or during the initialization phase. Bits[15:13] are the User Priority field, Bit 12 is the CFI/DEI field, and bits[11:0] are the VID field in the VLAN tag. The following list describes the bits of this field: - Bits[15:13]: User Priority - Bit 12: Canonical Format Indicator (CFI) or Drop Eligible Indicator (DEI) - Bits[11:0]: VLAN Identifier (VID) field of VLAN tag	

MAC Interrupt Enable Register

The EMAC_MAC_IEN register contains the masks for generating the interrupts.

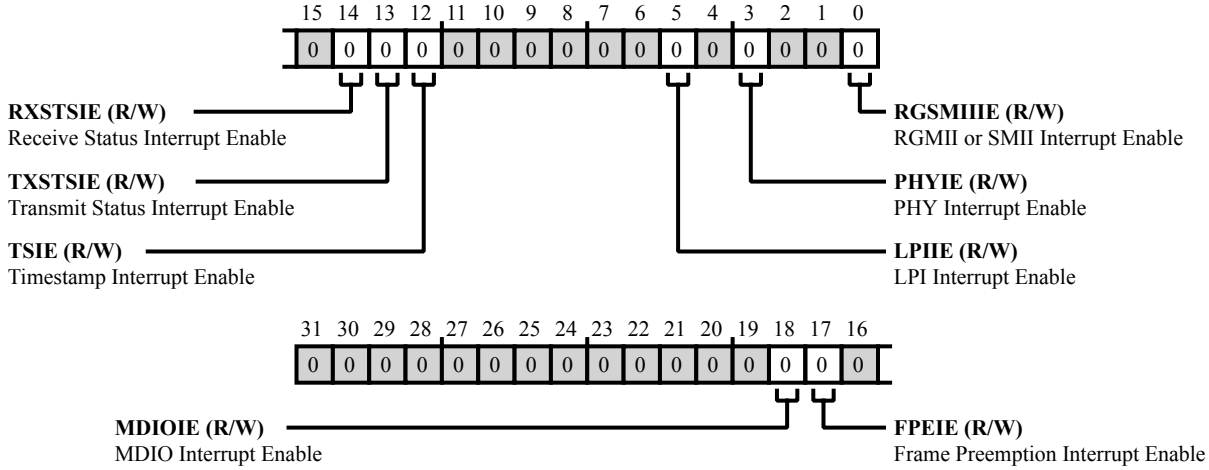

Figure 30-116: EMAC_MAC_IEN Register Diagram

Table 30-171: EMAC_MAC_IEN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
18 (R/W)	MDIOIE	MDIO Interrupt Enable. When the EMAC_MAC_IEN.MDIOIE bit is set, it enables the assertion of the interrupt when EMAC_MAC_ISTAT.MDIOIS = 1.	
		0	MDIO Interrupt is Disabled
		1	MDIO Interrupt is Enabled
17 (R/W)	FPEIE	Frame Preemption Interrupt Enable. When the EMAC_MAC_IEN.FPEIE bit is set, it enables the assertion of the interrupt when EMAC_MAC_ISTAT.FPEIS = 1.	
		0	Frame Preemption Interrupt is Disabled
		1	Frame Preemption Interrupt is Enabled
14 (R/W)	RXSTSIE	Receive Status Interrupt Enable. When the EMAC_MAC_IEN.RXSTSIE bit is set, it enables the assertion of the interrupt signal because of the configuration of the EMAC_MAC_ISTAT.RXSTSIS bit.	
		0	Receive Status Interrupt is Disabled
		1	Receive Status Interrupt is Enabled

Table 30-171: EMAC_MAC_IEN Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
13 (R/W)	TXSTSIE	Transmit Status Interrupt Enable. When the `EMAC_MAC_IEN.TXSTSIE` bit is set, it enables the assertion of the interrupt signal because of the configuration of the EMAC_MAC_ISTAT.TXSTSIS bit.	
		0	Disable
		1	Enable
12 (R/W)	TSIE	Timestamp Interrupt Enable. When the `EMAC_MAC_IEN.TSIE` bit is set, it enables the assertion of the interrupt signal because of the configuration of the EMAC_MAC_ISTAT.TSIS bit.	
		0	Disable
		1	Enable
5 (R/W)	LPIIE	LPI Interrupt Enable. When the `EMAC_MAC_IEN.LPIIE` bit is set, it enables the assertion of the interrupt signal because of EMAC_MAC_ISTAT.LPIIS.	
		0	LPI Interrupt is Disabled
		1	LPI Interrupt is Enabled
3 (R/W)	PHYIE	PHY Interrupt Enable. When the `EMAC_MAC_IEN.PHYIE` bit is set, it enables the assertion of the interrupt signal because of the EMAC_MAC_ISTAT.PHYIS bit.	
		0	PHY Interrupt is Disabled
		1	PHY Interrupt is Enabled
0 (R/W)	RGSMIIIE	RGMII or SMII Interrupt Enable. When the `EMAC_MAC_IEN.RGSMIIIE` bit is set, it enables the assertion of the interrupt signal because of the configuration of the EMAC_MAC_ISTAT.RGSMIIIS bit.	
		0	RGMII or SMII Interrupt is Disabled
		1	RGMII or SMII Interrupt is Enabled

MAC Interrupt Status Register

The EMAC_MAC_ISTAT register contains the status of interrupts.

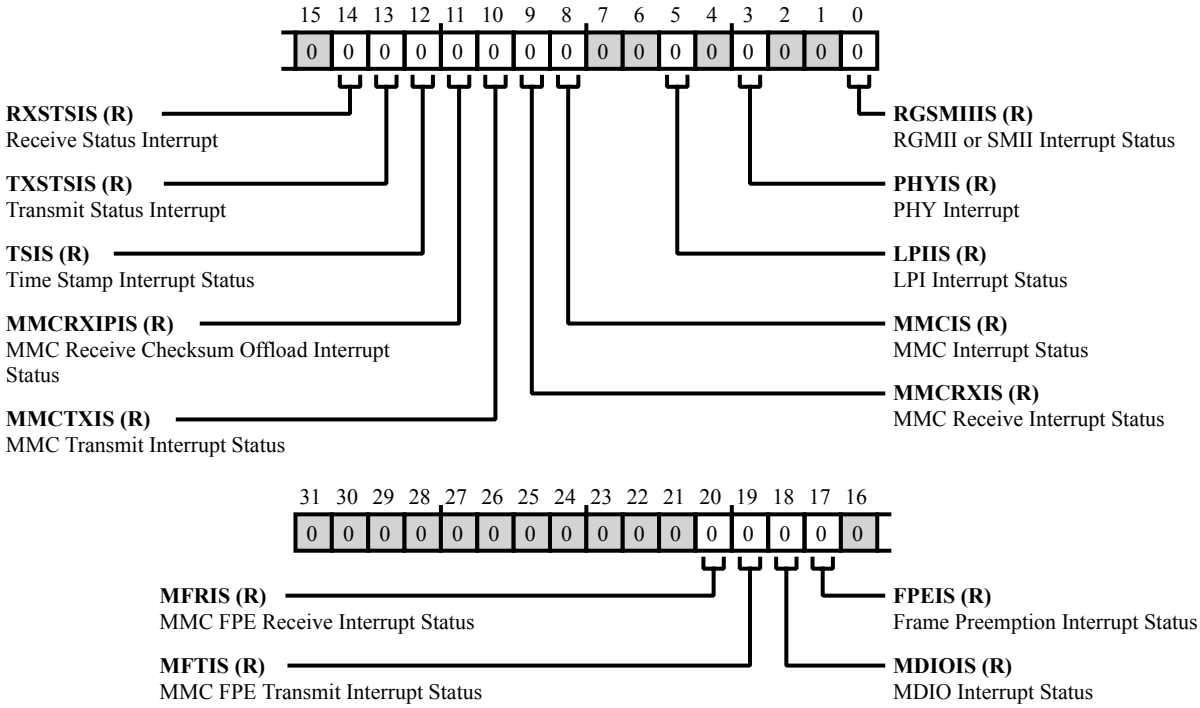

Figure 30-117: EMAC_MAC_ISTAT Register Diagram

Table 30-172: EMAC_MAC_ISTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
20 (R/NW)	MFRIS	MMC FPE Receive Interrupt Status. The EMAC_MAC_ISTAT.MFRIS bit is set (=1) when an interrupt is generated in the EMAC_MMC_FPE_RXINT register. The EMAC_MAC_ISTAT.MFRIS bit is cleared when all bits in this interrupt register are cleared. The EMAC_MAC_ISTAT.MFRIS bit is valid only when MMC and FPE support are enabled.	
		0	MMC FPE Receive Interrupt Status Not Active
		1	MMC FPE Receive Interrupt Status Active

Table 30-172: EMAC_MAC_ISTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
19 (R/NW)	MFTIS	MMC FPE Transmit Interrupt Status. The EMAC_MAC_ISTAT.MFTIS bit is set (=1) when an interrupt is generated in the EMAC_MMC_FPE_TXINT register. The EMAC_MAC_ISTAT.MFTIS bit is cleared when all bits in this interrupt register are cleared. The EMAC_MAC_ISTAT.MFTIS bit is valid only when MMC and FPE support are enabled.	
		0	MMC FPE Transmit Interrupt Status Not Active
		1	MMC FPE Transmit Interrupt Status Active
18 (R/NW)	MDIOIS	MDIO Interrupt Status. The EMAC_MAC_ISTAT.MDIOIS bit indicates an interrupt event after the completion of MDIO operation. To reset the EMAC_MAC_ISTAT.MDIOIS bit, the application has to read the EMAC_MAC_ISTAT.MDIOIS bit/write 1 to the EMAC_MAC_ISTAT.MDIOIS bit when EMAC_CSR_SW_CTL.RCWE = 1. Access restriction applies. Clears on read (or write of 1 when EMAC_CSR_SW_CTL.RCWE = 1). Self-set to 1 on internal event.	
		0	MDIO Interrupt Status Not Active
		1	MDIO Interrupt Status Active
17 (R/NW)	FPEIS	Frame Preemption Interrupt Status. The EMAC_MAC_ISTAT.FPEIS bit indicates an interrupt event during the operation of frame preemption (Bits[19:16] of EMAC_FPE_CTLSTAT register are set). To reset the EMAC_MAC_ISTAT.FPEIS bit, the application must clear the event in EMAC_FPE_CTLSTAT that caused the Interrupt.	
		0	Frame Preemption Interrupt Status Not Active
		1	Frame Preemption Interrupt Status Active
14 (R/NW)	RXSTSIS	Receive Status Interrupt. The EMAC_MAC_ISTAT.RXSTSIS bit indicates the status of received packets. The EMAC_MAC_ISTAT.RXSTSIS bit is set when the EMAC_RXTX_STAT.RWT = 1. The EMAC_MAC_ISTAT.RXSTSIS bit is cleared when the corresponding interrupt source bit is read (or corresponding interrupt source bit is written to 1 when EMAC_CSR_SW_CTL.RCWE = 1) in the EMAC_RXTX_STAT register.	
		0	Receive Interrupt Status Not Active
		1	Receive Interrupt Status Active

Table 30-172: EMAC_MAC_ISTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
13 (R/NW)	TXSTSIS	Transmit Status Interrupt. The EMAC_MAC_ISTAT.TXSTSIS bit indicates the status of transmitted packets. The EMAC_MAC_ISTAT.TXSTSIS bit is set when any of the following bits is set in the EMAC_RXTX_STAT register: Excessive Collision (EXCOL) Late Collision (LCOL) Excessive Deferral (EXDEF) Loss of Carrier (LCARR) No Carrier (NCARR) Jabber Timeout (TJT) The EMAC_MAC_ISTAT.TXSTSIS bit is cleared when the corresponding interrupt source bit is read (or corresponding interrupt source bit is written to 1 (when EMAC_CSR_SW_CTL.RCWE = 1) in the EMAC_RXTX_STAT register).	
		0	Status Not Active
		1	Status Active
12 (R/NW)	TSIS	Time Stamp Interrupt Status. If the time stamp feature is enabled, the EMAC_MAC_ISTAT.TSIS bit is set when any of the following conditions are true: The system time value is equal to or exceeds the value specified in the Target Time High and Low registers. There is an overflow in the seconds register. The Target Time Error occurred, that is, programmed target time already elapsed. If the Auxiliary Snapshot feature is enabled, the EMAC_MAC_ISTAT.TSIS bit is set when the auxiliary snapshot trigger is asserted. In configurations other than EQOS_CORE, when drop transmit status is enabled in MTL, the EMAC_MAC_ISTAT.TSIS bit is set when the captured transmit time stamp is updated in the EMAC_TXTMSTAT_NSEC and EMAC_TXTMSTAT_SEC registers. When PTP offload feature is enabled, the EMAC_MAC_ISTAT.TSIS bit is set when the captured transmit time stamp is updated in the EMAC_TXTMSTAT_NSEC and EMAC_TXTMSTAT_SEC registers, for PTO generated Delay Request and Pdelay request packets. The EMAC_MAC_ISTAT.TSIS bit is cleared when the corresponding interrupt source bit is read (or corresponding interrupt source bit is written to 1 (when EMAC_CSR_SW_CTL.RCWE = 1) in the EMAC_TM_STAT register.	
		0	Status Not Active
		1	Status Active

Table 30-172: EMAC_MAC_ISTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/NW)	MMCRXIPIS	MMC Receive Checksum Offload Interrupt Status. The EMAC_MAC_ISTAT.MMCRXIPIS bit is set (=1) when an interrupt is generated in the MMC Receive Checksum Offload Interrupt Register. The EMAC_MAC_ISTAT.MMCRXIPIS bit is cleared when all bits in this interrupt register are cleared. The EMAC_MAC_ISTAT.MMCRXIPIS bit is valid only when the Enable MAC Management Counters (MMC) and Enable Receive TCP/IP Checksum Check options are selected.	
		0	MMC Receive Checksum Offload Interrupt Status Not Active
		1	MMC Receive Checksum Offload Interrupt Status Active
10 (R/NW)	MMCTXIS	MMC Transmit Interrupt Status. The EMAC_MAC_ISTAT.MMCTXIS bit is set (=1) when an interrupt is generated in the EMAC_MMC_TXINT register. The EMAC_MAC_ISTAT.MMCTXIS bit is cleared when all bits in this interrupt register are cleared. The EMAC_MAC_ISTAT.MMCTXIS bit is valid only when the Enable MAC Management Counters (MMC) option is selected.	
		0	MMC Transmit Interrupt Status Not Active
		1	MMC Transmit Interrupt Status Active
9 (R/NW)	MMCRXIS	MMC Receive Interrupt Status. The EMAC_MAC_ISTAT.MMCRXIS bit is set (=1) when an interrupt is generated in the EMAC_MMC_RXINT register. The EMAC_MAC_ISTAT.MMCRXIS bit is cleared when all bits in this interrupt register are cleared. The EMAC_MAC_ISTAT.MMCRXIS bit is valid only when the Enable MAC Management Counters (MMC) option is selected.	
		0	MMC Receive Interrupt Status Not Active
		1	MMC Receive Interrupt Status Active
8 (R/NW)	MMCIS	MMC Interrupt Status. The EMAC_MAC_ISTAT.MMCIS bit is set (=1) when Bit 11, Bit 10, or Bit 9 is set (=1). The EMAC_MAC_ISTAT.MMCIS bit is cleared only when all these bits are low. The EMAC_MAC_ISTAT.MMCIS bit is valid only when the Enable MAC Management Counters (MMC) option is selected.	
		0	MMC Interrupt Status Not Active
		1	MMC Interrupt Status Active

Table 30-172: EMAC_MAC_ISTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (R/NW)	LPIIS	LPI Interrupt Status. When the Energy Efficient Ethernet feature is enabled, the EMAC_MAC_ISTAT.LPIIS bit is set for any LPI state entry or exit in the MAC transmitter or receiver. The EMAC_MAC_ISTAT.LPIIS bit is cleared when the corresponding interrupt source bit of the EMAC_LPI_CTLSTAT register is read (or corresponding interrupt source bit of EMAC_LPI_CTLSTAT register is written to 1 (when EMAC_CSR_SW_CTL.RCWE = 1).	
		0	LPI Interrupt Status Not Active
		1	LPI Interrupt Status Active
3 (R/NW)	PHYIS	PHY Interrupt. The EMAC_MAC_ISTAT.PHYIS bit is set when rising edge is detected on the phy_intr_i input. The EMAC_MAC_ISTAT.PHYIS bit is cleared when this register is read (or the EMAC_MAC_ISTAT.PHYIS bit is written to 1 (when EMAC_CSR_SW_CTL.RCWE = 1)).	
		0	PHY Interrupt Not Detected
		1	PHY Interrupt Detected
0 (R/NW)	RGSMIIIS	RGMII or SMII Interrupt Status. The EMAC_MAC_ISTAT.RGSMIIIS bit is set because of any change in value of the link status of RGMII or SMII interface (EMAC_PHYIF_CTLSTAT.LNKSTS). The EMAC_MAC_ISTAT.RGSMIIIS bit is cleared when the EMAC_PHYIF_CTLSTAT register is read (or EMAC_PHYIF_CTLSTAT.LNKSTS is written to 1 when EMAC_CSR_SW_CTL.RCWE = 1). The EMAC_MAC_ISTAT.RGSMIIIS bit is valid only when the optional RGMII or SMII PHY interface is selected.	
		0	RGMII or SMII Interrupt Status is Not Active
		1	RGMII or SMII Interrupt Status is Active

Layer 3 and Layer 4 Control Register

The EMAC_L3L4_CTL7 register controls the operations of filter 0 of layer 3 and layer 4.

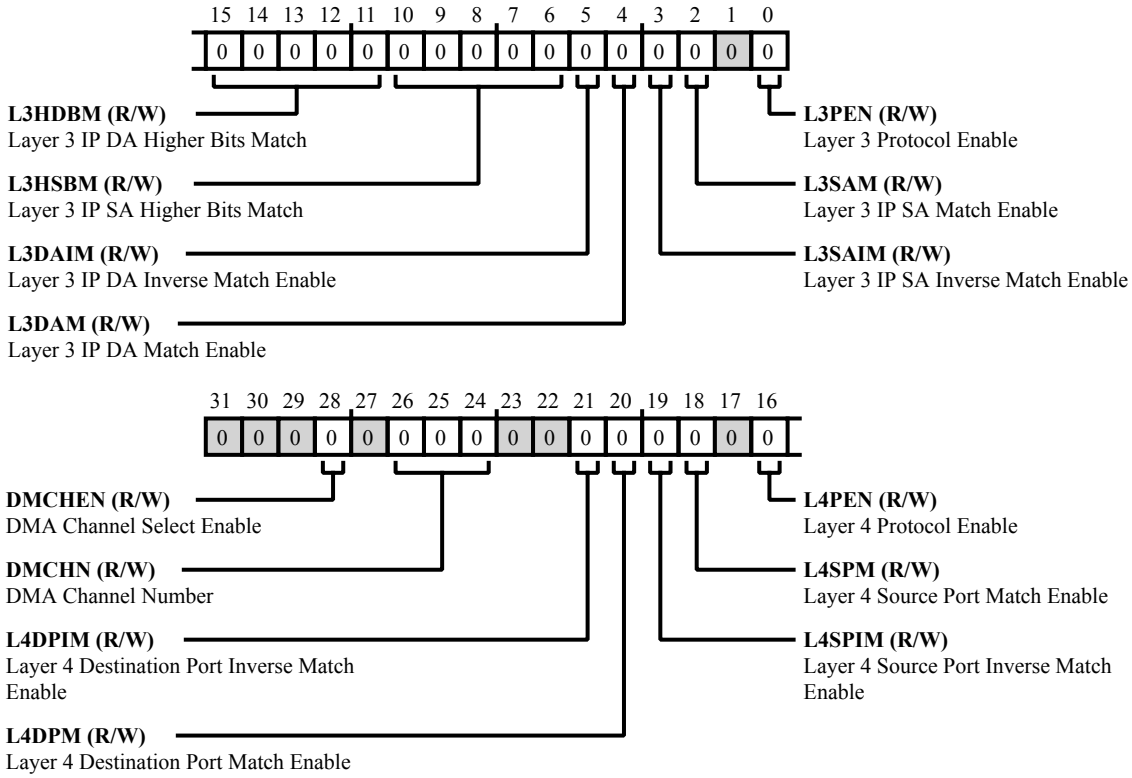

Figure 30-118: EMAC_L3L4_CTL7 Register Diagram

Table 30-173: EMAC_L3L4_CTL7 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
28 (R/W)	DMCHEN	DMA Channel Select Enable. When set, the EMAC_L3L4_CTL7.DMCHEN bit enables the selection of the DMA channel number for the packet that is passed by this L3_L4 filter. The DMA channel is indicated by the DMCHN bits. When EMAC_L3L4_CTL7.DMCHEN = 0, the DMA channel is not decided by this filter.	
		0	DMA Channel Select is Disabled
		1	DMA Channel Select is Enabled
26:24 (R/W)	DMCHN	DMA Channel Number. When DMCHEN is set (=1), the EMAC_L3L4_CTL7.DMCHN field selects the DMA channel number to which the packet passed by this filter is routed. The width of the EMAC_L3L4_CTL7.DMCHN field depends on the number of the DMA channels present in the configuration.	

Table 30-173: EMAC_L3L4_CTL7 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
21 (R/W)	L4DPIM	Layer 4 Destination Port Inverse Match Enable. When the EMAC_L3L4_CTL7.L4DPIM bit is set, the Layer 4 Destination Port number field is enabled for inverse matching. When EMAC_L3L4_CTL7.L4DPIM = 0, the Layer 4 Destination Port number field is enabled for perfect matching. The EMAC_L3L4_CTL7.L4DPIM bit is valid and applicable only when the EMAC_L3L4_CTL[n].L4DPM= 1.	
		0	Layer 4 Destination Port Inverse Match is Disabled
		1	Layer 4 Destination Port Inverse Match is Enabled
20 (R/W)	L4DPM	Layer 4 Destination Port Match Enable. When the EMAC_L3L4_CTL7.L4DPM bit is set, the Layer 4 Destination Port number field is enabled for matching. When EMAC_L3L4_CTL7.L4DPM = 0, the MAC ignores the Layer 4 Destination Port number field for matching.	
		0	Layer 4 Destination Port Match is Disabled
		1	Layer 4 Destination Port Match is Enabled
19 (R/W)	L4SPIM	Layer 4 Source Port Inverse Match Enable. When the EMAC_L3L4_CTL7.L4SPIM bit is set, the Layer 4 Source Port number field is enabled for inverse matching. When EMAC_L3L4_CTL7.L4SPIM = 0, the Layer 4 Source Port number field is enabled for perfect matching. The EMAC_L3L4_CTL7.L4SPIM bit is valid and applicable only when the EMAC_L3L4_CTL[n].L4SPM= 1.	
		0	Layer 4 Source Port Inverse Match is Disabled
		1	Layer 4 Source Port Inverse Match is Enabled
18 (R/W)	L4SPM	Layer 4 Source Port Match Enable. When the EMAC_L3L4_CTL7.L4SPM bit is set, the Layer 4 Source Port number field is enabled for matching. When EMAC_L3L4_CTL7.L4SPM = 0, the MAC ignores the Layer 4 Source Port number field for matching.	
		0	Layer 4 Source Port Match is Disabled
		1	Layer 4 Source Port Match is Enabled

Table 30-173: EMAC_L3L4_CTL7 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/W)	L4PEN	Layer 4 Protocol Enable. When the `EMAC_L3L4_CTL7.L4PEN` bit is set, the Source and Destination Port number fields of UDP packets are used for matching. When `EMAC_L3L4_CTL7.L4PEN` = 0, the Source and Destination Port number fields of TCP packets are used for matching. The layer 4 matching is done only when the EMAC_L3L4_CTL[n].L4SPM or EMAC_L3L4_CTL[n].L4DPM= 1.	
		0	Layer 4 Protocol is Disabled
		1	Layer 4 Protocol is Enabled
15:11 (R/W)	L3HDBM	Layer 3 IP DA Higher Bits Match. For IPv4 packets, the `EMAC_L3L4_CTL7.L3HDBM` field contains the number of higher bits of IP Destination Address that are matched in the IPv4 packets. The following list describes the values of this field: - 0: No bits are masked - 1: LSb[0] is masked - 2: Two LSbs [1:0] are masked - .. - 31: All bits except MSb are masked For IPv6 packets, the bits[12:11] of this field correspond to bits[6:5] of L3HSBM which indicate the number of lower bits of IP Source or Destination Address that are masked in the IPv6 packets. The following list describes the concatenated values of the L3HDBM[1:0] and L3HSBM bits: - 0: No bits are masked - 1: LSb[0] is masked - 2: Two LSbs [1:0] are masked - .. - 127: All bits except MSb are masked The `EMAC_L3L4_CTL7.L3HDBM` field is valid and applicable only when the L3DAM or L3SAM bit is set.	

Table 30-173: EMAC_L3L4_CTL7 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
10:6 (R/W)	L3HSBM	Layer 3 IP SA Higher Bits Match. For IPv4 packets, the EMAC_L3L4_CTL7.L3HSBM field contains the number of lower bits of IP Source Address that are masked for matching in the IPv4 packets. The following list describes the values of this field: - 0: No bits are masked - 1: LSb[0] is masked - 2: Two LSbs [1:0] are masked - .. - 31: All bits except MSb are masked For IPv6 packets, the EMAC_L3L4_CTL7.L3HSBM field contains bits[4:0] of L3HSBM. These bits indicate the number of higher bits of IP Source or Destination Address matched in the IPv6 packets. The EMAC_L3L4_CTL7.L3HSBM field is valid and applicable only when the EMAC_L3L4_CTL[n].L3DAM or L3SAM bit is set (=1).	
5 (R/W)	L3DAIM	Layer 3 IP DA Inverse Match Enable. When the EMAC_L3L4_CTL7.L3DAIM bit is set, the Layer 3 IP Destination Address field is enabled for inverse matching. When EMAC_L3L4_CTL7.L3DAIM = 0, the Layer 3 IP Destination Address field is enabled for perfect matching. The EMAC_L3L4_CTL7.L3DAIM bit is valid and applicable only when the EMAC_L3L4_CTL[n].L3DAM = 1.	
		0	Layer 3 IP DA Inverse Match is Disabled
		1	Layer 3 IP DA Inverse Match is Enabled
4 (R/W)	L3DAM	Layer 3 IP DA Match Enable. When the EMAC_L3L4_CTL7.L3DAM bit is set, the Layer 3 IP Destination Address field is enabled for matching. When EMAC_L3L4_CTL7.L3DAM = 0, the MAC ignores the Layer 3 IP Destination Address field for matching. Note: When EMAC_L3L4_CTL[n].L3PEN = 1, set either the EMAC_L3L4_CTL7.L3DAM bit or the L3SAM bit because either IPv6 DA or SA can be checked for filtering.	
		0	Layer 3 IP DA Match is Disabled
		1	Layer 3 IP DA Match is Enabled

Table 30-173: EMAC_L3L4_CTL7 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	L3SAIM	Layer 3 IP SA Inverse Match Enable. When the EMAC_L3L4_CTL7.L3SAIM bit is set, the Layer 3 IP Source Address field is enabled for inverse matching. When the EMAC_L3L4_CTL7.L3SAIM bit reset, the Layer 3 IP Source Address field is enabled for perfect matching. The EMAC_L3L4_CTL7.L3SAIM bit is valid and applicable only when EMAC_L3L4_CTL[n].L3DAM = 1.	
		0	Layer 3 IP SA Inverse Match is Disabled
		1	Layer 3 IP SA Inverse Match is Enabled
2 (R/W)	L3SAM	Layer 3 IP SA Match Enable. When the EMAC_L3L4_CTL7.L3SAM bit is set, the Layer 3 IP Source Address field is enabled for matching. When EMAC_L3L4_CTL7.L3SAM = 0, the MAC ignores the Layer 3 IP Source Address field for matching. Note: When the EMAC_L3L4_CTL[n].L3PEN bit is set, set either the EMAC_L3L4_CTL7.L3SAM bit or the EMAC_L3L4_CTL[n].L3DAM bit because either IPv6 SA or DA can be checked for filtering.	
		0	Layer 3 IP SA Match is Disabled
		1	Layer 3 IP SA Match is Enabled
0 (R/W)	L3PEN	Layer 3 Protocol Enable. When the EMAC_L3L4_CTL7.L3PEN bit is set, the Layer 3 IP Source or Destination Address matching is enabled for IPv6 packets. When EMAC_L3L4_CTL7.L3PEN = 0, the Layer 3 IP Source or Destination Address matching is enabled for IPv4 packets. The layer 3 matching is done only when the EMAC_L3L4_CTL[n].L3SAM or EMAC_L3L4_CTL[n].L3DAM bit is set (=1).	
		0	Layer 3 Protocol is Disabled
		1	Layer 3 Protocol is Enabled

Layer 3 and Layer 4 Control Register

The EMAC_L3L4_CTL[i] register controls the operations of filter 0 of layer 3 and layer 4.

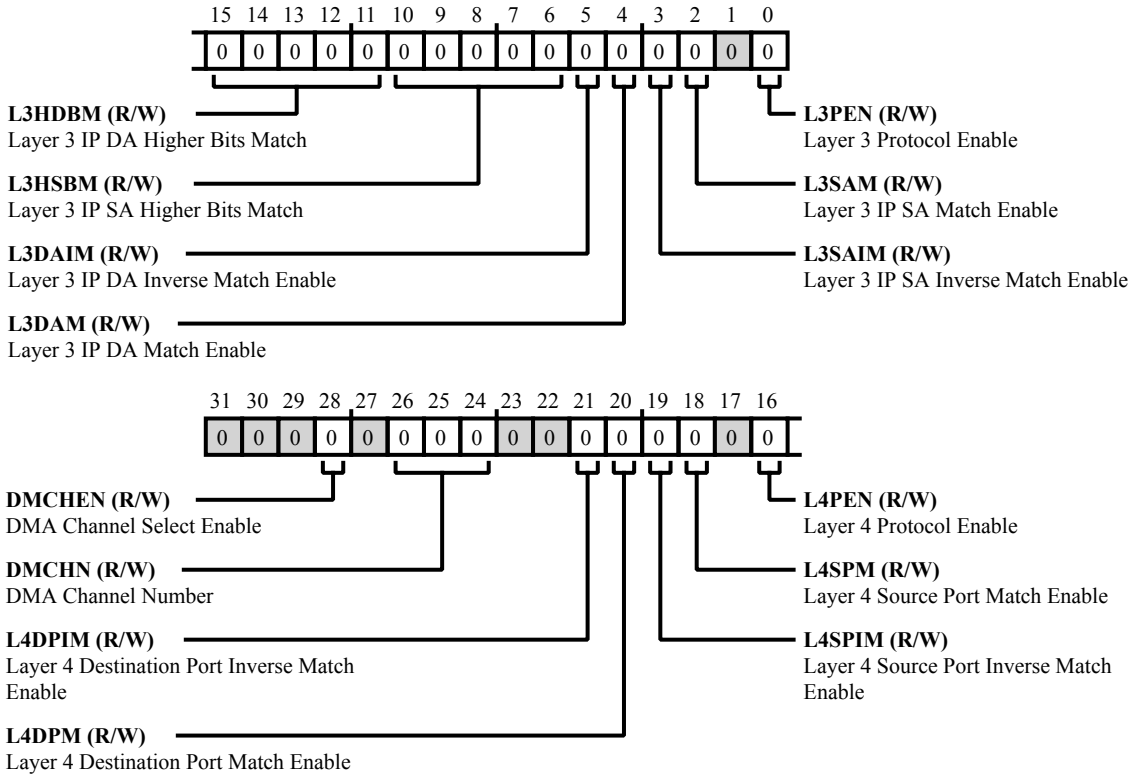

Figure 30-119: EMAC_L3L4_CTL[i] Register Diagram

Table 30-174: EMAC_L3L4_CTL[i] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
28 (R/W)	DMCHEN	DMA Channel Select Enable. When set, the EMAC_L3L4_CTL[i].DMCHEN bit enables the selection of the DMA channel number for the packet that is passed by this L3_L4 filter. The DMA channel is indicated by the DMCHN bits. When EMAC_L3L4_CTL[i].DMCHEN = 0, the DMA channel is not decided by this filter.	
		0	DMA Channel Select is Disabled
		1	DMA Channel Select is Enabled
26:24 (R/W)	DMCHN	DMA Channel Number. When DMCHEN is set (=1), the EMAC_L3L4_CTL[i].DMCHN field selects the DMA channel number to which the packet passed by this filter is routed. The width of the EMAC_L3L4_CTL[i].DMCHN field depends on the number of the DMA channels present in the configuration.	

Table 30-174: EMAC_L3L4_CTL[i] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
21 (R/W)	L4DPIM	Layer 4 Destination Port Inverse Match Enable. When the `EMAC_L3L4_CTL[i].L4DPIM` bit is set, the Layer 4 Destination Port number field is enabled for inverse matching. When `EMAC_L3L4_CTL[i].L4DPIM` = 0, the Layer 4 Destination Port number field is enabled for perfect matching. The `EMAC_L3L4_CTL[i].L4DPIM` bit is valid and applicable only when the EMAC_L3L4_CTL[n].L4DPM= 1.	
		0	Layer 4 Destination Port Inverse Match is Disabled
		1	Layer 4 Destination Port Inverse Match is Enabled
20 (R/W)	L4DPM	Layer 4 Destination Port Match Enable. When the `EMAC_L3L4_CTL[i].L4DPM` bit is set, the Layer 4 Destination Port number field is enabled for matching. When `EMAC_L3L4_CTL[i].L4DPM` = 0, the MAC ignores the Layer 4 Destination Port number field for matching.	
		0	Layer 4 Destination Port Match is Disabled
		1	Layer 4 Destination Port Match is Enabled
19 (R/W)	L4SPIM	Layer 4 Source Port Inverse Match Enable. When the `EMAC_L3L4_CTL[i].L4SPIM` bit is set, the Layer 4 Source Port number field is enabled for inverse matching. When `EMAC_L3L4_CTL[i].L4SPIM` = 0, the Layer 4 Source Port number field is enabled for perfect matching. The `EMAC_L3L4_CTL[i].L4SPIM` bit is valid and applicable only when the EMAC_L3L4_CTL[n].L4SPM= 1.	
		0	Layer 4 Source Port Inverse Match is Disabled
		1	Layer 4 Source Port Inverse Match is Enabled
18 (R/W)	L4SPM	Layer 4 Source Port Match Enable. When the `EMAC_L3L4_CTL[i].L4SPM` bit is set, the Layer 4 Source Port number field is enabled for matching. When `EMAC_L3L4_CTL[i].L4SPM` = 0, the MAC ignores the Layer 4 Source Port number field for matching.	
		0	Layer 4 Source Port Match is Disabled
		1	Layer 4 Source Port Match is Enabled

Table 30-174: EMAC_L3L4_CTL[i] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/W)	L4PEN	Layer 4 Protocol Enable. When the `EMAC_L3L4_CTL[i].L4PEN` bit is set, the Source and Destination Port number fields of UDP packets are used for matching. When `EMAC_L3L4_CTL[i].L4PEN` = 0, the Source and Destination Port number fields of TCP packets are used for matching. The layer 4 matching is done only when the EMAC_L3L4_CTL[n].L4SPM or EMAC_L3L4_CTL[n].L4DPM= 1.	
		0	Layer 4 Protocol is Disabled
		1	Layer 4 Protocol is Enabled
15:11 (R/W)	L3HDBM	Layer 3 IP DA Higher Bits Match. For IPv4 packets, the `EMAC_L3L4_CTL[i].L3HDBM` field contains the number of higher bits of IP Destination Address that are matched in the IPv4 packets. The following list describes the values of this field: - 0: No bits are masked - 1: LSb[0] is masked - 2: Two LSbs [1:0] are masked - .. - 31: All bits except MSb are masked For IPv6 packets, the bits[12:11] of this field correspond to bits[6:5] of L3HSBM which indicate the number of lower bits of IP Source or Destination Address that are masked in the IPv6 packets. The following list describes the concatenated values of the L3HDBM[1:0] and L3HSBM bits: - 0: No bits are masked - 1: LSb[0] is masked - 2: Two LSbs [1:0] are masked - .. - 127: All bits except MSb are masked The `EMAC_L3L4_CTL[i].L3HDBM` field is valid and applicable only when the L3DAM or L3SAM bit is set.	

Table 30-174: EMAC_L3L4_CTL[i] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
10:6 (R/W)	L3HSBM	Layer 3 IP SA Higher Bits Match. For IPv4 packets, the `EMAC_L3L4_CTL[i].L3HSBM` field contains the number of lower bits of IP Source Address that are masked for matching in the IPv4 packets. The following list describes the values of this field: - 0: No bits are masked - 1: LSb[0] is masked - 2: Two LSbs [1:0] are masked - .. - 31: All bits except MSb are masked For IPv6 packets, the `EMAC_L3L4_CTL[i].L3HSBM` field contains bits[4:0] of L3HSBM. These bits indicate the number of higher bits of IP Source or Destination Address matched in the IPv6 packets. The `EMAC_L3L4_CTL[i].L3HSBM` field is valid and applicable only when the EMAC_L3L4_CTL[n].L3DAM or L3SAM bit is set (=1).	
5 (R/W)	L3DAIM	Layer 3 IP DA Inverse Match Enable. When the `EMAC_L3L4_CTL[i].L3DAIM` bit is set, the Layer 3 IP Destination Address field is enabled for inverse matching. When `EMAC_L3L4_CTL[i].L3DAIM` = 0, the Layer 3 IP Destination Address field is enabled for perfect matching. The `EMAC_L3L4_CTL[i].L3DAIM` bit is valid and applicable only when the EMAC_L3L4_CTL[n].L3DAM = 1.	
		0	Layer 3 IP DA Inverse Match is Disabled
		1	Layer 3 IP DA Inverse Match is Enabled
4 (R/W)	L3DAM	Layer 3 IP DA Match Enable. When the `EMAC_L3L4_CTL[i].L3DAM` bit is set, the Layer 3 IP Destination Address field is enabled for matching. When `EMAC_L3L4_CTL[i].L3DAM` = 0, the MAC ignores the Layer 3 IP Destination Address field for matching. Note: When EMAC_L3L4_CTL[n].L3PEN = 1, set either the `EMAC_L3L4_CTL[i].L3DAM` bit or the L3SAM bit because either IPv6 DA or SA can be checked for filtering.	
		0	Layer 3 IP DA Match is Disabled
		1	Layer 3 IP DA Match is Enabled

Table 30-174: EMAC_L3L4_CTL[i] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	L3SAIM	Layer 3 IP SA Inverse Match Enable. When the `EMAC_L3L4_CTL[i].L3SAIM` bit is set, the Layer 3 IP Source Address field is enabled for inverse matching. When the `EMAC_L3L4_CTL[i].L3SAIM` bit reset, the Layer 3 IP Source Address field is enabled for perfect matching. The `EMAC_L3L4_CTL[i].L3SAIM` bit is valid and applicable only when EMAC_L3L4_CTL[n].L3DAM = 1.	
		0	Layer 3 IP SA Inverse Match is Disabled
		1	Layer 3 IP SA Inverse Match is Enabled
2 (R/W)	L3SAM	Layer 3 IP SA Match Enable. When the `EMAC_L3L4_CTL[i].L3SAM` bit is set, the Layer 3 IP Source Address field is enabled for matching. When `EMAC_L3L4_CTL[i].L3SAM` = 0, the MAC ignores the Layer 3 IP Source Address field for matching. Note: When the EMAC_L3L4_CTL[n].L3PEN bit is set, set either the `EMAC_L3L4_CTL[i].L3SAM` bit or the EMAC_L3L4_CTL[n].L3DAM bit because either IPv6 SA or DA can be checked for filtering.	
		0	Layer 3 IP SA Match is Disabled
		1	Layer 3 IP SA Match is Enabled
0 (R/W)	L3PEN	Layer 3 Protocol Enable. When the `EMAC_L3L4_CTL[i].L3PEN` bit is set, the Layer 3 IP Source or Destination Address matching is enabled for IPv6 packets. When `EMAC_L3L4_CTL[i].L3PEN` = 0, the Layer 3 IP Source or Destination Address matching is enabled for IPv4 packets. The layer 3 matching is done only when the EMAC_L3L4_CTL[n].L3SAM or EMAC_L3L4_CTL[n].L3DAM bit is set (=1).	
		0	Layer 3 Protocol is Disabled
		1	Layer 3 Protocol is Enabled

LPI Control and Status Register

The EMAC_LPI_CTLSTAT register controls the LPI functions and provides the LPI interrupt status. The status bits are cleared when this register is read.

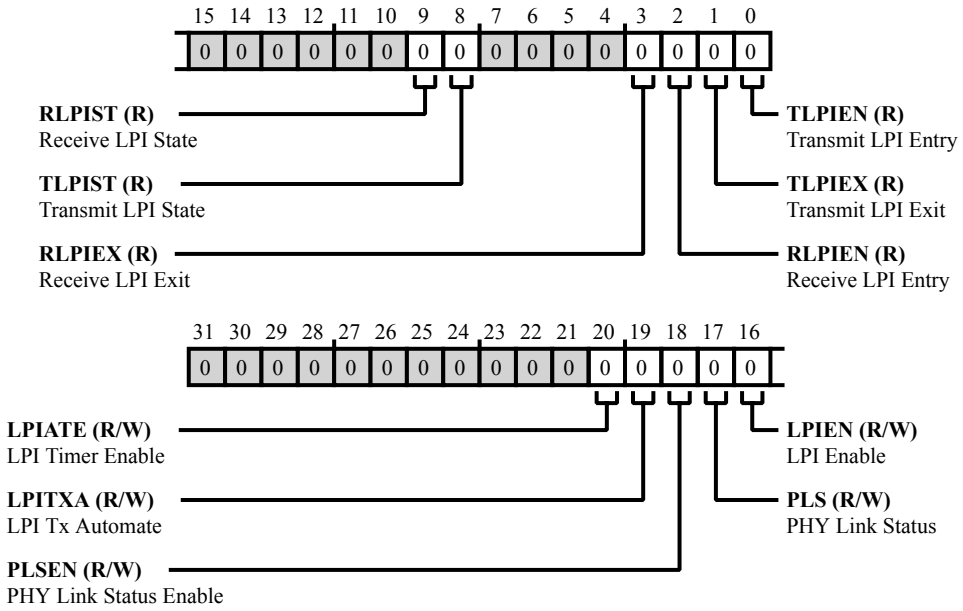

Figure 30-120: EMAC_LPI_CTLSTAT Register Diagram

Table 30-175: EMAC_LPI_CTLSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
20 (R/W)	LPIATE	LPI Timer Enable. The EMAC_LPI_CTLSTAT.LPIATE bit controls the automatic entry of the MAC transmitter into and exit out of the LPI state. When LPIATE, LPITXA and LPIEN bits are set, the MAC transmitter enters LPI state only when the complete MAC TX data path is IDLE for a period indicated by the EMAC_LPI_ENTR_TMR register. After entering LPI state, if the data path becomes non-IDLE (due to a new packet being accepted for transmission), the transmitter exits LPI state but does not clear LPIEN bit. This enables the re-entry into LPI state when it is IDLE again. When EMAC_LPI_CTLSTAT.LPIATE = 0, the LPI auto timer is disabled and MAC transmitter enters LPI state based on the settings of LPITXA and LPIEN bit descriptions.	
		0	LPI Timer is Disabled
		1	LPI Timer is Enabled

Table 30-175: EMAC_LPI_CTLSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
19 (R/W)	LPITXA	LPI Tx Automate. The EMAC_LPI_CTLSTAT.LPITXA bit controls the behavior of the MAC when it is entering or coming out of the LPI mode on the transmit side. If the EMAC_LPI_CTLSTAT.LPITXA and LPIEN bits are set (=1), the MAC enters the LPI mode only after all outstanding packets (in the IP) and pending packets (in the application interface) have been transmitted. The MAC comes out of the LPI mode when the application sends any packet for transmission or the application issues a Tx FIFO Flush command. In addition, the MAC automatically clears the LPIEN bit when it exits the LPI state. If Tx FIFO flush is set in EMAC_TQ0_OPMODE.FTQ, when the MAC is in the LPI mode, it exits the LPI mode. When the EMAC_LPI_CTLSTAT.LPITXA bit is 0, the LPIEN bit directly controls behavior of the MAC when it is entering or coming out of the LPI mode.	
		0	LPI Tx Automate is Disabled
		1	LPI Tx Automate is Enabled
18 (R/W)	PLSEN	PHY Link Status Enable. The EMAC_LPI_CTLSTAT.PLSEN bit enables the link status received on the RGMII receive paths to be used for activating the LPI LS TIMER. When the EMAC_LPI_CTLSTAT.PLSEN bit is set, the MAC uses the link-status bits of the EMAC_PHYIF_CTLSTAT register and the PLS bit for the LPI LS timer trigger. When EMAC_LPI_CTLSTAT.PLSEN = 0, the MAC ignores the link-status bits of the EMAC_PHYIF_CTLSTAT register and takes only the PLS bit.	
		0	PHY Link Status is Disabled
		1	PHY Link Status is Enabled
17 (R/W)	PLS	PHY Link Status. The EMAC_LPI_CTLSTAT.PLS bit indicates the link status of the PHY. The MAC transmitter asserts the LPI pattern only when the link status is up (OKAY) at least for the time indicated by the LPI LS TIMER. When the EMAC_LPI_CTLSTAT.PLS bit is set, the link is considered to be okay (UP) and when EMAC_LPI_CTLSTAT.PLS = 0, the link is considered to be down.	
		0	Link is Down
		1	Link is Okay (UP)

Table 30-175: EMAC_LPI_CTLSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/W)	LPIEN	LPI Enable. When the EMAC_LPI_CTLSTAT.LPIEN bit is set, it instructs the MAC transmitter to enter the LPI state. When EMAC_LPI_CTLSTAT.LPIEN = 0, it instructs the MAC to exit the LPI state and resume normal transmission. The EMAC_LPI_CTLSTAT.LPIEN bit is cleared when the LPITXA bit is set and the MAC exits the LPI state because of the arrival of a new packet for transmission.	
		0	LPI State is Disabled
		1	LPI State is Enabled
9 (R/NW)	RLPIST	Receive LPI State. When the EMAC_LPI_CTLSTAT.RLPIST bit is set, it indicates that the MAC is receiving the LPI pattern on the GMII or MII interface.	
		0	Receive LPI State Not Detected
		1	Receive LPI State Detected
8 (R/NW)	TLPIST	Transmit LPI State. When the EMAC_LPI_CTLSTAT.TLPIST bit is set, it indicates that the MAC is transmitting the LPI pattern on the GMII or MII interface.	
		0	Transmit LPI State Not Detected
		1	Transmit LPI State Detected
3 (R/NW)	RLPIEX	Receive LPI Exit. When the EMAC_LPI_CTLSTAT.RLPIEX bit is set, it indicates that the MAC receiver has stopped receiving the LPI pattern on the GMII or MII interface, exited the LPI state, and resumed the normal reception. The EMAC_LPI_CTLSTAT.RLPIEX bit is cleared by a read into this register (or the EMAC_LPI_CTLSTAT.RLPIEX bit is written to 1 when EMAC_CSR_SW_CTL.RCWE = 1). Note: The EMAC_LPI_CTLSTAT.RLPIEX bit might not be set if the MAC stops receiving the LPI pattern for a very short duration, such as, less than three clock cycles of SCLK0.	
		0	Receive LPI Exit Not Detected
		1	Receive LPI Exit Detected

Table 30-175: EMAC_LPI_CTLSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/NW)	RLPIEN	Receive LPI Entry. When the EMAC_LPI_CTLSTAT.RLPIEN bit is set, it indicates that the MAC receiver has received an LPI pattern and entered the LPI state. The EMAC_LPI_CTLSTAT.RLPIEN bit is cleared by a read into this register (or the EMAC_LPI_CTLSTAT.RLPIEN bit is written to 1 when EMAC_CSR_SW_CTL.RCWE = 1). Note: The EMAC_LPI_CTLSTAT.RLPIEN bit might not be set if the MAC stops receiving the LPI pattern for a very short duration, such as, less than three clock cycles of SCLK0.	
		0	Receive LPI Entry Not Detected
		1	Receive LPI Entry Detected
1 (R/NW)	TLPIEX	Transmit LPI Exit. When the EMAC_LPI_CTLSTAT.TLPIEX bit is set, it indicates that the MAC transmitter exited the LPI state after the application cleared the LPIEN bit and the LPI TW timer has expired. The EMAC_LPI_CTLSTAT.TLPIEX bit is cleared by a read into this register (or the EMAC_LPI_CTLSTAT.TLPIEX bit is written to 1 when EMAC_CSR_SW_CTL.RCWE = 1).	
		0	Transmit LPI Exit Not Detected
		1	Transmit LPI Exit Detected
0 (R/NW)	TLPIEN	Transmit LPI Entry. When the EMAC_LPI_CTLSTAT.TLPIEN bit is set, it indicates that the MAC transmitter has entered the LPI state because of the setting of the LPIEN bit. The EMAC_LPI_CTLSTAT.TLPIEN bit is cleared by a read into this register (or the EMAC_LPI_CTLSTAT.TLPIEN bit is written to 1 when EMAC_CSR_SW_CTL.RCWE = 1).	
		0	Transmit LPI Entry Not Detected
		1	Transmit LPI Entry Detected

Transmit LPI Entry Timer Register

The EMAC_LPI_ENTR_TMR register controls the Tx LPI entry timer. This counter is enabled only when EMAC_LPI_CTLSTAT.LPITE = 1.

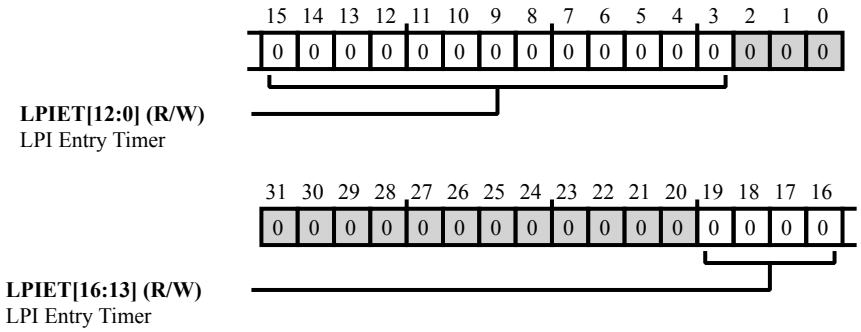

Figure 30-121: EMAC_LPI_ENTR_TMR Register Diagram

Table 30-176: EMAC_LPI_ENTR_TMR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
19:3 (R/W)	LPIET	LPI Entry Timer. The EMAC_LPI_ENTR_TMR.LPIET field specifies the time in microseconds the MAC waits to enter LPI mode, after it has transmitted all the frames. The EMAC_LPI_ENTR_TMR.LPIET field is valid and used only when LPITE and LPITXA are set (=1). Bits [2:0] are read-only so that the granularity of this timer is in steps of 8 microseconds.

LPI Timers Control Register

The EMAC_LPI_TMRSCTL register controls the timeout values in the LPI states. It specifies the time for which the MAC transmits the LPI pattern and also the time for which the MAC waits before resuming the normal transmission.

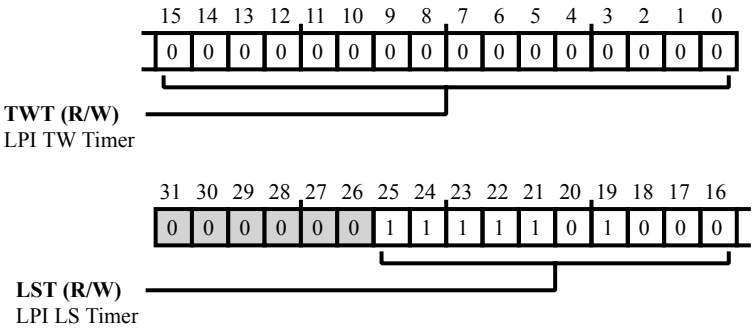

Figure 30-122: EMAC_LPI_TMRSCTL Register Diagram

Table 30-177: EMAC_LPI_TMRSCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
25:16 (R/W)	LST	LPI LS Timer. The EMAC_LPI_TMRSCTL.LST field specifies the minimum time (in milliseconds) for which the link status from the PHY should be up (OKAY) before the LPI pattern can be transmitted to the PHY. The MAC does not transmit the LPI pattern even when the LPIEN bit is set unless the LPI LS Timer reaches the programmed terminal count. The default value of the LPI LS Timer is 1000 (1 sec) as defined in the IEEE standard.
15:0 (R/W)	TWT	LPI TW Timer. The EMAC_LPI_TMRSCTL.TWT field specifies the minimum time (in microseconds) for which the MAC waits after it stops transmitting the LPI pattern to the PHY and before it resumes the normal transmission. The TLPIEX status bit is set after the expiry of this timer.

Layer 3 Address 0 Register 7

For IPv4 packets, the EMAC_L3_ADDR0_REG7 register contains the 32-bit IP Source Address field. For IPv6 packets, it contains bits[31:0] of the 128-bit IP Source Address or Destination Address field.

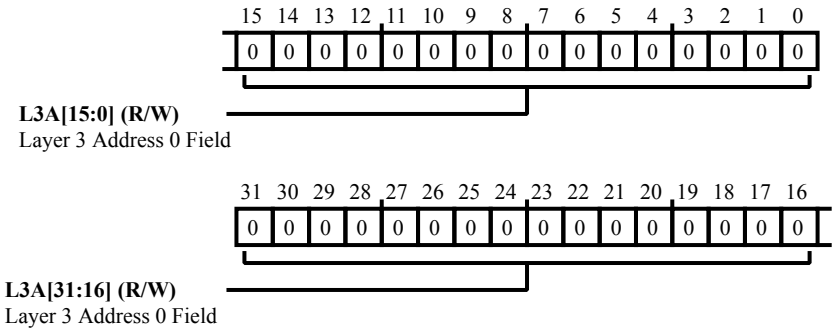

Figure 30-123: EMAC_L3_ADDR0_REG7 Register Diagram

Table 30-178: EMAC_L3_ADDR0_REG7 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	L3A	Layer 3 Address 0 Field. When EMAC_L3L4_CTL[n].L3PEN and EMAC_L3L4_CTL[n].L3SAM = 1, the EMAC_L3_ADDR0_REG7.L3A field contains the value to be matched with bits[31:0] of the IP Source Address field in the IPv6 packets. When EMAC_L3L4_CTL[n].L3PEN and EMAC_L3L4_CTL[n].L3DAM = 1, the EMAC_L3_ADDR0_REG7.L3A field contains the value to be matched with bits[31:0] of the IP Destination Address field in the IPv6 packets. When EMAC_L3L4_CTL[n].L3PEN = 0 and EMAC_L3L4_CTL[n].L3SAM = 1, the EMAC_L3_ADDR0_REG7.L3A field contains the value to be matched with the IP Source Address field in the IPv4 packets.

Layer 3 Address 0 Register [i]

For IPv4 packets, the `EMAC_L3_ADDR0_REG[i]` register contains the 32-bit IP Source Address field. For IPv6 packets, it contains bits[31:0] of the 128-bit IP Source Address or Destination Address field.

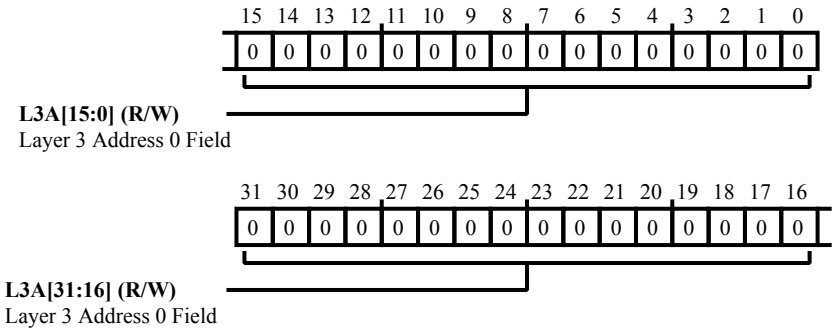

Figure 30-124: EMAC_L3_ADDR0_REG[i] Register Diagram

Table 30-179: EMAC_L3_ADDR0_REG[i] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	L3A	Layer 3 Address 0 Field. When EMAC_L3L4_CTL[n].L3PEN and EMAC_L3L4_CTL[n].L3SAM = 1, the `EMAC_L3_ADDR0_REG[i].L3A` field contains the value to be matched with bits[31:0] of the IP Source Address field in the IPv6 packets. When EMAC_L3L4_CTL[n].L3PEN and EMAC_L3L4_CTL[n].L3DAM = 1, the `EMAC_L3_ADDR0_REG[i].L3A` field contains the value to be matched with bits[31:0] of the IP Destination Address field in the IPv6 packets. When EMAC_L3L4_CTL[n].L3PEN = 0 and EMAC_L3L4_CTL[n].L3SAM = 1, the `EMAC_L3_ADDR0_REG[i].L3A` field contains the value to be matched with the IP Source Address field in the IPv4 packets.

Layer 3 Address 1 Register 7

For IPv4 packets, the EMAC_L3_ADDR1_REG7 register contains the 32-bit IP Destination Address field. For IPv6 packets, it contains bits[63:32] of the 128-bit IP Source Address or Destination Address field.

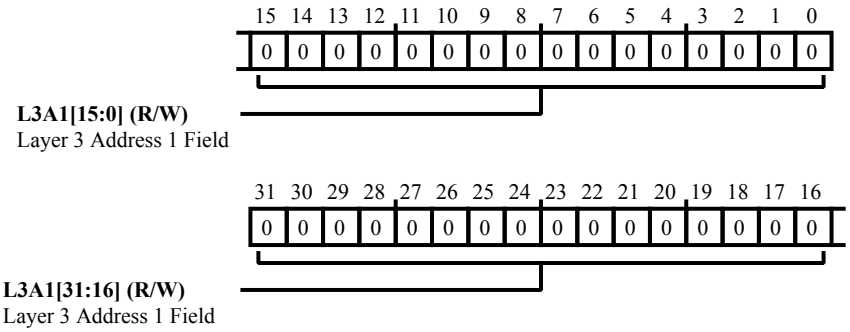

Figure 30-125: EMAC_L3_ADDR1_REG7 Register Diagram

Table 30-180: EMAC_L3_ADDR1_REG7 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	L3A1	Layer 3 Address 1 Field. When EMAC_L3L4_CTL[n].L3PEN = 1 and EMAC_L3L4_CTL[n].L3SAM =1, the EMAC_L3_ADDR1_REG7.L3A1 field contains the value to be matched with bits[63:32] of the IP Source Address field in the IPv6 packets. When EMAC_L3L4_CTL[n].L3PEN = 1 and EMAC_L3L4_CTL[n].L3DAM =1, the EMAC_L3_ADDR1_REG7.L3A1 field contains the value to be matched with bits[63:32] of the IP Destination Address field in the IPv6 packets. When EMAC_L3L4_CTL[n].L3PEN = 0 and EMAC_L3L4_CTL[n].L3SAM =1, the EMAC_L3_ADDR1_REG7.L3A1 field contains the value to be matched with the IP Destination Address field in the IPv4 packets.

Layer 3 Address 1 Register [i]

For IPv4 packets, the `EMAC_L3_ADDR1_REG[i]` register contains the 32-bit IP Destination Address field. For IPv6 packets, it contains bits[63:32] of the 128-bit IP Source Address or Destination Address field.

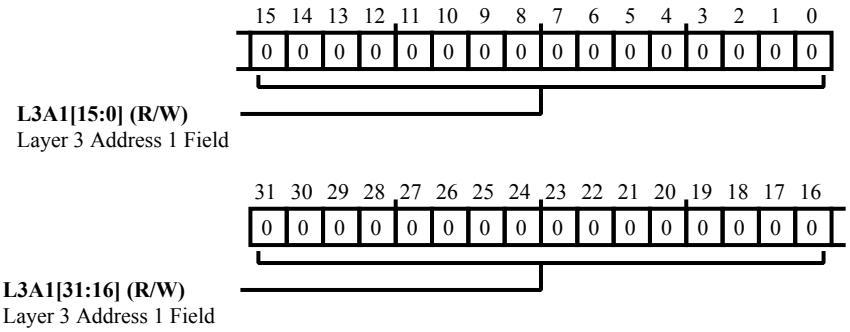

Figure 30-126: EMAC_L3_ADDR1_REG[i] Register Diagram

Table 30-181: EMAC_L3_ADDR1_REG[i] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	L3A1	Layer 3 Address 1 Field. When EMAC_L3L4_CTL[n].L3PEN = 1 and EMAC_L3L4_CTL[n].L3SAM =1, the `EMAC_L3_ADDR1_REG[i].L3A1` field contains the value to be matched with bits[63:32] of the IP Source Address field in the IPv6 packets. When EMAC_L3L4_CTL[n].L3PEN = 1 and EMAC_L3L4_CTL[n].L3DAM =1, the `EMAC_L3_ADDR1_REG[i].L3A1` field contains the value to be matched with bits[63:32] of the IP Destination Address field in the IPv6 packets. When EMAC_L3L4_CTL[n].L3PEN = 0 and EMAC_L3L4_CTL[n].L3SAM =1, the `EMAC_L3_ADDR1_REG[i].L3A1` field contains the value to be matched with the IP Destination Address field in the IPv4 packets.

Layer 3 Address 2 Register 7

The EMAC_L3_ADDR2_REG7 register is reserved for IPv4 packets. For IPv6 packets, the EMAC_L3_ADDR2_REG7 register contains bits[95:64] of 128-bit IP Source Address or Destination Address field.

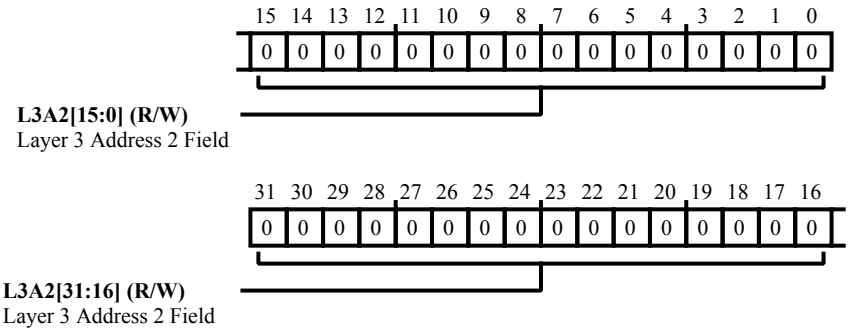

Figure 30-127: EMAC_L3_ADDR2_REG7 Register Diagram

Table 30-182: EMAC_L3_ADDR2_REG7 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	L3A2	Layer 3 Address 2 Field. When EMAC_L3L4_CTL[n].L3PEN = 1 and EMAC_L3L4_CTL[n].L3SAM =1, the EMAC_L3_ADDR2_REG7.L3A2 field contains the value to be matched with bits[95:64] of the IP Source Address field in the IPv6 packets. When EMAC_L3L4_CTL[n].L3PEN = 1 and EMAC_L3L4_CTL[n].L3DAM =1, the EMAC_L3_ADDR2_REG7.L3A2 field contains the value to be matched with bits[95:64] of the IP Destination Address field in the IPv6 packets. When EMAC_L3L4_CTL[n].L3PEN = 0, the EMAC_L3_ADDR2_REG7.L3A2 field is not used.

Layer 3 Address 2 Register [i]

The EMAC_L3_ADDR2_REG[i] register is reserved for IPv4 packets. For IPv6 packets, the EMAC_L3_ADDR2_REG[i] register contains bits[95:64] of 128-bit IP Source Address or Destination Address field.

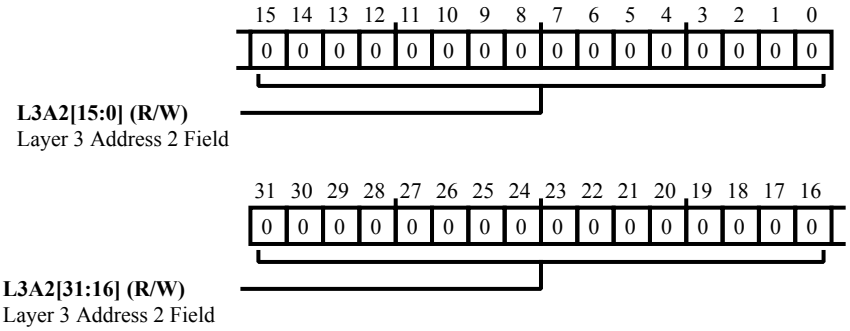

Figure 30-128: EMAC_L3_ADDR2_REG[i] Register Diagram

Table 30-183: EMAC_L3_ADDR2_REG[i] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	L3A2	Layer 3 Address 2 Field. When EMAC_L3L4_CTL[n].L3PEN = 1 and EMAC_L3L4_CTL[n].L3SAM =1, the EMAC_L3_ADDR2_REG[i].L3A2 field contains the value to be matched with bits[95:64] of the IP Source Address field in the IPv6 packets. When EMAC_L3L4_CTL[n].L3PEN = 1 and EMAC_L3L4_CTL[n].L3DAM =1, the EMAC_L3_ADDR2_REG[i].L3A2 field contains the value to be matched with bits[95:64] of the IP Destination Address field in the IPv6 packets. When EMAC_L3L4_CTL[n].L3PEN = 0, the EMAC_L3_ADDR2_REG[i].L3A2 field is not used.

Layer 3 Address 3 Register 7

The EMAC_L3_ADDR3_REG7 register is reserved for IPv4 packets. For IPv6 packets, the EMAC_L3_ADDR3_REG7 register contains bits[127:96] of 128-bit IP Source Address or Destination Address field.

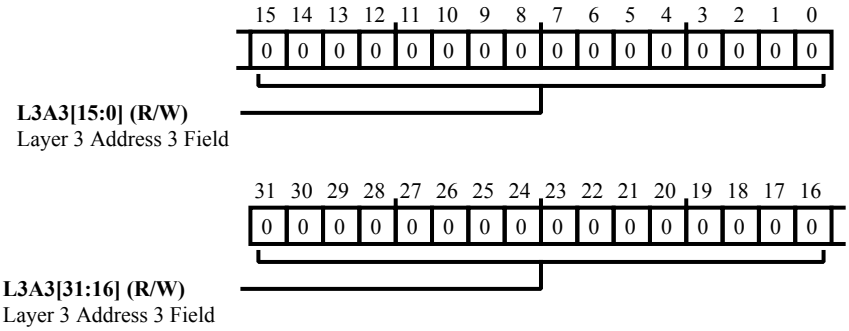

Figure 30-129: EMAC_L3_ADDR3_REG7 Register Diagram

Table 30-184: EMAC_L3_ADDR3_REG7 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	L3A3	Layer 3 Address 3 Field. When MAC_L3L4_CTL[n].L3PEN = 1 and EMAC_L3L4_CTL[n].L3SAM =1, the EMAC_L3_ADDR3_REG7.L3A3 field contains the value to be matched with bits[127:96] of the IP Source Address field in the IPv6 packets. When EMAC_L3L4_CTL[n].L3PEN = 1 and EMAC_L3L4_CTL[n].L3DAM =1, this field contains the value to be matched with bits[127:96] of the IP Destination Address field in the IPv6 packets. When EMAC_L3L4_CTL[n].L3PEN = 0 and EMAC_L3L4_CTL[n].L3SAM =1, this field is not used.

Layer 3 Address 3 Register [i]

The EMAC_L3_ADDR3_REG[i] register is reserved for IPv4 packets. For IPv6 packets, the EMAC_L3_ADDR3_REG[i] register contains bits[127:96] of 128-bit IP Source Address or Destination Address field.

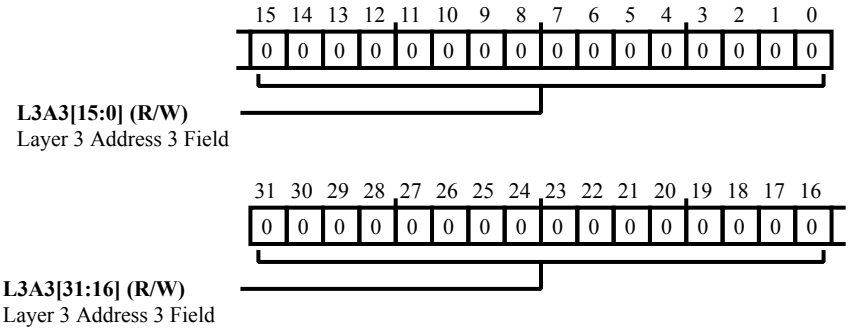

Figure 30-130: EMAC_L3_ADDR3_REG[i] Register Diagram

Table 30-185: EMAC_L3_ADDR3_REG[i] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	L3A3	Layer 3 Address 3 Field. When MAC_L3L4_CTL[n].L3PEN = 1 and EMAC_L3L4_CTL[n].L3SAM =1, the EMAC_L3_ADDR3_REG[i].L3A3 field contains the value to be matched with bits[127:96] of the IP Source Address field in the IPv6 packets. When EMAC_L3L4_CTL[n].L3PEN = 1 and EMAC_L3L4_CTL[n].L3DAM =1, this field contains the value to be matched with bits[127:96] of the IP Destination Address field in the IPv6 packets. When EMAC_L3L4_CTL[n].L3PEN = 0 and EMAC_L3L4_CTL[n].L3SAM =1, this field is not used.

Layer 4 Address Register [i]

The EMAC_L4_ADDR7 register is double synchronized to the Rx clock domain. Thus, for proper synchronization updates, the program should perform consecutive writes to the same layer 3/4 address registers only after at least four clock cycles delay of the (G) MII clock domain.

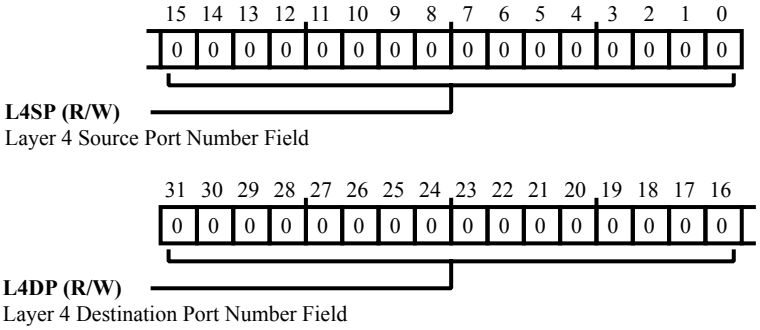

Figure 30-131: EMAC_L4_ADDR7 Register Diagram

Table 30-186: EMAC_L4_ADDR7 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/W)	L4DP	Layer 4 Destination Port Number Field. When EMAC_L3L4_CTL[n].L4PEN = 0 and EMAC_L3L4_CTL[n].L4DPM =1, this field contains the value to be matched with the TCP Destination Port Number field in the IPv4 or IPv6 packets. When the EMAC_L3L4_CTL[n].L4PEN = 0 and EMAC_L3L4_CTL[n].L4DPM =1, this field contains the value to be matched with the UDP Destination Port Number field in the IPv4 or IPv6 packets.
15:0 (R/W)	L4SP	Layer 4 Source Port Number Field. When EMAC_L3L4_CTL[n].L4PEN = 0 and EMAC_L3L4_CTL[n].L4SPM =1, the EMAC_L4_ADDR7.L4SP field contains the value to be matched with the TCP Source Port Number field in the IPv4 or IPv6 packets. When the EMAC_L3L4_CTL[n].L4PEN = 1 and EMAC_L3L4_CTL[n].L4SPM =1, the EMAC_L4_ADDR7.L4SP field contains the value to be matched with the UDP Source Port Number field in the IPv4 or IPv6 packets.

Layer 4 Address Register [i]

The `EMAC_L4_ADDR[i]` register is double synchronized to the Rx clock domain. Thus, for proper synchronization updates, the program should perform consecutive writes to the same layer 3/4 address registers only after at least four clock cycles delay of the (G) MII clock domain.

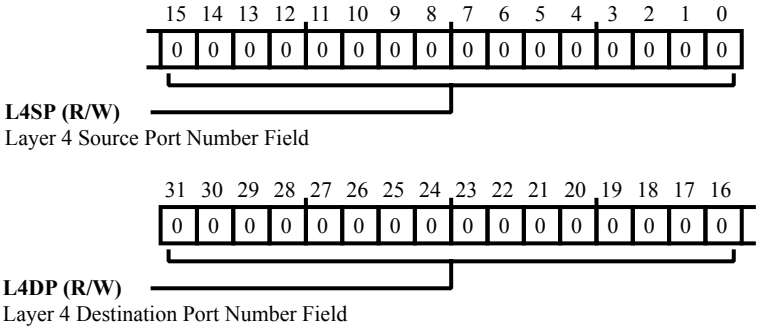

Figure 30-132: EMAC_L4_ADDR[i] Register Diagram

Table 30-187: EMAC_L4_ADDR[i] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/W)	L4DP	Layer 4 Destination Port Number Field. When EMAC_L3L4_CTL[n].L4PEN = 0 and EMAC_L3L4_CTL[n].L4DPM =1, this field contains the value to be matched with the TCP Destination Port Number field in the IPv4 or IPv6 packets. When the EMAC_L3L4_CTL[n].L4PEN = 0 and EMAC_L3L4_CTL[n].L4DPM =1, this field contains the value to be matched with the UDP Destination Port Number field in the IPv4 or IPv6 packets.
15:0 (R/W)	L4SP	Layer 4 Source Port Number Field. When EMAC_L3L4_CTL[n].L4PEN = 0 and EMAC_L3L4_CTL[n].L4SPM =1, the `EMAC_L4_ADDR[i].L4SP` field contains the value to be matched with the TCP Source Port Number field in the IPv4 or IPv6 packets. When the EMAC_L3L4_CTL[n].L4PEN = 1 and EMAC_L3L4_CTL[n].L4SPM =1, the `EMAC_L4_ADDR[i].L4SP` field contains the value to be matched with the UDP Source Port Number field in the IPv4 or IPv6 packets.

PTP Log Message Interval Register

The EMAC_LOG_MSG_INTVL register contains the periodic intervals for automatic PTP packet generation.

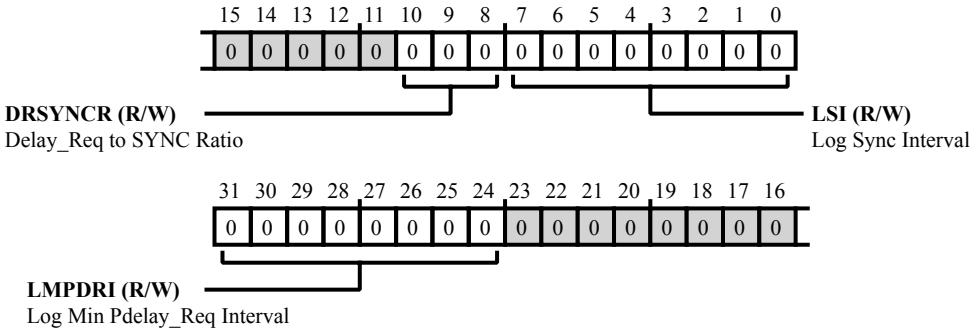

Figure 30-133: EMAC_LOG_MSG_INTVL Register Diagram

Table 30-188: EMAC_LOG_MSG_INTVL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:24 (R/W)	LMPDRI	Log Min Pdelay_Req Interval. The EMAC_LOG_MSG_INTVL.LMPDRI field indicates logMinPdelayReqInterval of PTP node. This is used to schedule the periodic Pdelay request packet transmission. Allowed values are -15 to 15.Negative value must be represented in 2's-complement form. For example, if the required value is -1, the value programmed must be 0xFF.	
10:8 (R/W)	DRSYNCR	Delay_Req to SYNC Ratio. In completer mode, the EMAC_LOG_MSG_INTVL.DRSYNCR field is used for controlling the frequency of Delay_Req messages transmitted. The requester sends this information (logMinDelayReqInterval) in the DelayResp PTP messages to the completer. The EMAC module receiver processes this value from the received DelayResp messages and updates this field accordingly. In completer mode, the host must not write/update this register unless it has to override the received value. In requester mode, the sum of this field and logSyncInterval (LSI) field is provided in the logMinDelayReqInterval field of the generated multicast Delay_Resp PTP message. Access restriction applies. Updated based on the event. Write 1 to set. Write 0 to clear.	
		0	DelayReq Generated for Every Received SYNC
		1	DelayReq Generated Every Alternate Reception of SYNC
		2	For Every 4 SYNC Messages
		3	For Every 8 SYNC Messages
		4	For Every 16 SYNC Messages
		5	For Every 32 SYNC Messages

Table 30-188: EMAC_LOG_MSG_INTVL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		6	Reserved
7:0 (R/W)	LSI	Log Sync Interval. The `EMAC_LOG_MSG_INTVL.LSI` field indicates the periodicity of the automatically generated SYNC message when the PTP node is the requester. Allowed values are -15 to 15. Negative value must be represented in 2's-complement form. For example, if the required value is -1, the value programmed must be 0xFF.	

MDIO Address Register

The EMAC_MDIO_ADDR register controls the management cycles to external PHY through a management interface.

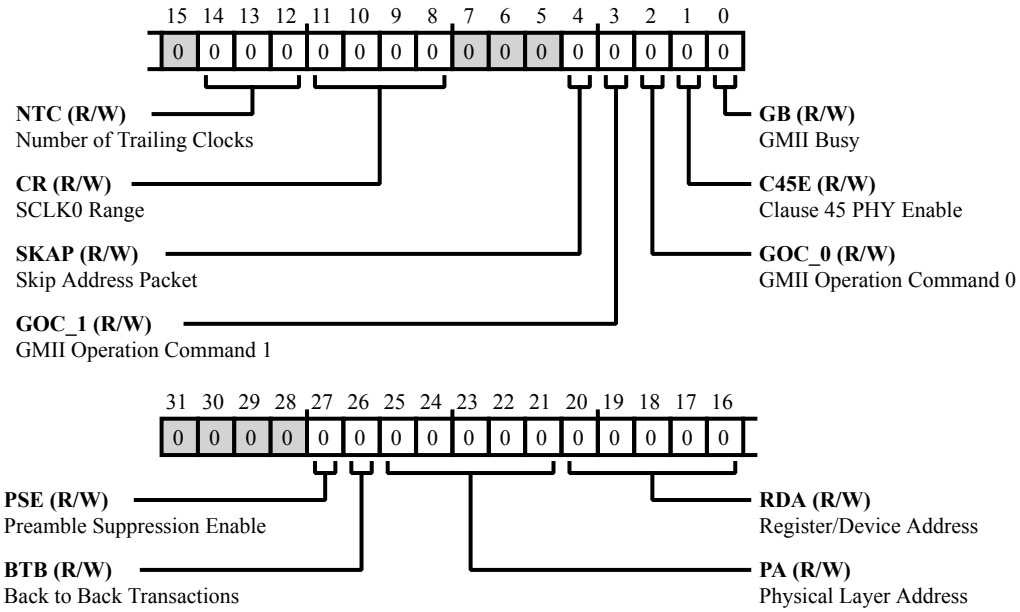

Figure 30-134: EMAC_MDIO_ADDR Register Diagram

Table 30-189: EMAC_MDIO_ADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
27 (R/W)	PSE	Preamble Suppression Enable. When the EMAC_MDIO_ADDR.PSE bit is set, the SMA suppresses the 32-bit preamble and transmits MDIO frames with only 1 preamble bit. When the EMAC_MDIO_ADDR.PSE bit is 0, the MDIO frame always has 32 bits of preamble as defined in the IEEE specifications.	
		0	Preamble Suppression Disabled
		1	Preamble Suppression Enabled

Table 30-189: EMAC_MDIO_ADDR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
26 (R/W)	BTB	Back to Back Transactions. When the EMAC_MDIO_ADDR.BTB bit is set and the NTC has value greater than 0, the MAC informs the completion of a read or write command at the end of frame transfer (before the trailing clocks are transmitted). The software can thus initiate the next command which is executed immediately irrespective of the number trailing clocks generated for the previous frame. When EMAC_MDIO_ADDR.BTB = 0, then the read/write command completion (GB is cleared) only after the trailing clocks are generated. In this mode, it is ensured that the NTC is always generated after each frame. The EMAC_MDIO_ADDR.BTB bit must not be set when NTC=0.	
		0	Back to Back Transactions Disabled
		1	Back to Back Transactions Enabled
25:21 (R/W)	PA	Physical Layer Address. The EMAC_MDIO_ADDR.PA field indicates which Clause 22 PHY devices (out of 32 devices) the MAC is accessing. The EMAC_MDIO_ADDR.PA field indicates which Clause 45 capable PHYs (out of 32 PHYs) the MAC is accessing.	
20:16 (R/W)	RDA	Register/Device Address. The EMAC_MDIO_ADDR.RDA field selects the PHY register in selected Clause 22 PHY device. These bits select the Device (MMD) in selected Clause 45 capable PHY.	
14:12 (R/W)	NTC	Number of Trailing Clocks. The EMAC_MDIO_ADDR.NTC field controls the number of trailing clock cycles generated on ETHx_MDC (MDC) after the end of transmission of MDIO frame. The valid values can be from 0 to 7. Programming the value to 3'h3 indicates that there are additional three clock cycles on the MDC line after the end of MDIO frame transfer.	

Table 30-189: EMAC_MDIO_ADDR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
11:8 (R/W)	CR	SCLK0 Range. The EMAC_MDIO_ADDR.CR field indicates the frequency of the MDC clock according to the SCLK0 frequency used: 0000: SCLK0 = 60-100 MHz; MDC clock = SCLK0/42 0001: SCLK0 = 100-150 MHz; MDC clock = SCLK0/62 0010: SCLK0 = 20-35 MHz; MDC clock = SCLK0/16 0011: SCLK0 = 35-60 MHz; MDC clock = SCLK0/26 0100: SCLK0 = 150-250 MHz; MDC clock = SCLK0/102 0101: Reserved 0110: Reserved 0111: Reserved The suggested range of SCLK0 clock frequency applicable for each value (when bit 11 = 0) ensures that the MDC clock is approximately between 1.0 MHz to 2.5 MHz frequency range. When bit 11 is set, a higher frequency of the MDC clock can be achieved than the frequency limit of 2.5 MHz (specified in the IEEE 802.3) and program a clock divider of lower value. For example, when SCLK0 is of 100 MHz frequency and program these bits as 1010; the resultant MDC clock is 12.5 MHz which is beyond the range specified in IEEE 802.3. Program the following values only if the interfacing chips support faster MDC clocks: 1000: SCLK0 /4 1001: SCLK0 /6 1010: SCLK0 /8 1011: SCLK0 /10 1100: SCLK0 /12 1101: SCLK0 /14 1110: SCLK0 /16 1111: SCLK0 /18	
4 (R/W)	SKAP	Skip Address Packet. When the EMAC_MDIO_ADDR.SKAP bit is set, the SMA does not send the address packets before read, write, or post-read increment address packets. The EMAC_MDIO_ADDR.SKAP bit is valid only when EMAC_MDIO_ADDR.C45E = 1.	
		0	Skip Address Packet is Disabled
		1	Skip Address Packet is Enabled

Table 30-189: EMAC_MDIO_ADDR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	GOC_1	GMII Operation Command 1. The EMAC_MDIO_ADDR.GOC_1 bit is higher bit of the operation command to the PHY, GOC_1 and GOC_O is encoded as follows: 00: Reserved 01: Write 10: Post read increment address for clause 45 PHY 11: Read When clause 22 PHY is enabled, only write and read commands are valid.	
		0	GMII Operation Command 1 is Disabled
		1	GMII Operation Command 1 is Enabled
2 (R/W)	GOC_0	GMII Operation Command 0. EMAC_MDIO_ADDR.GOC_0 is the lower bit of the operation command to the PHY. When in SMA mode (MDIO requester) the EMAC_MDIO_ADDR.GOC_0 bit along with GOC_1 determines the operation to be performed to the PHY.	
		0	GMII Operation Command 0 is Disabled
		1	GMII Operation Command 0 is Enabled
1 (R/W)	C45E	Clause 45 PHY Enable. When the EMAC_MDIO_ADDR.C45E bit is set, Clause 45 capable PHY is connected to MDIO. When EMAC_MDIO_ADDR.C45E = 0, Clause 22 capable PHY is connected to MDIO.	
		0	Clause 45 PHY is Disabled
		1	Clause 45 PHY is Enabled

Table 30-189: EMAC_MDIO_ADDR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	GB	GMII Busy. The application sets the EMAC_MDIO_ADDR.GB bit to instruct the SMA to initiate a read or write access to the MDIO completer. The MAC clears the EMAC_MDIO_ADDR.GB bit after the MDIO frame transfer is completed. Hence the software must not write or change any of the fields in EMAC_MDIO_ADDR and EMAC_MDIO_DATA registers as long as this bit is set. For write transfers, the application must first write 16-bit data in the GDl field (and also RA field when EMAC_MDIO_ADDR.C45E = 1) in EMAC_MDIO_DATA register before setting the EMAC_MDIO_ADDR.GB bit. When EMAC_MDIO_ADDR.C45E = 1, it should also write to EMAC_MDIO_DATA.RA before initiating a read transfer. When a read transfer is completed (GB=0), the data read from the PHY register is valid in EMAC_MDIO_DATA.GD. Note: Even if the addressed PHY is not present, there is no change in the functionality of the EMAC_MDIO_ADDR.GB bit. Access restriction applies. Write 1 to set. Self-cleared. Writing 0 has no effect.	
		0	GMII Busy is Disabled
		1	GMII Busy is Enabled

MDIO Data Register

The EMAC_MDIO_DATA register stores the write data to be written to the PHY register located at the address specified in EMAC_MDIO_ADDR. The EMAC_MDIO_DATA register also stores the read data from the PHY register located at the address specified by MDIO Address register.

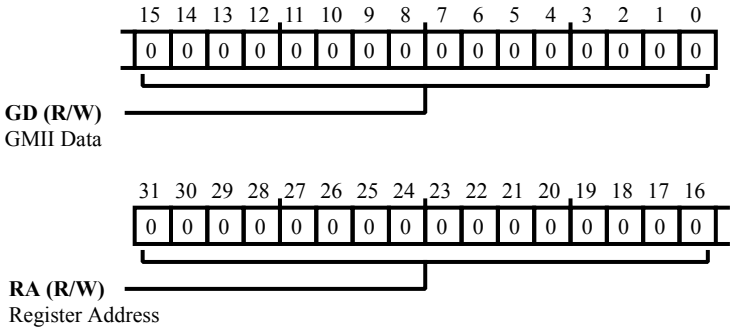

Figure 30-135: EMAC_MDIO_DATA Register Diagram

Table 30-190: EMAC_MDIO_DATA Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/W)	RA	Register Address. The EMAC_MDIO_DATA.RA field is valid only when EMAC_MDIO_ADDR.C45E = 1. It contains the register address in the PHY for the intended MDIO frame.
15:0 (R/W)	GD	GMII Data. The EMAC_MDIO_DATA.GD field contains the 16-bit data value read from the PHY after a management read operation or the 16-bit data value to be written to the PHY before a management write operation.

PHY Interface Control and Status Register

The EMAC_PHYIF_CTLSTAT register indicates the status signals received by the RGMII interface (selected at reset) from the PHY. The EMAC_PHYIF_CTLSTAT register is optional.

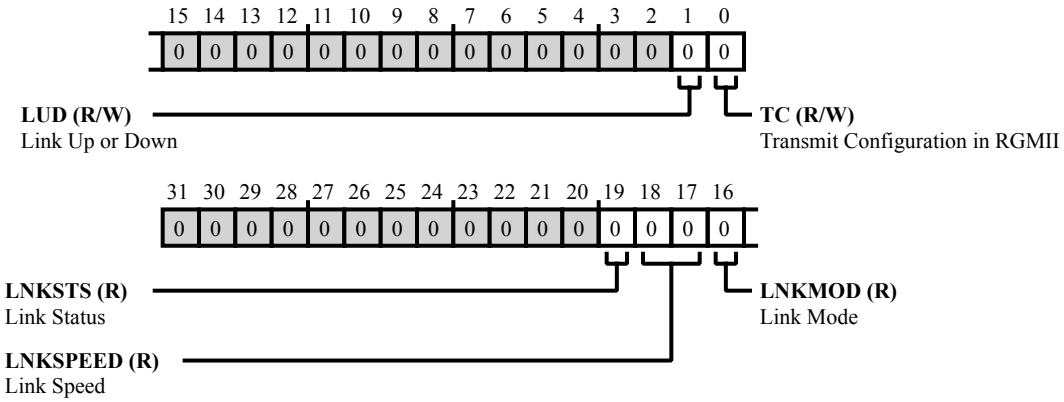

Figure 30-136: EMAC_PHYIF_CTLSTAT Register Diagram

Table 30-191: EMAC_PHYIF_CTLSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
19 (R/NW)	LNKSTS	Link Status. The EMAC_PHYIF_CTLSTAT.LNKSTS bit indicates whether the link is up (1'b1) or down (1'b0).	
		0	Link Down
		1	Link up
18:17 (R/NW)	LNKSPEED	Link Speed. The EMAC_PHYIF_CTLSTAT.LNKSPEED bit indicates the current speed of the link.	
		0	2.5 MHz
		1	25 MHz
		2	125 MHz
		3	Reserved
16 (R/NW)	LNKMOD	Link Mode. The EMAC_PHYIF_CTLSTAT.LNKMOD bit indicates the current mode of operation of the link.	
		0	Half-duplex Mode
		1	Full-duplex Mode

Table 30-191: EMAC_PHYIF_CTLSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W)	LUD	Link Up or Down. The `EMAC_PHYIF_CTLSTAT.LUD` bit indicates whether the link is up or down during transmission of configuration in the RGMII, SGMII, or SMII interface.	
		0	Link Down
		1	Link Up
0 (R/W)	TC	Transmit Configuration in RGMII. When set, the `EMAC_PHYIF_CTLSTAT.TC` bit enables the transmission of duplex mode, link speed, and link up or down information to the PHY in the RGMII port. When `EMAC_PHYIF_CTLSTAT.TC` = 0, no such information is driven to the PHY.	
		0	Disable Transmit Configuration in RGMII
		1	Enable Transmit Configuration in RGMII

PPS n Interval Register

The EMAC_PPS[n]_INTVL register contains the number of units of sub-second increment value between the rising edges of ETH0_PTPPPSn signal output.

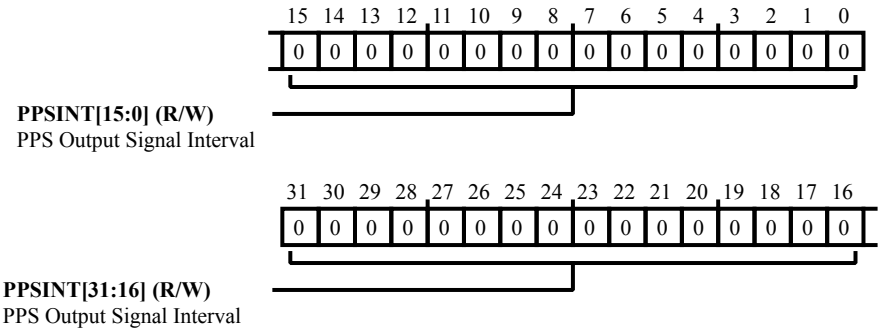

Figure 30-137: EMAC_PPS[n]_INTVL Register Diagram

Table 30-192: EMAC_PPS[n]_INTVL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	PPSINT	PPS Output Signal Interval. The EMAC_PPS[n]_INTVL.PPSINT field stores the interval between the rising edges of the ETH0_PTPPPSn signal output. The interval is stored in terms of number of units of sub-second increment value. Program one value less than the required interval. For example, if the PTP reference clock is 50 MHz (period of 20 ns), and desired interval between the rising edges of the ETH0_PTPPPSn signal output is 100 ns (that is, 5 units of sub-second increment value), program value 4 (5-1) in this register.

PPS n Target Time Nanoseconds Register

PPS0 Target Time Nanoseconds register.

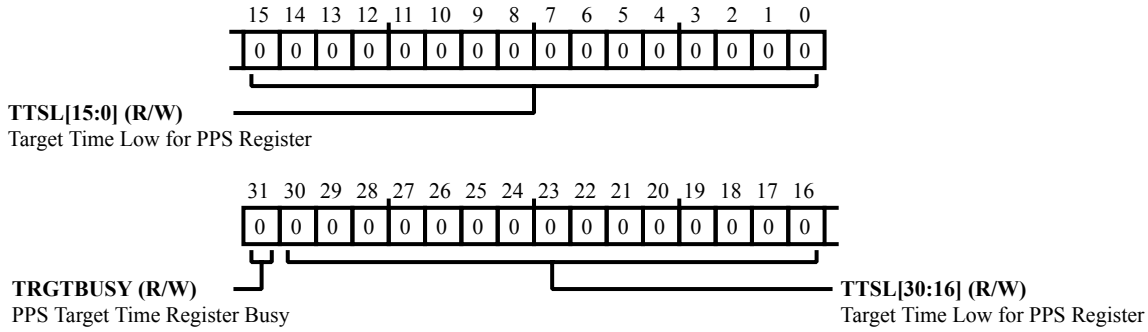

Figure 30-138: EMAC_PPS[n]_TGTM_NSEC Register Diagram

Table 30-193: EMAC_PPS[n]_TGTM_NSEC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	TRGTBUSY	PPS Target Time Register Busy. The MAC sets the `EMAC_PPS[n]_TGTM_NSEC.TRGTBUSY` bit when the EMAC_PPS_CTL.PPSCMD0 field is programmed to 010 or 011. Programming the PPSCMD0 field to 010 or 011 instructs the MAC to synchronize the Target Time registers to the PTP clock domain. The MAC clears the `EMAC_PPS[n]_TGTM_NSEC.TRGTBUSY` bit after synchronizing the Target Time Registers to the PTP clock domain The application must not update the Target Time Registers when the `EMAC_PPS[n]_TGTM_NSEC.TRGTBUSY` bit is read as 1. Otherwise, the synchronization of the previous programmed time gets corrupted.	
		0	PPS Target Time Register Busy Status is Not Detected
		1	PPS Target Time Register Busy is Detected
30:0 (R/W)	TTSL	Target Time Low for PPS Register. The `EMAC_PPS[n]_TGTM_NSEC` field stores the time in (signed) nanoseconds. When the value of the time stamp matches the value in both target time stamp registers, the MAC starts or stops the PPS signal output and generates an interrupt (if enabled) based on the TRGTMODSEL0 field (Bits [6:5]) in EMAC_PPS_CTL. When EMAC_TM_CTL.TSCTRLSSR = 0, this value should be (time in ns / 0.465). The actual start or stop time of the PPS signal output might have an error margin up to one unit of sub-second increment value. When EMAC_TM_CTL.TSCTRLSSR = 1, this value should not exceed 0x3B9A_C9FF. The actual start or stop time of the PPS signal output might have an error margin up to one unit of sub-second increment value. Access restriction applies. Write 1 to set. Self-cleared. Writing 0 has no effect.	

PPS n Target Time Seconds Register

The EMAC_PPS[n]_TGTM_SEC register, along with the EMAC_PPS[n]_TGTM_NSEC register, is used to schedule an interrupt event (bit 1 of EMAC_TM_STAT) when the system time exceeds the value programmed in these registers.

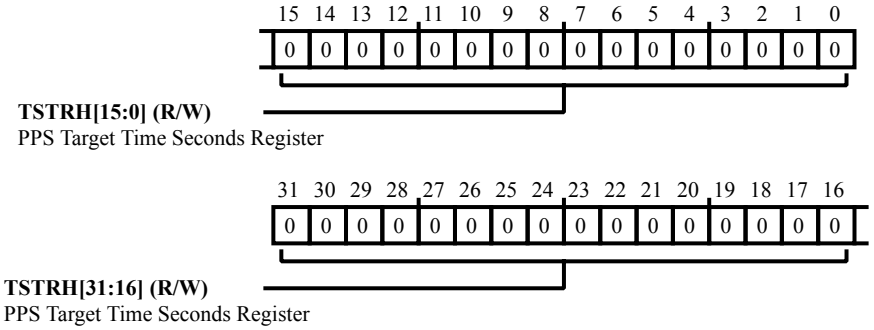

Figure 30-139: EMAC_PPS[n]_TGTM_SEC Register Diagram

Table 30-194: EMAC_PPS[n]_TGTM_SEC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	TSTRH	PPS Target Time Seconds Register. The EMAC_PPS[n]_TGTM_SEC.TSTRH field stores the time in seconds. When the time stamp value matches or exceeds both target time stamp registers, the MAC starts or stops the PPS signal output and generates an interrupt (if enabled) based on the target time mode selected for the corresponding PPS output in the EMAC_PPS_CTL register. If EMAC_TM_CTL.PTGE = 1 with the presentation time control set in recovery mode, then these bits indicate the TPT being programmed by the application and in generation mode it indicates the CPT generated at the sampled trigger.

PPS n Width Register

The EMAC_PPS[n]_WID register contains the number of units of sub-second increment value between the rising and corresponding falling edges of ETH0_PTPPPSn signal output.

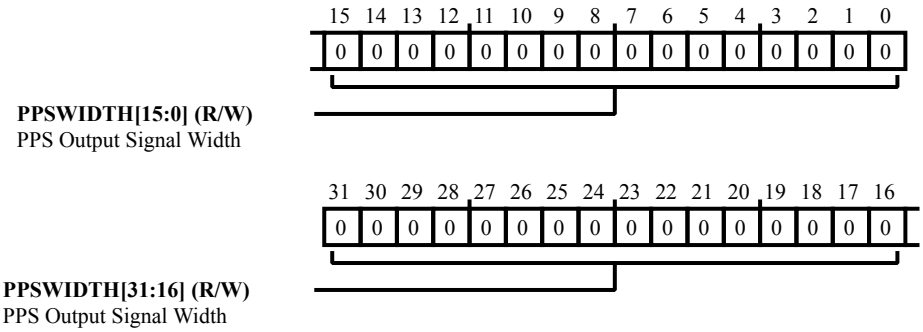

Figure 30-140: EMAC_PPS[n]_WID Register Diagram

Table 30-195: EMAC_PPS[n]_WID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	PPSWIDTH	PPS Output Signal Width. The EMAC_PPS[n]_WID.PPSWIDTH field store the width between the rising edge and corresponding falling edge of PPS signal output. The width is stored in terms of number of units of sub-second increment value. Program one value less than the required interval. For example, if PTP reference clock is 50 MHz (period of 20 ns), and width between the rising and corresponding falling edges of PPS signal output is 80 ns (that is, four units of sub-second increment value), program value 3 (4-1) in this register. Note: The value programmed in this register must be lesser than the value programmed in the EMAC_PPS[n]_INTVL register.

PPS Control Register

Bits[30:24] of the EMAC_PPS_CTL register are valid only when four flexible PPS outputs are selected. Bits[22:16] are valid only when three or more flexible PPS outputs are selected. Bits[14:8] are valid only when two or more flexible PPS outputs are selected. Bits[6:4] are valid only when flexible PPS feature is selected.

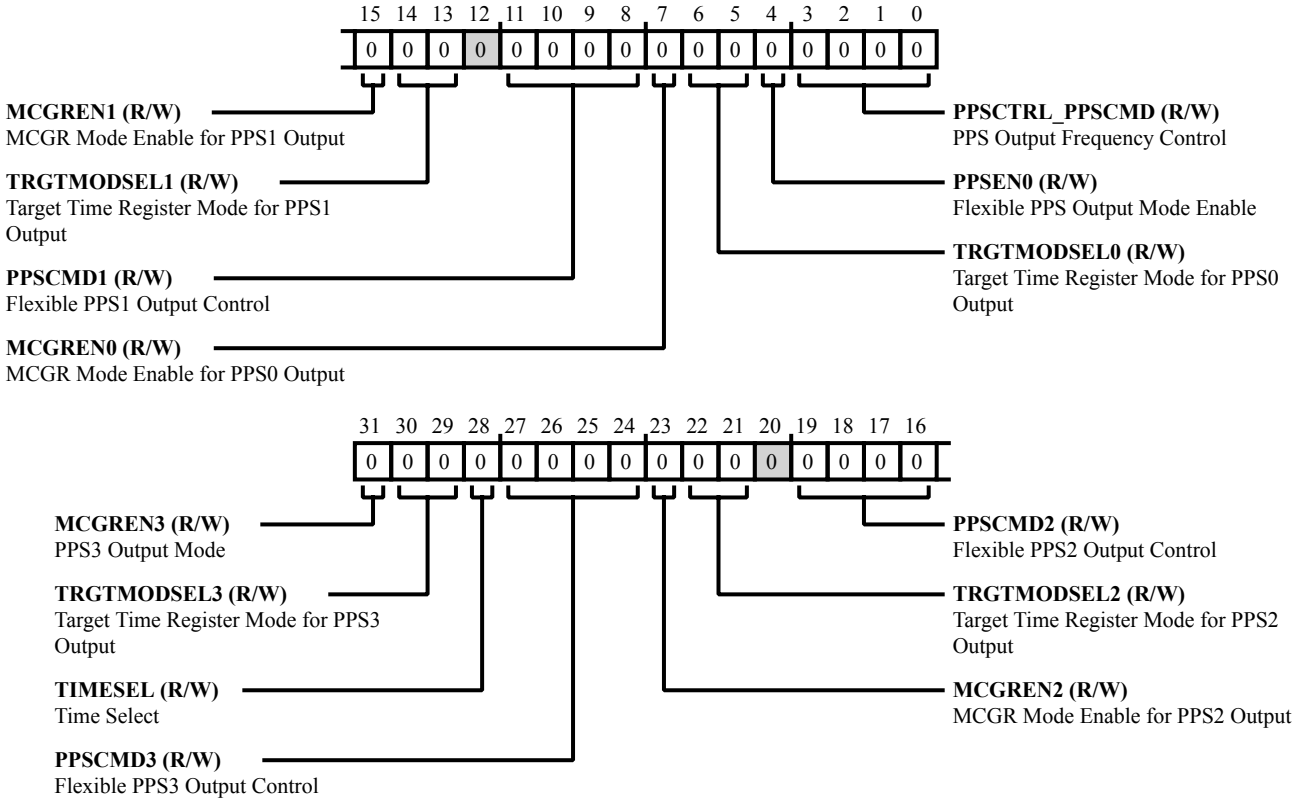

Figure 30-141: EMAC_PPS_CTL Register Diagram

Table 30-196: EMAC_PPS_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	MCGREN3	PPS3 Output Mode. The EMAC_PPS_CTL.MCGREN3 bit indicates whether the 3rd PPS instance operates in PPS or MCGR mode.	
		0	PPS Mode
		1	MCGR Mode

Table 30-196: EMAC_PPS_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
30:29 (R/W)	TRGTMODSEL3	Target Time Register Mode for PPS3 Output. The EMAC_PPS_CTL.TRGTMODSEL3 field indicates the target time registers (EMAC_PPS[3]_TGTM_SEC and EMAC_PPS[3]_TGTM_NSEC) mode for PPS3 output signal.	
		0	Generate the Interrupt Only. Target time registers are programmed only for generating the interrupt event. The flexible PPS function must not be enabled in this mode, otherwise spurious transitions may me observed on the corresponding ETH0_PTPPPS output port.
		1	Enable MCGR Interrupt. The interrupt status bit is indicated by EMAC_TM_STAT.TSTARGT3.
		2	Generate Interrupt and Start/Stop the PPS Output Signal
		3	Start/ Stop the PPS Output Signal Generation. No Interrupt is Asserted
28 (R/W)	TIMESEL	Time Select. When the EMAC_PPS_CTL.TIMESEL bit is set, 64 bit PTP time is used to capture time at MCGR trigger[0] input. When EMAC_PPS_CTL.TIMESEL = 0, presentation time is used to capture time at trigger input, maintaining backward compatibility.	
27:24 (R/W)	PPSCMD3	Flexible PPS3 Output Control. The EMAC_PPS_CTL.PPSCMD3 field controls the flexible PPS3 output (ETH0_PTPPS3) signal. The EMAC_PPS_CTL.PPSCMD3 field is similar to the PPSCMD0[2:0] field. When EMAC_PPS_CTL.MCGREN3= 1, the EMAC_PPS_CTL.PPSCMD3 field indicated by the four bits [27:24] are taken as Presentation Time Control bits for media clock generation and recovery for comparator instance 3. The EMAC_PPS_CTL.PPSCMD3 field is similar to the PPSCMD0 Presentation Time Control bits. When EMAC_PPS_CTL.MCGREN3= 0, only 3 bits from [26:24] are used as PPSCMD3 and the fourth bit must be cleared (=0). Access restriction applies. Write 1 to set. Self-cleared. Writing 0 has no effect.	
23 (R/W)	MCGREN2	MCGR Mode Enable for PPS2 Output. The EMAC_PPS_CTL.MCGREN2 field enables the 2nd PPS instance to operate in PPS or MCGR mode.	
		0	PPS Mode
		1	MCGR Mode

Table 30-196: EMAC_PPS_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
22:21 (R/W)	TRGTMODSEL2	Target Time Register Mode for PPS2 Output. The EMAC_PPS_CTL.TRGTMODSEL2 field indicates the target time registers (EMAC_PPS[2]_TGTM_SEC and EMAC_PPS[2]_TGTM_NSEC) mode for PPS2 output signal.	
		0	Generate the Interrupt Event. Target time registers are programmed only for generating the interrupt event. The flexible PPS function must not be enabled in this mode, otherwise spurious transitions may me observed on the corresponding ETH0_PTPPPS output port.
		1	Enable MCGR Interrupt. The interrupt status bit is indicated by TSTARGT3.
		2	Generate Interrupt and Start/Stop the PPS Output Signal
		3	Start/ Stop the PPS Output Signal Generation. No Interrupt is Asserted
19:16 (R/W)	PPSCMD2	Flexible PPS2 Output Control. The EMAC_PPS_CTL.PPSCMD2 field controls the flexible PPS2 output (ETH0_PTPPS2) signal. The EMAC_PPS_CTL.PPSCMD2 field is similar to the PPSCMD0 field. When EMAC_PPS_CTL.MCGREN2= 1, the EMAC_PPS_CTL.PPSCMD2 field indicated by the four bits, [19:16] are taken as Presentation Time Control bits for media clock generation and recovery for comparator instance 2. The EMAC_PPS_CTL.PPSCMD2 field is similar to the PPSCMD0 Presentation Time Control bits. When EMAC_PPS_CTL.MCGREN2= 0, only 3 bits, [18:16] are used as PPSCMD2 and the fourth bit must be configured as 0. Access restriction applies. Write 1 to set. Self-cleared. Writing 0 has no effect.	
15 (R/W)	MCGREN1	MCGR Mode Enable for PPS1 Output. The EMAC_PPS_CTL.MCGREN1 field enables the 1st PPS instance to operate in PPS or MCGR mode.	
		0	PPS Mode
		1	MCGR Mode

Table 30-196: EMAC_PPS_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
14:13 (R/W)	TRGTMODSEL1	Target Time Register Mode for PPS1 Output. The EMAC_PPS_CTL.TRGTMODSEL1 field indicates the target time registers (EMAC_PPS[1]_TGTM_SEC and EMAC_PPS[1]_TGTM_NSEC) mode for PPS1 output signal.	
		0	Generate the Interrupt Event. Target time registers are programmed only for generating the interrupt event. The flexible PPS function must not be enabled in this mode, otherwise spurious transitions may me observed on the corresponding ETH0_PTPPPS output port.
		1	Enable MCGR Interrupt. The interrupt status bit is indicated by TSTARGT3.
		2	Generate Interrupt and Start/Stop the PPS Output Signal
		3	Start/ Stop the PPS Output Signal Generation. No Interrupt is Asserted
11:8 (R/W)	PPSCMD1	Flexible PPS1 Output Control. The EMAC_PPS_CTL.PPSCMD1 field controls the flexible PPS1 output (ETH0_PTPPS1) signal. The EMAC_PPS_CTL.PPSCMD1 field is similar to the PPSCMD0 field. When EMAC_PPS_CTL.MCGREN1= 1, PPSCMD1 indicated by the four bits [11:8] are taken as Presentation Time Control bits for media clock generation and recovery for comparator instance 1. The EMAC_PPS_CTL.PPSCMD1 field is similar to the PPSCMD0 Presentation Time Control bits. When EMAC_PPS_CTL.MCGREN1= 0, only 3 bits, [10:8] are used as PPSCMD1 and the fourth bit must be cleared (=0). Access restriction applies. Write 1 to set. Self-cleared. Writing 0 has no effect.	
7 (R/W)	MCGREN0	MCGR Mode Enable for PPS0 Output. The EMAC_PPS_CTL.MCGREN0 field enables the 0th PPS instance to operate in PPS or MCGR mode. When set, it operates in MCGR mode and when cleared, it operates in PPS mode.	
		0	PPS Mode
		1	MCGR Mode

Table 30-196: EMAC_PPS_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6:5 (R/W)	TRGTMODSEL0	Target Time Register Mode for PPS0 Output. The `EMAC_PPS_CTL.TRGTMODSEL0` field indicates the target time registers (EMAC_PPS[0]_TGTM_SEC and EMAC_PPS[0]_TGTM_NSEC) mode for PPS0 output signal.	
		0	Generate the Interrupt Event. The target time registers are programmed only for generating the interrupt event. The flexible PPS function must not be enabled in this mode, otherwise spurious transitions may be observed on the corresponding ETH0_PTPPPS output port.
		1	Enable MCGR Interrupt. The status bit is indicated by TSTARGT.
		2	Generate the Interrupt Event and PPS Output Signal
		3	Start/ Stop the PPS Output Signal Generation. No Interrupt is Asserted
4 (R/W)	PPSEN0	Flexible PPS Output Mode Enable. When the `EMAC_PPS_CTL.PPSEN0` bit is set (=1), bits[3:0] function as PPSCMD. When the `EMAC_PPS_CTL.PPSEN0` bit is cleared (=0), bits[3:0] function as PPSCTRL (fixed PPS mode).	
		0	Flexible PPS Output Mode is Disabled
		1	Flexible PPS Output Mode is Enabled

Table 30-196: EMAC_PPS_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
3:0 (R/W)	PPSCTRL_PPSCMD	PPS Output Frequency Control. The EMAC_PPS_CTL.PPSCTRL_PPSCMD field controls the frequency of the ETH0_PTPPPS0 output (PTP clock) signal. The default value is 0000, and the PPS output is 1 pulse (of width PTP clock) every second. For other values of EMAC_PPS_CTL.PPSCTRL_PPSCMD, the PPS output becomes a generated clock of following frequencies: - 0001: The binary rollover is 2 Hz, and the digital rollover is 1 Hz. - 0010: The binary rollover is 4 Hz, and the digital rollover is 2 Hz. - 0011: The binary rollover is 8 Hz; digital rollover is 4 Hz. - 0100: The binary rollover is 16 Hz; digital rollover is 8 Hz. ... - 1111: The binary rollover is 32.768 KHz; digital rollover is 16.384 KHz. See the Fixed Pulse-Per-Second Output topic for details. When EMAC_PPS_CTL.PPSCTRL_PPSCMD = 0011, the PPS (4 Hz) is a sequence of: Three clocks of 50 percent duty cycle and 268 ms period. A fourth clock of 195 ms period (134 ms low and 61 ms high). This behavior is due to the non-linear toggling of bits in the digital rollover mode in the EMAC_TM_NSEC register. For Flexible PPS Output (ETH0_PTPPPS0) control, programming the EMAC_PPS_CTL.PPSCTRL_PPSCMD bits with a non-zero value instructs the MAC to initiate an event. When the command is transferred or synchronized to the PTP clock domain, the bits are cleared automatically. Software should ensure that these bits are programmed only when they are 'all-zero'. When EMAC_PPS_CTL.MCGREN0 = 1, the EMAC_PPS_CTL.PPSCTRL_PPSCMD bits are treated as presentation time control bits: - 0000: MCGR operation is not carried out. If configured to this value in the middle of clock recovery or generation, all processing inputs are flushed. - 0001: Capture the presentation time at the rising edge of the EMAC0_MCG_PST trigger request into the EMAC_PPS[0]_TGTM_SEC register. - 0010: Capture the presentation time at the falling edge of the EMAC0_MCG_PST trigger request into the EMAC_PPS[0]_TGTM_SEC register. - 0011: Capture the presentation time at both edges of the EMAC0_MCG_PST trigger request into the EMAC_PPS[0]_TGTM_SEC register. - 0100-1000: Reserved - 1001: Toggle output on compare - 1010: Pulse output low on compare for one PTP clock cycle. - 1011: Pulse output high on compare for one PTP clock cycle. - 1100-1111: Reserved

PTP Time Stamp Offload Control Register

The EMAC_PTO_CTL register controls the PTP offload engine operation.

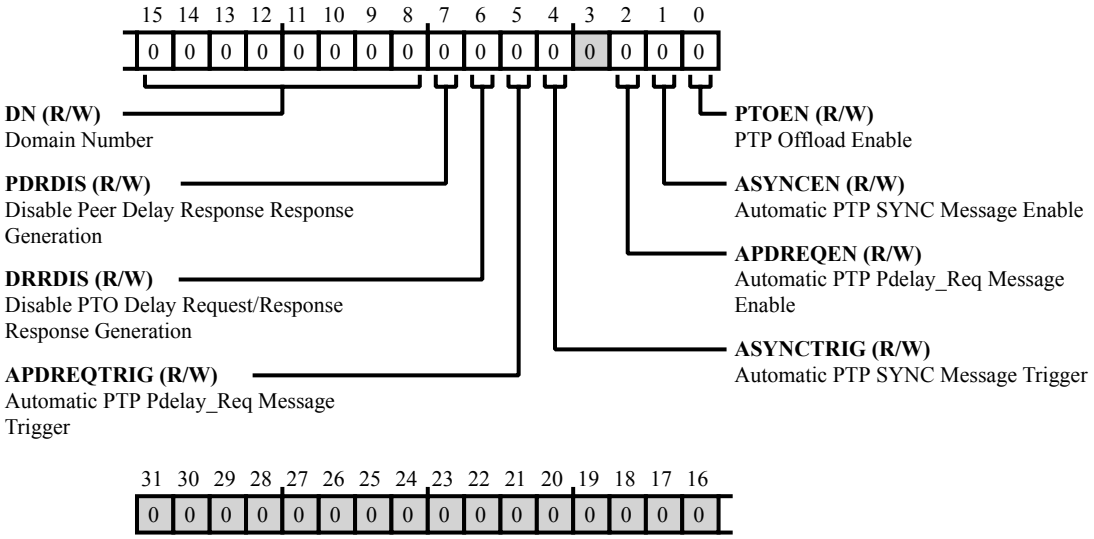

Figure 30-142: EMAC_PTO_CTL Register Diagram

Table 30-197: EMAC_PTO_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15:8 (R/W)	DN	Domain Number. The EMAC_PTO_CTL.DN field indicates the domain number in which the PTP node is operating.	
7 (R/W)	PDRDIS	Disable Peer Delay Response Response Generation. When the EMAC_PTO_CTL.PDRDIS bit is set, the peer delay response (Pdelay_Resp) response is not be generated for received peer delay request (Pdelay_Req) request packet, as required by the programmed mode. Note: Setting the EMAC_PTO_CTL.PDRDIS bit to 1 affects the normal PTP Offload operation and the time synchronization. So, the EMAC_PTO_CTL.PDRDIS bit must be set only if there is problem with Pdelay_Resp generation in hardware and/or Pdelay_Resp generation is handled by software.	
		0	Peer Delay Response Response Generation is Enabled
		1	Peer Delay Response Response Generation is Disabled

Table 30-197: EMAC_PTO_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6 (R/W)	DRRDIS	Disable PTO Delay Request/Response Response Generation. When the EMAC_PTO_CTL.DRRDIS bit is set, the delay request and delay response is not generated for received SYNC and delay request packet respectively, as required by the programmed mode.	
		0	PTO Delay Request/Response Response Generation is Enabled
		1	PTO Delay Request/Response Response Generation is Disabled
5 (R/W)	APDREQTRIG	Automatic PTP Pdelay_Req Message Trigger. When the EMAC_PTO_CTL.APDREQTRIG bit is set, one PTP Pdelay_Req message is transmitted. The EMAC_PTO_CTL.APDREQTRIG bit is automatically cleared after the PTP Pdelay_Req message is transmitted. The application should set the EMAC_PTO_CTL.APDREQEN bit for this operation. Access restriction applies. Write 1 to set. Self-cleared. Writing 0 has no effect.	
		0	Automatic PTP Pdelay_Req Message Trigger is Disabled
		1	Automatic PTP Pdelay_Req Message Trigger is Enabled
4 (R/W)	ASYNCTRIG	Automatic PTP SYNC Message Trigger. When the EMAC_PTO_CTL.ASYNCTRIG bit is set, one PTP SYNC message is transmitted. The EMAC_PTO_CTL.ASYNCTRIG bit is automatically cleared after the PTP SYNC message is transmitted. The application should set the EMAC_PTO_CTL.ASYNCEN bit for this operation. Access restriction applies. Write 1 to set. Self-cleared. Writing 0 has no effect.	
		0	Automatic PTP SYNC Message Trigger is Disabled
		1	Automatic PTP SYNC Message Trigger is Enabled
2 (R/W)	APDREQEN	Automatic PTP Pdelay_Req Message Enable. When the EMAC_PTO_CTL.APDREQEN bit is set, PTP Pdelay_Req message is generated periodically based on interval programmed or trigger from application, when the MAC is programmed to be in peer-to-peer transparent mode.	
		0	Automatic PTP Pdelay_Req Message is Disabled
		1	Automatic PTP Pdelay_Req Message is Enabled
1 (R/W)	ASYNCEN	Automatic PTP SYNC Message Enable. When the EMAC_PTO_CTL.ASYNCEN bit is set, PTP SYNC message is generated periodically based on interval programmed or trigger from application, when the MAC is programmed to be in clock requester mode.	
		0	Automatic PTP SYNC Message is Disabled
		1	Automatic PTP SYNC Message is Enabled

Table 30-197: EMAC_PTO_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	PTOEN	PTP Offload Enable. When the `EMAC_PTO_CTL.PTOEN` bit is set, the PTP offload feature is enabled.	
		0	PTP Offload Feature is Disabled
		1	PTP Offload Feature is Enabled

MAC Packet Filter Register

The EMAC_MACPKT_FILT register contains the filter controls for receiving packets. Some of the controls from this register go to the address check block of the MAC which performs the first level of address filtering. The second level of filtering is performed on the incoming packet based on other controls such as Pass Bad Packets and Pass Control Packets.

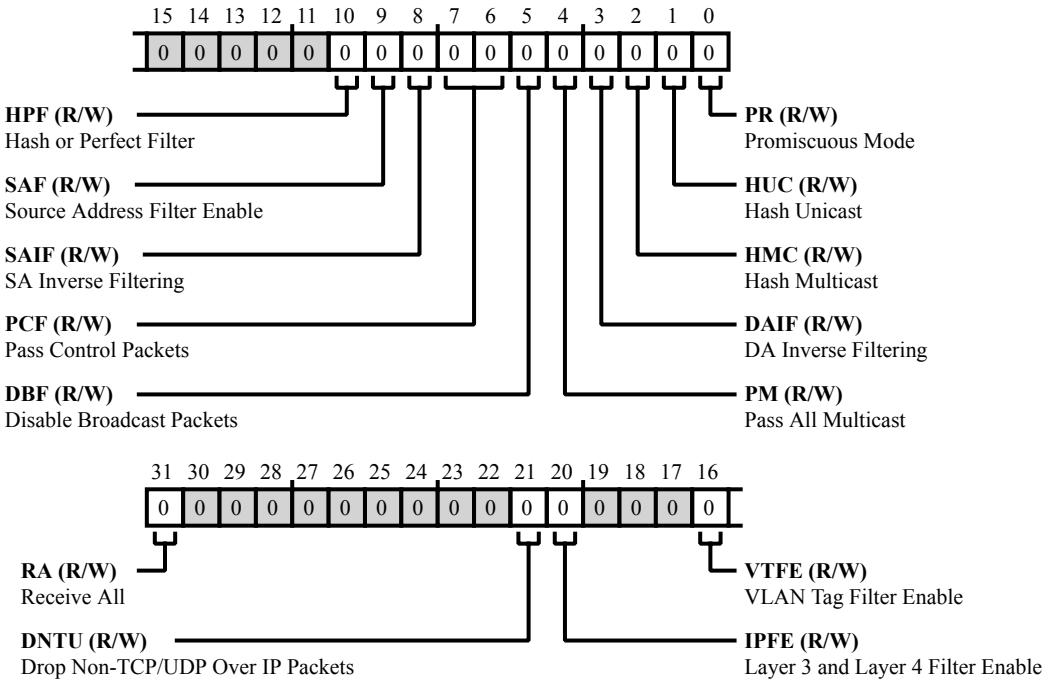

Figure 30-143: EMAC_MACPKT_FILT Register Diagram

Table 30-198: EMAC_MACPKT_FILT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	RA	Receive All. When the EMAC_MACPKT_FILT.RA bit is set, the MAC receiver module passes all received packets to the application, irrespective of whether they pass the address filter or not. The result of the SA or DA filtering is updated (pass or fail) in the corresponding bit in the Rx status word. When EMAC_MACPKT_FILT.RA = 0, the receiver module passes only those packets to the application that pass the SA or DA address filter.	
		0	Receive All is Disabled
		1	Receive All is Enabled

Table 30-198: EMAC_MACPKT_FILT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
21 (R/W)	DNTU	Drop Non-TCP/UDP Over IP Packets. When the EMAC_MACPKT_FILT.DNTU bit is set, the MAC drops the non-TCP or UDP over IP packets. The MAC forward only those packets that are processed by the layer 4 filter. When EMAC_MACPKT_FILT.DNTU = 0, the MAC forwards all non-TCP or UDP over IP packets.	
		0	Forward Non-TCP/UDP Over IP Packets
		1	Drop Non-TCP/UDP Over IP Packets
20 (R/W)	IPFE	Layer 3 and Layer 4 Filter Enable. When the EMAC_MACPKT_FILT.IPFE bit is set, the MAC drops packets that do not match the enabled layer 3 and layer 4 filters. If layer 3 or layer 4 filters are not enabled for matching, the EMAC_MACPKT_FILT.IPFE bit does not have any effect. When EMAC_MACPKT_FILT.IPFE = 0, the MAC forwards all packets irrespective of the match status of the layer 3 and layer 4 fields.	
		0	Layer 3 and Layer 4 Filters are Disabled
		1	Layer 3 and Layer 4 Filters are Enabled
16 (R/W)	VTFE	VLAN Tag Filter Enable. When the EMAC_MACPKT_FILT.VTFE bit is set, the MAC drops the VLAN tagged packets that do not match the VLAN tag. When EMAC_MACPKT_FILT.VTFE = 0, the MAC forwards all packets irrespective of the match status of the VLAN tag.	
		0	VLAN Tag Filter is Disabled
		1	VLAN Tag Filter is Enabled
10 (R/W)	HPF	Hash or Perfect Filter. When the EMAC_MACPKT_FILT.HPF bit is set, the address filter passes a packet if it matches either the perfect filtering or hash filtering as configured by the EMAC_MACPKT_FILT.HUC or EMAC_MACPKT_FILT.HMC bit. When EMAC_MACPKT_FILT.HPF = 0 and the EMAC_MACPKT_FILT.HUC or EMAC_MACPKT_FILT.HMC bit is set, the packet is passed only if it matches the hash filter.	
		0	Hash or Perfect Filter is Disabled
		1	Hash or Perfect Filter is Enabled

Table 30-198: EMAC_MACPKT_FILT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W)	SAF	Source Address Filter Enable. When the EMAC_MACPKT_FILT.SAF bit is set, the MAC compares the SA field of the received packets with the values programmed in the enabled SA registers. If the comparison fails, the MAC drops the packet. When EMAC_MACPKT_FILT.SAF = 0, the MAC forwards the received packet to the application with updated SAF bit of the Rx status depending on the SA address comparison. Note: According to the IEEE specification, bit 47 of the SA is reserved. However, in the EMAC module, the MAC compares all 48 bits. The software driver should take this into consideration while programming the MAC address registers for SA.	
		0	SA Filtering is Disabled
		1	SA Filtering is Enabled
8 (R/W)	SAIF	SA Inverse Filtering. When the EMAC_MACPKT_FILT.SAIF bit is set, the address check block operates in the inverse filtering mode for SA address comparison. If the SA of a packet matches the values programmed in the SA registers, it is marked as failing the SA address filter. When EMAC_MACPKT_FILT.SAIF = 0, if the SA of a packet does not match the values programmed in the SA registers, it is marked as failing the SA address filter.	
		0	SA Inverse Filtering is Disabled
		1	SA Inverse Filtering is Enabled
7:6 (R/W)	PCF	Pass Control Packets. The EMAC_MACPKT_FILT.PCF field control the forwarding of all control packets (including unicast and multicast pause packets).	
		0	MAC filters all control packets from reaching the application
		1	MAC forwards all control packets except pause packets to the application even if they fail the address filter
		2	MAC forwards all control packets to the application even if they fail the address filter
		3	MAC forwards the control packets that pass the address filter

Table 30-198: EMAC_MACPKT_FILT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (R/W)	DBF	Disable Broadcast Packets. When the EMAC_MACPKT_FILT.DBF bit is set, the AFM module blocks all the incoming broadcast packets. In addition, it overrides all other filter settings. When EMAC_MACPKT_FILT.DBF = 0, the AFM module passes all received broadcast packets.	
		0	Enable Broadcast Packets
		1	Disable Broadcast Packets
4 (R/W)	PM	Pass All Multicast. When the EMAC_MACPKT_FILT.PM bit is set, it indicates that all the received packets with a multicast destination address (first bit in the destination address field is '1') are passed. When EMAC_MACPKT_FILT.PM = 0, filtering of multicast packet depends on the EMAC_MACPKT_FILT.HMC bit.	
		0	Pass All Multicast is Disabled
		1	Pass All Multicast is Enabled
3 (R/W)	DAIF	DA Inverse Filtering. When the EMAC_MACPKT_FILT.DAIF bit is set, the address check block operates in inverse filtering mode for the DA address comparison for both unicast and multicast packets. When EMAC_MACPKT_FILT.DAIF = 0, normal filtering of packets is performed.	
		0	DA Inverse Filtering is Disabled
		1	DA Inverse Filtering is Enabled
2 (R/W)	HMC	Hash Multicast. When the EMAC_MACPKT_FILT.HMC bit is set, the MAC performs the destination address filtering of received multicast packets according to the hash table. When EMAC_MACPKT_FILT.HMC = 0, the MAC performs the perfect destination address filtering for multicast packets, that is, it compares the DA field with the values programmed in DA registers.	
		0	Hash Multicast is Disabled
		1	Hash Multicast is Enabled

Table 30-198: EMAC_MACPKT_FILT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W)	HUC	Hash Unicast. When the EMAC_MACPKT_FILT.HUC bit is set, the MAC performs the destination address filtering of unicast packets according to the hash table. When EMAC_MACPKT_FILT.HUC = 0, the MAC performs a perfect destination address filtering for unicast packets, that is, it compares the DA field with the values programmed in DA registers.	
		0	Hash Unicast is Disabled
		1	Hash Unicast is Enabled
0 (R/W)	PR	Promiscuous Mode. When the EMAC_MACPKT_FILT.PR bit is set, the address filtering module passes all incoming packets irrespective of the destination or source address. The SA or DA filter fails status bits of the Rx status word are always cleared when EMAC_MACPKT_FILT.PR is set.	
		0	Promiscuous Mode is Disabled
		1	Promiscuous Mode is Enabled

Presentation Time Update Register

The EMAC_PRSNTM_UPDT register holds the 32-bit value of MAC 1722 Presentation Time in ns, that should be added to the Current Presentation Time Counter value. Init happens when EMAC_TM_CTL.TSINIT = 1, and update happens when EMAC_TM_CTL.TSUPDT = 1.

The EMAC_PRSNTM_UPDT register exists when DWC_EQOS_FLEXI_PPS_OUT_EN is configured.

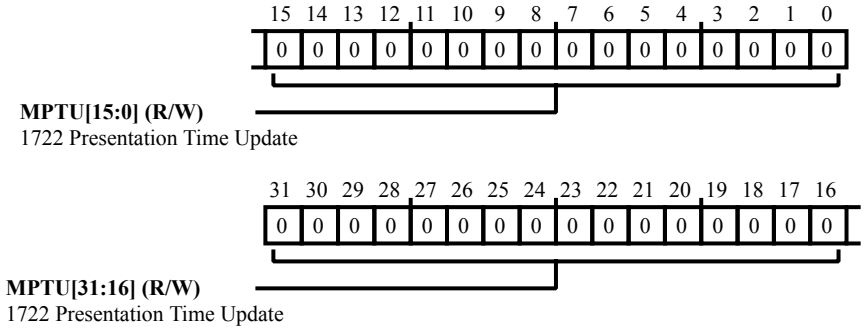

Figure 30-144: EMAC_PRSNTM_UPDT Register Diagram

Table 30-199: EMAC_PRSNTM_UPDT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	MPTU	1722 Presentation Time Update. The EMAC_PRSNTM_UPDT.MPTU field holds the init value or the update value for the presentation time. When used for update, this field holds the 32-bit value in ns, that should be added to the Current Presentation Time Counter value. When EMAC_TM_NSECUPDT.ADDSUB = 1, this value is directly used for subtraction.

Presentation Time Nanosecond Register

The EMAC_PRSNTM_NSEC register contains the 32-bit binary rollover equivalent time of the PTP system time in ns.

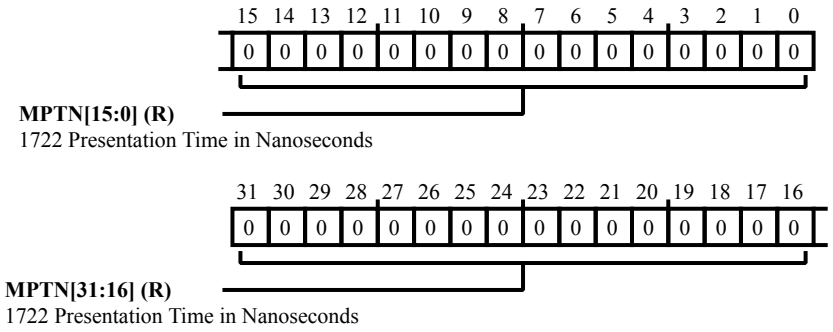

Figure 30-145: EMAC_PRSNTM_NSEC Register Diagram

Table 30-200: EMAC_PRSNTM_NSEC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	MPTN	1722 Presentation Time in Nanoseconds. The EMAC_PRSNTM_NSEC.MPTN field indicates the value of the 32-bit binary rollover equivalent time of the PTP system time in nanoseconds.

Queue 0 Transmit Flow Control Register

The EMAC_Q0_TXFLOW_CTL register controls the generation and reception of the Control (Pause Command) packets by the flow control module of the MAC. A write to a register with the Busy bit set (=1) triggers the Flow Control block to generate a Pause packet. The fields of the control packet are selected as specified in the 802.3x specification, and the Pause Time value from this register is used in the Pause Time field of the control packet. The Busy bit remains set until the control packet is transferred onto the cable. The application must make sure that the Busy bit is cleared before writing to the register.

When the PFCE bit in the MAC_Rx_Flow_Ctrl register is enabled, this register controls the generation of Priority Flow Control (PFC) frames with priorities mapped according to PSRQ0 in the MAC_RxQ_Ctrl2 register.

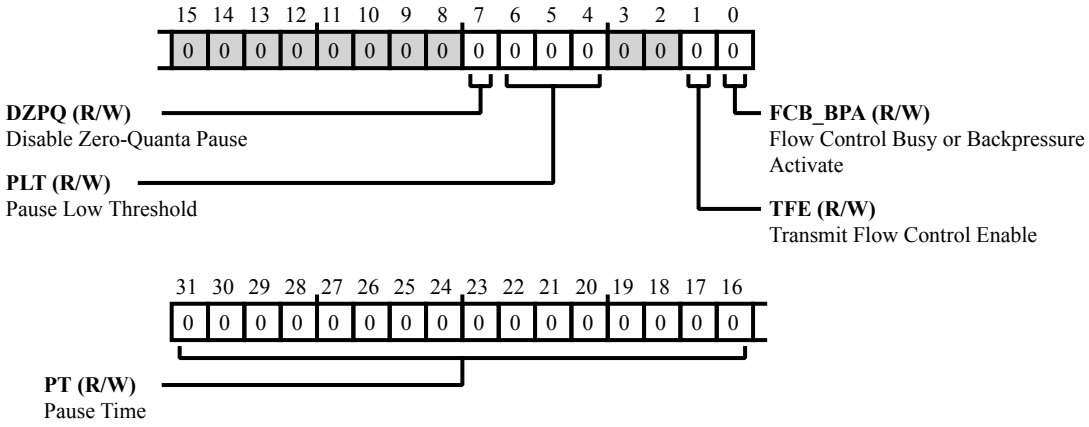

Figure 30-146: EMAC_Q0_TXFLOW_CTL Register Diagram

Table 30-201: EMAC_Q0_TXFLOW_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/W)	PT	Pause Time. The EMAC_Q0_TXFLOW_CTL.PT field holds the value to be used in the Pause Time field in the Tx control packet. If the Pause Time bits are configured to be double-synchronized to the (G)MII clock domain, consecutive writes to this register should be performed only after at least four clock cycles in the destination clock domain.

Table 30-201: EMAC_Q0_TXFLOW_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	DZPQ	Disable Zero-Quanta Pause. When the `EMAC_Q0_TXFLOW_CTL.DZPQ` bit is set, it disables the automatic generation of the zero-quanta Pause packets on deassertion of the flow-control signal from the FIFO layer (MTL or external sideband flow control signal sbd_flowctrl_i or mti_flowctrl_i). When `EMAC_Q0_TXFLOW_CTL.DZPQ` = 0, normal operation with automatic zero-quanta Pause packet generation is enabled.	
		0	Zero-Quanta Pause Packet Generation is Enabled
		1	Zero-Quanta Pause Packet Generation is Disabled
6:4 (R/W)	PLT	Pause Low Threshold. The `EMAC_Q0_TXFLOW_CTL.PLT` field configures the threshold of the Pause timer at which the input flow control signal mti_flowctrl_i (or sbd_flowctrl_i) is checked for automatic retransmission of the Pause packet. The threshold values should be always less than the Pause Time configured in Bits[31:16]. For example, if PT = 100H (256 slot times), and PLT = 001, a second Pause packet is automatically transmitted if the mti_flowctrl_i signal is asserted at 228 (256-28) slot times after the first Pause packet is transmitted. The following list provides the threshold values for different values. The slot time is defined as the time taken to transmit 512 bits (64 bytes) on the GMII or MII interface. This (approximate) computation is based on the packet size (64, 1518, 2000, 9018, 16384, or 32768) + 2 Pause Packet Size + IPG in Slot Times.	
		0	Pause Time Minus 4 Slot Times
		1	Pause Time Minus 28 Slot Times
		2	Pause Time Minus 36 Slot Times
		3	Pause Time Minus 144 Slot Times
		4	Pause Time Minus 256 Slot Times
		5	Pause Time Minus 512 Slot Times
		6	Reserved

Table 30-201: EMAC_Q0_TXFLOW_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W)	TFE	Transmit Flow Control Enable. In the full-duplex mode, when the EMAC_Q0_TXFLOW_CTL.TFE bit is set, the MAC enables the flow control operation to Tx Pause packets. When EMAC_Q0_TXFLOW_CTL.TFE = 0, the flow control operation in the MAC is disabled, and the MAC does not transmit any Pause packets. In the half-duplex mode, when the EMAC_Q0_TXFLOW_CTL.TFE bit is set, the MAC enables the back pressure operation. When EMAC_Q0_TXFLOW_CTL.TFE = 0, the back pressure feature is disabled.	
		0	Transmit Flow Control is Disabled
		1	Transmit Flow Control is Enabled
0 (R/W)	FCB_BPA	Flow Control Busy or Backpressure Activate. The EMAC_Q0_TXFLOW_CTL.FCB_BPA bit initiates a Pause packet in the full-duplex mode and activates the backpressure function in the half-duplex mode if the TFE bit is set. In full-duplex mode, the EMAC_Q0_TXFLOW_CTL.FCB_BPA bit should be read as 1'b0 before writing to this register. To initiate a Pause packet, the application must set the EMAC_Q0_TXFLOW_CTL.FCB_BPA bit to 1'b1. During Control packet transfer, the EMAC_Q0_TXFLOW_CTL.FCB_BPA bit continues to be set to indicate that a packet transmission is in progress. When Pause packet transmission is complete, the MAC resets the EMAC_Q0_TXFLOW_CTL.FCB_BPA bit to 1'b0. Do not write to this register until the EMAC_Q0_TXFLOW_CTL.FCB_BPA bit is cleared. When the EMAC_Q0_TXFLOW_CTL.FCB_BPA bit is set (and TFE bit is set) in the half-duplex mode, the MAC asserts the back pressure. During back pressure, when the MAC receives a new packet, the transmitter starts sending a JAM pattern resulting in a collision. This control register bit is logically OR'ed with the mti_flowctrl_i input signal for the back pressure function. When the MAC is configured for the full-duplex mode, the BPA is automatically disabled. Access restriction applies. Write 1 to set. Self-cleared. Writing 0 has no effect.	
		0	Flow Control Busy or Backpressure Activate is Disabled
		1	Flow Control Busy or Backpressure Activate is Enabled

Queue [i] Transmit Flow Control Register

The EMAC_Q[i]_TXFLOW_CTL register controls the generation and reception of the Control (Pause Command) packets by the Flow control module of the MAC. A write to a register with the Busy bit set (= 1) triggers the Flow Control block to generate a Pause packet. The fields of the control packet are selected as specified in the 802.3x specification, and the Pause Time value from this register is used in the Pause Time field of the control packet. The Busy bit remains set until the control packet is transferred onto the cable. The application must make sure that the Busy bit is cleared before writing to the register. (EMAC_RXFLOW_CTL.PFCE = 1.)

The register controls the generation of PFC control packets of priorities mapped per the PSRQn field in the EMAC_RXQ_CTL2.EMAC_RXQ_CTL3 registers.

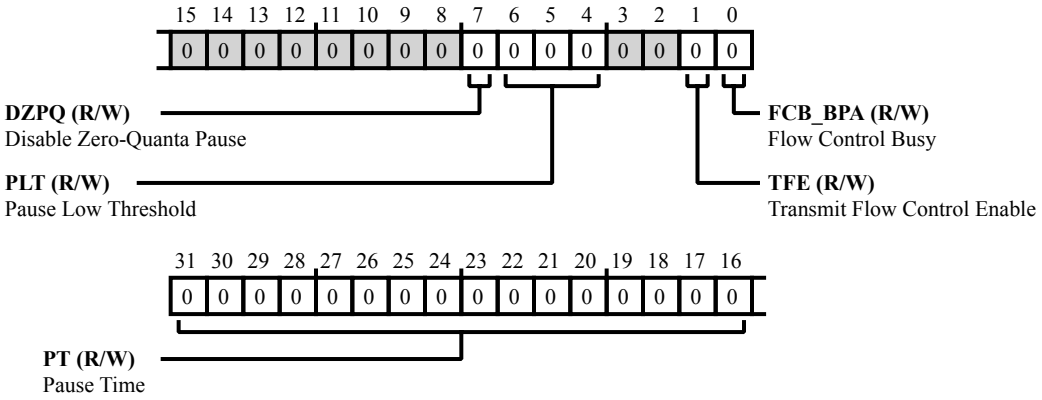

Figure 30-147: EMAC_Q[i]_TXFLOW_CTL Register Diagram

Table 30-202: EMAC_Q[i]_TXFLOW_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:16 (R/W)	PT	Pause Time. The EMAC_Q[i]_TXFLOW_CTL.PT field holds the value to be used in the Pause Time field in the Tx control packet. The bits are configured to be double-synchronized to the (G)MII clock domain. Hence, consecutive writes to this register should be performed only after at least four clock cycles in the (G)MII clock domain.	
7 (R/W)	DZPQ	Disable Zero-Quanta Pause. When the EMAC_Q[i]_TXFLOW_CTL.DZPQ bit is set, it disables the automatic generation of the zero-quanta Pause packets on deassertion of the flow-control signal from the FIFO layer. When EMAC_Q[i]_TXFLOW_CTL.DZPQ = 0, normal operation with automatic zero-quanta Pause packet generation is enabled.	
		0	Zero-Quanta Pause Packet Generation is Enabled
		1	Zero-Quanta Pause Packet Generation is Disabled

Table 30-202: EMAC_Q[i]_TXFLOW_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6:4 (R/W)	PLT	Pause Low Threshold. The `EMAC_Q[i]_TXFLOW_CTL.PLT` field configures the threshold of the Pause timer at which the input flow control signal mti_flowctrl_i is checked for automatic retransmission of the Pause packet. The threshold values must be less than the Pause Time (PT) configured in bits[31:16]. For example, if PT = 100H (256 slot times), and PLT = 001, a second pause packet is automatically transmitted if the mti_flowctrl_i signal is asserted at 228 (256-28) slot times after the first pause packet is transmitted. The following list provides the threshold values for different values. The slot time is defined as the time taken to transmit 512 bits (64 bytes) on the GMII or MII interface. This (approximate) computation is based on the packet size (64, 1518, 2000, 9018, 16384, or 32768) + 2 Pause Packet Size + IPG in Slot Times.	
		0	PT - 4 Slot Times
		1	PT - 28 Slot Times
		2	PT - 36 Slot Times
		3	PT - 144 Slot Times
		4	PT - 256 Slot Times
		5	PT - 512 Slot Times
		6	Reserved
1 (R/W)	TFE	Transmit Flow Control Enable. When the `EMAC_Q[i]_TXFLOW_CTL.TFE` bit is set in full-duplex mode, the MAC enables the flow control operation to Tx pause packets. When `EMAC_Q[i]_TXFLOW_CTL.TFE` = 0, the flow control operation in the MAC is disabled, and the MAC does not transmit any pause packets.	
		0	Transmit Flow Control is Disabled
		1	Transmit Flow Control is Enabled

Table 30-202: EMAC_Q[i]_TXFLOW_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	FCB_BPA	Flow Control Busy. The EMAC_Q[i]_TXFLOW_CTL.FCB_BPA bit initiates a PFC packet if EMAC_Q[i]_TXFLOW_CTL.TFE = 1. To initiate a PFC packet, the application must set the EMAC_Q[i]_TXFLOW_CTL.FCB_BPA bit to 1'b1. During the control packet transfer, the EMAC_Q[i]_TXFLOW_CTL.FCB_BPA bit continues to be set to indicate that a packet transmission is in progress. When PFC packet transmission is complete, the MAC resets the EMAC_Q[i]_TXFLOW_CTL.FCB_BPA bit to 1'b0. Do not write to this register until the EMAC_Q[i]_TXFLOW_CTL.FCB_BPA bit is cleared. Access restriction applies. Write 1 to set. Self-cleared. Writing 0 has no effect.	
		0	Flow Control Busy or Backpressure Activate is Disabled
		1	Flow Control Busy or Backpressure Activate is Enabled

Receive Queue Control 0 Register

The EMAC_RXQ_CTL0 register controls the queue management in the MAC receiver.

Note: In multiple Rx queues configuration, all the queues are disabled by default. Enable the Rx queue by programming the corresponding field in this register.

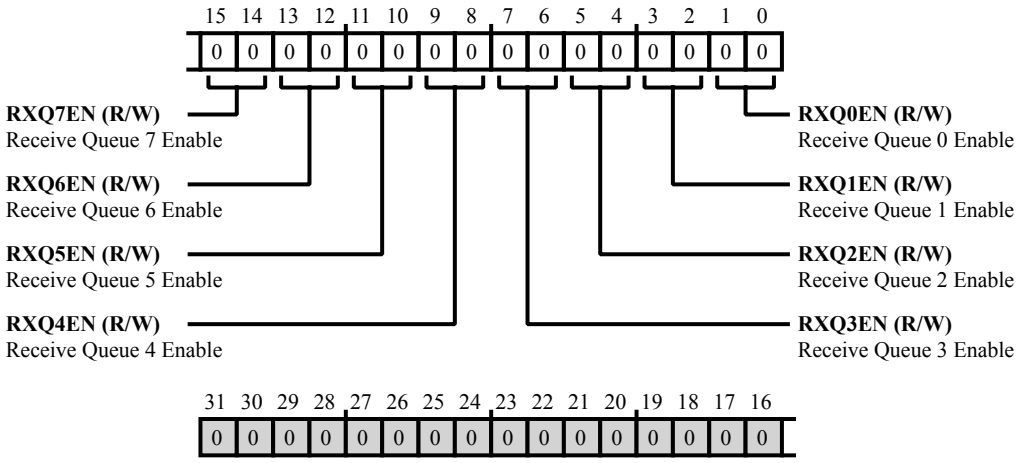

Figure 30-148: EMAC_RXQ_CTL0 Register Diagram

Table 30-203: EMAC_RXQ_CTL0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15:14 (R/W)	RXQ7EN	Receive Queue 7 Enable. The EMAC_RXQ_CTL0.RXQ7EN field is similar to the RXQ0EN field.	
		0	Queue Not Enabled
		1	Queue Enabled for AV
		2	Queue Enabled for DCB/Generic
		3	Reserved
13:12 (R/W)	RXQ6EN	Receive Queue 6 Enable. The EMAC_RXQ_CTL0.RXQ6EN field is similar to the RXQ0EN field.	
		0	Queue Not Enabled
		1	Queue Enabled for AV
		2	Queue Enabled for DCB/Generic
		3	Reserved

Table 30-203: EMAC_RXQ_CTL0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
11:10 (R/W)	RXQ5EN	Receive Queue 5 Enable. The `EMAC_RXQ_CTL0.RXQ5EN` field is similar to the RXQ0EN field.	
		0	Queue Not Enabled
		1	Queue Enabled for AV
		2	Queue Enabled for DCB/Generic
		3	Reserved
9:8 (R/W)	RXQ4EN	Receive Queue 4 Enable. The `EMAC_RXQ_CTL0.RXQ4EN` field is similar to the RXQ0EN field.	
		0	Queue Not Enabled
		1	Queue Enabled for AV
		2	Queue Enabled for DCB/Generic
		3	Reserved
7:6 (R/W)	RXQ3EN	Receive Queue 3 Enable. The `EMAC_RXQ_CTL0.RXQ3EN` field is similar to the RXQ0EN field.	
		0	Queue Not Enabled
		1	Queue Enabled for AV
		2	Queue Enabled for DCB/Generic
		3	Reserved
5:4 (R/W)	RXQ2EN	Receive Queue 2 Enable. The `EMAC_RXQ_CTL0.RXQ2EN` field is similar to the RXQ0EN field.	
		0	Queue Not Enabled
		1	Queue Enabled for AV
		2	Queue Enabled for DCB/Generic
		3	Reserved
3:2 (R/W)	RXQ1EN	Receive Queue 1 Enable. The `EMAC_RXQ_CTL0.RXQ1EN` field is similar to the RXQ0EN field.	
		0	Queue Not Enabled
		1	Queue Enabled for AV
		2	Queue Enabled for DCB/Generic
		3	Reserved

Table 30-203: EMAC_RXQ_CTL0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1:0 (R/W)	RXQ0EN	Receive Queue 0 Enable. The `EMAC_RXQ_CTL0.RXQ0EN` field indicates whether Rx queue 0 is enabled for AV or DCB.	
		0	Queue Not Enabled
		1	Queue Enabled for AV
		2	Queue Enabled for DCB/Generic
		3	Reserved

Receive Queue Control 1 Register

The EMAC_RXQ_CTL1 register controls the routing of multicast, broadcast, AV, DCB, and untagged packets to the Rx queues.

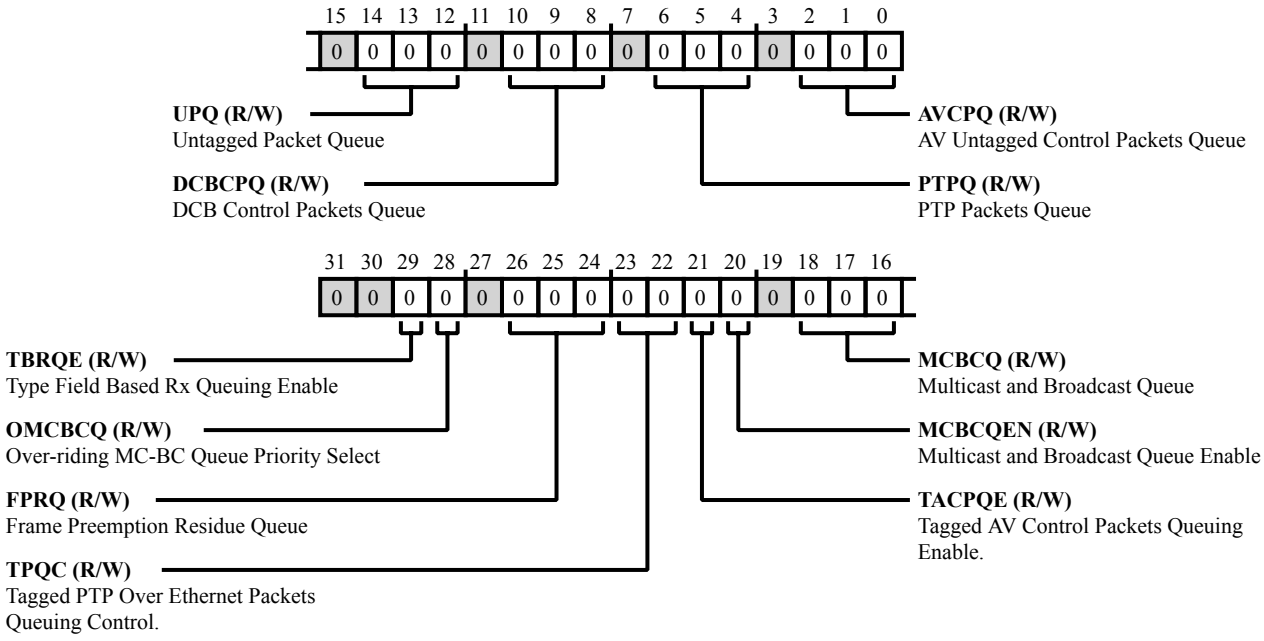

Figure 30-149: EMAC_RXQ_CTL1 Register Diagram

Table 30-204: EMAC_RXQ_CTL1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
29 (R/W)	TBRQE	Type Field Based Rx Queuing Enable. When the EMAC_RXQ_CTL1.TBRQE bit is set, it enables the Type field based Rx queuing where the Type field of received packet is compared with programmed TYP field in MAC_TMRQ_Regs(n) and if a match occurs the packet is routed to the corresponding TMRQ field.	
28 (R/W)	OMCBCQ	Over-riding MC-BC Queue Priority Select. When set (=1), the EMAC_RXQ_CTL1.OMCBCQ bit indicates that the priority of MCBCQ is reduced and the received packet is first routed to PTPQ, AVCPQ, DCBCPQ depending on packet type. When cleared (=0), the EMAC_RXQ_CTL1.OMCBCQ bit indicates that the received multicast/broadcast packet is routed to MCBCQ.	
		0	Overriding MCBCQ Priority Disabled
		1	Overriding MCBCQ Priority Enabled

Table 30-204: EMAC_RXQ_CTL1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
26:24 (R/W)	FPRQ	Frame Preemption Residue Queue. The EMAC_RXQ_CTL1.FPRQ field holds the Rx queue number to which the residual preemption frames must be forwarded. Preemption frames that are tagged and pass the SA/DA/VLAN filtering are routed based on PSRQ and all other frames are treated as residual frames and is routed to the queue number mentioned in this field. The queue 0 is used as a default queue for express frames, so this field cannot be programmed to a value 0.	
23:22 (R/W)	TPQC	Tagged PTP Over Ethernet Packets Queuing Control.. The EMAC_RXQ_CTL1.TPQC field controls the routing of the VLAN Tagged PTPoE packets. The following programmable options are allowed: - 2'b00: VLAN Tagged PTPoE packets are routed as generic VLAN Tagged packet (based on PSRQ for only non-AV enabled Rx queue). - 2'b01: VLAN Tagged PTPoE packets are routed to Rx queue specified by PTPQ field (Rx queue can be enabled for AV or non-AV traffic). - 2'b10: VLAN Tagged PTPoE packets are routed to only AV enabled Rx queues based on PSRQ. - 2'b11: Reserved If DWC_EQOS_AV_ENABLE is not selected in the configuration, the following programmable options are allowed. - 1'b0: VLAN Tagged PTPoE packets are routed as generic VLAN Tagged packet (based on PSRQ for DCB/Generic enabled Rx queues). - 1'b1: VLAN Tagged PTPoE packets are routed to Rx queue specified by PTPQ field.	
21 (R/W)	TACPQE	Tagged AV Control Packets Queuing Enable.. When the EMAC_RXQ_CTL1.TACPQE bit is set, the MAC routes the received Tagged AV Control packets to the Rx queue specified by AVCPQ field. When EMAC_RXQ_CTL1.TACPQE = 0, the MAC routes the received Tagged AV Control packets based on the tag priority matching the PSRQn fields in EMAC_RXQ_CTL2 and EMAC_RXQ_CTL3 registers.	
		0	Tagged AV Control Packets Queuing is Disabled
		1	Tagged AV Control Packets Queuing is Enabled
20 (R/W)	MCBCQEN	Multicast and Broadcast Queue Enable. The EMAC_RXQ_CTL1.MCBCQEN bit specifies that multicast or broadcast packets routing to the Rx queue is enabled and the multicast or broadcast packets must be routed to Rx queue specified in the EMAC_RXQ_CTL1.MCBCQ field.	
		0	Multicast and Broadcast Queue is Disabled
		1	Multicast and Broadcast Queue is Enabled

Table 30-204: EMAC_RXQ_CTL1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
18:16 (R/W)	MCBCQ	Multicast and Broadcast Queue. The `EMAC_RXQ_CTL1.MCBCQ` field specifies the Rx queue onto which Multicast or Broadcast Packets are routed. Any Rx queue enabled for Generic/DCB/AV traffic can be used to route the Multicast or Broadcast Packets.	
		0	Receive Queue 0
		1	Receive Queue 1
		2	Receive Queue 2
		3	Receive Queue 3
		4	Receive Queue 4
		5	Receive Queue 5
		6	Receive Queue 6
		7	Receive Queue 7
14:12 (R/W)	UPQ	Untagged Packet Queue. The `EMAC_RXQ_CTL1.UPQ` field indicates the Rx queue to which untagged packets are to be routed. Any Rx queue enabled for generic/DCB/AV traffic can be used to route the untagged packets.	
		0	Receive Queue 0
		1	Receive Queue 1
		2	Receive Queue 2
		3	Receive Queue 3
		4	Receive Queue 4
		5	Receive Queue 5
		6	Receive Queue 6
		7	Receive Queue 7
10:8 (R/W)	DCBCPQ	DCB Control Packets Queue. The `EMAC_RXQ_CTL1.DCBCPQ` field specifies the Rx queue on which the received DCB control packets are routed. The DCB data packets are routed based on the EMAC_Q[n]_TXFLOW_CTL.PRSQ field of corresponding queue.	
		0	Receive Queue 0
		1	Receive Queue 1
		2	Receive Queue 2
		3	Receive Queue 3
		4	Receive Queue 4

Table 30-204: EMAC_RXQ_CTL1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		5	Receive Queue 5
		6	Receive Queue 6
		7	Receive Queue 7
6:4 (R/W)	PTPQ	PTP Packets Queue. The `EMAC_RXQ_CTL1.PTPQ` field specifies the Rx queue on which the PTP packets sent over the Ethernet payload (not over IPv4 or IPv6) are routed. When EMAC_TM_CTL.AV8021ASMEN = 1, only untagged PTP over Ethernet packets are routed on an Rx queue. If the bit is not set, then based on programming of the `EMAC_RXQ_CTL1.TPQC` field, both tagged and untagged PTPoE packets can be routed to this Rx queue.	
		0	Receive Queue 0
		1	Receive Queue 1
		2	Receive Queue 2
		3	Receive Queue 3
		4	Receive Queue 4
		5	Receive Queue 5
		6	Receive Queue 6
		7	Receive Queue 7
2:0 (R/W)	AVCPQ	AV Untagged Control Packets Queue. The `EMAC_RXQ_CTL1.AVCPQ` field specifies the receive queue on which the received AV tagged and untagged control packets are routed. The AV tagged (when `EMAC_RXQ_CTL1.TACPQE`= 1) and untagged control packets are routed to receive queue specified by this field.	
		0	Receive Queue 0
		1	Receive Queue 1
		2	Receive Queue 2
		3	Receive Queue 3
		4	Receive Queue 4
		5	Receive Queue 5
		6	Receive Queue 6
		7	Receive Queue 7

Receive Queue Control 2 Register

The EMAC_RXQ_CTL2 register controls the routing of tagged packets based on the USP (user priority) field of the received packets to the Rx queues 0 to 3.

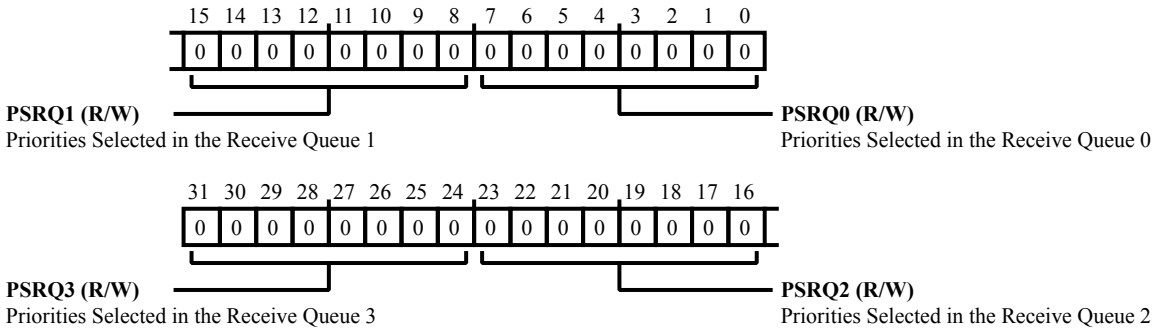

Figure 30-150: EMAC_RXQ_CTL2 Register Diagram

Table 30-205: EMAC_RXQ_CTL2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	PSRQ3	Priorities Selected in the Receive Queue 3. The EMAC_RXQ_CTL2.PSRQ3 field selects the priorities assigned to Rx queue 3. All packets with priorities that match the values set in this field are routed to Rx queue 3. For example, if PSRQ3[6, 3] are set, packets with USP field equal to 3 or 6 are routed to Rx queue 3. The software must ensure that the content of this field is mutually exclusive to the PSRQ fields for other queues, that is, the same priority is not mapped to multiple Rx queues. This field also determines the priorities to be included in the PFC packet sent to remote station when Rx queue 3 crosses the flow control threshold settings.
23:16 (R/W)	PSRQ2	Priorities Selected in the Receive Queue 2. The EMAC_RXQ_CTL2.PSRQ2 field selects the priorities assigned to Rx queue 2. All packets with priorities that match the values set in this field are routed to Rx queue 2. For example, if PSRQ2[1, 0] are set, packets with USP field equal to 1 or 0 are routed to Rx queue 2. The software must ensure that the content of this field is mutually exclusive to the PSRQ fields for other queues, that is, the same priority is not mapped to multiple Rx queues. This field also determines the priorities to be included in the PFC packet sent to remote station when Rx queue 2 crosses the flow control threshold settings.

Table 30-205: EMAC_RXQ_CTL2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15:8 (R/W)	PSRQ1	Priorities Selected in the Receive Queue 1. The `EMAC_RXQ_CTL2.PSRQ1` field selects the priorities assigned to Rx queue 1. All packets with priorities that match the values set in this field are routed to Rx queue 1. For example, if PSRQ1[4] is set, packets with USP field equal to 4 are routed to Rx queue 1. The software must ensure that the content of this field is mutually exclusive to the PSRQ fields for other queues, that is, the same priority is not mapped to multiple Rx queues. This field also determines the priorities to be included in the PFC packet sent to remote station when Rx queue 1 crosses the flow control threshold settings.
7:0 (R/W)	PSRQ0	Priorities Selected in the Receive Queue 0. The `EMAC_RXQ_CTL2.PSRQ0` field selects the priorities assigned to Rx queue 0. All packets with priorities that match the values configured in this field are routed to Rx queue 0. For example, if PSRQ0[5] is set, packets with USP field equal to 5 are routed to Rx queue 0. The software must ensure that the content of this field is mutually exclusive to the PSRQ fields for other queues, that is, the same priority is not mapped to multiple Rx queues. This field also determines the priorities to be included in the PFC packet sent to remote station when Rx queue 0 crosses the flow control threshold settings.

Receive Queue Control 3 Register

The EMAC_RXQ_CTL3 register controls the routing of tagged packets based on the USP (user priority) field of the received packets to the Rx queues 4 to 7.

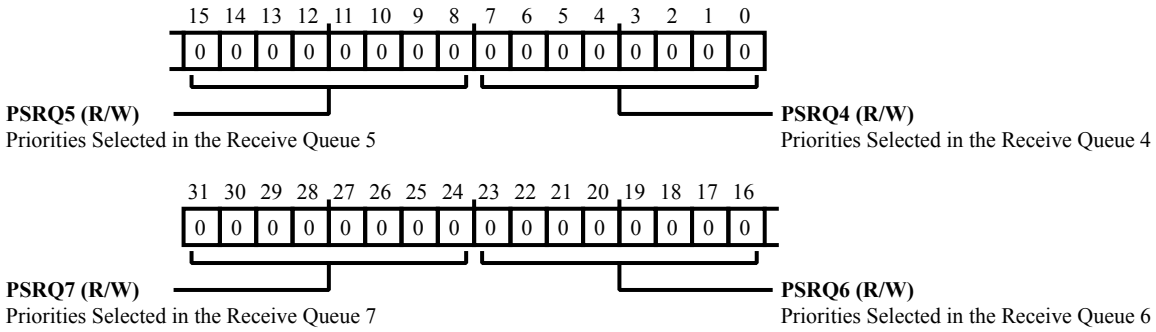

Figure 30-151: EMAC_RXQ_CTL3 Register Diagram

Table 30-206: EMAC_RXQ_CTL3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	PSRQ7	Priorities Selected in the Receive Queue 7. The EMAC_RXQ_CTL3.PSRQ7 field selects the priorities assigned to Rx queue 7. All packets with priorities that match the values set in this field are routed to Rx queue 7. For example, if PSRQ7[7, 4] are set, packets with USP field equal to 7 or 4 are routed to Rx queue 7. The software must ensure that the content of this field is mutually exclusive to the PSRQ fields for other queues, that is, the same priority is not mapped to multiple Rx queues. This field also determines the priorities to be included in the PFC packet sent to remote station when Rx queue 7 crosses the flow control threshold settings.
23:16 (R/W)	PSRQ6	Priorities Selected in the Receive Queue 6. The EMAC_RXQ_CTL3.PSRQ6 field selects the priorities assigned to Rx queue 6. All packets with priorities that match the values set in this field are routed to Rx queue 6. For example, if PSRQ6[5] are set, packets with USP field equal to 5 are routed to Rx queue 6. The software must ensure that the content of this field is mutually exclusive to the PSRQ fields for other queues, that is, the same priority is not mapped to multiple Rx queues. This field also determines the priorities to be included in the PFC packet sent to remote station when Rx queue 6 crosses the flow control threshold settings.

Table 30-206: EMAC_RXQ_CTL3 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15:8 (R/W)	PSRQ5	Priorities Selected in the Receive Queue 5. The `EMAC_RXQ_CTL3.PSRQ5` field selects the priorities assigned to Rx queue 5. All packets with priorities that match the values set in this field are routed to Rx queue 5. For example, if PSRQ5[6] is set, packets with USP field equal to 6 are routed to Rx queue 5. The software must ensure that the content of this field is mutually exclusive to the PSRQ fields for other queues, that is, the same priority is not mapped to multiple Rx queues. This field also determines the priorities to be included in the PFC packet sent to remote station when Rx queue 5 crosses the flow control threshold settings.
7:0 (R/W)	PSRQ4	Priorities Selected in the Receive Queue 4. The `EMAC_RXQ_CTL3.PSRQ4` field selects the priorities assigned to Rx queue 4. All packets with priorities that match the values set in this field are routed to Rx queue 4. For example, if PSRQ4[7:4] is set, packets with USP field equal to 7, 6, 5, or 4 are routed to Rx queue 4. The software must ensure that the content of this field is mutually exclusive to the PSRQ fields for other queues, that is, the same priority is not mapped to multiple Rx queues. This field also determines the priorities to be included in the PFC packet sent to remote station when Rx queue 4 crosses the flow control threshold settings.

Receive Queue Control 4 Register

The EMAC_RXQ_CTL4 register controls the routing of unicast and multicast packets that fail the Destination or Source address filter to the Rx queues.

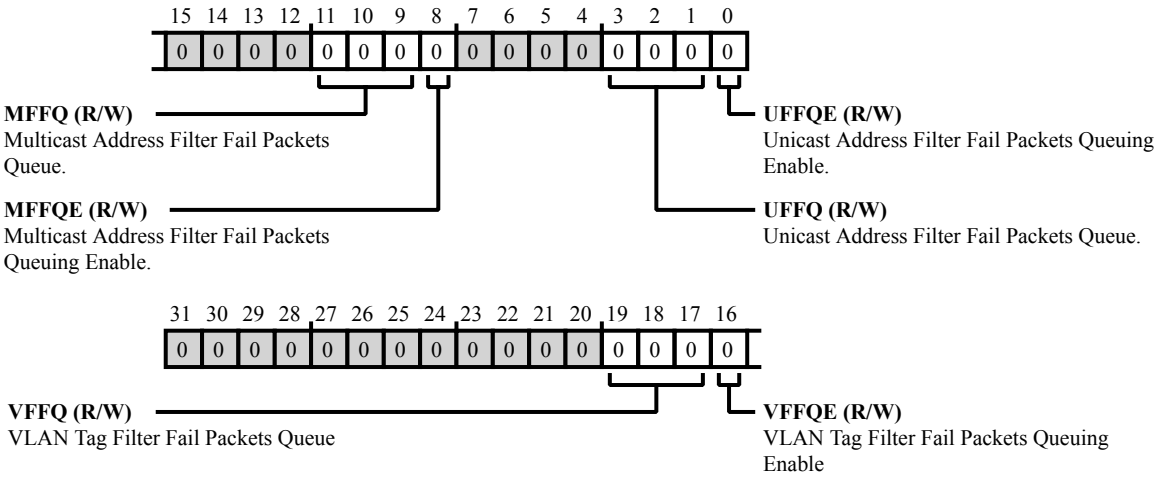

Figure 30-152: EMAC_RXQ_CTL4 Register Diagram

Table 30-207: EMAC_RXQ_CTL4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
19:17 (R/W)	VFFQ	VLAN Tag Filter Fail Packets Queue. The EMAC_RXQ_CTL4.VFFQ field holds the Rx queue number to which the tagged packets failing the Destination or Source Address filter (and EMAC_RXQ_CTL4.UFFQE/ EMAC_RXQ_CTL4.MFFQE = 0) or failing the VLAN tag filter must be routed to. The EMAC_RXQ_CTL4.VFFQ field is valid only when EMAC_RXQ_CTL4.VFFQE = 1.	
16 (R/W)	VFFQE	VLAN Tag Filter Fail Packets Queuing Enable. When the EMAC_RXQ_CTL4.VFFQE bit is set, the tagged packets which fail the Destination or Source address filter or fail the VLAN tag filter, are routed to the Rx queue number programmed in the EMAC_RXQ_CTL4.VFFQ field. When EMAC_RXQ_CTL4.VFFQE = 0, the tagged packets which fail the Destination or Source address filter or fail the VLAN tag filter are routed based on other routing options. The EMAC_RXQ_CTL4.VFFQE bit is valid only when the EMAC_MACPKT_FILT.RA = 1.	
		0	VLAN Tag Filter Fail Packets Queuing is Disabled
		1	VLAN Tag Filter Fail Packets Queuing is Enabled

Table 30-207: EMAC_RXQ_CTL4 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
11:9 (R/W)	MFFQ	Multicast Address Filter Fail Packets Queue.. The EMAC_RXQ_CTL4.MFFQ field holds the Rx queue number to which the Multicast packets failing the Destination or Source Address filter are routed to. The EMAC_RXQ_CTL4.MFFQ field is valid only when EMAC_RXQ_CTL4.MFFQE = 1.	
8 (R/W)	MFFQE	Multicast Address Filter Fail Packets Queuing Enable.. When the EMAC_RXQ_CTL4.MFFQE bit is set, the Multicast packets which fail the Destination or Source address filter is routed to the Rx queue Number programmed in the EMAC_RXQ_CTL4.MFFQ. When EMAC_RXQ_CTL4.MFFQE = 0, the Multicast packets which fail the Destination or Source address filter is routed based on other routing options. The EMAC_RXQ_CTL4.MFFQE bit is valid only when EMAC_MACPKT_FILT.RA = 1.	
		0	Multicast Address Filter Fail Packets Queuing is Disabled
		1	Multicast Address Filter Fail Packets Queuing is Enabled
3:1 (R/W)	UFFQ	Unicast Address Filter Fail Packets Queue.. The EMAC_RXQ_CTL4.UFFQ field holds the Rx queue number to which the Unicast packets failing the Destination or Source Address filter are routed to. The EMAC_RXQ_CTL4.UFFQ field is valid only when EMAC_RXQ_CTL4.UFFQE = 1.	
0 (R/W)	UFFQE	Unicast Address Filter Fail Packets Queuing Enable.. When the EMAC_RXQ_CTL4.UFFQE bit is set, the Unicast packets which fail the Destination or Source address filter is routed to the Rx queue number programmed in the EMAC_RXQ_CTL4.UFFQ field. When EMAC_RXQ_CTL4.UFFQE = 0, the Unicast packets which fail the Destination or Source address filter is routed based on other routing options. The EMAC_RXQ_CTL4.UFFQE bit is valid only when EMAC_MACPKT_FILT.RA = 1.	
		0	Unicast Address Filter Fail Packets Queuing is Disabled
		1	Unicast Address Filter Fail Packets Queuing is Enabled

Receive Flow Control Register

The EMAC_RXFLOW_CTL register controls the pausing of MAC transmit based on the received pause packet.

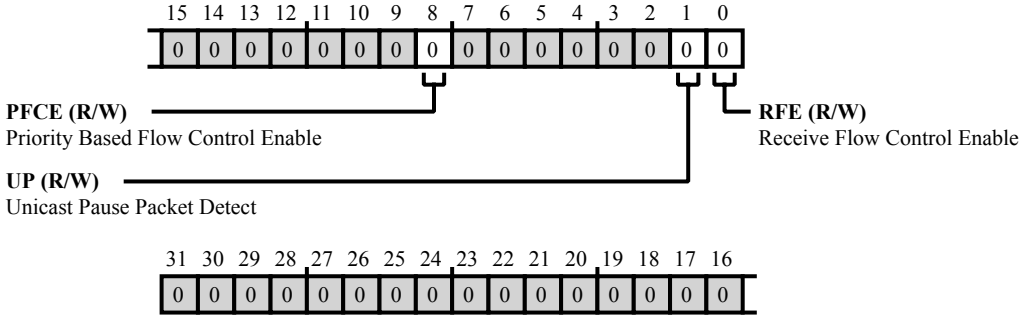

Figure 30-153: EMAC_RXFLOW_CTL Register Diagram

Table 30-208: EMAC_RXFLOW_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W)	PFCE	Priority Based Flow Control Enable. When the EMAC_RXFLOW_CTL.PFCE bit is set, it enables generation and reception of priority-based flow control (PFC) packets. When EMAC_RXFLOW_CTL.PFCE = 0, it enables generation and reception of 802.3x Pause control packets.	
		0	Priority Based Flow Control is Disabled
		1	Priority Based Flow Control is Enabled
1 (R/W)	UP	Unicast Pause Packet Detect. A pause packet is processed when it has the unique multicast address specified in the IEEE 802.3. When the EMAC_RXFLOW_CTL.UP bit is set, the MAC can also detect Pause packets with unicast address of the station. This unicast address should be as specified in EMAC_ADDR0_HI and EMAC_ADDR0_LO. When EMAC_RXFLOW_CTL.UP = 0, the MAC only detects Pause packets with unique multicast address. Note: The MAC does not process a Pause packet if the multicast address is different from the unique multicast address. This is also applicable to the received PFC packet when the Priority Flow Control (PFC) is enabled. The unique multicast address (0x01_80_C2_00_00_01) is as specified in IEEE 802.1 Qbb-2011.	
		0	Unicast Pause Packet Detect Disabled
		1	Unicast Pause Packet Detect Enabled

Table 30-208: EMAC_RXFLOW_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	RFE	Receive Flow Control Enable. When the `EMAC_RXFLOW_CTL.RFE` bit is set and the MAC is operating in full-duplex mode, the MAC decodes the received Pause packet and disables its transmitter for a specified (Pause) time. When `EMAC_RXFLOW_CTL.RFE` = 0 or the MAC is operating in half-duplex mode, the decode function of the Pause packet is disabled. When PFC is enabled, flow control is enabled for PFC packets. The MAC decodes the received PFC packet and disables the Transmit queue, with matching priorities, for a duration of received Pause time.	
		0	Receive Flow Control is Disabled
		1	Receive Flow Control is Enabled

Receive Transmit Status Register

The EMAC_RXTX_STAT register contains the receive and transmit error status.

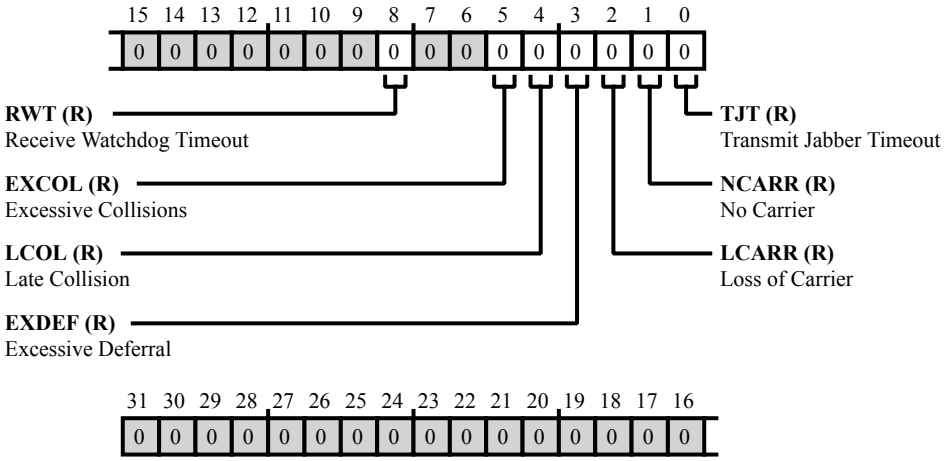

Figure 30-154: EMAC_RXTX_STAT Register Diagram

Table 30-209: EMAC_RXTX_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/NW)	RWT	Receive Watchdog Timeout. The EMAC_RXTX_STAT.RWT bit is set when a packet with length greater than 2,048 bytes is received (10, 240 bytes when jumbo packet mode is enabled (EMAC_MAC_CFG.JE = 1) and EMAC_MAC_CFG.WD = 0. The EMAC_RXTX_STAT.RWT bit is set when a packet with length greater than 16,383 bytes is received and EMAC_MAC_CFG.WD = 1. Access restriction applies. Clears on read (or write of 1 when EMAC_CSR_SW_CTL.RCWE = 1). Self-set to 1 on internal event.	
		0	No Receive Watchdog Timeout
		1	Receive Watchdog Timed Out
5 (R/NW)	EXCOL	Excessive Collisions. When EMAC_MTL_OPMODE.DTXSTS = 1, the EMAC_RXTX_STAT.EXCOL bit indicates that the transmission aborted after 16 successive collisions while attempting to transmit the current packet. When EMAC_MAC_CFG.DR = 1, the EMAC_RXTX_STAT.EXCOL bit is set after the first collision and the packet transmission is aborted. Access restriction applies. Clears on read (or write of 1 when EMAC_CSR_SW_CTL.RCWE = 1). Self-set to 1 on internal event.	
		0	No Collision
		1	Excessive Collision is Sensed

Table 30-209: EMAC_RXTX_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/NW)	LCOL	Late Collision. When EMAC_MTL_OPMODE.DTXSTS = 1, the `EMAC_RXTX_STAT.LCOL` bit indicates that the packet transmission aborted because a collision occurred after the collision window (64 bytes including Preamble in MII mode; 512 bytes including Preamble and Carrier Extension in GMII mode). The `EMAC_RXTX_STAT.LCOL` bit is not valid if the Underflow error occurs. Access restriction applies. Clears on read (or write of 1 when EMAC_CSR_SW_CTL.RCWE = 1). Self-set to 1 on internal event.	
		0	No Collision
		1	Late Collision is Sensed
3 (R/NW)	EXDEF	Excessive Deferral. When EMAC_MTL_OPMODE.DTXSTS = 1 and EMAC_MAC_CFG.DC = 1, the `EMAC_RXTX_STAT.EXDEF` bit indicates that the transmission ended because of excessive deferral of over 24,288 bit times (155,680 in 1000/2500 Mbps mode or when jumbo packet mode is enabled (EMAC_MAC_CFG.JE = 1)). Access restriction applies. Clears on read (or write of 1 when EMAC_CSR_SW_CTL.RCWE = 1). Self-set to 1 on internal event.	
		0	No Excessive Deferral
		1	Excessive Deferral
2 (R/NW)	LCARR	Loss of Carrier. When EMAC_MTL_OPMODE.DTXSTS = 1, the `EMAC_RXTX_STAT.LCARR` bit indicates that the loss of carrier occurred during packet transmission, that is, the ETHx_CRS signal was inactive for one or more transmission clock periods during packet transmission. The `EMAC_RXTX_STAT.LCARR` bit is valid only for packets transmitted without collision. Access restriction applies. Clears on read (or write of 1 when EMAC_CSR_SW_CTL.RCWE = 1). Self-set to 1 on internal event.	
		0	Carrier is Present
		1	Loss of Carrier
1 (R/NW)	NCARR	No Carrier. When EMAC_MTL_OPMODE.DTXSTS = 1, the `EMAC_RXTX_STAT.NCARR` bit indicates that the carrier signal from the PHY is not present at the end of preamble transmission. Access restriction applies. Clears on read (or write of 1 when EMAC_CSR_SW_CTL.RCWE = 1). Self-set to 1 on internal event.	
		0	Carrier is Present
		1	No Carrier

Table 30-209: EMAC_RXTX_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/NW)	TJT	Transmit Jabber Timeout. The `EMAC_RXTX_STAT.TJT` bit indicates that the Transmit Jabber Timer expired which happens when the packet size exceeds 2,048 bytes (10,240 bytes when jumbo packet mode is enabled (EMAC_MAC_CFG.JE = 1) and EMAC_MAC_CFG.JD = 0. The `EMAC_RXTX_STAT.TJT` bit is set when the packet size exceeds 16,383 bytes and the EMAC_MAC_CFG.JD = 1. Access restriction applies. Clears on read (or write of 1 when EMAC_CSR_SW_CTL.RCWE = 1). Self-set to 1 on internal event.	
		0	No Transmit Jabber Timeout
		1	Transmit Jabber Timeout Occurred

Source Port Identity 0 Register

The EMAC_SRCPRT_IDNTY0 register contains bits[31:0] of the 80-bit source port identity of the PTP node.

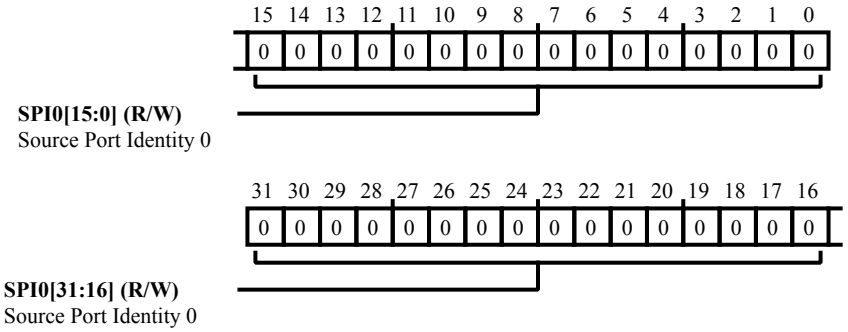

Figure 30-155: EMAC_SRCPRT_IDNTY0 Register Diagram

Table 30-210: EMAC_SRCPRT_IDNTY0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	SPI0	Source Port Identity 0. The EMAC_SRCPRT_IDNTY0.SPI0 field indicates bits [31:0] of sourcePortIdentity of PTP node.

Source Port Identity 1 Register

The EMAC_SRCPRT_IDNTY1 register contains bits[63:32] of the 80-bit Source Port Identity of the PTP node.

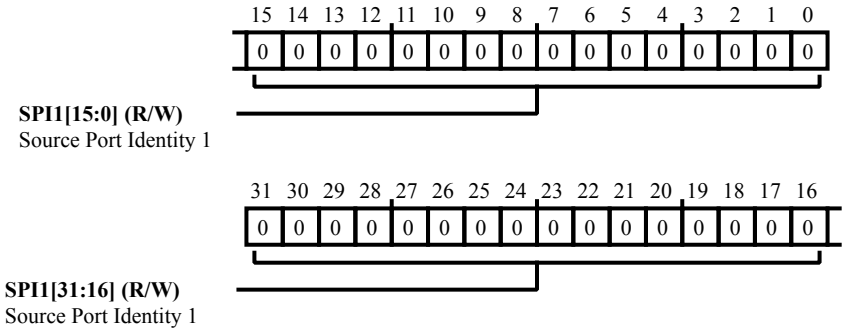

Figure 30-156: EMAC_SRCPRT_IDNTY1 Register Diagram

Table 30-211: EMAC_SRCPRT_IDNTY1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	SPI1	Source Port Identity 1. The EMAC_SRCPRT_IDNTY1.SPI1 field indicates bits [63:32] of sourcePortIdentity of PTP node.

Source Port Identity 2 Register

The EMAC_SRCPRT_IDNTY2 register contains bits[79:64] of the 80-bit Source Port Identity of the PTP node.

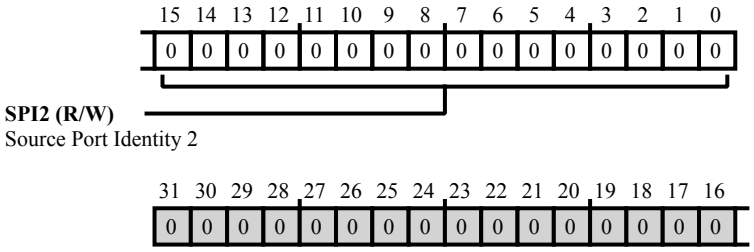

Figure 30-157: EMAC_SRCPRT_IDNTY2 Register Diagram

Table 30-212: EMAC_SRCPRT_IDNTY2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	SPI2	Source Port Identity 2. The EMAC_SRCPRT_IDNTY2.SPI2 field indicates bits [79:64] of sourcePortIdentity of PTP node.

Subsecond Increment Register

The EMAC_TM_SUBSEC register specifies the value to be added to the internal system time register every cycle of PTP clock.

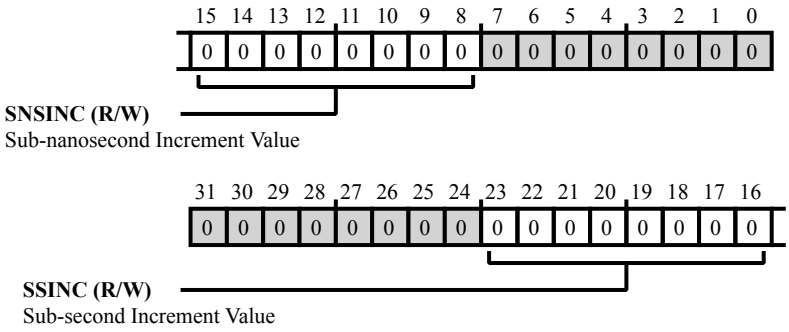

Figure 30-158: EMAC_TM_SUBSEC Register Diagram

Table 30-213: EMAC_TM_SUBSEC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
23:16 (R/W)	SSINC	Sub-second Increment Value. The value programmed in the EMAC_TM_SUBSEC.SSINC field is accumulated every PTP clock cycle with the contents of the sub-second register. For example, when the PTP clock is 50 MHz (period is 20 ns), program 20 (0x14) when the EMAC_TM_NSEC register has an accuracy of 1 ns (EMAC_TM_CTL.TSCTRLSSR = 1). When EMAC_TM_CTL.TSCTRLSSR = 0, the EMAC_TM_NSEC register has a resolution of ~0.465 ns. In this case, program a value of 43 (0x2B) which is derived by 20 ns/0.465.
15:8 (R/W)	SNSINC	Sub-nanosecond Increment Value. The EMAC_TM_SUBSEC.SNSINC field contains the sub-nanosecond increment value, represented in nanoseconds multiplied by 2^8. This value is accumulated with the sub-nanoseconds field of the subsecond register. For example, when EMAC_TM_CTL.TSCTRLSSR = 1. and if the required increment is 5.3ns, then EMAC_TM_SUBSEC.SSINC should be 0x05 and EMAC_TM_SUBSEC.SNSINC should be 0x4C.

System Time Higher Word Seconds Register

System Time - Higher Word Seconds register.

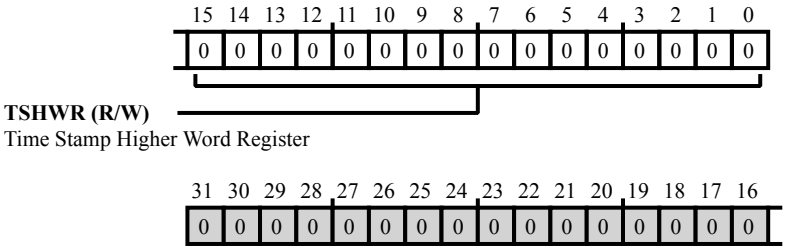

Figure 30-159: EMAC_TM_HISEC Register Diagram

Table 30-214: EMAC_TM_HISEC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	TSHWR	Time Stamp Higher Word Register. The `EMAC_TM_HISEC.TSHWR` field contains the most-significant 16-bits of time stamp seconds value. The `EMAC_TM_HISEC` register is optional. Add this register by selecting the Add IEEE 1588 Higher Word Register option. The `EMAC_TM_HISEC` register is directly written to initialize the value and it is incremented when there is an overflow from 32 bits of the EMAC_TM_SEC register. Access restriction applies. Updated based on the event. Write 1 to set. Write 0 to clear.

System Time Nanoseconds Register

The EMAC_TM_NSEC register, along with System Time Seconds register, indicates the current value of the system time maintained by the MAC.

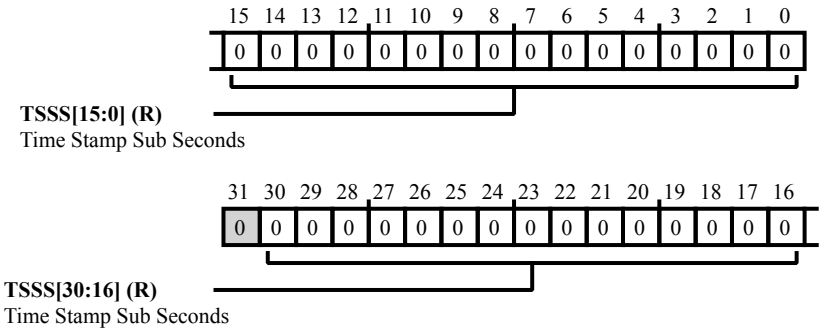

Figure 30-160: EMAC_TM_NSEC Register Diagram

Table 30-215: EMAC_TM_NSEC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
30:0 (R/NW)	TSSS	Time Stamp Sub Seconds. The value in the EMAC_TM_NSEC.TSSS field has the sub-second representation of time, with an accuracy of 0.46 ns. (EMAC_TM_CTL.TSCTRLSSR = 1), each bit represents 1 ns. The maximum value is 0x3B9A_C9FF after which it rolls over to zero.

System Time Nanoseconds Update Register

MAC System Time Nanoseconds Update register.

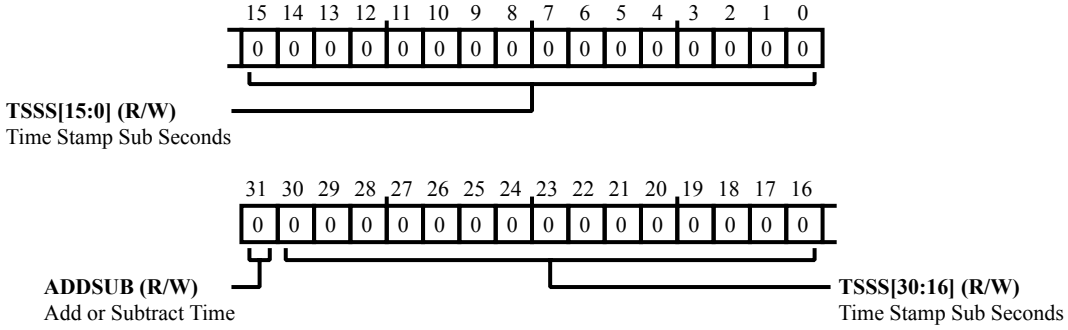

Figure 30-161: EMAC_TM_NSECUPDT Register Diagram

Table 30-216: EMAC_TM_NSECUPDT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	ADDSUB	Add or Subtract Time. When the `EMAC_TM_NSECUPDT.ADDSUB` bit is set, the time value is subtracted with the contents of the update register. When `EMAC_TM_NSECUPDT.ADDSUB` = 0, the time value is added with the contents of the update register.	
		0	Add Time
		1	Subtract Time

Table 30-216: EMAC_TM_NSECUPDT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
30:0 (R/W)	TSSS	Time Stamp Sub Seconds. The `EMAC_TM_NSECUPDT.TSSS` field is the sub-seconds part of the update. When EMAC_TM_NSECUPDT.ADDSUB = 1, the `EMAC_TM_NSECUPDT.TSSS` field must be programmed with the complement of the sub-seconds part of the update value as described. When EMAC_TM_NSECUPDT.ADDSUB = 0, the `EMAC_TM_NSECUPDT.TSSS` field must be programmed with the sub-seconds part of the update value, with an accuracy based on the EMAC_TM_CTL.TSCTRLSSR bit. For EMAC_TM_CTL.TSCTRLSSR = 1: -- The programmed value must be 10^9 - <sub-second value>. -- Each bit represents 1 ns and the programmed value should not exceed 0x3B9A_C9FF. For EMAC_TM_CTL.TSCTRLSSR = 0: -- The programmed value must be 2^{31} - <sub-second_value>. -- Each bit represents an accuracy of 0.46 ns. For example, to subtract 2.000000001 seconds from the system time, then the EMAC_TM_NSECUPDT.TSSS field must be 0x7FFF_FFFF (that is, 2^{31} - 1), when EMAC_TM_CTL.TSCTRLSSR = 0 and 0x3B9A_C9FF (that is, 10^9 - 1), when EMAC_TM_CTL.TSCTRLSSR = 1.

System Time Seconds Register

The EMAC_TM_SEC register, along with the EMAC_TM_NSEC register, indicates the current value of the system time maintained by the MAC. Though it is updated on a continuous basis, there is some delay from the actual time because of clock domain transfer latencies (from PTP clock to SCLK0).

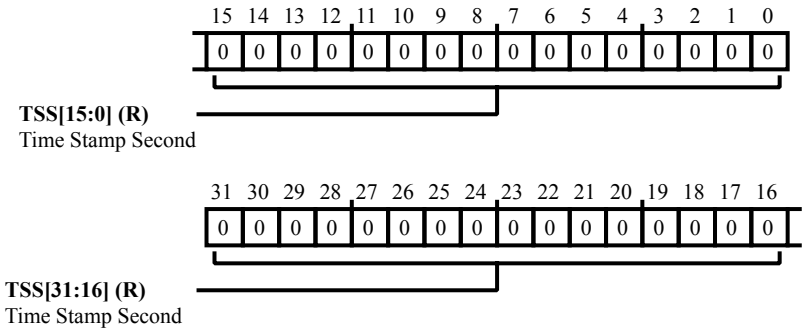

Figure 30-162: EMAC_TM_SEC Register Diagram

Table 30-217: EMAC_TM_SEC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	TSS	Time Stamp Second. The value in the EMAC_TM_SEC.TSS field indicates the current value in seconds of the System Time maintained by the MAC.

System Time Seconds Update Register

The EMAC_TM_SECUPDT register, along with the EMAC_TM_NSECUPDT register, initializes or updates the system time maintained by the MAC. Write both registers before setting the EMAC_TM_CTL.TSINIT or EMAC_TM_CTL.TSUPDT bits.

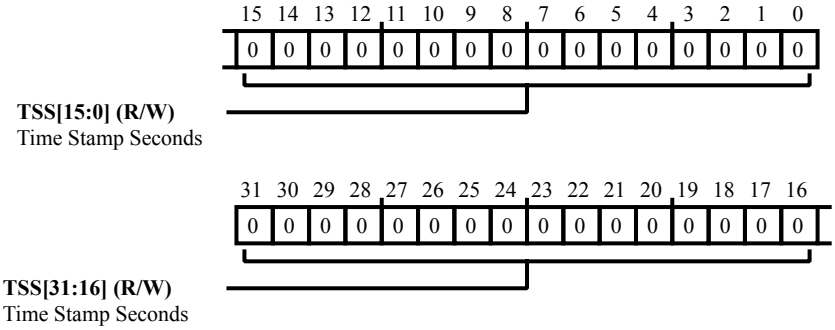

Figure 30-163: EMAC_TM_SECUPDT Register Diagram

Table 30-218: EMAC_TM_SECUPDT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	TSS	Time Stamp Seconds. The value in the EMAC_TM_SECUPDT.TSS field is the seconds part of the update. When EMAC_TM_NSECUPDT.ADDSUB = 0, the EMAC_TM_SECUPDT.TSS field must be programmed with the seconds part of the update value. When EMAC_TM_NSECUPDT.ADDSUB = 1, the EMAC_TM_SECUPDT.TSS field must be programmed with the complement of the seconds part of the update value. For example, to subtract 2.000000001 seconds from the system time, the EMAC_TM_SECUPDT.TSS field must be 0xFFFF_FFFE (that is, 2^{32} - 2).

Time Stamp Addend Register

The EMAC_TM_ADDEND register value is used only when the system time is configured for Fine Update mode (EMAC_TM_CTL.TSCFUPDT). The content of this register is added to a 32-bit accumulator in every clock cycle (PTP clock) and the system time is updated when the accumulator overflows.

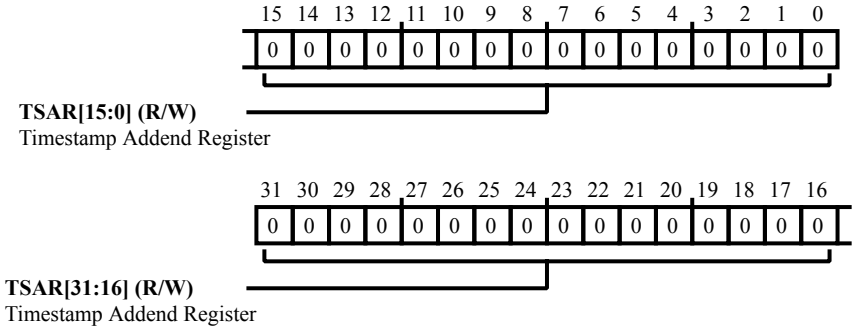

Figure 30-164: EMAC_TM_ADDEND Register Diagram

Table 30-219: EMAC_TM_ADDEND Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	TSAR	Timestamp Addend Register. The EMAC_TM_ADDEND.TSAR field indicates the 32-bit time value to be added to the Accumulator register to achieve time synchronization.

Time Stamp Control Register

The EMAC_TM_CTL register controls the operation of the System Time generator and processing of PTP packets for time stamping in the receiver.

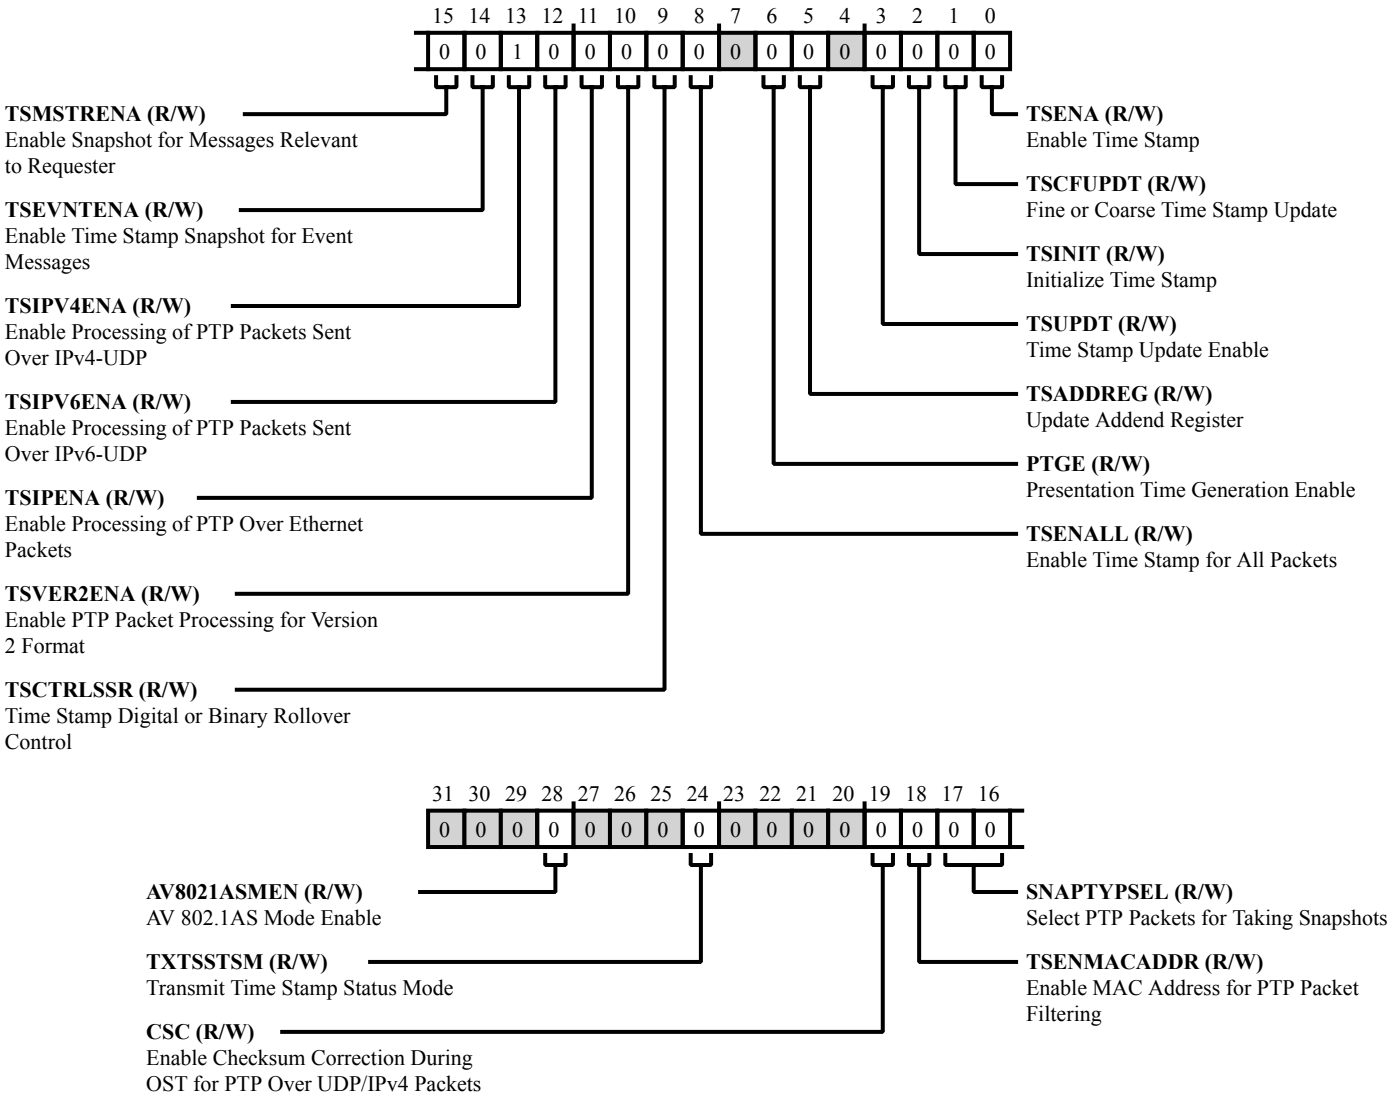

Figure 30-165: EMAC_TM_CTL Register Diagram

Table 30-220: EMAC_TM_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
28 (R/W)	AV8021ASMEN	AV 802.1AS Mode Enable. When the EMAC_TM_CTL.AV8021ASMEN bit is set, the MAC processes only untagged PTP over Ethernet packets for providing PTP status and capturing time stamp snapshots, that is, IEEE 802.1AS mode of operation. When PTP offload feature is enabled, for the purpose of PTP offload, the transport specific field in the PTP header is generated and checked based on the value of the EMAC_TM_CTL.AV8021ASMEN bit.	
		0	AV 802.1AS Mode is Disabled
		1	AV 802.1AS Mode is Enabled
24 (R/W)	TXTSSTSM	Transmit Time Stamp Status Mode. When the EMAC_TM_CTL.TXTSSTSM bit is set, the MAC overwrites the earlier transmit time stamp status even if it is not read by the software. The MAC indicates this by setting the EMAC_TXTMSTAT_NSEC.TXTSSMIS bit. When EMAC_TM_CTL.TXTSSTSM = 0, the MAC ignores the time stamp status of current packet if the time stamp status of previous packet is not read by the software. The MAC indicates this by setting the EMAC_TXTMSTAT_NSEC.TXTSSMIS bit.	
		0	Disable
		1	Enable
19 (R/W)	CSC	Enable Checksum Correction During OST for PTP Over UDP/IPv4 Packets. When the EMAC_TM_CTL.CSC bit is set, the last two bytes of PTP message sent over UDP/IPv4 is updated to keep the UDP checksum correct, for changes made to origin time stamp and/or correction field as part of one step time stamp operation. The application forms the packet with these two dummy bytes. When cleared (=0), no updates are done to keep the UDP checksum correct. The application forms the packet with UDP checksum configured to 0.	
		0	Checksum Correction During OST for PTP Over UDP/IPv4 Packets is Disabled
		1	Checksum Correction During OST for PTP Over UDP/IPv4 Packets is Enabled

Table 30-220: EMAC_TM_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
18 (R/W)	TSENMACADDR	Enable MAC Address for PTP Packet Filtering. When the EMAC_TM_CTL.TSENMACADDR bit is set, the DA MAC address (that matches any MAC Address register) is used to filter the PTP packets when PTP is directly sent over Ethernet. When the EMAC_TM_CTL.TSENMACADDR bit is set, received PTP packets with DA containing a special multicast or unicast address that matches the one programmed in MAC address registers are considered for processing as indicated, when PTP is directly sent over Ethernet. For normal time stamping operation, MAC address registers 0 to 31 is considered for unicast destination address matching. For PTP offload, only MAC address register 0 is considered for unicast destination address matching.	
		0	MAC Address for PTP Packet Filtering is Disabled
		1	MAC Address for PTP Packet Filtering is Enabled
17:16 (R/W)	SNAPTYPSEL	Select PTP Packets for Taking Snapshots. The EMAC_TM_CTL.SNAPTYPSEL field, along with bits 15 and 14, decide the set of PTP packet types for which snapshot needs to be taken.	
15 (R/W)	TSMSTRENA	Enable Snapshot for Messages Relevant to Requester. When the EMAC_TM_CTL.TSMSTRENA bit is set, the snapshot is taken only for the messages that are relevant to the requester. Otherwise, the snapshot is taken for the messages relevant to the target node.	
		0	Disable
		1	Enable
14 (R/W)	TSEVNTENA	Enable Time Stamp Snapshot for Event Messages. When the EMAC_TM_CTL.TSEVNTENA bit is set, the time stamp snapshot is taken only for event messages (SYNC, Delay_Req, Pdelay_Req, or Pdelay_Resp). When EMAC_TM_CTL.TSEVNTENA = 0, the snapshot is taken for all messages except Announce, Management, and Signaling.	
		0	Timestamp Snapshot for Event Messages is Disabled
		1	Timestamp Snapshot for Event Messages is Enabled

Table 30-220: EMAC_TM_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
13 (R/W)	TSIPV4ENA	Enable Processing of PTP Packets Sent Over IPv4-UDP. When the EMAC_TM_CTL.TSIPV4ENA bit is set, the MAC receiver processes the PTP packets encapsulated in IPv4-UDP packets. When EMAC_TM_CTL.TSIPV4ENA = 0, the MAC ignores the PTP transported over IPv4 UDP packets. The EMAC_TM_CTL.TSIPV4ENA bit is set by default.	
		0	Processing of PTP Packets Sent Over IPv4-UDP is Disabled
		1	Processing of PTP Packets Sent Over IPv4-UDP is Enabled
12 (R/W)	TSIPV6ENA	Enable Processing of PTP Packets Sent Over IPv6-UDP. When the EMAC_TM_CTL.TSIPV6ENA bit is set, the MAC receiver processes the PTP packets encapsulated in IPv6-UDP packets. When the EMAC_TM_CTL.TSIPV6ENA bit is clear, the MAC ignores the PTP transported over IPv6 UDP packets.	
		0	Processing of PTP Packets Sent Over IPv6-UDP is Disabled
		1	Processing of PTP Packets Sent Over IPv6-UDP is Enabled
11 (R/W)	TSIPENA	Enable Processing of PTP Over Ethernet Packets. When the EMAC_TM_CTL.TSIPENA bit is set, the MAC receiver processes the PTP packets encapsulated directly in the Ethernet packets. When EMAC_TM_CTL.TSIPENA = 0, the MAC ignores the PTP over Ethernet packets.	
		0	Processing of PTP Over Ethernet Packets is Disabled
		1	Processing of PTP Over Ethernet Packets is Enabled
10 (R/W)	TSVER2ENA	Enable PTP Packet Processing for Version 2 Format. When the EMAC_TM_CTL.TSVER2ENA bit is set, the IEEE 1588 version 2 format is used to process the PTP packets. When EMAC_TM_CTL.TSVER2ENA = 0, the IEEE 1588 version 1 format is used to process the PTP packets. The IEEE 1588 formats are described in 'PTP Processing and Control'.	
		0	PTP Packet Processing for Version 2 Format is Disabled
		1	PTP Packet Processing for Version 2 Format is Enabled

Table 30-220: EMAC_TM_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W)	TSCTRLSSR	Time Stamp Digital or Binary Rollover Control. When the EMAC_TM_CTL.TSCTRLSSR bit is set, the time stamp low register rolls over after 0x3B9A_C9FF value (that is, 1 nanosecond accuracy) and increments the time stamp (high) seconds. When EMAC_TM_CTL.TSCTRLSSR = 0, the rollover value of sub-second register is 0x7FFF_FFFF. The sub-second increment must be programmed correctly depending on the PTP reference clock frequency and the value of the EMAC_TM_CTL.TSCTRLSSR bit.	
		0	Disable
		1	Enable
8 (R/W)	TSENALL	Enable Time Stamp for All Packets. When the EMAC_TM_CTL.TSENALL bit is set, the time stamp snapshot is enabled for all packets received by the MAC.	
		0	Disable
		1	Enable
6 (R/W)	PTGE	Presentation Time Generation Enable. When the EMAC_TM_CTL.PTGE bit is set, presentation time generation is enabled.	
		0	Presentation Time Generation is Disabled
		1	Presentation Time Generation is Enabled
5 (R/W)	TSADDREG	Update Addend Register. When the EMAC_TM_CTL.TSADDREG bit is set, the content of the EMAC_TM_ADDEND register is updated in the PTP block for fine correction. The EMAC_TM_CTL.TSADDREG bit is cleared when the update is complete. The EMAC_TM_CTL.TSADDREG bit should be zero before it is set. Access restriction applies. Write 1 to set. Self-cleared. Writing 0 has no effect.	
		0	Addend Register is Not Updated
		1	Addend Register is Updated

Table 30-220: EMAC_TM_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	TSUPDT	Time Stamp Update Enable. When EMAC_TM_CTL.TSUPDT = 1, the system time is updated (added or subtracted) with the value specified in the EMAC_TM_SECUPDT and EMAC_TM_NSECUPDT registers. The EMAC_TM_CTL.TSUPDT bit should be zero before updating it. The EMAC_TM_CTL.TSUPDT bit is reset when the update is complete in hardware. The EMAC_TM_HISEC register (if enabled while configuring the IP) is not updated. When Media Clock Generation and Recovery is enabled, the EMAC_PRSNTM_UPDT register should also be updated before setting this field. Access restriction applies. Write 1 to set. Self-cleared. Writing 0 has no effect.	
		0	Disable
		1	Enable
2 (R/W)	TSINIT	Initialize Time Stamp. When the EMAC_TM_CTL.TSINIT bit is set, the system time is initialized (overwritten) with the value specified in the EMAC_TM_SECUPDT and EMAC_TM_NSECUPDT registers. The EMAC_TM_CTL.TSINIT bit should be zero before it is updated. The EMAC_TM_CTL.TSINIT bit is cleared when the initialization is complete. The EMAC_TM_HISEC register (if enabled while configuration the IP) can only be initialized. When media clock generation and recovery is enabled the EMAC_PRSNTM_UPDT register must also be updated before setting this field. Access restriction applies. Write 1 to set. Self-cleared. Writing 0 has no effect.	
		0	Disable
		1	Enable
1 (R/W)	TSCFUPDT	Fine or Coarse Time Stamp Update. When the EMAC_TM_CTL.TSCFUPDT bit is set, the fine method is used to update system time stamp. When EMAC_TM_CTL.TSCFUPDT = 0, coarse method is used to update the system time stamp.	
		0	Coarse Method is Used to Update System Timestamp
		1	Fine Method is Used to Update System Timestamp

Table 30-220: EMAC_TM_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	TSENA	Enable Time Stamp. When the EMAC_TM_CTL.TSENA bit is set, the time stamp is added for transmit and receive packets. When disabled, time stamp is not added for transmit and receive packets and the time stamp generator is also suspended. Initialize the time stamp (system time) after enabling this mode. On the receive side, the MAC processes the 1588 packets only if the EMAC_TM_CTL.TSENA bit is set.	
		0	Disable
		1	Enable

Time Stamp Egress Asymmetry Correction Register

The EMAC_TM_EGASYM_CORR register contains the egress asymmetry correction value to be used while updating the correction field in PDelay_Req PTP messages.

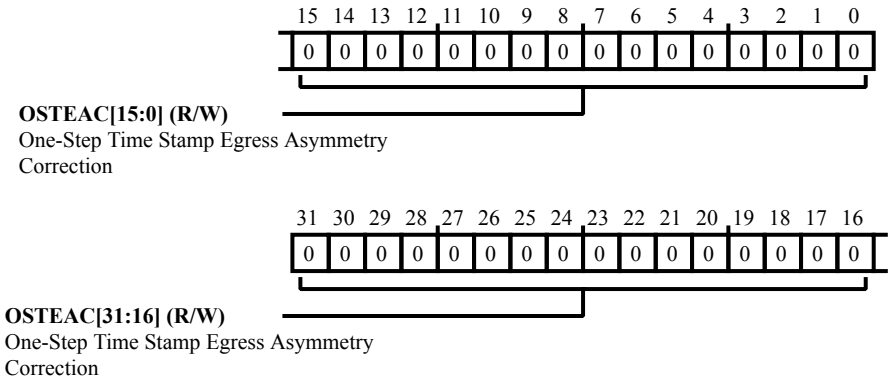

Figure 30-166: EMAC_TM_EGASYM_CORR Register Diagram

Table 30-221: EMAC_TM_EGASYM_CORR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	OSTEAC	One-Step Time Stamp Egress Asymmetry Correction. The EMAC_TM_EGASYM_CORR.OSTEAC field contains the egress path asymmetry value to be subtracted from correctionField of Pdelay_Resp PTP packet. The programmed value must be the negated value in units of nanoseconds multiplied by 2^{16}. For example, if the required correction is +2.5 ns, the programmed value must be 0xFFFD_8000, which is the 2's complement of 0x0002_8000(2.5 * 216). Similarly, if the required correction is -3.3 ns, the programmed value is 0x0003_4CCC (3.3 * 216).

Time Stamp Egress Correction Nanosecond Register

The EMAC_TM_EGCORR_NSEC register contains the correction value in nanoseconds to be used with the captured time stamp value in the egress path.

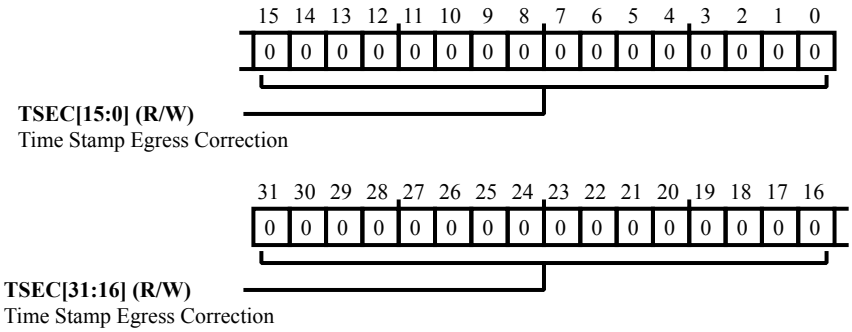

Figure 30-167: EMAC_TM_EGCORR_NSEC Register Diagram

Table 30-222: EMAC_TM_EGCORR_NSEC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	TSEC	Time Stamp Egress Correction. The EMAC_TM_EGCORR_NSEC.TSEC field contains the nanoseconds part of the egress path correction value as defined by the Egress Correction expression.

Time Stamp Egress Correction Sub Nanosecond Register

The EMAC_TM_EGCORR_SNSEC register contains the sub-nanosecond part of the correction value to be used with the captured time stamp value, for egress direction.

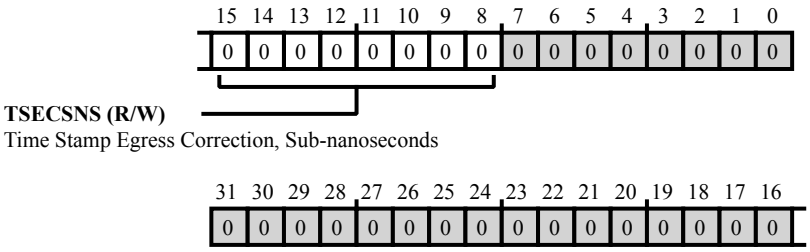

Figure 30-168: EMAC_TM_EGCORR_SNSEC Register Diagram

Table 30-223: EMAC_TM_EGCORR_SNSEC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:8 (R/W)	TSECSNS	Time Stamp Egress Correction, Sub-nanoseconds. The EMAC_TM_EGCORR_SNSEC.TSECSNS field contains the sub-nanoseconds part of the egress path correction value as defined by the Egress Correction expression.

Time Stamp Egress Latency Register

The EMAC_TM_EG_LTNCY register holds the egress MAC latency.

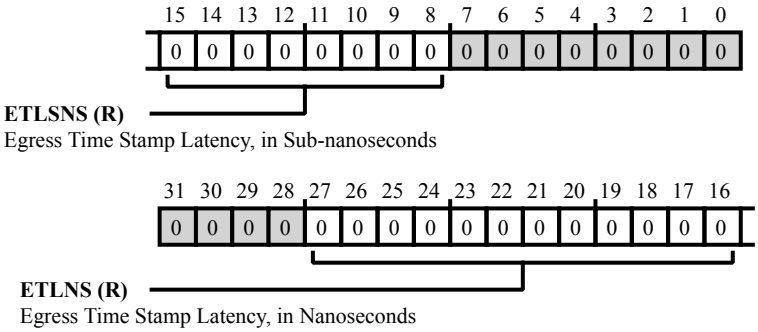

Figure 30-169: EMAC_TM_EG_LTNCY Register Diagram

Table 30-224: EMAC_TM_EG_LTNCY Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
27:16 (R/NW)	ETLNS	Egress Time Stamp Latency, in Nanoseconds. The EMAC_TM_EG_LTNCY register holds the average latency in nanoseconds between the actual point (GMII/MII) where the egress time stamp is taken and the output ports (ETHx_TXDx) of the MAC.
15:8 (R/NW)	ETLSNS	Egress Time Stamp Latency, in Sub-nanoseconds. The EMAC_TM_EG_LTNCY register holds the average latency in sub-nanoseconds between the actual point (GMII/MII) where the egress time stamp is taken and the output ports (phy_txd_o) of the MAC.

Time Stamp Ingress Asymmetry Correction Register

The EMAC_TM_INGASYM_CORR register contains the Ingress Asymmetry Correction value to be used while updating correction field in PDelay_Resp PTP messages.

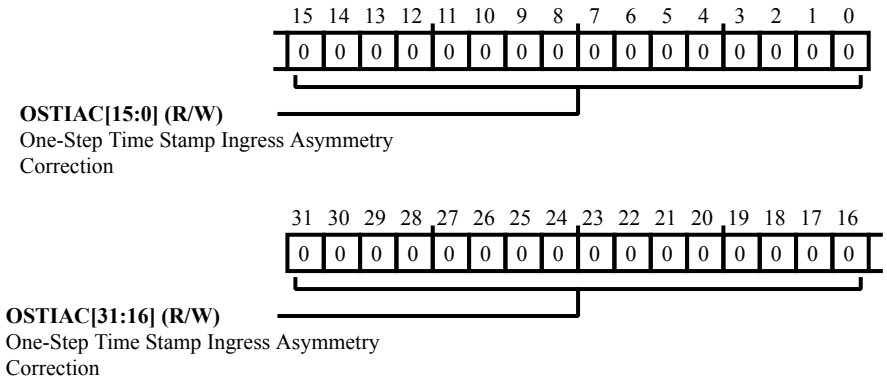

Figure 30-170: EMAC_TM_INGASYM_CORR Register Diagram

Table 30-225: EMAC_TM_INGASYM_CORR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	OSTIAC	One-Step Time Stamp Ingress Asymmetry Correction. The EMAC_TM_INGASYM_CORR.OSTIAC field contains the ingress path asymmetry value to be added to correctionField of Pdelay_Resp PTP packet. The programmed value should be in units of nanoseconds and multiplied by 2^{16}. For example, 2.5 ns is represented as 0x00028000. The value can also be negative, which is represented in 2's complement form with bit 31 representing the sign bit.

Time Stamp Ingress Correction Nanosecond Register

The EMAC_TM_INGCORR_NSEC register contains the correction value in nanoseconds to be used with the captured time stamp value in the ingress path.

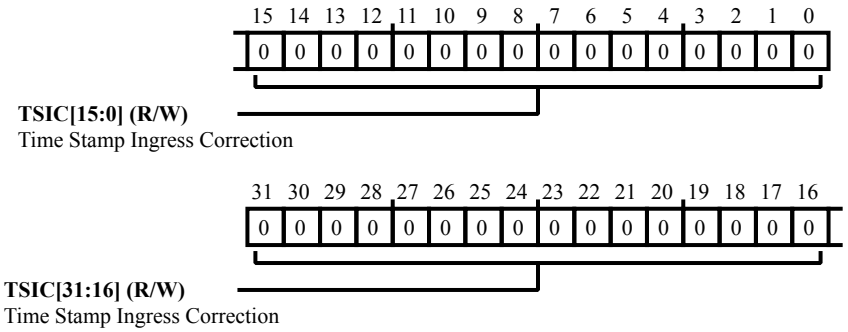

Figure 30-171: EMAC_TM_INGCORR_NSEC Register Diagram

Table 30-226: EMAC_TM_INGCORR_NSEC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	TSIC	Time Stamp Ingress Correction. The EMAC_TM_INGCORR_NSEC.TSIC field contains the ingress path correction value as defined by the Ingress Correction expression.

Time Stamp Ingress Correction Sub Nanosecond Register

The EMAC_TM_INGCORR_SNSEC register contains the sub-nanosecond part of the correction value to be used with the captured time stamp value, for ingress direction.

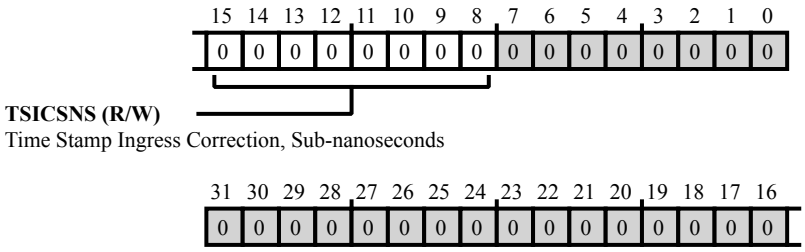

Figure 30-172: EMAC_TM_INGCORR_SNSEC Register Diagram

Table 30-227: EMAC_TM_INGCORR_SNSEC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:8 (R/W)	TSICSNS	Time Stamp Ingress Correction, Sub-nanoseconds. The EMAC_TM_INGCORR_SNSEC.TSICSNS field contains the sub-nanoseconds part of the ingress path correction value as defined by the Ingress Correction expression.

Time Stamp Ingress Latency Register

The EMAC_TM_ING_LTNCY register holds the ingress MAC latency.

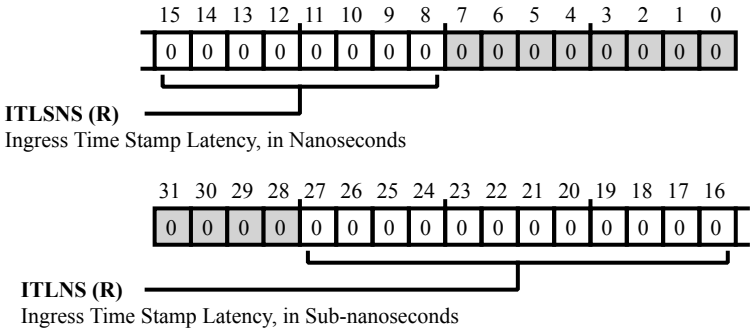

Figure 30-173: EMAC_TM_ING_LTNCY Register Diagram

Table 30-228: EMAC_TM_ING_LTNCY Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
27:16 (R/NW)	ITLNS	Ingress Time Stamp Latency, in Sub-nanoseconds. The EMAC_TM_ING_LTNCY register holds the average latency in sub-nanoseconds between the input ports (ETHx_RXDx) of MAC and the actual point (GMII/MII) where the ingress time stamp is taken. Ingress correction value is computed as described in the section, "Ingress Correction".
15:8 (R/NW)	ITLSNS	Ingress Time Stamp Latency, in Nanoseconds. The EMAC_TM_ING_LTNCY register holds the average latency in nanoseconds between the input ports (phy_rxd_i) of MAC and the actual point (GMII/MII) where the ingress time stamp is taken. Ingress correction value is computed as described in the section, "Ingress Correction".

Time Stamp Status Register

All bits except bits[27:25] are cleared when the application reads the EMAC_TM_STAT register.

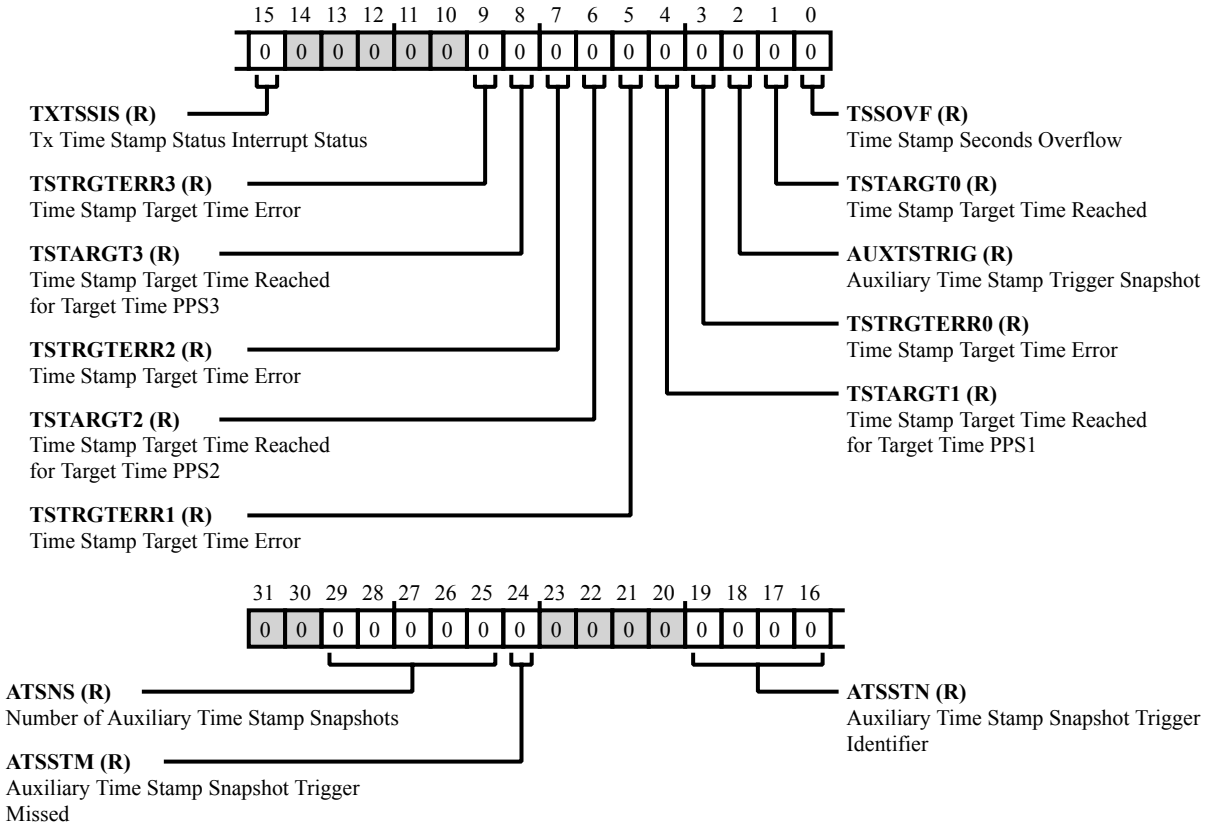

Figure 30-174: EMAC_TM_STAT Register Diagram

Table 30-229: EMAC_TM_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:25 (R/NW)	ATSNS	Number of Auxiliary Time Stamp Snapshots. The EMAC_TM_STAT.ATSNS field indicates the number of snapshots available in the FIFO. A value equal to the selected depth of FIFO (4, 8, or 16) indicates that the Auxiliary Snapshot FIFO is full. These bits are cleared (to 00000) when the Auxiliary snapshot FIFO clear bit is set. The EMAC_TM_STAT.ATSNS bit is valid only if the Add IEEE 1588 Auxiliary Snapshot option is selected.

Table 30-229: EMAC_TM_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
24 (R/NW)	ATSSTM	Auxiliary Time Stamp Snapshot Trigger Missed. The EMAC_TM_STAT.ATSSTM bit is set when the auxiliary time stamp snapshot FIFO is full and external trigger was set. This indicates that the latest snapshot is not stored in the FIFO. The EMAC_TM_STAT.ATSSTM bit is valid only if the Add IEEE 1588 Auxiliary Snapshot option is selected.	
		0	Status Not Detected
		1	Status Detected
19:16 (R/NW)	ATSSTN	Auxiliary Time Stamp Snapshot Trigger Identifier. The EMAC_TM_STAT.ATSSTN field identifies the auxiliary trigger inputs for which the time stamp available in the Auxiliary Snapshot Register is applicable. When more than one bit is set at the same time, it means that corresponding auxiliary triggers were sampled at the same clock. These bits are applicable only if the number of auxiliary snapshots is more than one. One bit is assigned for each trigger as shown in the following list: - Bit 16: Auxiliary trigger 0 - Bit 17: Auxiliary trigger 1 - Bit 18: Auxiliary trigger 2 - Bit 19: Auxiliary trigger 3 The software can read this register to find the triggers that are set when the time stamp is taken.	
15 (R/NW)	TXTSSIS	Tx Time Stamp Status Interrupt Status. When the drop transmit status is enabled in MTL, the EMAC_TM_STAT.TXTSSIS bit is set when the captured transmit time stamp is updated in the EMAC_TXTMSTAT_NSEC and EMAC_TXTMSTAT_SEC registers. When PTP offload feature is enabled, the EMAC_TM_STAT.TXTSSIS bit is set when the captured transmit time stamp is updated in the EMAC_TXTMSTAT_NSEC and EMAC_TXTMSTAT_SEC registers, for PTO generated Delay Request and Pdelay request packets. The EMAC_TM_STAT.TXTSSIS bit is cleared when the EMAC_TXTMSTAT_SEC register is read (or write to EMAC_TXTMSTAT_SEC register when EMAC_CSR_SW_CTL.RCWE = 1).	
		0	Status Not Detected
		1	Status Detected

Table 30-229: EMAC_TM_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/NW)	TSTRGTERR3	Time Stamp Target Time Error. The EMAC_TM_STAT.TSTRGTERR3 bit is set when the latest target time programmed in the EMAC_PPS[3]_TGTM_SEC and EMAC_PPS[3]_TGTM_NSEC registers elapses. The EMAC_TM_STAT.TSTRGTERR3 bit is cleared when the application reads the EMAC_TM_STAT.TSTRGTERR3 bit. Access restriction applies. Clears on read (or the EMAC_TM_STAT.TSTRGTERR3 bit is written to 1 when EMAC_CSR_SW_CTL.RCWE = 1). Self-set to 1 on internal event.	
		0	Status Not Detected
		1	Status Detected
8 (R/NW)	TSTARGT3	Time Stamp Target Time Reached for Target Time PPS3. When the EMAC_TM_STAT.TSTARGT3 bit is set and EMAC_PPS_CTL.MCGREN3 = 0, it indicates that the value of system time is greater than or equal to the value specified in the EMAC_PPS[3]_TGTM_SEC and EMAC_PPS[3]_TGTM_NSEC registers. When the EMAC_TM_STAT.TSTARGT3 bit is set and EMAC_PPS_CTL.MCGREN3 = 1, it indicates that EMAC0_MCGR3 trigger request is asserted. Access restriction applies. Clears on read (or the EMAC_TM_STAT.TSTARGT3 bit is written to 1 when EMAC_CSR_SW_CTL.RCWE = 1). Self-set to 1 on internal event.	
		0	Status Not Detected
		1	Status Detected
7 (R/NW)	TSTRGTERR2	Time Stamp Target Time Error. The EMAC_TM_STAT.TSTRGTERR2 bit is set when the latest target time programmed in the EMAC_PPS[2]_TGTM_SEC and EMAC_PPS[2]_TGTM_NSEC registers elapses. The EMAC_TM_STAT.TSTRGTERR2 bit is cleared when the application reads the EMAC_TM_STAT.TSTRGTERR2 bit. Access restriction applies. Clears on read (or the EMAC_TM_STAT.TSTRGTERR2 bit is written to 1 when EMAC_CSR_SW_CTL.RCWE = 1). Self-set to 1 on internal event.	
		0	Status Not Detected
		1	Status Detected

Table 30-229: EMAC_TM_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6 (R/NW)	TSTARGT2	Time Stamp Target Time Reached for Target Time PPS2. When the EMAC_TM_STAT.TSTARGT2 bit is set and EMAC_PPS_CTL.MCGREN2 = 0, it indicates that the value of system time is greater than or equal to the value specified in the EMAC_PPS[2]_TGTM_SEC and EMAC_PPS[2]_TGTM_NSEC registers. When the EMAC_TM_STAT.TSTARGT2 bit is set and EMAC_PPS_CTL.MCGREN2 = 1, it indicates that EMAC0_MCGR2 trigger request is asserted. Access restriction applies. Clears on read (or the EMAC_TM_STAT.TSTARGT2 bit is written to 1 when EMAC_CSR_SW_CTL.RCWE = 1). Self-set to 1 on internal event.	
		0	Status Not Detected
		1	Status Detected
5 (R/NW)	TSTRGTERR1	Time Stamp Target Time Error. The EMAC_TM_STAT.TSTRGTERR1 bit is set when the latest target time programmed in the EMAC_PPS[1]_TGTM_SEC and EMAC_PPS[1]_TGTM_NSEC registers elapses. The EMAC_TM_STAT.TSTRGTERR1 bit is cleared when the application reads the EMAC_TM_STAT.TSTRGTERR1 bit. Access restriction applies. Clears on read (or the EMAC_TM_STAT.TSTRGTERR1 bit is written to 1 when EMAC_CSR_SW_CTL.RCWE = 1). Self-set to 1 on internal event.	
		0	Status Not Detected
		1	Status Detected
4 (R/NW)	TSTARGT1	Time Stamp Target Time Reached for Target Time PPS1. When the EMAC_TM_STAT.TSTARGT1 bit is set and EMAC_PPS_CTL.MCGREN1 = 0, it indicates that the value of system time is greater than or equal to the value specified in the EMAC_PPS[1]_TGTM_SEC and EMAC_PPS[1]_TGTM_NSEC registers. When the EMAC_TM_STAT.TSTARGT1 bit is set and EMAC_PPS_CTL.MCGREN1 = 1, it indicates that EMAC0_MCGR1 trigger request is asserted. Access restriction applies. Clears on read (or the EMAC_TM_STAT.TSTARGT1 bit is written to 1 when EMAC_CSR_SW_CTL.RCWE = 1). Self-set to 1 on internal event.	
		0	Status Not Detected
		1	Status Detected

Table 30-229: EMAC_TM_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/NW)	TSTRGTERR0	Time Stamp Target Time Error. The EMAC_TM_STAT.TSTRGTERR0 bit is set when the latest target time programmed in the EMAC_PPS[n]_TGTM_SEC and EMAC_PPS[n]_TGTM_NSEC registers elapses. The EMAC_TM_STAT.TSTRGTERR0 bit is cleared when the application reads the EMAC_TM_STAT.TSTRGTERR0 bit. Access restriction applies. Clears on read (or the EMAC_TM_STAT.TSTRGTERR0 bit is written to 1 when EMAC_CSR_SW_CTL.RCWE = 1). Self-set to 1 on internal event.	
		0	Status Not Detected
		1	Status Detected
2 (R/NW)	AUXTSTRIG	Auxiliary Time Stamp Trigger Snapshot. The EMAC_TM_STAT.AUXTSTRIG bit is set (=1) when the auxiliary snapshot is written to the FIFO. The EMAC_TM_STAT.AUXTSTRIG bit is valid only if the Add IEEE 1588 Auxiliary Snapshot option is selected. Access restriction applies. Clears on read (or the EMAC_TM_STAT.AUXTSTRIG bit is written to 1 when EMAC_CSR_SW_CTL.RCWE = 1). Self-set to 1 on internal event.	
		0	Auxiliary Timestamp Trigger Snapshot Status Not Detected
		1	Auxiliary Timestamp Trigger Snapshot Status Detected
1 (R/NW)	TSTARGT0	Time Stamp Target Time Reached. When the EMAC_TM_STAT.TSTARGT0 bit is set and EMAC_PPS_CTL.MCGREN0 = 0, it indicates that the value of system time is greater than or equal to the value specified in the EMAC_PPS[n]_TGTM_SEC and EMAC_PPS[n]_TGTM_NSEC registers. When the EMAC_TM_STAT.TSTARGT0 bit is set and EMAC_PPS_CTL.MCGREN0 = 1, it indicates that EMAC0_MCGR trigger request is asserted. Access restriction applies. Clears on read (or the EMAC_TM_STAT.TSTARGT0 bit is written to 1 when EMAC_CSR_SW_CTL.RCWE = 1). Self-set to 1 on internal event.

		1	Status Detected

Table 30-229: EMAC_TM_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/NW)	TSSOVF	Time Stamp Seconds Overflow. When the `EMAC_TM_STAT.TSSOVF` bit is set, it indicates that the seconds value of the time stamp (when supporting version 2 format) has overflowed beyond 32'hFFFF_FFFF. Access restriction applies. Clears on read (or the `EMAC_TM_STAT.TSSOVF` bit is written to 1 when EMAC_CSR_SW_CTL.RCWE = 1). Self-set to 1 on internal event.	
		0	Status Not Detected
		1	Status Detected

Transmit Queue Priority Mapping 0 Register

The EMAC_TXQ_PRTY_MAP0 register contains the priority values assigned to Tx queue 0 through Tx queue 3.

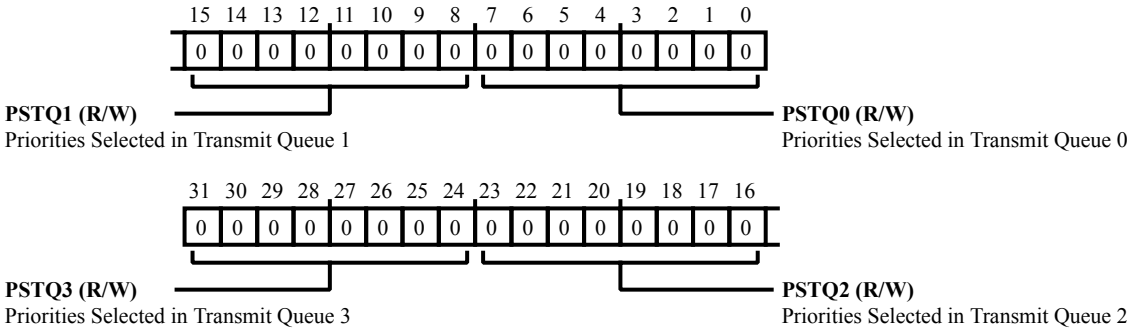

Figure 30-175: EMAC_TXQ_PRTY_MAP0 Register Diagram

Table 30-230: EMAC_TXQ_PRTY_MAP0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	PSTQ3	Priorities Selected in Transmit Queue 3. The EMAC_TXQ_PRTY_MAP0.PSTQ3 bit is similar to the PSTQ0 bit.
23:16 (R/W)	PSTQ2	Priorities Selected in Transmit Queue 2. The EMAC_TXQ_PRTY_MAP0.PSTQ2 bit is similar to the PSTQ0 bit.
15:8 (R/W)	PSTQ1	Priorities Selected in Transmit Queue 1. The EMAC_TXQ_PRTY_MAP0.PSTQ1 bit is similar to the PSTQ0 bit.
7:0 (R/W)	PSTQ0	Priorities Selected in Transmit Queue 0. The EMAC_TXQ_PRTY_MAP0.PSTQ0 field holds the priorities assigned to Tx queue 0 by the software. The EMAC_TXQ_PRTY_MAP0.PSTQ0 field determines if Tx queue 0 should be blocked from transmitting specified pause time when a PFC packet is received with priorities matching the priorities programmed in this field. If the content of this field is not mutually exclusive to the corresponding fields of other Transmit queues, that is, same priority is mapped to multiple Tx queues, the MAC blocks all queues with matching priority, for the specified time.

Transmit Queue Priority Mapping 1 Register

The EMAC_TXQ_PRTY_MAP1 register contains the priority values assigned to Tx queue 4 through Tx queue 7.

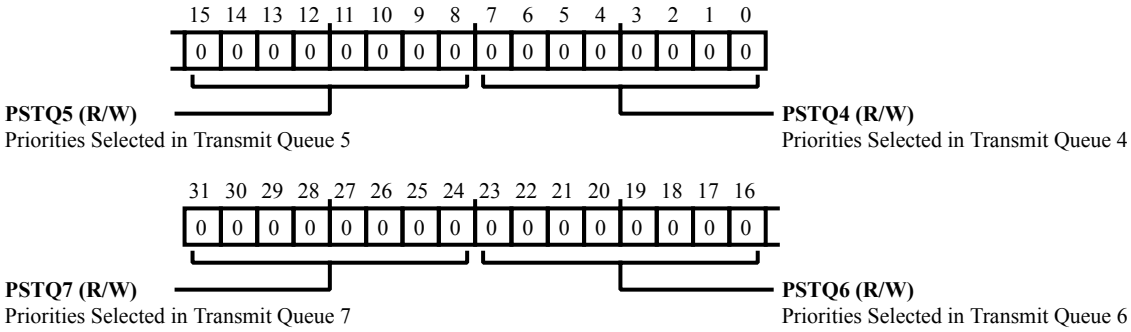

Figure 30-176: EMAC_TXQ_PRTY_MAP1 Register Diagram

Table 30-231: EMAC_TXQ_PRTY_MAP1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	PSTQ7	Priorities Selected in Transmit Queue 7. The EMAC_TXQ_PRTY_MAP1.PSTQ7 bit is similar to the PSTQ4 bit.
23:16 (R/W)	PSTQ6	Priorities Selected in Transmit Queue 6. The EMAC_TXQ_PRTY_MAP1.PSTQ6 bit is similar to the PSTQ4 bit.
15:8 (R/W)	PSTQ5	Priorities Selected in Transmit Queue 5. The EMAC_TXQ_PRTY_MAP1.PSTQ5 bit is similar to the PSTQ4 bit.
7:0 (R/W)	PSTQ4	Priorities Selected in Transmit Queue 4. The EMAC_TXQ_PRTY_MAP1.PSTQ4 field holds the priorities assigned to Tx queue 4 by the software. The EMAC_TXQ_PRTY_MAP1.PSTQ4 field determines if Tx queue 4 should be blocked from transmitting specified pause time when a PFC packet is received with priorities matching the priorities programmed in this field. If the content of this field is not mutually exclusive to corresponding fields of other Transmit queues, that is, same priority is mapped to multiple Tx queues, the MAC blocks all queues with matching priority for specified time.

Transmit Time Stamp Status Nanoseconds Register

The EMAC_TXTMSTAT_NSEC register contains the nanosecond part of time stamp captured for transmit packets when Tx status is disabled. The EMAC_TXTMSTAT_NSEC register, along with EMAC_TXTMSTAT_SEC, gives the 64-bit time stamp captured for the PTP packet successfully transmitted by the MAC. This value is considered to be read by the application when the last byte of the EMAC_TXTMSTAT_NSEC register is read. In the little-endian mode, this means when bits[31:24] are read; in big-endian mode, bits[7:0] are read. If the application does not read these registers and time stamp of another packet is captured, then either the current time stamp is lost (overwritten) or the new time stamp is lost (dropped), depending on the configuration of the EMAC_TM_CTL.TXTSSTSM bit. The status bit EMAC_TM_STAT.TXTSSIS is set when the MAC transmitter captures the time stamp.

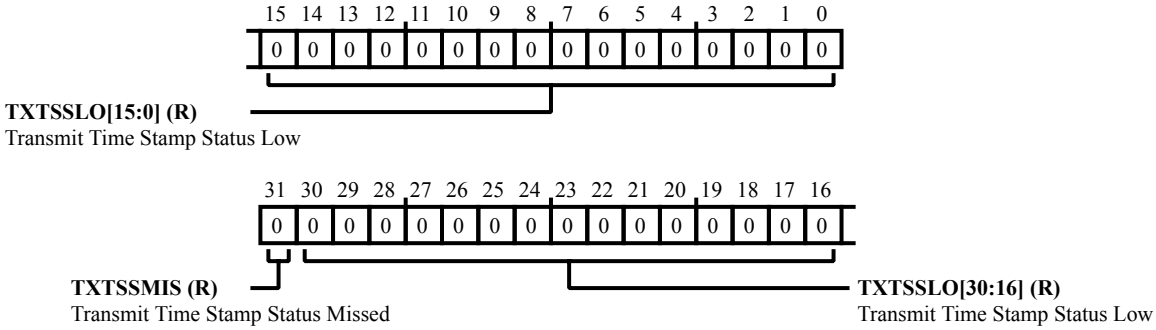

Figure 30-177: EMAC_TXTMSTAT_NSEC Register Diagram

Table 30-232: EMAC_TXTMSTAT_NSEC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/NW)	TXTSSMIS	Transmit Time Stamp Status Missed. When the EMAC_TXTMSTAT_NSEC.TXTSSMIS bit is set, it indicates one of the following: The time stamp of the current packet is ignored if EMAC_TM_CTL.TXTSSTSM = 0. The time stamp of the previous packet is overwritten with time stamp of the current packet if EMAC_TM_CTL.TXTSSTSM = 1. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	Status Not Detected
		1	Status Detected
30:0 (R/NW)	TXTSSLO	Transmit Time Stamp Status Low. The EMAC_TXTMSTAT_NSEC.TXTSSLO field contains the 31 bits of the nanoseconds field of the transmit packet's captured time stamp.	

Transmit Time Stamp Status Seconds Register

The EMAC_TXTMSTAT_SEC register contains the higher 32 bits of the time stamp (in seconds) captured when a PTP packet is transmitted.

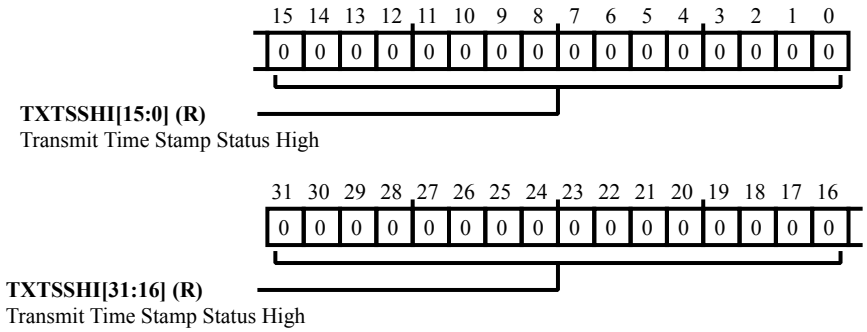

Figure 30-178: EMAC_TXTMSTAT_SEC Register Diagram

Table 30-233: EMAC_TXTMSTAT_SEC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	TXTSSHI	Transmit Time Stamp Status High. The EMAC_TXTMSTAT_SEC.TXTSSHI field contains the lower 32 bits of the seconds field of transmit packet's captured time stamp.

VLAN Hash Table Register

When EMAC_VLANTAG_CTL.VTHM = 1, the 16-bit EMAC_VLAN_HASHTBL register is used for group address filtering based on the VLAN tag. For hash filtering, the content of the 16-bit VLAN tag or 12-bit VLAN ID (based on EMAC_VLANTAG_CTL.ETV) in the incoming packet is passed through the CRC logic. The upper four bits of the calculated hash value are used to index the contents of the VLAN hash table. For example, hash value of 4b'1000 selects bit 8 of the VLAN hash table.

The hash value of the destination address is calculated in the following way:

1. Calculate the 32-bit CRC for the VLAN tag or ID (For steps to calculate CRC32, see Section 3.2.8 of IEEE 802.3).

2. Perform bitwise reversal for the value obtained in step 1.

3. Take the upper four bits from the value obtained in step 2. The VLAN hash table register is configured to be double-synchronized to the (G)MII clock domain, the synchronization is triggered only when bits[15:8] (in little-endian mode) or bits[7:0] (in big-endian mode) of this register are written.

Consecutive writes to this register should be performed after at least four clock cycles in the (G)MII clock domain.

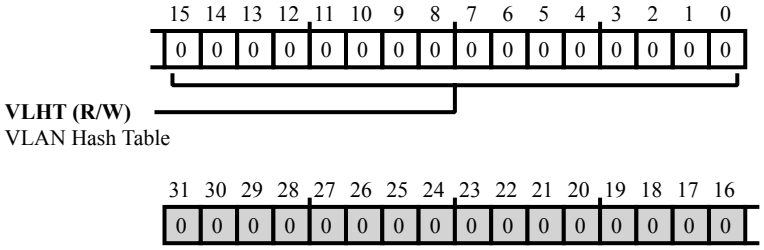

Figure 30-179: EMAC_VLAN_HASHTBL Register Diagram

Table 30-234: EMAC_VLAN_HASHTBL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VLHT	VLAN Hash Table. The EMAC_VLAN_HASHTBL.VLHT field contains the 16-bit VLAN Hash Table.

VLAN Tag Inclusion or Replacement Register

The EMAC_VLAN_INCL register contains the VLAN tag for insertion or replacement in the Transmit packets. It also contains the VLAN tag insertion controls.

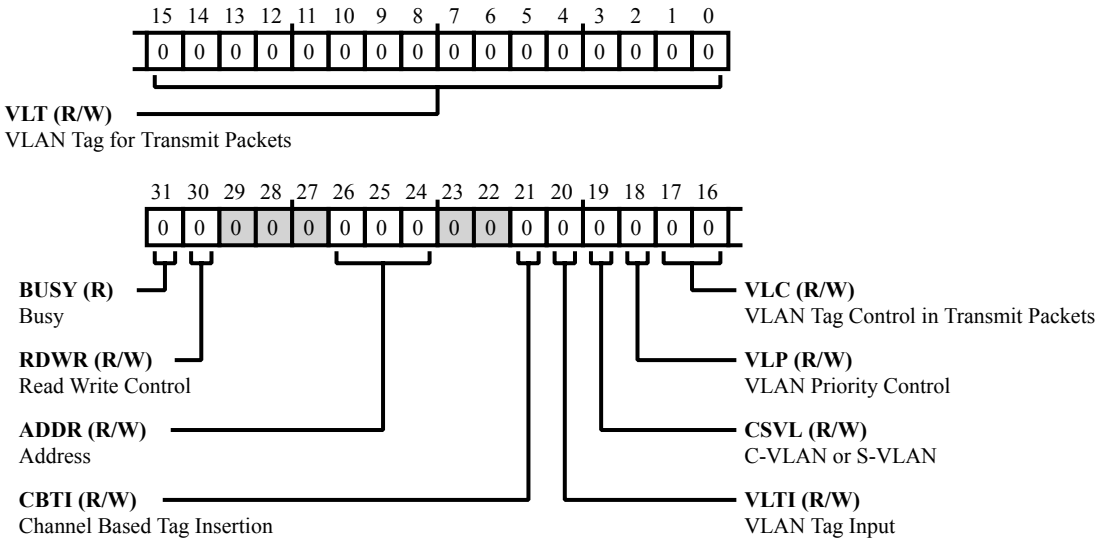

Figure 30-180: EMAC_VLAN_INCL Register Diagram

Table 30-235: EMAC_VLAN_INCL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/NW)	BUSY	Busy. The EMAC_VLAN_INCL.BUSY bit indicates the status of the read/write operation of indirect access to the queue/channel specific VLAN inclusion register. For write operation write to a register is complete when EMAC_VLAN_INCL.BUSY = 0. For read operation the read data is valid when the bit is reset. The application must make sure that EMAC_VLAN_INCL.BUSY = 0 before attempting subsequent access to this register.	
		0	Busy Status Not Detected
		1	Busy Status Detected
30 (R/W)	RDWR	Read Write Control. The EMAC_VLAN_INCL.RDWR bit controls the read or write operation for indirectly accessing the queue/channel specific VLAN Inclusion register. When set indicates write operation and when cleared (=0) indicates read operation. This does not have any effect when CBTI is reset.	
		0	Read Operation of Indirect Access
		1	Write Operation of Indirect Access

Table 30-235: EMAC_VLAN_INCL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
26:24 (R/W)	ADDR	Address. The EMAC_VLAN_INCL.ADDR field selects one of the queue/channel specific VLAN Inclusion register for read/write access. This does not have any effect when CBTI is reset.	
21 (R/W)	CBTI	Channel Based Tag Insertion. When the EMAC_VLAN_INCL.CBTI bit is set, outer VLAN tag is inserted for every packets transmitted by the MAC. The tag value is taken from the queue/channel specific VLAN tag register. The VLTI, VLP, VLC, and VLT fields of this register are ignored when the EMAC_VLAN_INCL.CBTI bit is set. When the EMAC_VLAN_INCL.CBTI bit is set, a write operation to byte 3 of this register initiates the read/write access to the indirect register. When cleared (=0), outer VLAN operation is based on the setting of VLTI, VLP, VLC and VLT fields of this register.	
		0	Channel Based Tag Insertion is Disabled
		1	Channel Based Tag Insertion is Enabled
20 (R/W)	VLTI	VLAN Tag Input. When the EMAC_VLAN_INCL.VLTI bit is set, it indicates that the VLAN tag to be inserted or replaced in Tx packet should be taken from: - The Tx descriptor	
		0	VLAN Tag Input is Disabled
		1	VLAN Tag Input is Enabled
19 (R/W)	CSVL	C-VLAN or S-VLAN. When the EMAC_VLAN_INCL.CSVL bit is set, S-VLAN type (0x88A8) is inserted or replaced in the 13th and 14th bytes of transmitted packets. When EMAC_VLAN_INCL.CSVL = 0, C-VLAN type (0x8100) is inserted or replaced in the 13th and 14th bytes of transmitted packets.	
		0	C-VLAN Type (0x8100) is Inserted or Replaced
		1	S-VLAN Type (0x88A8) is Inserted or Replaced
18 (R/W)	VLP	VLAN Priority Control. When the EMAC_VLAN_INCL.VLP bit is set, the control bits[17:16] are used for VLAN deletion, insertion, or replacement. When EMAC_VLAN_INCL.VLP = 0, the mti_vlan_ctrl_i control input is used and bits[17:16] are ignored.	
		0	VLAN Priority Control is Disabled
		1	VLAN Priority Control is Enabled

Table 30-235: EMAC_VLAN_INCL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
17:16 (R/W)	VLC	VLAN Tag Control in Transmit Packets. The `EMAC_VLAN_INCL.VLC` field indicates the VLAN tag control in transmit packets. 2'b00: No VLAN tag deletion, insertion, or replacement 2'b01: VLAN tag deletion The MAC removes the VLAN type (bytes 13 and 14) and VLAN tag (bytes 15 and 16) of all transmitted packets with VLAN tags. 2'b10: VLAN tag insertion The MAC inserts VLT in bytes 15 and 16 of the packet after inserting the Type value (0x8100 or 0x88a8) in bytes 13 and 14. This operation is performed on all transmitted packets, irrespective of whether they already have a VLAN tag. 2'b11: VLAN tag replacement The MAC replaces VLT in bytes 15 and 16 of all VLAN-type transmitted packets (Bytes 13 and 14 are 0x8100 or 0x88a8). Note: Changes to this field take effect only on the start of a packet. If this field is written when a packet is being transmitted, only the subsequent packet can use the updated value, that is, the current packet does not use the updated value.	
		0	No VLAN Tag Deletion, Insertion, or Replacement
		1	VLAN Tag Deletion
		2	VLAN Tag Insertion
		3	VLAN Tag Replacement
15:0 (R/W)	VLT	VLAN Tag for Transmit Packets. The `EMAC_VLAN_INCL.VLT` field contains the value of the VLAN tag to be inserted or replaced. The value must only be changed when the transmit lines are inactive or during the initialization phase. Bits[15:13] are the User Priority field, Bit 12 is the CFI/DEI field, and Bits[11:0] are the VID field in the VLAN tag. The following list describes the bits of this field: Bits[15:13]: User Priority Bit 12: Canonical Format Indicator (CFI) or Drop Eligible Indicator (DEI) Bits[11:0]: VLAN Identifier (VID) field of VLAN tag	

VLAN Tag Control Register

The EMAC_VLANTAG_CTL register contains control and status bits for VLAN filtering operation. It is also used for indirect addressing. It contains the address offset, command type and busy bit for CSR access of the per VLAN tag registers.

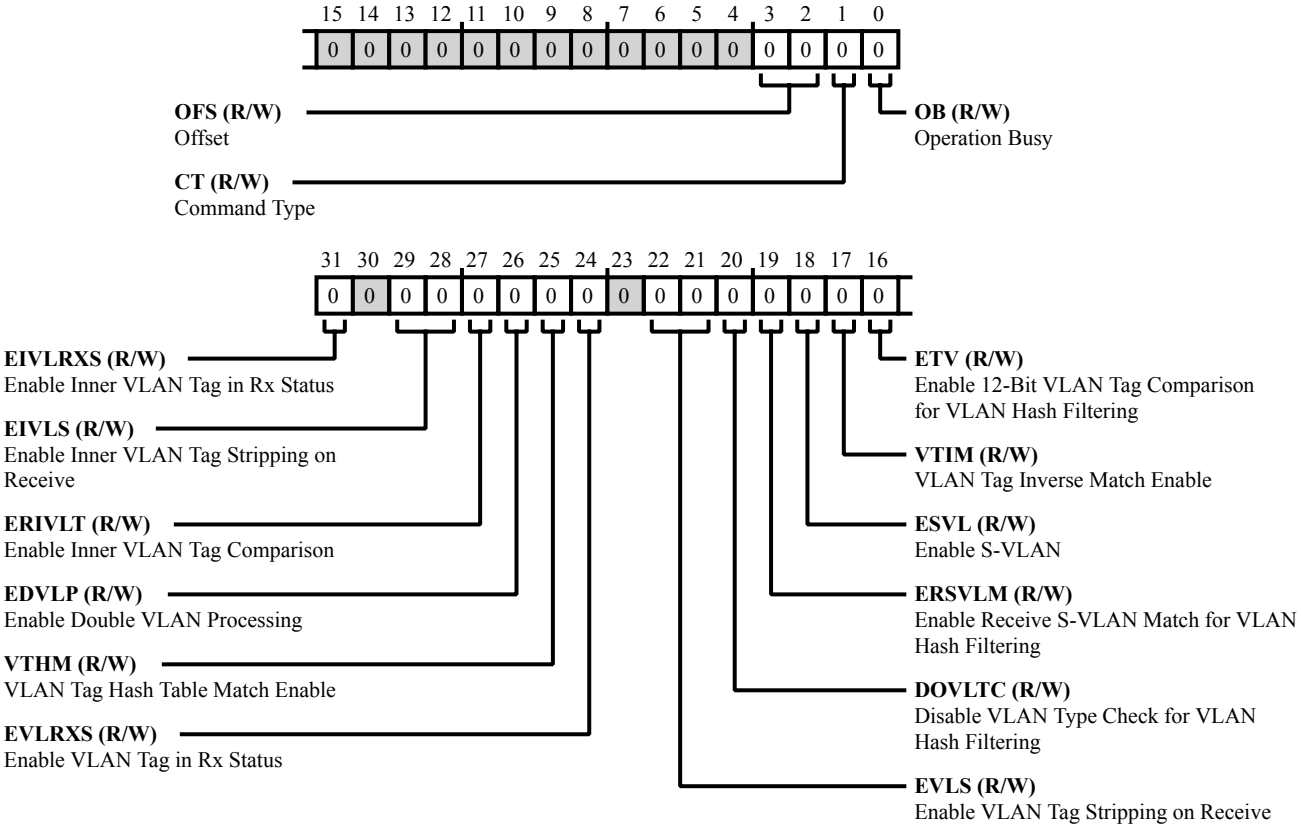

Figure 30-181: EMAC_VLANTAG_CTL Register Diagram

Table 30-236: EMAC_VLANTAG_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	EIVLRXS	Enable Inner VLAN Tag in Rx Status. When the EMAC_VLANTAG_CTL.EIVLRXS bit is set, the MAC provides the inner VLAN tag in the Rx status. When EMAC_VLANTAG_CTL.EIVLRXS = 0, the MAC does not provide the inner VLAN tag in Rx status.	
		0	Inner VLAN Tag in Rx Status is Disabled
		1	Inner VLAN Tag in Rx Status is Enabled

Table 30-236: EMAC_VLANTAG_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
29:28 (R/W)	EIVLS	Enable Inner VLAN Tag Stripping on Receive. The EMAC_VLANTAG_CTL.EIVLS field indicates the stripping operation on inner VLAN tag in received packet.	
		0	Do Not Strip
		1	Strip If VLAN Filter Passes
		2	Strip If VLAN Filter Fails
		3	Always Strip
27 (R/W)	ERIVLT	Enable Inner VLAN Tag Comparison. When the EMAC_VLANTAG_CTL.ERIVLT bit, EMAC_VLANTAG_CTL.VTHM bit, and the EMAC_VLANTAG_CTL.EDVLP field are set, the MAC receiver enables VLAN hash filtering operation on the inner VLAN tag (if present). When EMAC_VLANTAG_CTL.ERIVLT = 0 and EMAC_VLANTAG_CTL.VTHM = 1, the MAC receiver enables VLAN hash filtering operation on the outer VLAN tag (if present). The EMAC_VLANTAG_CTL.ERSVLM bit and EMAC_VLANTAG_CTL.DOVLTC bit determines which VLAN type is enabled for filtering.	
		0	Inner VLAN Tag is Disabled
		1	Inner VLAN Tag is Enabled
26 (R/W)	EDVLP	Enable Double VLAN Processing. When the EMAC_VLANTAG_CTL.EDVLP bit is set, the MAC enables processing of up to two VLAN tags on Tx and Rx (if present). When EMAC_VLANTAG_CTL.EDVLP = 0, the MAC enables processing of up to one VLAN tag on Tx and Rx (if present).	
		0	Double VLAN Processing is Disabled
		1	Double VLAN Processing is Enabled

Table 30-236: EMAC_VLANTAG_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
25 (R/W)	VTHM	VLAN Tag Hash Table Match Enable. When the EMAC_VLANTAG_CTL.VTHM bit is set, the most significant four bits of CRC of VLAN tag are used to index the content of the EMAC_VLAN_HASHTBL_REGn. A value of 1 in the VLAN hash table register, corresponding to the index, indicates that the packet matched the VLAN hash table. When EMAC_VLANTAG_CTL.ETV= 1, the CRC of the 12-bit VLAN Identifier (VID) is used for comparison. When EMAC_VLANTAG_CTL.ETV= 0, the CRC of the 16-bit VLAN tag is used for comparison. When EMAC_VLANTAG_CTL.VTHM = 0, the VLAN Hash match operation is not performed.	
		0	VLAN Tag Hash Table Match is Disabled
		1	VLAN Tag Hash Table Match is Enabled
24 (R/W)	EVLRXS	Enable VLAN Tag in Rx Status. When the EMAC_VLANTAG_CTL.EVLRXS bit is set, MAC provides the outer VLAN Tag in the Rx status. When EMAC_VLANTAG_CTL.EVLRXS = 0, the MAC does not provide the outer VLAN tag in Rx status.	
		0	VLAN Tag in Rx Status is Disabled
		1	VLAN Tag in Rx Status is Enabled
22:21 (R/W)	EVLS	Enable VLAN Tag Stripping on Receive. The EMAC_VLANTAG_CTL.EVLS field indicates the stripping operation on the outer VLAN tag in received packet.	
		0	Do Not Strip
		1	Strip If VLAN Filter Passes
		2	Strip If VLAN Filter Fails
		3	Always Strip
20 (R/W)	DOVLTC	Disable VLAN Type Check for VLAN Hash Filtering. When the EMAC_VLANTAG_CTL.DOVLTC bit is set, the MAC VLAN hash filter does not check whether the VLAN tag specified by the EMAC_VLANTAG_CTL.ERIVLT bit is of type S-VLAN or C-VLAN. When EMAC_VLANTAG_CTL.DOVLTC = 0, the MAC VLAN hash filter filters or matches the VLAN tag specified by the EMAC_VLANTAG_CTL.ERIVLT bit only when VLAN tag type is similar to the one specified by the EMAC_VLANTAG_CTL.ERSVLM bit.	
		0	VLAN Type Check is Enabled
		1	VLAN Type Check is Disabled

Table 30-236: EMAC_VLANTAG_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
19 (R/W)	ERSVLM	Enable Receive S-VLAN Match for VLAN Hash Filtering. When the EMAC_VLANTAG_CTL.ERSVLM bit is set, the MAC receiver enables VLAN hash filtering or matching for S-VLAN (type = 0x88A8) packets. When EMAC_VLANTAG_CTL.ERSVLM = 0, the MAC receiver enables VLAN hash filtering or matching for C-VLAN (type = 0x8100) packets. The EMAC_VLANTAG_CTL.ERIVLT bit determines the VLAN tag position considered for VLAN hash filtering or matching.	
		0	Receive S-VLAN Match is Disabled
		1	Receive S-VLAN Match is Enabled
18 (R/W)	ESVL	Enable S-VLAN. When the EMAC_VLANTAG_CTL.ESVL bit is set, the MAC transmitter and receiver consider the S-VLAN packets (type = 0x88A8) as valid VLAN tagged packets.	
		0	S-VLAN is Disabled
		1	S-VLAN is Enabled
17 (R/W)	VTIM	VLAN Tag Inverse Match Enable. When the EMAC_VLANTAG_CTL.VTIM bit is set, the EMAC_VLANTAG_CTL.VTIM bit enables the VLAN tag inverse matching. The packets without matching VLAN tag are marked as matched. When cleared (=0), the EMAC_VLANTAG_CTL.VTIM bit enables the VLAN tag perfect matching. The packets with matched VLAN tag are marked as matched.	
		0	VLAN Tag Inverse Match is Disabled
		1	VLAN Tag Inverse Match is Enabled
16 (R/W)	ETV	Enable 12-Bit VLAN Tag Comparison for VLAN Hash Filtering. When the EMAC_VLANTAG_CTL.ETV bit is set, a 12-bit VLAN identifier is used for VLAN hash filtering instead of the complete 16-bit VLAN tag. Bits[11:0] of VLAN tag in the received VLAN-tagged packet are used for hash-based VLAN filtering. When EMAC_VLANTAG_CTL.ETV = 0, all 16 bits of the 15th and 16th bytes of the received VLAN packet are used for VLAN hash filtering.	
		0	12-Bit VLAN Tag Comparison is Disabled
		1	12-Bit VLAN Tag Comparison is Enabled
3:2 (R/W)	OFS	Offset. The EMAC_VLANTAG_CTL.OFS field holds the address offset of the MAC VLAN Tag Filter Register which the application is trying to access. The width of the field depends on the number of MAC VLAN tag registers enabled.	

Table 30-236: EMAC_VLANTAG_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W)	CT	Command Type. The EMAC_VLANTAG_CTL.CT bit indicates if the current register access is a read or a write. When set, the EMAC_VLANTAG_CTL.CT bit indicates a read operation. When cleared (=0), it indicates a write operation.	
		0	Write Operation
		1	Read Operation
0 (R/W)	OB	Operation Busy. The EMAC_VLANTAG_CTL.OB bit is set along with a read or write command for initiating the indirect access to per VLAN Tag Filter register. The EMAC_VLANTAG_CTL.OB bit is reset when the read or write command to per VLAN Tag Filter indirect access register is complete. The next indirect register access can be initiated only after EMAC_VLANTAG_CTL.OB = 0. During a write operation, the bit is reset only after the data has been written into the Per VLAN Tag register. During a read operation, the data should be read from the EMAC_VLANTAG_DAT register only after EMAC_VLANTAG_CTL.OB = 0.	
		0	Operation Busy is Disabled
		1	Operation Busy is Enabled

VLAN Tag Indirect Access Data Register

The EMAC_VLANTAG_DAT register holds the read/write data for Indirect Access of the Per VLAN Tag registers. During the read access, this field contains valid read data only after the OB bit is reset. During the write access, this field should be valid prior to EMAC_VLANTAG_CTL.OB = 1

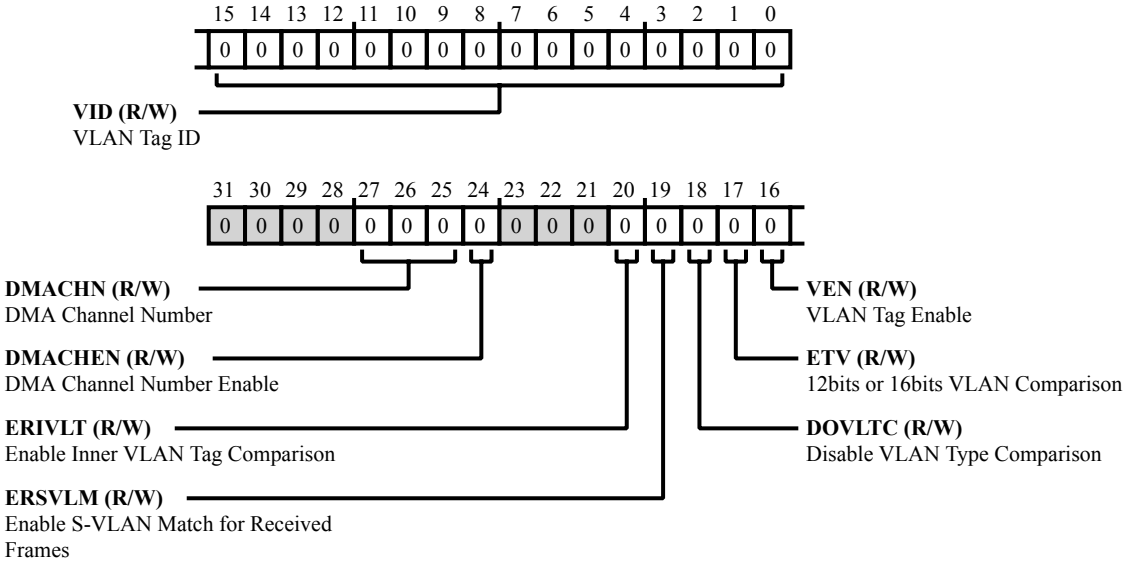

Figure 30-182: EMAC_VLANTAG_DAT Register Diagram

Table 30-237: EMAC_VLANTAG_DAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
27:25 (R/W)	DMACHN	DMA Channel Number. The EMAC_VLANTAG_DAT.DMACHN field indicates the DMA channel number to which the VLAN tagged frame is to be routed, when the routing is based on the VLAN tag filter. If the routing is not based on the VLAN tag filter, this field does not need to be programmed.	
24 (R/W)	DMACHEN	DMA Channel Number Enable. The EMAC_VLANTAG_DAT.DMACHEN bit is the enable for the DMA channel number value programmed in the field DMACH. When EMAC_VLANTAG_DAT.DMACHEN = 0, the routing does not occur based on VLAN filter result. The frame is routed based on DA-based DMA channel routing.	
		0	DMA Channel Number is Disabled
		1	DMA Channel Number is Enabled

Table 30-237: EMAC_VLANTAG_DAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
20 (R/W)	ERIVLT	Enable Inner VLAN Tag Comparison. The EMAC_VLANTAG_DAT.ERIVLT bit is valid only when the Double VLAN Tag Enable of the filter is set. When the EMAC_VLANTAG_DAT.ERIVLT bit and the EDVLP field are set, the MAC receiver enables operation on the inner VLAN tag (if present). When EMAC_VLANTAG_DAT.ERIVLT = 0, the MAC receiver enables operation on the outer VLAN tag (if present).	
		0	Inner VLAN Tag Comparison is Disabled
		1	Inner VLAN Tag Comparison is Enabled
19 (R/W)	ERSVLM	Enable S-VLAN Match for Received Frames. The EMAC_VLANTAG_DAT.ERSVLM bit is valid only when VLAN Tag enable of the filter is set. When the EMAC_VLANTAG_DAT.ERSVLM bit is set, the MAC receiver enables filtering or matching for S-VLAN (Type = 0x88A8) packets. When EMAC_VLANTAG_DAT.ERSVLM = 0, the MAC receiver enables filtering or matching for C-VLAN (Type = 0x8100) packets.	
		0	Receive S-VLAN Match is Disabled
		1	Receive S-VLAN Match is Enabled
18 (R/W)	DOVLTC	Disable VLAN Type Comparison. The EMAC_VLANTAG_DAT.DOVLTC bit is valid only when VLAN tag enable of the filter is set. When the EMAC_VLANTAG_DAT.DOVLTC bit is set, the MAC does not check whether the VLAN tag specified by the Enable Inner VLAN Tag Comparison bit is of type S-VLAN or C-VLAN. When EMAC_VLANTAG_DAT.DOVLTC = 0, the MAC filters or matches the VLAN Tag specified by the Enable Inner VLAN Tag Comparison bit only when VLAN Tag type is similar to the one specified by the Enable S-VLAN match for received frames bit.	
		0	VLAN Type Comparison is Enabled
		1	VLAN Type Comparison is Disabled

Table 30-237: EMAC_VLANTAG_DAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/W)	ETV	12bits or 16bits VLAN Comparison. The EMAC_VLANTAG_DAT.ETV bit is valid only when VEN of the filter is set. When the EMAC_VLANTAG_DAT.ETV bit is set, a 12-bit VLAN identifier is used for comparing and filtering instead of the complete 16-bit VLAN tag. Bits [11:0] of VLAN tag are compared with the corresponding field in the received VLAN-tagged packet.	
		0	16 Bit VLAN Comparison
		1	12 Bit VLAN Comparison
16 (R/W)	VEN	VLAN Tag Enable. The EMAC_VLANTAG_DAT.VEN bit is used to enable or disable the VLAN tag. When the EMAC_VLANTAG_DAT.VEN bit is set, the MAC compares the VLAN tag of received packet with the VLAN Tag ID. When EMAC_VLANTAG_DAT.VEN = 0, no comparison is performed irrespective of the programming of the other fields.	
		0	VLAN Tag is Disabled
		1	VLAN Tag is Enabled
15:0 (R/W)	VID	VLAN Tag ID. The EMAC_VLANTAG_DAT.VID field holds the VLAN tag value which is used by the MAC for perfect comparison. It is valid when VLAN Tag Enable is set.	

Watchdog Timeout Register

The EMAC_WDT_TMOUT register controls the watchdog timeout for received packets.

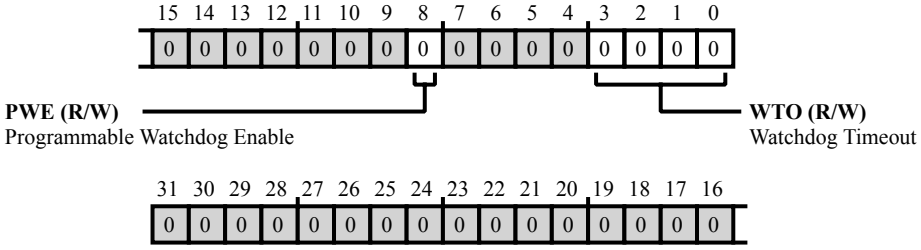

Figure 30-183: EMAC_WDT_TMOUT Register Diagram

Table 30-238: EMAC_WDT_TMOUT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W)	PWE	Programmable Watchdog Enable. When the EMAC_WDT_TMOUT.PWE bit is set and the EMAC_MAC_CFG.WD = 0, the EMAC_WDT_TMOUT.WTO field is used as watchdog timeout for a received packet. When the EMAC_WDT_TMOUT.PWE bit is cleared, the watchdog timeout for a received packet is controlled by EMAC_MAC_CFG.WD and EMAC_MAC_CFG.JE = 1.	
		0	Programmable Watchdog is Disabled
		1	Programmable Watchdog is Enabled
3:0 (R/W)	WTO	Watchdog Timeout. When the EMAC_WDT_TMOUT.PWE bit is set and EMAC_MAC_CFG.WD = 0, the EMAC_WDT_TMOUT.WTO field is used as watchdog timeout for a received packet. If the length of a received packet exceeds the value of this field, such packet is terminated and declared as an error packet. Note: When the EMAC_WDT_TMOUT.PWE bit is set, the value in this field should be more than 1,522 (0x05F2). Otherwise, the IEEE 802.3-specified valid tagged packets are declared as error packets and then dropped.

MMC Control Register

The EMAC_MMC_CTRL register establishes the operating mode of MMC.

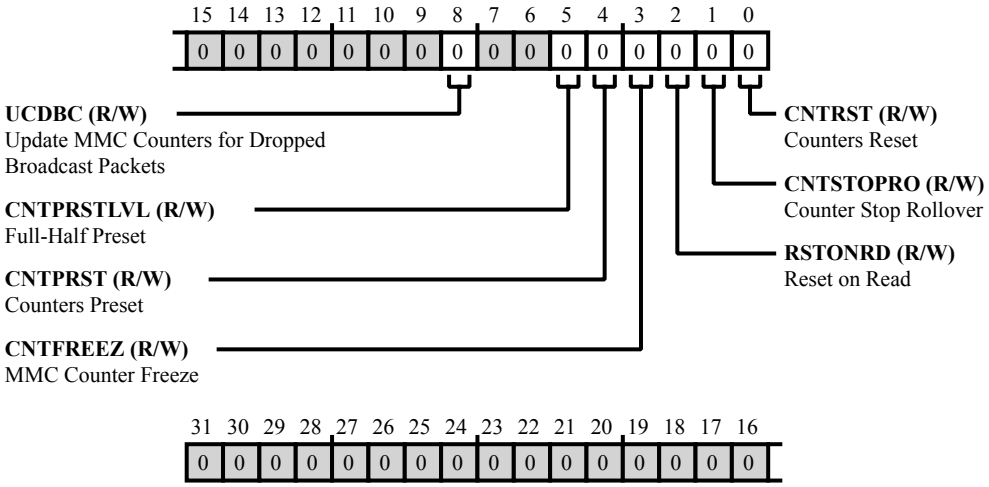

Figure 30-184: EMAC_MMC_CTRL Register Diagram

Table 30-239: EMAC_MMC_CTRL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W)	UCDBC	Update MMC Counters for Dropped Broadcast Packets. Note: The EMAC_MMC_CTRL.CNTRST bit has a higher priority than the EMAC_MMC_CTRL.CNTPRST bit. Therefore, when the software tries to set both bits in the same write cycle, all counters are cleared and the EMAC_MMC_CTRL.CNTPRST bit is not set. When EMAC_MMC_CTRL.UCDBC is set (=1), the MAC updates all related MMC counters for broadcast packets that are dropped because of the EMAC_MACPKT_FILT.DBF bit. When EMAC_MMC_CTRL.UCDBC is cleared (=0), the MMC counters are not updated for dropped broadcast packets.	
		0	Update MMC Counters for Dropped Broadcast Packets is Disabled
		1	Update MMC Counters for Dropped Broadcast Packets is Enabled

Table 30-239: EMAC_MMC_CTRL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (R/W)	CNTPRSTLVL	Full-Half Preset. When EMAC_MMC_CTRL.CNTPRSTLVL = 0 and EMAC_MMC_CTRL.CNTPRST = 1, all MMC counters are preset to almost-half value. All octet counters are preset to 0x7FFF_F800 (Half 2KB) and all packet-counters gets preset to 0x7FFF_FFF0 (Half 16). When EMAC_MMC_CTRL.CNTPRSTLVL= 1 and EMAC_MMC_CTRL.CNTPRST = 1, all MMC counters are preset to almost-full value. All octet counters get preset to 0xFFFF_F800 (Full 2KB) and all packet-counters gets preset to 0xFFFF_FFF0 (Full 16). For 16-bit counters, the almost-half preset values are 0x7800 and 0x7FF0 for the respective octet and packet counters. Similarly, the almost-full preset values for the 16-bit counters are 0xF800 and 0xFFF0.	
		0	Full-Half Preset is Disabled
		1	Full-Half Preset is Enabled
4 (R/W)	CNTPRST	Counters Preset. When the EMAC_MMC_CTRL.CNTPRST bit is set, all counters are initialized or preset to almost full or almost half according to the EMAC_MMC_CTRL.CNTPRSTLVL bit. The EMAC_MMC_CTRL.CNTPRST bit is cleared automatically after 1 clock cycle. The EMAC_MMC_CTRL.CNTPRST bit, along with the EMAC_MMC_CTRL.CNTPRSTLVL bit, is useful for debugging and testing the assertion of interrupts because of MMC counter becoming half-full or full. Access restriction applies. Self-cleared. Write 0 to clear. Write 1 to set.	
		0	Counters Preset is Disabled
		1	Counters Preset is Enabled
3 (R/W)	CNTFREEZ	MMC Counter Freeze. When the EMAC_MMC_CTRL.CNTFREEZ bit is set (=1), it freezes all MMC counters to their current value. Until EMAC_MMC_CTRL.CNTFREEZ = 0, no MMC counter is updated because of any transmitted or received packet. If any MMC counter is read with the reset on read bit set, then that counter is also cleared in this mode.	
		0	MMC Counter Freeze is Disabled
		1	MMC Counter Freeze is Enabled

Table 30-239: EMAC_MMC_CTRL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W)	RSTONRD	Reset on Read. When the `EMAC_MMC_CTRL.RSTONRD` bit is set (=1), the MMC counters are reset to zero after read (self-clearing after reset). The counters are cleared when the least significant byte lane (Bits[7:0]) is read.	
		0	Reset on Read is Disabled
		1	Reset on Read is Enabled
1 (R/W)	CNTSTOPRO	Counter Stop Rollover. When the `EMAC_MMC_CTRL.CNTSTOPRO` bit is set (=1), the counter does not roll over to zero after reaching the maximum value.	
		0	Counter Stop Rollover is Disabled
		1	Counter Stop Rollover is Enabled
0 (R/W)	CNTRST	Counters Reset. When the `EMAC_MMC_CTRL.CNTRST` bit is set (=1), all counters are reset. The `EMAC_MMC_CTRL.CNTRST` bit is cleared automatically after 1 clock cycle. Access restriction applies. Self-cleared. Write 0 to clear. Write 1 to set.	
		0	Counters are Not Reset
		1	All Counters are Reset

MMC Receive FPE Interrupt Status Register

The EMAC_MMC_FPE_RXINT register maintains the interrupts generated from all FPE-related receive statistics counters. The EMAC_MMC_FPE_RXINT register maintains the interrupts generated when transmit statistic counters reach half their maximum values (0x8000_0000 for the 32-bit counter and 0x8000 for 16-bit counter), and when they cross their maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter). When the Counter Stop Rollover is set, the interrupts are set but the counter remains at all-ones.

The EMAC_MMC_FPE_RXINT register is a 32-bit register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits[7:0]) of the respective counter must be read to clear the interrupt bit.

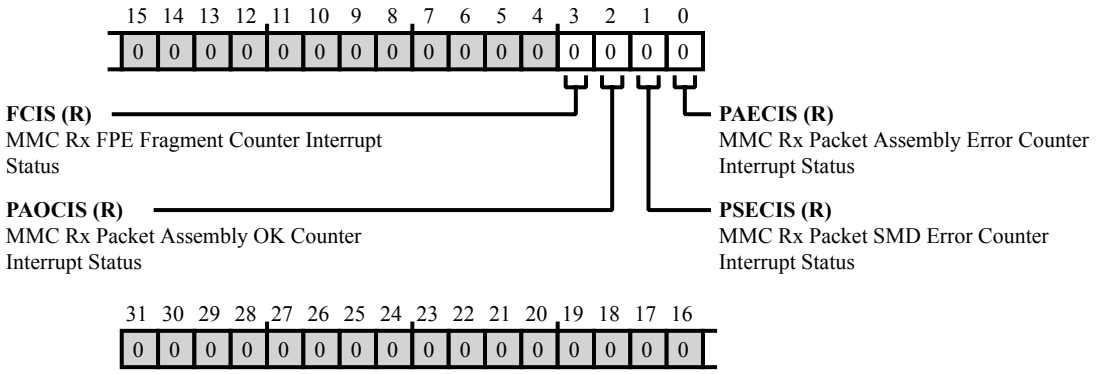

Figure 30-185: EMAC_MMC_FPE_RXINT Register Diagram

Table 30-240: EMAC_MMC_FPE_RXINT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/NW)	FCIS	MMC Rx FPE Fragment Counter Interrupt Status. The EMAC_MMC_FPE_RXINT.FCIS bit is set when the EMAC_RXFPE_FRGMNT_CNT counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event. Exists when any one of the RX/TX MMC counters are enabled during FPE-enabled configuration.	
		0	MMC Rx FPE Fragment Counter Interrupt Status Not Detected
		1	MMC Rx FPE Fragment Counter Interrupt Status Detected

Table 30-240: EMAC_MMC_FPE_RXINT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/NW)	PAOCIS	MMC Rx Packet Assembly OK Counter Interrupt Status. The `EMAC_MMC_FPE_RXINT.PAOCIS` bit is set when the EMAC_RXPKT_ASOK_CNT counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event. Exists when any one of the RX/TX MMC counters are enabled during FPE-enabled configuration.	
		0	MMC Rx Packet Assembly OK Counter Interrupt Status Not Detected
		1	MMC Rx Packet Assembly OK Counter Interrupt Status Detected
1 (R/NW)	PSECIS	MMC Rx Packet SMD Error Counter Interrupt Status. The `EMAC_MMC_FPE_RXINT.PSECIS` bit is set when the EMAC_RXPKT_SMDERR_CNT counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event. Exists when any one of the RX/TX MMC counters are enabled during FPE-enabled configuration.	
		0	MMC Rx Packet SMD Error Counter Interrupt Status Not Detected
		1	MMC Rx Packet SMD Error Counter Interrupt Status Detected
0 (R/NW)	PAECIS	MMC Rx Packet Assembly Error Counter Interrupt Status. The `EMAC_MMC_FPE_RXINT.PAECIS` bit is set when the EMAC_RXPKT_ASERR_CNT counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event. Exists when any one of the RX/TX MMC counters are enabled during FPE-enabled configuration.	
		0	MMC Rx Packet Assembly Error Counter Interrupt Status Not Detected
		1	MMC Rx Packet Assembly Error Counter Interrupt Status Detected

MMC Receive FPE Interrupt Mask Register

The EMAC_MMC_FPE_RXIMSK register maintains the masks for interrupts generated from all FPE-related receive statistics counters. The EMAC_MMC_RXIMSK register maintains the masks for the interrupts generated when FPE-related receive statistic counters reach half of their maximum value or the maximum values. The EMAC_MMC_FPE_RXIMSK register is 32 bit wide.

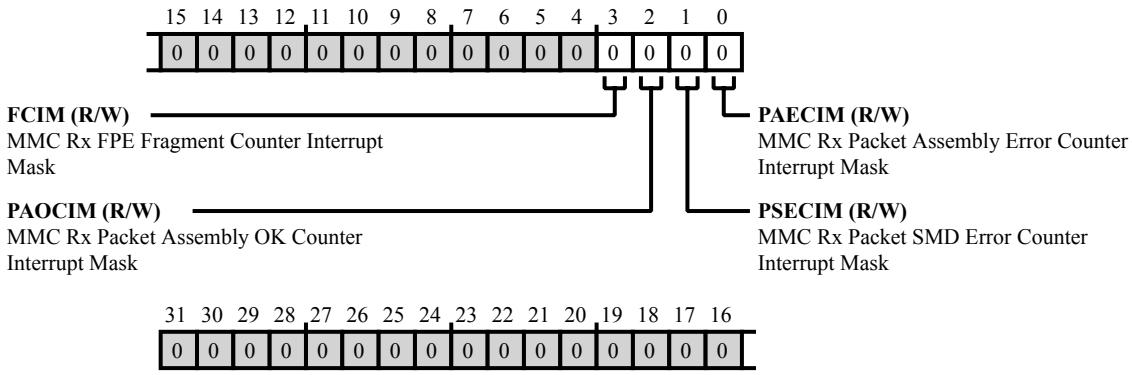

Figure 30-186: EMAC_MMC_FPE_RXIMSK Register Diagram

Table 30-241: EMAC_MMC_FPE_RXIMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	FCIM	MMC Rx FPE Fragment Counter Interrupt Mask. Setting the EMAC_MMC_FPE_RXIMSK.FCIM bit masks the interrupt when the EMAC_TXFPE_FRGMNT_CNT counter reaches half of the maximum value or the maximum value. Exists when any one of the RX/TX MMC counters are enabled during FPE-enabled configuration.	
		0	MMC Rx FPE Fragment Counter Interrupt Mask is Disabled
		1	MMC Rx FPE Fragment Counter Interrupt Mask is Enabled

Table 30-241: EMAC_MMC_FPE_RXIMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W)	PAOCIM	MMC Rx Packet Assembly OK Counter Interrupt Mask. Setting the `EMAC_MMC_FPE_RXIMSK.PAOCIM` bit masks the interrupt when the EMAC_RXPKT_ASOK_CNT counter reaches half of the maximum value or the maximum value. Exists when any one of the RX/TX MMC counters are enabled during an FPE-enabled configuration.	
		0	MMC Rx Packet Assembly OK Counter Interrupt Mask is Disabled
		1	MMC Rx Packet Assembly OK Counter Interrupt Mask is Enabled
1 (R/W)	PSECIM	MMC Rx Packet SMD Error Counter Interrupt Mask. Setting the `EMAC_MMC_FPE_RXIMSK.PSECIM` bit masks the interrupt when the EMAC_RXPKT_SMDERR_CNT counter reaches half of the maximum value or the maximum value. Exists when any one of the RX/TX MMC counters are enabled during FPE-enabled configuration.	
		0	MMC Rx Packet SMD Error Counter Interrupt Mask is Disabled
		1	MMC Rx Packet SMD Error Counter Interrupt Mask is Enabled
0 (R/W)	PAECIM	MMC Rx Packet Assembly Error Counter Interrupt Mask. Setting the `EMAC_MMC_FPE_RXIMSK.PAECIM` bit masks the interrupt when the EMAC_RXPKT_ASERR_CNT counter reaches half of the maximum value or the maximum value. Exists when any one of the RX/TX MMC counters are enabled during FPE-enabled configuration.	
		0	MMC Rx Packet Assembly Error Counter Interrupt Mask is Disabled
		1	MMC Rx Packet Assembly Error Counter Interrupt Mask is Enabled

MMC Transmit FPE Interrupt Status Register

The EMAC_MMC_FPE_TXINT register maintains the interrupts generated from all FPE related Transmit statistics counters. The MMC FPE Transmit Interrupt register maintains the interrupts generated when transmit statistic counters reach half their maximum values (0x8000_0000 for 32 bit counter and 0x8000 for 16 bit counter), and when they cross their maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter). When Counter Stop Rollover is set, the interrupts are set but the counter remains at all-ones. The MMC FPE Transmit Interrupt register is a 32 bit register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits[7:0]) of the respective counter must be read to clear the interrupt bit.

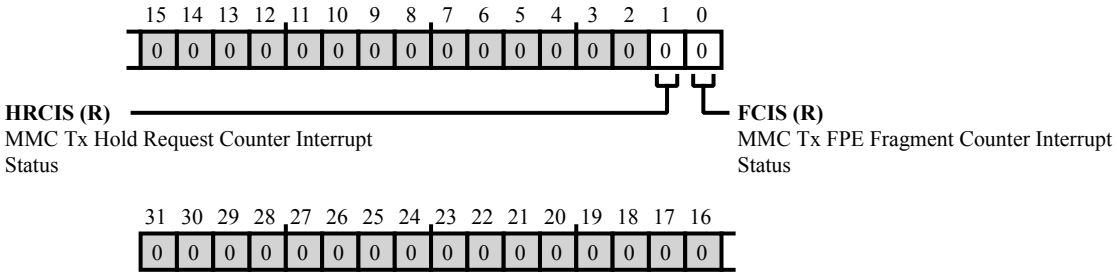

Figure 30-187: EMAC_MMC_FPE_TXINT Register Diagram

Table 30-242: EMAC_MMC_FPE_TXINT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/NW)	HRCIS	MMC Tx Hold Request Counter Interrupt Status. The EMAC_MMC_FPE_TXINT.HRCIS bit is set when the EMAC_TXHLDRQ_CNT counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event. Exists when any one of the RX/TX MMC counters are enabled during FPE with AV_EST Enabled configuration.	
		0	MMC Tx Hold Request Counter Interrupt Status Not Detected
		1	MMC Tx Hold Request Counter Interrupt Status Detected

Table 30-242: EMAC_MMC_FPE_TXINT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/NW)	FCIS	MMC Tx FPE Fragment Counter Interrupt Status. The `EMAC_MMC_FPE_TXINT.FCIS` bit is set when the EMAC_TXFPE_FRGMNT_CNT counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event. Exists when any one of the RX/TX MMC counters are enabled during FPE-enabled configuration.	
		0	MMC Tx FPE Fragment Counter Interrupt Status Not Detected
		1	MMC Tx FPE Fragment Counter Interrupt Status Detected

MMC Transmit FPE Interrupt Mask Register

The EMAC_MMC_FPE_TXIMSK register maintains the masks for interrupts generated from all FPE related Transmit statistics counters. The MMC Receive Interrupt Mask register maintains the masks for the interrupts generated when FPE related receive statistic counters reach half of their maximum value or the maximum values. The EMAC_MMC_FPE_TXIMSK register is 32 bit wide.

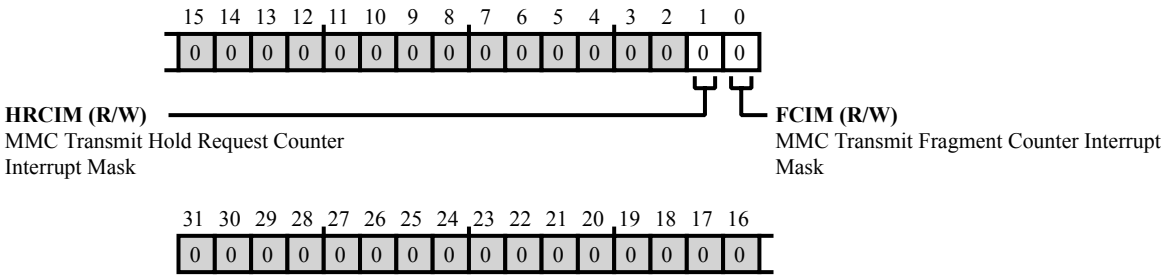

Figure 30-188: EMAC_MMC_FPE_TXIMSK Register Diagram

Table 30-243: EMAC_MMC_FPE_TXIMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W)	HRCIM	MMC Transmit Hold Request Counter Interrupt Mask. Setting the EMAC_MMC_FPE_TXIMSK.HRCIM bit masks the interrupt when the EMAC_TXHLDRQ_CNT counter reaches half of the maximum value or the maximum value.	
		0	MMC Transmit Hold Request Counter Interrupt Mask is Disabled
		1	MMC Transmit Hold Request Counter Interrupt Mask is Enabled
0 (R/W)	FCIM	MMC Transmit Fragment Counter Interrupt Mask. Setting the EMAC_MMC_FPE_TXIMSK.FCIM bit masks the interrupt when the EMAC_TXFPE_FRGMNT_CNT counter reaches half of the maximum value or the maximum value. Exists when any one of the RX/TX MMC counters are enabled during FPE-enabled configuration.	
		0	MMC Transmit Fragment Counter Interrupt Mask is Disabled
		1	MMC Transmit Fragment Counter Interrupt Mask is Enabled

MMC Receive IPC Interrupt Status Register

The EMAC_MMC_IPC_RXINT register maintains the interrupt that the receive IPC statistic counters generate.

The EMAC_MMC_IPC_RXINT register maintains the interrupts generated when receive IPC statistic counters reach half their maximum values (0x8000_0000 for 32 bit counter and 0x8000 for 16 bit counter), and when they cross their maximum values (0xFFFF_FFFF for 32 bit counter and 0xFFFF for 16 bit counter). When Counter Stop Rollover is set, the interrupts are set but the counter remains at all-ones.

The EMAC_MMC_IPC_RXINT register is 32 bit wide. When the MMC IPC counter that caused the interrupt is read, its corresponding interrupt bit is cleared. The counter's least-significant byte lane (Bits[7:0]) must be read to clear the interrupt bit.

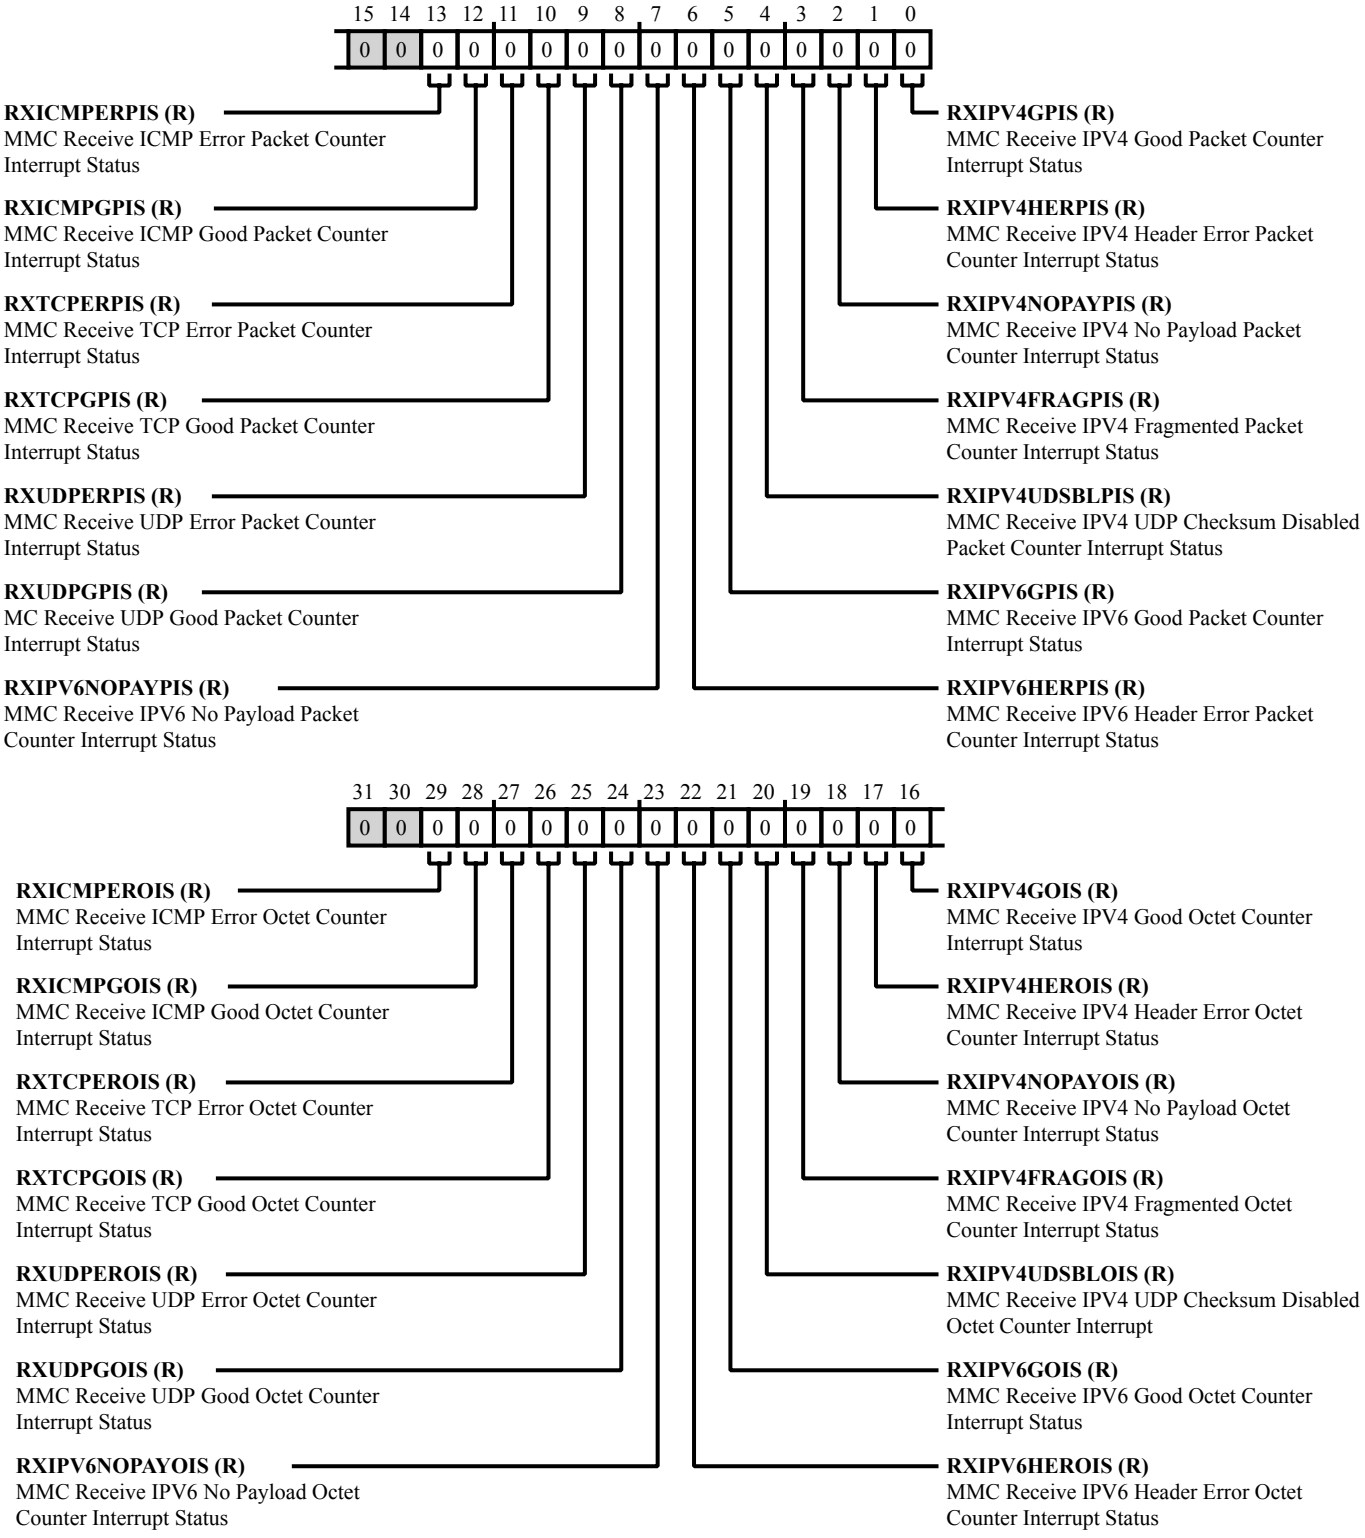

Figure 30-189: EMAC_MMC_IPC_RXINT Register Diagram

Table 30-244: EMAC_MMC_IPC_RXINT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
29 (R/NW)	RXICMPEROIS	MMC Receive ICMP Error Octet Counter Interrupt Status. The `EMAC_MMC_IPC_RXINT.RXICMPEROIS` bit is set when the EMAC_RXICMP_ERR_OCNT counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Receive ICMP Error Octet Counter Interrupt Status Not Detected
		1	MMC Receive ICMP Error Octet Counter Interrupt Status Detected
28 (R/NW)	RXICMPGOIS	MMC Receive ICMP Good Octet Counter Interrupt Status. The `EMAC_MMC_IPC_RXINT.RXICMPGOIS` bit is set when the EMAC_RXICMP_OCNT_G counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Receive ICMP Good Octet Counter Interrupt Status Not Detected
		1	MMC Receive ICMP Good Octet Counter Interrupt Status Detected
27 (R/NW)	RXTCPEROIS	MMC Receive TCP Error Octet Counter Interrupt Status. The `EMAC_MMC_IPC_RXINT.RXTCPEROIS` bit is set when the EMAC_RXTCP_ERR_OCNT counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Receive TCP Error Octet Counter Interrupt Status Not Detected
		1	MMC Receive TCP Error Octet Counter Interrupt Status Detected
26 (R/NW)	RXTCPGOIS	MMC Receive TCP Good Octet Counter Interrupt Status. The `EMAC_MMC_IPC_RXINT.RXTCPGOIS` bit is set when the EMAC_RXTCP_OCNT_G counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Receive TCP Good Octet Counter Interrupt Status Not Detected
		1	MMC Receive TCP Good Octet Counter Interrupt Status Detected

Table 30-244: EMAC_MMC_IPC_RXINT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
25 (R/NW)	RXUDPEROIS	MMC Receive UDP Error Octet Counter Interrupt Status. The `EMAC_MMC_IPC_RXINT.RXUDPEROIS` bit is set when the EMAC_RXUDP_ERR_OCNT counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Receive UDP Error Octet Counter Interrupt Status Not Detected
		1	MMC Receive UDP Error Octet Counter Interrupt Status Detected
24 (R/NW)	RXUDPGOIS	MMC Receive UDP Good Octet Counter Interrupt Status. The `EMAC_MMC_IPC_RXINT.RXUDPGOIS` bit is set when the EMAC_RXUDP_OCNT_G counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Receive UDP Good Octet Counter Interrupt Status Not Detected
		1	MMC Receive UDP Good Octet Counter Interrupt Status Detected
23 (R/NW)	RXIPV6NOPAYOIS	MMC Receive IPV6 No Payload Octet Counter Interrupt Status. The `EMAC_MMC_IPC_RXINT.RXIPV6NOPAYOIS` bit is set when the EMAC_RXIPV6_PYLD_OCNT counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Receive IPV6 No Payload Octet Counter Interrupt Status Not Detected
		1	MMC Receive IPV6 No Payload Octet Counter Interrupt Status Detected
22 (R/NW)	RXIPV6HEROIS	MMC Receive IPV6 Header Error Octet Counter Interrupt Status. The `EMAC_MMC_IPC_RXINT.RXIPV6HEROIS` bit is set when the EMAC_RXIPV6_HDRERR_OCNT counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Receive IPV6 Header Error Octet Counter Interrupt Status Not Detected
		1	MMC Receive IPV6 Header Error Octet Counter Interrupt Status Detected

Table 30-244: EMAC_MMC_IPC_RXINT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
21 (R/NW)	RXIPV6GOIS	MMC Receive IPV6 Good Octet Counter Interrupt Status. The `EMAC_MMC_IPC_RXINT.RXIPV6GOIS` bit is set when the EMAC_RXIPV6_OCNT_G counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Receive IPV6 Good Octet Counter Interrupt Status Not Detected
		1	MMC Receive IPV6 Good Octet Counter Interrupt Status Detected
20 (R/NW)	RXIPV4UDSBLOIS	MMC Receive IPV4 UDP Checksum Disabled Octet Counter Interrupt. The `EMAC_MMC_IPC_RXINT.RXIPV4UDSBLOIS` bit is set when the EMAC_RXIPV4_UDPCSD_OCNT reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Receive IPV4 UDP Checksum Disabled Octet Counter Interrupt Status Not Detected
		1	MMC Receive IPV4 UDP Checksum Disabled Octet Counter Interrupt Status Detected
19 (R/NW)	RXIPV4FRAGOIS	MMC Receive IPV4 Fragmented Octet Counter Interrupt Status. The `EMAC_MMC_IPC_RXINT.RXIPV4FRAGOIS` bit is set when the EMAC_RXIPV4_FRGMT_OCNT counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Receive IPV4 Fragmented Octet Counter Interrupt Status Not Detected
		1	MMC Receive IPV4 Fragmented Octet Counter Interrupt Status Detected
18 (R/NW)	RXIPV4NOPAYOIS	MMC Receive IPV4 No Payload Octet Counter Interrupt Status. The `EMAC_MMC_IPC_RXINT.RXIPV4NOPAYOIS` bit is set when the EMAC_RXIPV4_PYLD_OCNT counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Receive IPV4 No Payload Octet Counter Interrupt Status Not Detected
		1	MMC Receive IPV4 No Payload Octet Counter Interrupt Status Detected

Table 30-244: EMAC_MMC_IPC_RXINT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/NW)	RXIPV4HEROIS	MMC Receive IPV4 Header Error Octet Counter Interrupt Status. The `EMAC_MMC_IPC_RXINT.RXIPV4HEROIS` bit is set when the EMAC_RXIPV4_HDRERR_OCNT counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Receive IPV4 Header Error Octet Counter Interrupt Status Not Detected
		1	MMC Receive IPV4 Header Error Octet Counter Interrupt Status Detected
16 (R/NW)	RXIPV4GOIS	MMC Receive IPV4 Good Octet Counter Interrupt Status. The `EMAC_MMC_IPC_RXINT.RXIPV4GOIS` bit is set when the EMAC_RXIPV4_OCNT_G counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Receive IPV4 Good Octet Counter Interrupt Status Not Detected
		1	MMC Receive IPV4 Good Octet Counter Interrupt Status Detected
13 (R/NW)	RXICMPERPIS	MMC Receive ICMP Error Packet Counter Interrupt Status. The `EMAC_MMC_IPC_RXINT.RXICMPERPIS` bit is set when the EMAC_RXICMP_ERR_PCNT counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Receive ICMP Error Packet Counter Interrupt Status Not Detected
		1	MMC Receive ICMP Error Packet Counter Interrupt Status Detected
12 (R/NW)	RXICMPGPIS	MMC Receive ICMP Good Packet Counter Interrupt Status. The `EMAC_MMC_IPC_RXINT.RXICMPGPIS` bit is set when the EMAC_RXICMP_PCNT_G counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Receive ICMP Good Packet Counter Interrupt Status Not Detected
		1	MMC Receive ICMP Good Packet Counter Interrupt Status Detected

Table 30-244: EMAC_MMC_IPC_RXINT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/NW)	RXTCPERPIS	MMC Receive TCP Error Packet Counter Interrupt Status. The `EMAC_MMC_IPC_RXINT.RXTCPERPIS` bit is set when the EMAC_RXTCP_ERR_PCNT counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Receive TCP Error Packet Counter Interrupt Status Not Detected
		1	MMC Receive TCP Error Packet Counter Interrupt Status Detected
10 (R/NW)	RXTCPGPIS	MMC Receive TCP Good Packet Counter Interrupt Status. The `EMAC_MMC_IPC_RXINT.RXTCPGPIS` bit is set when the EMAC_RXTCP_PCNT_G counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Receive TCP Good Packet Counter Interrupt Status Not Detected
		1	MMC Receive TCP Good Packet Counter Interrupt Status Detected
9 (R/NW)	RXUDPERPIS	MMC Receive UDP Error Packet Counter Interrupt Status. The `EMAC_MMC_IPC_RXINT.RXUDPERPIS` bit is set when the EMAC_RXUDP_ERR_PCNT counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Receive UDP Error Packet Counter Interrupt Status Not Detected
		1	MMC Receive UDP Error Packet Counter Interrupt Status Detected
8 (R/NW)	RXUDPGPIS	MC Receive UDP Good Packet Counter Interrupt Status. The `EMAC_MMC_IPC_RXINT.RXUDPGPIS` bit is set when the EMAC_RXUDP_PCNT_G counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Receive UDP Good Packet Counter Interrupt Status Not Detected
		1	MMC Receive UDP Good Packet Counter Interrupt Status Detected

Table 30-244: EMAC_MMC_IPC_RXINT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/NW)	RXIPV6NOPAYPIS	MMC Receive IPV6 No Payload Packet Counter Interrupt Status. The `EMAC_MMC_IPC_RXINT.RXIPV6NOPAYPIS` bit is set when the EMAC_RXIPV6_PYLD_PCNT counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Receive IPV6 No Payload Packet Counter Interrupt Status Not Detected
		1	MMC Receive IPV6 No Payload Packet Counter Interrupt Status Detected
6 (R/NW)	RXIPV6HERPIS	MMC Receive IPV6 Header Error Packet Counter Interrupt Status. The `EMAC_MMC_IPC_RXINT.RXIPV6HERPIS` bit is set when the EMAC_RXIPV6_HDRERR_PCNT counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Receive IPV6 Header Error Packet Counter Interrupt Status Not Detected
		1	MMC Receive IPV6 Header Error Packet Counter Interrupt Status Detected
5 (R/NW)	RXIPV6GPIS	MMC Receive IPV6 Good Packet Counter Interrupt Status. The `EMAC_MMC_IPC_RXINT.RXIPV6GPIS` bit is set when the EMAC_RXIPV6_PCNT_G counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Receive IPV6 Good Packet Counter Interrupt Status Not Detected
		1	MMC Receive IPV6 Good Packet Counter Interrupt Status Detected
4 (R/NW)	RXIPV4UDSBLPIS	MMC Receive IPV4 UDP Checksum Disabled Packet Counter Interrupt Status. The `EMAC_MMC_IPC_RXINT.RXIPV4UDSBLPIS` bit is set when the EMAC_RXIPV4_UDPCSD_PCNT counter reaches half of the maximum value or the maximum value.	
		0	MMC Receive IPV4 UDP Checksum Disabled Packet Counter Interrupt Status Not Detected
		1	MMC Receive IPV4 UDP Checksum Disabled Packet Counter Interrupt Status Detected

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/NW)	RXIPV4FRAGPIS	MMC Receive IPV4 Fragmented Packet Counter Interrupt Status. The `EMAC_MMC_IPC_RXINT.RXIPV4FRAGPIS` bit is set when the EMAC_RXIPV4_FRGMT_PCNT counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Receive IPV4 Fragmented Packet Counter Interrupt Status Not Detected
		1	MMC Receive IPV4 Fragmented Packet Counter Interrupt Status Detected
2 (R/NW)	RXIPV4NOPAYPIS	MMC Receive IPV4 No Payload Packet Counter Interrupt Status. The `EMAC_MMC_IPC_RXINT.RXIPV4NOPAYPIS` bit is set when the EMAC_RXIPV4_PYLD_PCNT counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Receive IPV4 No Payload Packet Counter Interrupt Status Not Detected
		1	MMC Receive IPV4 No Payload Packet Counter Interrupt Status Detected
1 (R/NW)	RXIPV4HERPIS	MMC Receive IPV4 Header Error Packet Counter Interrupt Status. The `EMAC_MMC_IPC_RXINT.RXIPV4HERPIS` bit is set when the EMAC_RXIPV4_HDRERR_PCNT counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Receive IPV4 Header Error Packet Counter Interrupt Status Not Detected
		1	MMC Receive IPV4 Header Error Packet Counter Interrupt Status Detected
0 (R/NW)	RXIPV4GPIS	MMC Receive IPV4 Good Packet Counter Interrupt Status. The `EMAC_MMC_IPC_RXINT.RXIPV4GPIS` bit is set when the EMAC_RXIPV4_PCNT_G counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Receive IPV4 Good Packet Counter Interrupt Status Not Detected
		1	MMC Receive IPV4 Good Packet Counter Interrupt Status Detected

MMC Receive IPC Interrupt Mask Register

The EMAC_MMC_IPC_RXIMSK register maintains the mask for the interrupt generated from the receive IPC statistic counters.

The MMC Receive Checksum Off load Interrupt Mask register maintains the masks for the interrupts generated when the receive IPC (Checksum Off load) statistic counters reach half their maximum value, and when they reach their maximum values. The EMAC_MMC_IPC_RXIMSK register is 32 bits wide.

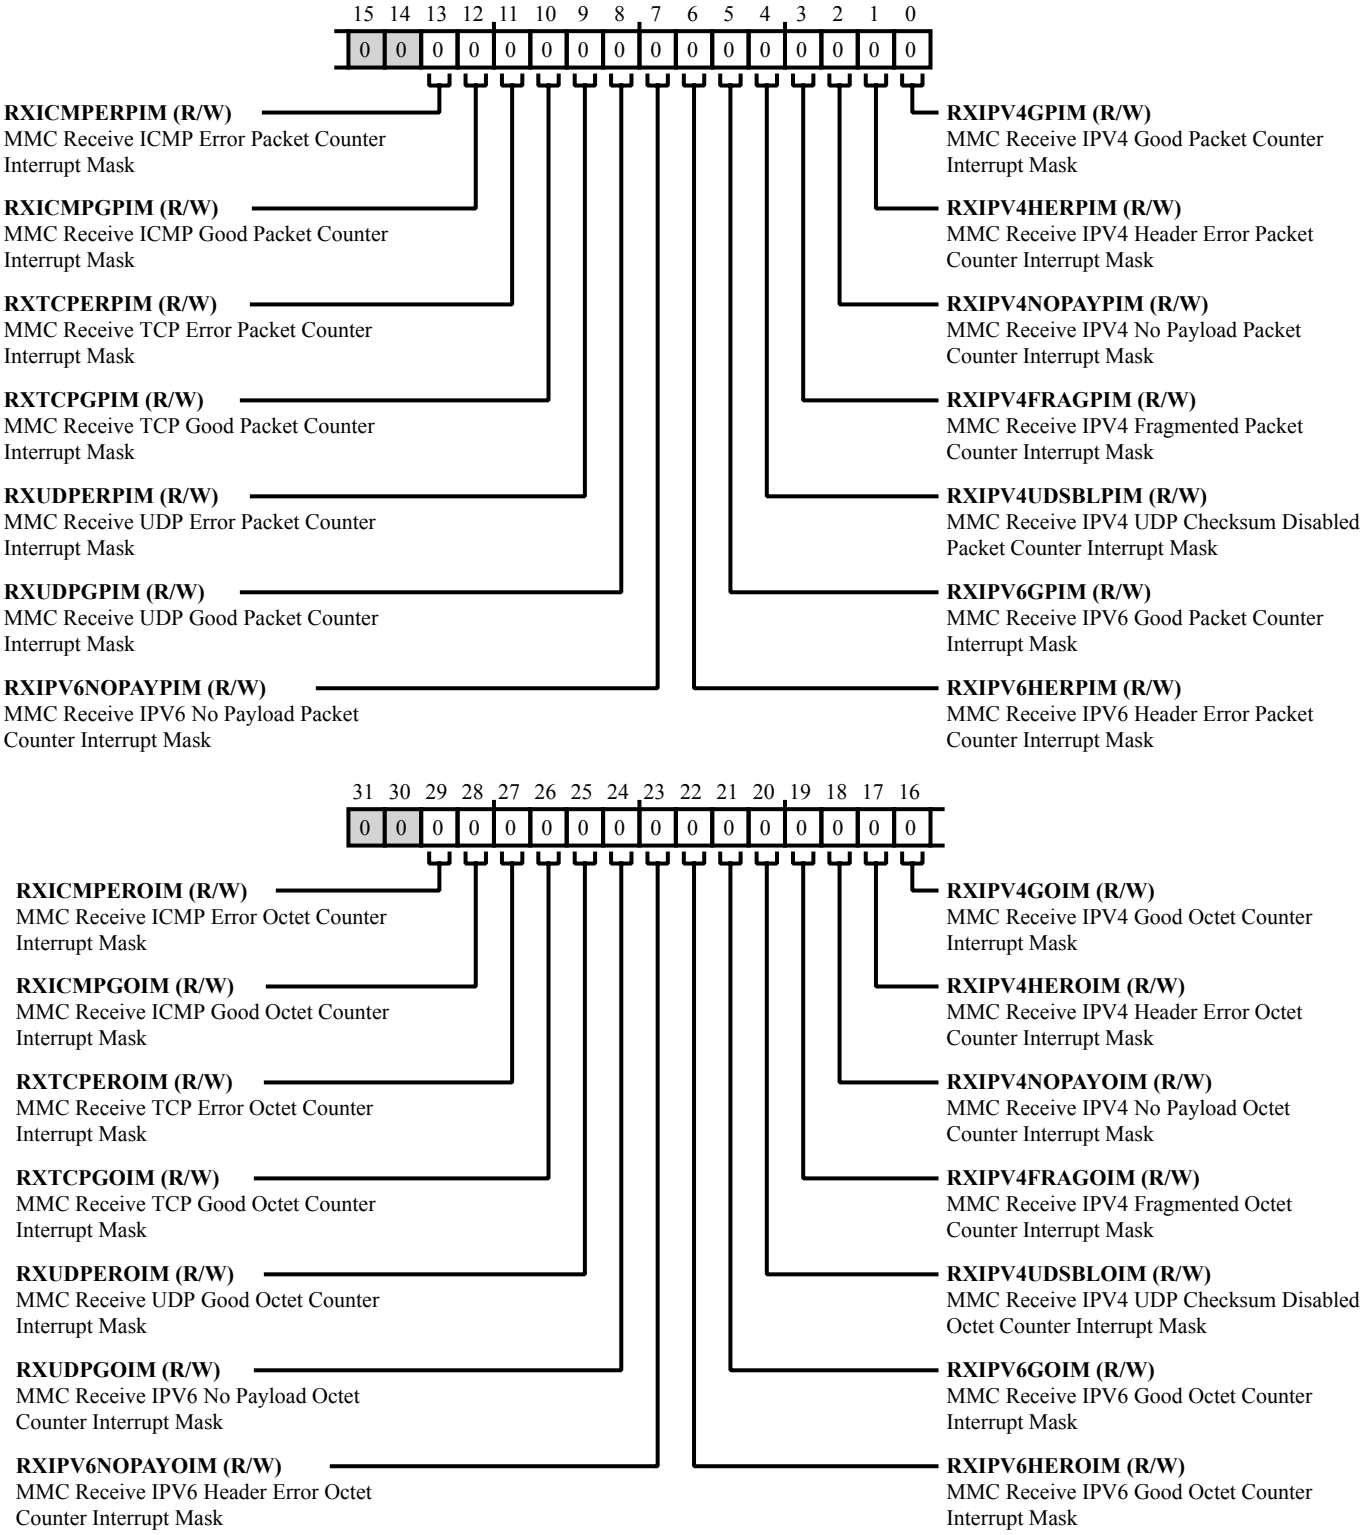

Figure 30-190: EMAC_MMC_IPC_RXIMSK Register Diagram

Table 30-245: EMAC_MMC_IPC_RXIMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
29 (R/W)	RXICMPEROIM	MMC Receive ICMP Error Octet Counter Interrupt Mask. Setting the `EMAC_MMC_IPC_RXIMSK.RXICMPEROIM` bit masks the interrupt when the EMAC_RXICMP_ERR_OCNT counter reaches half of the maximum value or the maximum value.	
		0	MMC Receive ICMP Error Octet Counter Interrupt Mask is Disabled
		1	MMC Receive ICMP Error Octet Counter Interrupt Mask is Enabled
28 (R/W)	RXICMPGOIM	MMC Receive ICMP Good Octet Counter Interrupt Mask. Setting the `EMAC_MMC_IPC_RXIMSK.RXICMPGOIM` bit masks the interrupt when the EMAC_RXICMP_OCNT_G counter reaches half of the maximum value or the maximum value.	
		0	MMC Receive ICMP Good Octet Counter Interrupt Mask is Disabled
		1	MMC Receive ICMP Good Octet Counter Interrupt Mask is Enabled
27 (R/W)	RXTCPEROIM	MMC Receive TCP Error Octet Counter Interrupt Mask. Setting the `EMAC_MMC_IPC_RXIMSK.RXTCPEROIM` bit masks the interrupt when the EMAC_RXTCP_ERR_OCNT counter reaches half of the maximum value or the maximum value.	
		0	MMC Receive TCP Error Octet Counter Interrupt Mask is Disabled
		1	MMC Receive TCP Error Octet Counter Interrupt Mask is Enabled
26 (R/W)	RXTCPGOIM	MMC Receive TCP Good Octet Counter Interrupt Mask. Setting the `EMAC_MMC_IPC_RXIMSK.RXTCPGOIM` bit masks the interrupt when the EMAC_RXTCP_OCNT_G counter reaches half of the maximum value or the maximum value.	
		0	MMC Receive TCP Good Octet Counter Interrupt Mask is Disabled
		1	MMC Receive TCP Good Octet Counter Interrupt Mask is Enabled

		0	MMC Receive IPV6 Good Octet Counter Interrupt Mask is Disabled
		1	MMC Receive IPV6 Good Octet Counter Interrupt Mask is Enabled
20 (R/W)	RXIPV4UDSBLOIM	MMC Receive IPV4 UDP Checksum Disabled Octet Counter Interrupt Mask. Setting the `EMAC_MMC_IPC_RXIMSK.RXIPV4UDSBLOIM` bit masks the interrupt when the EMAC_RXIPV4_UDPCSD_OCNT counter reaches half of the maximum value or the maximum value.	
		0	MMC Receive IPV4 UDP Checksum Disabled Octet Counter Interrupt Mask is Disabled
		1	MMC Receive IPV4 UDP Checksum Disabled Octet Counter Interrupt Mask is Enabled
19 (R/W)	RXIPV4FRAGOIM	MMC Receive IPV4 Fragmented Octet Counter Interrupt Mask. Setting the `EMAC_MMC_IPC_RXIMSK.RXIPV4FRAGOIM` bit masks the interrupt when the EMAC_RXIPV4_FRGMT_OCNT counter reaches half of the maximum value or the maximum value.	
		0	MMC Receive IPV4 Fragmented Octet Counter Interrupt Mask is Disabled
		1	MMC Receive IPV4 Fragmented Octet Counter Interrupt Mask is Enabled
18 (R/W)	RXIPV4NOPAYOIM	MMC Receive IPV4 No Payload Octet Counter Interrupt Mask. Setting the `EMAC_MMC_IPC_RXIMSK.RXIPV4NOPAYOIM` bit masks the interrupt when the EMAC_RXIPV4_PYLD_OCNT counter reaches half of the maximum value or the maximum value.	
		0	MMC Receive IPV4 No Payload Octet Counter Interrupt Mask is Disabled
		1	MMC Receive IPV4 No Payload Octet Counter Interrupt Mask is Enabled

Table 30-245: EMAC_MMC_IPC_RXIMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/W)	RXIPV4HEROIM	MMC Receive IPV4 Header Error Octet Counter Interrupt Mask. Setting the `EMAC_MMC_IPC_RXIMSK.RXIPV4HEROIM` bit masks the interrupt when the EMAC_RXIPV4_HDRERR_OCNT counter reaches half of the maximum value or the maximum value.	
		0	MMC Receive IPV4 Header Error Octet Counter Interrupt Mask is Disabled
		1	MMC Receive IPV4 Header Error Octet Counter Interrupt Mask is Enabled
16 (R/W)	RXIPV4GOIM	MMC Receive IPV4 Good Octet Counter Interrupt Mask. Setting the `EMAC_MMC_IPC_RXIMSK.RXIPV4GOIM` bit masks the interrupt when the EMAC_RXIPV4_OCNT_G counter reaches half of the maximum value or the maximum value.	
		0	MMC Receive IPV4 Good Octet Counter Interrupt Mask is Disabled
		1	MMC Receive IPV4 Good Octet Counter Interrupt Mask is Enabled
13 (R/W)	RXICMPERPIM	MMC Receive ICMP Error Packet Counter Interrupt Mask. Setting the `EMAC_MMC_IPC_RXIMSK.RXICMPERPIM` bit masks the interrupt when the EMAC_RXICMP_ERR_PCNT counter reaches half of the maximum value or the maximum value.	
		0	MMC Receive ICMP Error Packet Counter Interrupt Mask is Disabled
		1	MMC Receive ICMP Error Packet Counter Interrupt Mask is Enabled
12 (R/W)	RXICMPGPIM	MMC Receive ICMP Good Packet Counter Interrupt Mask. Setting the `EMAC_MMC_IPC_RXIMSK.RXICMPGPIM` bit masks the interrupt when the EMAC_RXICMP_PCNT_G counter reaches half of the maximum value or the maximum value.	
		0	MMC Receive ICMP Good Packet Counter Interrupt Mask is Disabled
		1	MMC Receive ICMP Good Packet Counter Interrupt Mask is Enabled

Table 30-245: EMAC_MMC_IPC_RXIMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W)	RXTCPERPIM	MMC Receive TCP Error Packet Counter Interrupt Mask. Setting the `EMAC_MMC_IPC_RXIMSK.RXTCPERPIM` bit masks the interrupt when the EMAC_RXTCP_ERR_PCNT counter reaches half of the maximum value or the maximum value.	
		0	MMC Receive TCP Error Packet Counter Interrupt Mask is Disabled
		1	MMC Receive TCP Error Packet Counter Interrupt Mask is Enabled
10 (R/W)	RXTCPGPIM	MMC Receive TCP Good Packet Counter Interrupt Mask. Setting the `EMAC_MMC_IPC_RXIMSK.RXTCPGPIM` bit masks the interrupt when the EMAC_RXTCP_PCNT_G counter reaches half of the maximum value or the maximum value.	
		0	MMC Receive TCP Good Packet Counter Interrupt Mask is Disabled
		1	MMC Receive TCP Good Packet Counter Interrupt Mask is Enabled
9 (R/W)	RXUDPERPIM	MMC Receive UDP Error Packet Counter Interrupt Mask. Setting the `EMAC_MMC_IPC_RXIMSK.RXUDPERPIM` bit masks the interrupt when the EMAC_RXUDP_ERR_PCNT counter reaches half of the maximum value or the maximum value.	
		0	MMC Receive UDP Error Packet Counter Interrupt Mask is Disabled
		1	MMC Receive UDP Error Packet Counter Interrupt Mask is Enabled
8 (R/W)	RXUDPGPIM	MMC Receive UDP Good Packet Counter Interrupt Mask. Setting the `EMAC_MMC_IPC_RXIMSK.RXUDPGPIM` bit masks the interrupt when the EMAC_RXUDP_PCNT_G counter reaches half of the maximum value or the maximum value.	
		0	MMC Receive UDP Good Packet Counter Interrupt Mask is Disabled
		1	MMC Receive UDP Good Packet Counter Interrupt Mask is Enabled

Table 30-245: EMAC_MMC_IPC_RXIMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	RXIPV6NOPAYPIM	MMC Receive IPV6 No Payload Packet Counter Interrupt Mask. Setting the `EMAC_MMC_IPC_RXIMSK.RXIPV6NOPAYPIM` bit masks the interrupt when the EMAC_RXIPV4_PYLD_PCNT counter reaches half of the maximum value or the maximum value.	
		0	MMC Receive IPV6 No Payload Packet Counter Interrupt Mask is Disabled
		1	MMC Receive IPV6 No Payload Packet Counter Interrupt Mask is Enabled
6 (R/W)	RXIPV6HERPIM	MMC Receive IPV6 Header Error Packet Counter Interrupt Mask. Setting the `EMAC_MMC_IPC_RXIMSK.RXIPV6HERPIM` bit masks the interrupt when the EMAC_RXIPV6_HDRERR_PCNT counter reaches half of the maximum value or the maximum value.	
		0	MMC Receive IPV6 Header Error Packet Counter Interrupt Mask is Disabled
		1	MMC Receive IPV6 Header Error Packet Counter Interrupt Mask is Enabled
5 (R/W)	RXIPV6GPIM	MMC Receive IPV6 Good Packet Counter Interrupt Mask. Setting the `EMAC_MMC_IPC_RXIMSK.RXIPV6GPIM` bit masks the interrupt when the EMAC_RXIPV6_PCNT_G counter reaches half of the maximum value or the maximum value.	
		0	MMC Receive IPV6 Good Packet Counter Interrupt Mask is Disabled
		1	MMC Receive IPV6 Good Packet Counter Interrupt Mask is Enabled
4 (R/W)	RXIPV4UDSBLPIM	MMC Receive IPV4 UDP Checksum Disabled Packet Counter Interrupt Mask. Setting the `EMAC_MMC_IPC_RXIMSK.RXIPV4UDSBLPIM` bit masks the interrupt when the EMAC_RXIPV4_UDPCSD_PCNT counter reaches half of the maximum value or the maximum value.	
		0	MMC Receive IPV4 UDP Checksum Disabled Packet Counter Interrupt Mask is Disabled
		1	MMC Receive IPV4 UDP Checksum Disabled Packet Counter Interrupt Mask is Enabled

Table 30-245: EMAC_MMC_IPC_RXIMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	RXIPV4FRAGPIM	MMC Receive IPV4 Fragmented Packet Counter Interrupt Mask. Setting the `EMAC_MMC_IPC_RXIMSK.RXIPV4FRAGPIM` bit masks the interrupt when the EMAC_RXIPV4_FRGMT_PCNT counter reaches half of the maximum value or the maximum value.	
		0	MMC Receive IPV4 Fragmented Packet Counter Interrupt Mask is Disabled
		1	MMC Receive IPV4 Fragmented Packet Counter Interrupt Mask is Enabled
2 (R/W)	RXIPV4NOPAYPIM	MMC Receive IPV4 No Payload Packet Counter Interrupt Mask. Setting the `EMAC_MMC_IPC_RXIMSK.RXIPV4NOPAYPIM` bit masks the interrupt when the EMAC_RXIPV4_PYLD_PCNT counter reaches half of the maximum value or the maximum value.	
		0	MMC Receive IPV4 No Payload Packet Counter Interrupt Mask is Disabled
		1	MMC Receive IPV4 No Payload Packet Counter Interrupt Mask is Enabled
1 (R/W)	RXIPV4HERPIM	MMC Receive IPV4 Header Error Packet Counter Interrupt Mask. Setting the `EMAC_MMC_IPC_RXIMSK.RXIPV4HERPIM` bit masks the interrupt when the EMAC_RXIPV4_HDRERR_PCNT counter reaches half of the maximum value or the maximum value.	
		0	MMC Receive IPV4 Header Error Packet Counter Interrupt Mask is Disabled
		1	MMC Receive IPV4 Header Error Packet Counter Interrupt Mask is Enabled
0 (R/W)	RXIPV4GPIM	MMC Receive IPV4 Good Packet Counter Interrupt Mask. Setting the `EMAC_MMC_IPC_RXIMSK.RXIPV4GPIM` bit masks the interrupt when the EMAC_RXIPV4_PCNT_G counter reaches half of the maximum value or the maximum value.	
		0	MMC Receive IPV4 Good Packet Counter Interrupt Mask is Disabled
		1	MMC Receive IPV4 Good Packet Counter Interrupt Mask is Enabled

MMC Receive FPE Fragment Counter Register

The EMAC_RXFPE_FRGMNT_CNT register provides the number of additional mPackets received due to preemption.

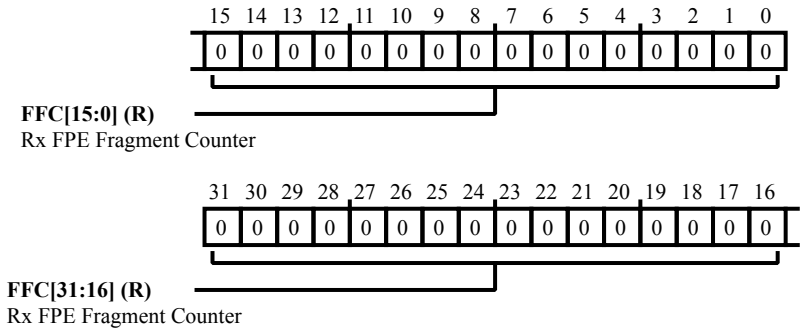

Figure 30-191: EMAC_RXFPE_FRGMNT_CNT Register Diagram

Table 30-246: EMAC_RXFPE_FRGMNT_CNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	FFC	Rx FPE Fragment Counter. The EMAC_RXFPE_FRGMNT_CNT.FFC field indicates the number of additional mPackets received due to preemption. Exists when at least one of the RX/TX MMC counters are enabled during an FPE-enabled configuration.

MMC Receive Interrupt Status Register

The EMAC_MMC_RXINT register maintains the interrupts generated from all receive statistics counters when the following occurs:

Receive statistic counters reach half of their maximum values (0x8000_0000 for 32-bit counter and 0x8000 for 16-bit counter).

Receive statistic counters cross their maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter).

When the Counter Stop Rollover is set, interrupts are set but the counter remains at all-ones. The EMAC_MMC_RXINT register is a 32 bit register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits[7:0]) of the respective counter must be read to clear the interrupt bit.

Note: R_SS_RC means that this register bit is set internally, and it is cleared when the counter register is read.

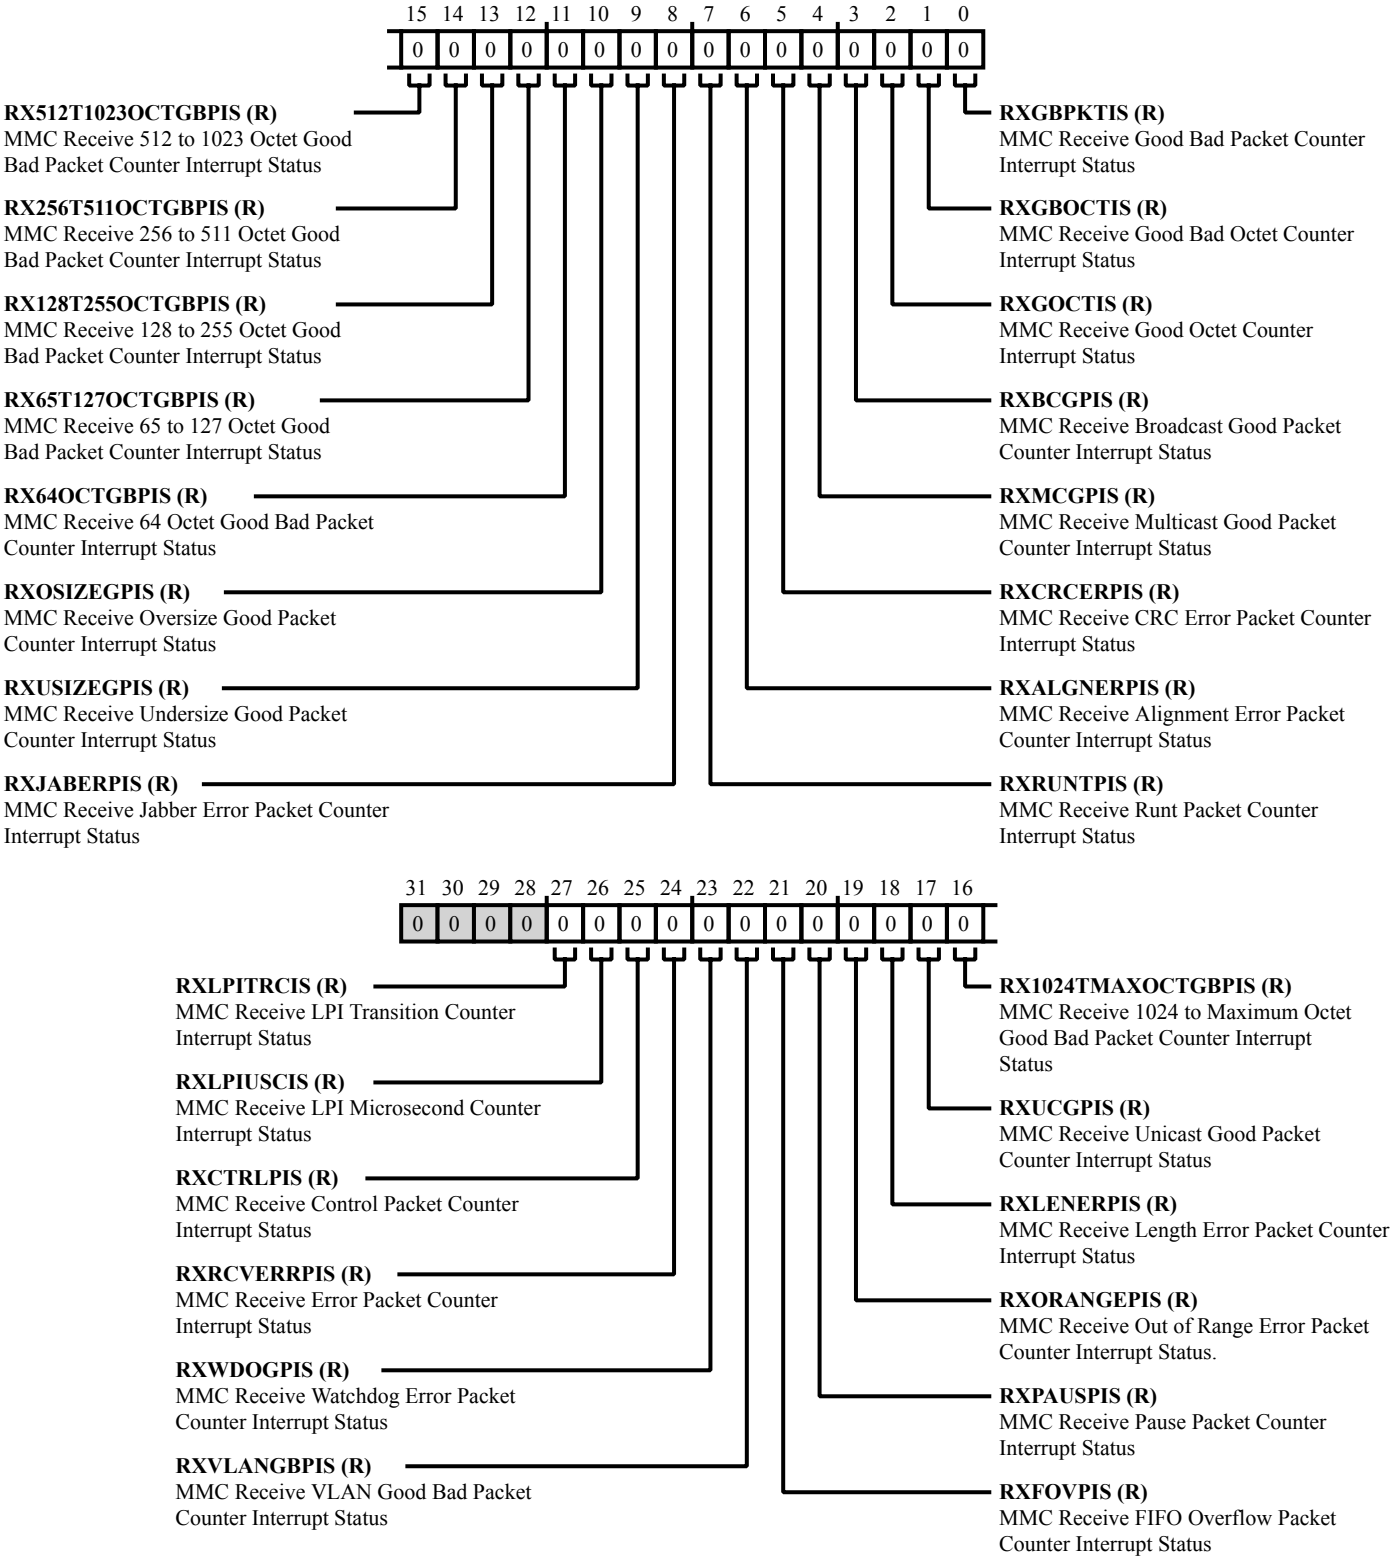

Figure 30-192: EMAC_MMC_RXINT Register Diagram

Table 30-247: EMAC_MMC_RXINT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
27 (R/NW)	RXLPITRCIS	MMC Receive LPI Transition Counter Interrupt Status. The `EMAC_MMC_RXINT.RXLPITRCIS` bit is set when the EMAC_RX_LPITRAN_CNT register reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Receive LPI Transition Counter Interrupt Status Not Detected
		1	MMC Receive LPI Transition Counter Interrupt Status Detected
26 (R/NW)	RXLPIUSCIS	MMC Receive LPI Microsecond Counter Interrupt Status. The `EMAC_MMC_RXINT.RXLPIUSCIS` bit is set when the EMAC_RX_LPIUSEC_CNT register reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Receive LPI Microsecond Counter Interrupt Status Not Detected
		1	MMC Receive LPI Microsecond Counter Interrupt Status Detected
25 (R/NW)	RXCTRLPIS	MMC Receive Control Packet Counter Interrupt Status. The `EMAC_MMC_RXINT.RXCTRLPIS` bit is set when the EMAC_RX_CTL_PCNT_G register reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Receive Control Packet Counter Interrupt Status Not Detected
		1	MMC Receive Control Packet Counter Interrupt Status Detected
24 (R/NW)	RXRCVERRPIS	MMC Receive Error Packet Counter Interrupt Status. The `EMAC_MMC_RXINT.RXRCVERRPIS` bit is set when the EMAC_RX_ERR_PCNT register reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Receive Error Packet Counter Interrupt Status Not Detected
		1	MMC Receive Error Packet Counter Interrupt Status Detected

Table 30-247: EMAC_MMC_RXINT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
23 (R/NW)	RXWDOGPIS	MMC Receive Watchdog Error Packet Counter Interrupt Status. The `EMAC_MMC_RXINT.RXWDOGPIS` bit is set when the EMAC_RX_WDTERR_PCNT register reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Receive Watchdog Error Packet Counter Interrupt Status Not Detected
		1	MMC Receive Watchdog Error Packet Counter Interrupt Status Detected
22 (R/NW)	RXVLANGBPIS	MMC Receive VLAN Good Bad Packet Counter Interrupt Status. The `EMAC_MMC_RXINT.RXVLANGBPIS` bit is set when the EMAC_RX_VLAN_PCNT_GB register reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Receive VLAN Good Bad Packet Counter Interrupt Status Not Detected
		1	MMC Receive VLAN Good Bad Packet Counter Interrupt Status Detected
21 (R/NW)	RXFOVPIS	MMC Receive FIFO Overflow Packet Counter Interrupt Status. The `EMAC_MMC_RXINT.RXFOVPIS` bit is set when the EMAC_RX_FIFOOVFL_PCNT register reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Receive FIFO Overflow Packet Counter Interrupt Status Not Detected
		1	MMC Receive FIFO Overflow Packet Counter Interrupt Status Detected
20 (R/NW)	RXPAUSPIS	MMC Receive Pause Packet Counter Interrupt Status. The `EMAC_MMC_RXINT.RXPAUSPIS` bit is set when the EMAC_RX_PAUSE_PCNT register reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Receive Pause Packet Counter Interrupt Status Not Detected
		1	MMC Receive Pause Packet Counter Interrupt Status Detected

Table 30-247: EMAC_MMC_RXINT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
19 (R/NW)	RXORANGEPIS	MMC Receive Out of Range Error Packet Counter Interrupt Status.. The `EMAC_MMC_RXINT.RXORANGEPIS` bit is set when the EMAC_RX_OR-TYPE_PCNT register reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Receive Out of Range Error Packet Counter Interrupt Status Not Detected
		1	MMC Receive Out of Range Error Packet Counter Interrupt Status Detected
18 (R/NW)	RXLENERPIS	MMC Receive Length Error Packet Counter Interrupt Status. The `EMAC_MMC_RXINT.RXLENERPIS` bit is set when the EMAC_RX_LE-NERR_PCNT register reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Receive Length Error Packet Counter Interrupt Status Not Detected
		1	MMC Receive Length Error Packet Counter Interrupt Status Detected
17 (R/NW)	RXUCGPIS	MMC Receive Unicast Good Packet Counter Interrupt Status. The `EMAC_MMC_RXINT.RXUCGPIS` bit is set when the EMAC_RX_UCST_PCNT_G register reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Receive Unicast Good Packet Counter Interrupt Status Not Detected
		1	MMC Receive Unicast Good Packet Counter Interrupt Status Detected
16 (R/NW)	RX1024TMAXOCTGBPIS	MMC Receive 1024 to Maximum Octet Good Bad Packet Counter Interrupt Status. The `EMAC_MMC_RXINT.RX1024TMAXOCTGBPIS` bit is set when the EMAC_RX1024TOMAX_GB register reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Receive 1024 to Maximum Octet Good Bad Packet Counter Interrupt Status Not Detected
		1	MMC Receive 1024 to Maximum Octet Good Bad Packet Counter Interrupt Status Detected

Table 30-247: EMAC_MMC_RXINT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/NW)	RX512T1023OCTGBPIS	MMC Receive 512 to 1023 Octet Good Bad Packet Counter Interrupt Status. The `EMAC_MMC_RXINT.RX512T1023OCTGBPIS` bit is set when the EMAC_RX512TO1023_GB register reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Receive 512 to 1023 Octet Good Bad Packet Counter Interrupt Status Not Detected
		1	MMC Receive 512 to 1023 Octet Good Bad Packet Counter Interrupt Status Detected
14 (R/NW)	RX256T511OCTGBPIS	MMC Receive 256 to 511 Octet Good Bad Packet Counter Interrupt Status. The `EMAC_MMC_RXINT.RX256T511OCTGBPIS` bit is set when the EMAC_RX256TO511_GB register reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Receive 256 to 511 Octet Good Bad Packet Counter Interrupt Status Not Detected
		1	MMC Receive 256 to 511 Octet Good Bad Packet Counter Interrupt Status Detected
13 (R/NW)	RX128T255OCTGBPIS	MMC Receive 128 to 255 Octet Good Bad Packet Counter Interrupt Status. The `EMAC_MMC_RXINT.RX128T255OCTGBPIS` bit is set when the EMAC_RX128TO255_GB register reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Receive 128 to 255 Octet Good Bad Packet Counter Interrupt Status Not Detected
		1	MMC Receive 128 to 255 Octet Good Bad Packet Counter Interrupt Status Detected
12 (R/NW)	RX65T127OCTGBPIS	MMC Receive 65 to 127 Octet Good Bad Packet Counter Interrupt Status. The `EMAC_MMC_RXINT.RX65T127OCTGBPIS` bit is set when the EMAC_RX65TO127_GB register reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Receive 65 to 127 Octet Good Bad Packet Counter Interrupt Status Not Detected
		1	MMC Receive 65 to 127 Octet Good Bad Packet Counter Interrupt Status Detected

Table 30-247: EMAC_MMC_RXINT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/NW)	RX64OCTGBPIS	MMC Receive 64 Octet Good Bad Packet Counter Interrupt Status. The `EMAC_MMC_RXINT.RX64OCTGBPIS` bit is set when the EMAC_RX64_GB register reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Receive 64 Octet Good Bad Packet Counter Interrupt Status Not Detected
		1	MMC Receive 64 Octet Good Bad Packet Counter Interrupt Status Detected
10 (R/NW)	RXOSIZEGPIS	MMC Receive Oversize Good Packet Counter Interrupt Status. The `EMAC_MMC_RXINT.RXOSIZEGPIS` bit is set when the EMAC_RX_OVRSZ_PCNT register reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Receive Oversize Good Packet Counter Interrupt Status Not Detected
		1	MMC Receive Oversize Good Packet Counter Interrupt Status Detected
9 (R/NW)	RXUSIZEGPIS	MMC Receive Undersize Good Packet Counter Interrupt Status. The `EMAC_MMC_RXINT.RXUSIZEGPIS` bit is set when the EMAC_RX_UNDRSZ_PCNT_G register reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Receive Undersize Good Packet Counter Interrupt Status Not Detected
		1	MMC Receive Undersize Good Packet Counter Interrupt Status Detected
8 (R/NW)	RXJABERPIS	MMC Receive Jabber Error Packet Counter Interrupt Status. The `EMAC_MMC_RXINT.RXJABERPIS` bit is set when the EMAC_RX_JBERR_PCNT register reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Receive Jabber Error Packet Counter Interrupt Status Not Detected
		1	MMC Receive Jabber Error Packet Counter Interrupt Status Detected

Table 30-247: EMAC_MMC_RXINT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/NW)	RXRUNTPIS	MMC Receive Runt Packet Counter Interrupt Status. The `EMAC_MMC_RXINT.RXRUNTPIS` bit is set when the EMAC_RX_RNTERR_PCNT register reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Receive Runt Packet Counter Interrupt Status Not Detected
		1	MMC Receive Runt Packet Counter Interrupt Status Detected
6 (R/NW)	RXALGNERPIS	MMC Receive Alignment Error Packet Counter Interrupt Status. The `EMAC_MMC_RXINT.RXALGNERPIS` bit is set when the EMAC_RX_ALGNERR_PCNT register reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Receive Alignment Error Packet Counter Interrupt Status Not Detected
		1	MMC Receive Alignment Error Packet Counter Interrupt Status Detected
5 (R/NW)	RXCRCERPIS	MMC Receive CRC Error Packet Counter Interrupt Status. The `EMAC_MMC_RXINT.RXCRCERPIS` bit is set when the EMAC_RX_CRCERR_PCNT register reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Receive CRC Error Packet Counter Interrupt Status Not Detected
		1	MMC Receive CRC Error Packet Counter Interrupt Status Detected
4 (R/NW)	RXMCGPIS	MMC Receive Multicast Good Packet Counter Interrupt Status. The `EMAC_MMC_RXINT.RXMCGPIS` bit is set when the EMAC_RX_MCST_PCNT_G register reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Receive Multicast Good Packet Counter Interrupt Status Not Detected
		1	MMC Receive Multicast Good Packet Counter Interrupt Status Detected

Table 30-247: EMAC_MMC_RXINT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/NW)	RXBCGPIS	MMC Receive Broadcast Good Packet Counter Interrupt Status. The `EMAC_MMC_RXINT.RXBCGPIS` bit is set when the EMAC_RX_BCERR_PCNT_G register reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Receive Broadcast Good Packet Counter Interrupt Status Not Detected
		1	MMC Receive Broadcast Good Packet Counter Interrupt Status Detected
2 (R/NW)	RXGOCTIS	MMC Receive Good Octet Counter Interrupt Status. The `EMAC_MMC_RXINT.RXGOCTIS` bit is set when the EMAC_RX_OCNT_G register reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Receive Good Octet Counter Interrupt Status Not Detected
		1	MMC Receive Good Octet Counter Interrupt Status Detected
1 (R/NW)	RXGBOCTIS	MMC Receive Good Bad Octet Counter Interrupt Status. The `EMAC_MMC_RXINT.RXGBOCTIS` bit is set when the EMAC_RX_OCNT_GB register reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Receive Good Bad Octet Counter Interrupt Status Not Detected
		1	MMC Receive Good Bad Octet Counter Interrupt Status Detected
0 (R/NW)	RXGBPKTIS	MMC Receive Good Bad Packet Counter Interrupt Status. The `EMAC_MMC_RXINT.RXGBPKTIS` bit is set when the EMAC_RX_PCNT_GB register reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Receive Good Bad Packet Counter Interrupt Status Not Detected
		1	MMC Receive Good Bad Packet Counter Interrupt Status Detected

MMC Receive Interrupt Mask Register

The EMAC_MMC_RXIMSK register maintains the masks for the interrupts generated when receive statistic counters reach half of their maximum value or the maximum values.

The EMAC_MMC_RXIMSK register is 32 bit wide.

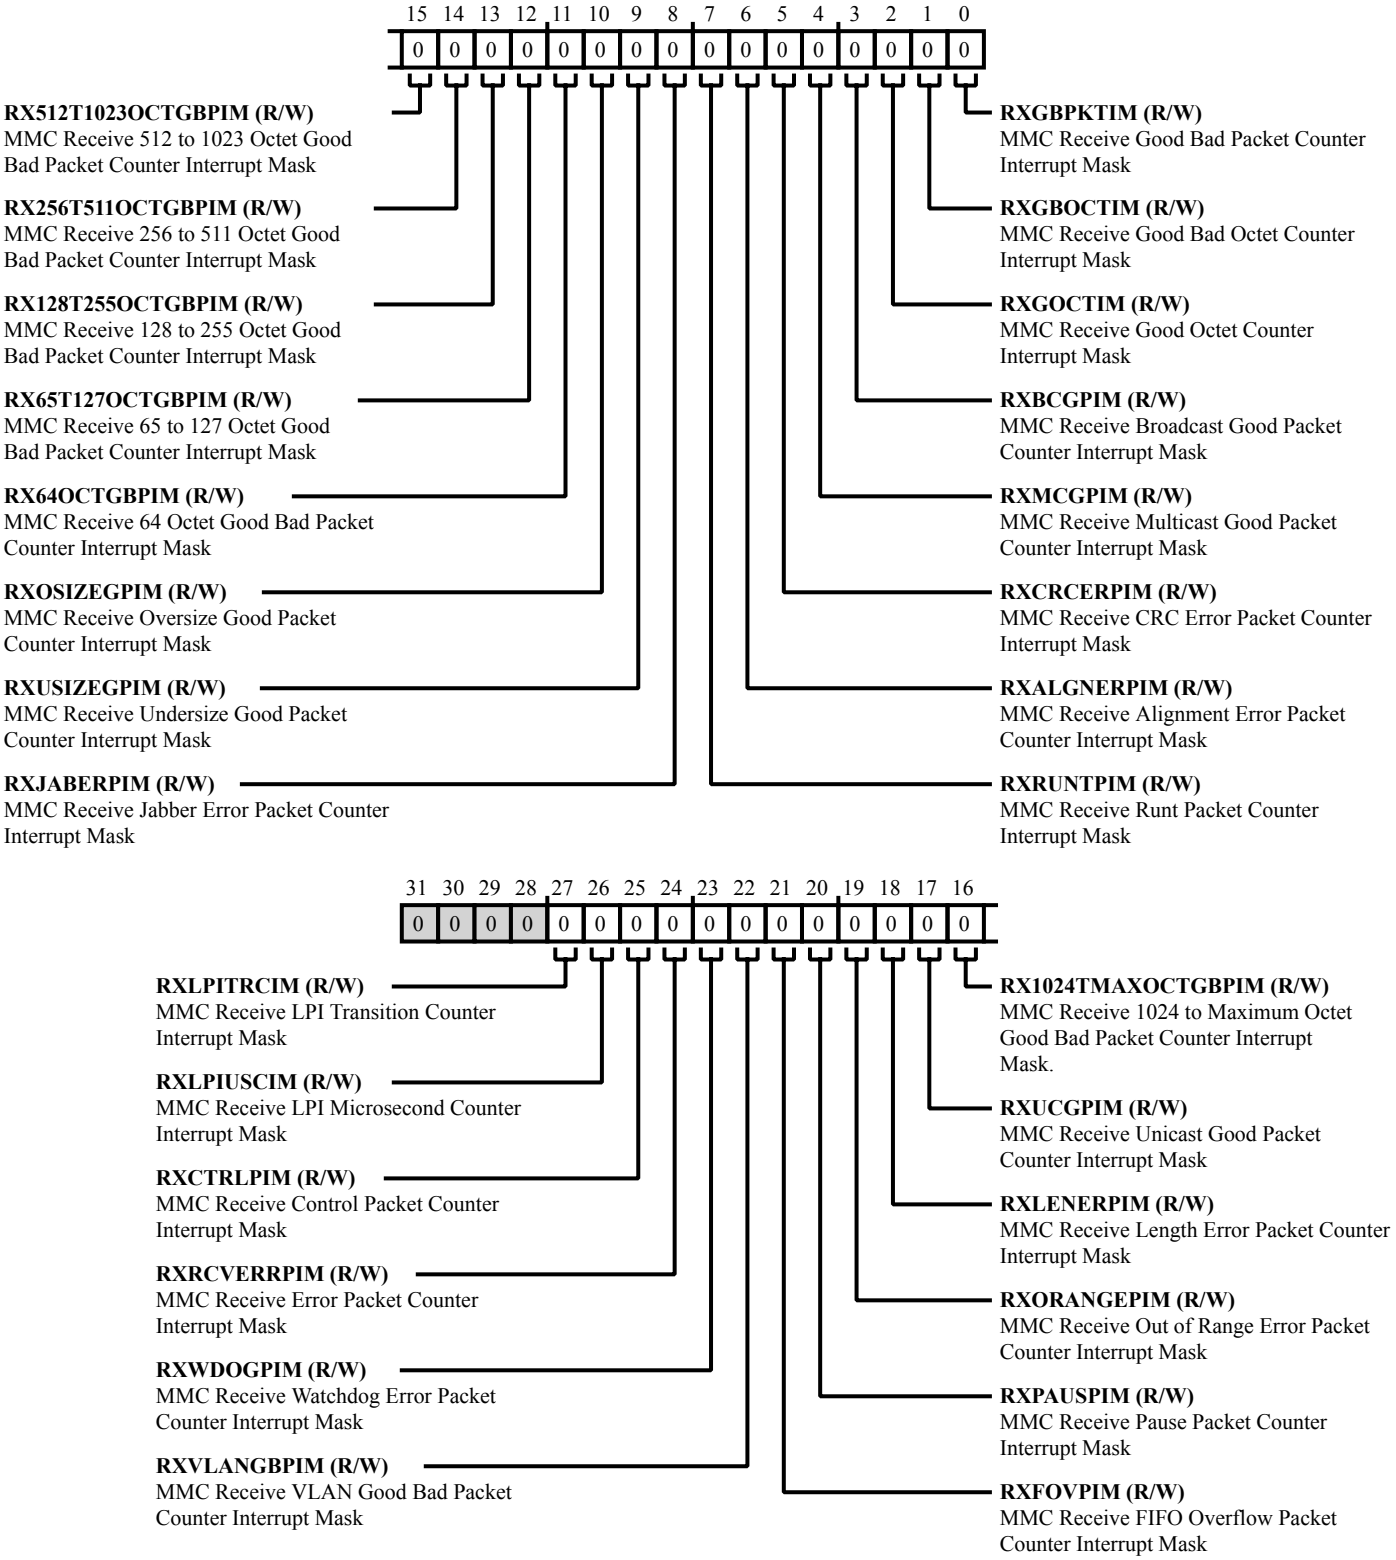

Figure 30-193: EMAC_MMC_RXIMSK Register Diagram

Table 30-248: EMAC_MMC_RXIMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
27 (R/W)	RXLPITRCIM	MMC Receive LPI Transition Counter Interrupt Mask. Setting the `EMAC_MMC_RXIMSK.RXLPITRCIM` bit masks the interrupt when the EMAC_RX_LPITRAN_CNT register reaches half of the maximum value or the maximum value.	
		0	MMC Receive LPI Transition Counter Interrupt Mask is Disabled
		1	MMC Receive LPI Transition Counter Interrupt Mask is Enabled
26 (R/W)	RXLPIUSCIM	MMC Receive LPI Microsecond Counter Interrupt Mask. Setting the `EMAC_MMC_RXIMSK.RXLPIUSCIM` bit masks the interrupt when the EMAC_RX_LPIUSEC_CNT register reaches half of the maximum value or the maximum value.	
		0	MMC Receive LPI Microsecond Counter Interrupt Mask is Disabled
		1	MMC Receive LPI Microsecond Counter Interrupt Mask is Enabled
25 (R/W)	RXCTRLPIM	MMC Receive Control Packet Counter Interrupt Mask. Setting the `EMAC_MMC_RXIMSK.RXCTRLPIM` bit masks the interrupt when the EMAC_RXICMP_PCNT_G register reaches half of the maximum value or the maximum value.	
		0	MMC Receive Control Packet Counter Interrupt Mask is Disabled
		1	MMC Receive Control Packet Counter Interrupt Mask is Enabled
24 (R/W)	RXRCVERRPIM	MMC Receive Error Packet Counter Interrupt Mask. Setting the `EMAC_MMC_RXIMSK.RXRCVERRPIM` bit masks the interrupt when the EMAC_RX_ERR_PCNT register reaches half of the maximum value or the maximum value.	
		0	MMC Receive Error Packet Counter Interrupt Mask is Disabled
		1	MMC Receive Error Packet Counter Interrupt Mask is Enabled

Table 30-248: EMAC_MMC_RXIMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
23 (R/W)	RXWDOGPIM	MMC Receive Watchdog Error Packet Counter Interrupt Mask. Setting the `EMAC_MMC_RXIMSK.RXWDOGPIM` bit masks the interrupt when the EMAC_RX_WDTERR_PCNT register reaches half of the maximum value or the maximum value.	
		0	MMC Receive Watchdog Error Packet Counter Interrupt Mask is Disabled
		1	MMC Receive Watchdog Error Packet Counter Interrupt Mask is Enabled
22 (R/W)	RXVLANGBPIM	MMC Receive VLAN Good Bad Packet Counter Interrupt Mask. Setting the `EMAC_MMC_RXIMSK.RXVLANGBPIM` bit masks the interrupt when the EMAC_RX_VLAN_PCNT_GB register reaches half of the maximum value or the maximum value.	
		0	MMC Receive VLAN Good Bad Packet Counter Interrupt Mask is Disabled
		1	MMC Receive VLAN Good Bad Packet Counter Interrupt Mask is Enabled
21 (R/W)	RXFOVPIM	MMC Receive FIFO Overflow Packet Counter Interrupt Mask. Setting the `EMAC_MMC_RXIMSK.RXFOVPIM` bit masks the interrupt when the EMAC_RX_FIFOOVFL_PCNT register reaches half of the maximum value or the maximum value.	
		0	MMC Receive FIFO Overflow Packet Counter Interrupt Mask is Disabled
		1	MMC Receive FIFO Overflow Packet Counter Interrupt Mask is Enabled
20 (R/W)	RXPAUSPIM	MMC Receive Pause Packet Counter Interrupt Mask. Setting the `EMAC_MMC_RXIMSK.RXPAUSPIM` bit masks the interrupt when the EMAC_RX_PAUSE_PCNT register reaches half of the maximum value or the maximum value.	
		0	MMC Receive Pause Packet Counter Interrupt Mask is Disabled
		1	MMC Receive Pause Packet Counter Interrupt Mask is Enabled

Table 30-248: EMAC_MMC_RXIMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
19 (R/W)	RXORANGEPIM	MMC Receive Out of Range Error Packet Counter Interrupt Mask. Setting the `EMAC_MMC_RXIMSK.RXORANGEPIM` bit masks the interrupt when the EMAC_RX_ORTYPE_PCNT register reaches half of the maximum value or the maximum value.	
		0	MMC Receive Out of Range Error Packet Counter Interrupt Mask is Disabled
		1	MMC Receive Out of Range Error Packet Counter Interrupt Mask is Enabled
18 (R/W)	RXLENERPIM	MMC Receive Length Error Packet Counter Interrupt Mask. Setting the `EMAC_MMC_RXIMSK.RXLENERPIM` bit masks the interrupt when the EMAC_RX_LENERR_PCNT register reaches half of the maximum value or the maximum value.	
		0	MMC Receive Length Error Packet Counter Interrupt Mask is Disabled
		1	MMC Receive Length Error Packet Counter Interrupt Mask is Enabled
17 (R/W)	RXUCGPIM	MMC Receive Unicast Good Packet Counter Interrupt Mask. Setting the `EMAC_MMC_RXIMSK.RXUCGPIM` bit masks the interrupt when the EMAC_RX_UCST_PCNT_G register reaches half of the maximum value or the maximum value.	
		0	MMC Receive Unicast Good Packet Counter Interrupt Mask is Disabled
		1	MMC Receive Unicast Good Packet Counter Interrupt Mask is Enabled
16 (R/W)	RX1024TMAXOCTGB-PIM	MMC Receive 1024 to Maximum Octet Good Bad Packet Counter Interrupt Mask.. Setting the `EMAC_MMC_RXIMSK.RX1024TMAXOCTGBPIM` bit masks the interrupt when the EMAC_RX1024TOMAX_GB register reaches half of the maximum value or the maximum value.	
		0	MMC Receive 1024 to Maximum Octet Good Bad Packet Counter Interrupt Mask is Disabled
		1	MMC Receive 1024 to Maximum Octet Good Bad Packet Counter Interrupt Mask is Enabled

Table 30-248: EMAC_MMC_RXIMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	RX512T1023OCTGBPIM	MMC Receive 512 to 1023 Octet Good Bad Packet Counter Interrupt Mask. Setting the `EMAC_MMC_RXIMSK.RX512T1023OCTGBPIM` bit masks the interrupt when the EMAC_RX512TO1023_GB counter reaches half of the maximum value or the maximum value.	
		0	MMC Receive 512 to 1023 Octet Good Bad Packet Counter Interrupt Mask is Disabled
		1	MMC Receive 512 to 1023 Octet Good Bad Packet Counter Interrupt Mask is Enabled
14 (R/W)	RX256T511OCTGBPIM	MMC Receive 256 to 511 Octet Good Bad Packet Counter Interrupt Mask. Setting the `EMAC_MMC_RXIMSK.RX256T511OCTGBPIM` bit masks the interrupt when the EMAC_RX256TO511_GB register reaches half of the maximum value or the maximum value.	
		0	MMC Receive 256 to 511 Octet Good Bad Packet Counter Interrupt Mask is Disabled
		1	MMC Receive 256 to 511 Octet Good Bad Packet Counter Interrupt Mask is Enabled
13 (R/W)	RX128T255OCTGBPIM	MMC Receive 128 to 255 Octet Good Bad Packet Counter Interrupt Mask. Setting the `EMAC_MMC_RXIMSK.RX128T255OCTGBPIM` bit masks the interrupt when the EMAC_RX128TO255_GB register reaches half of the maximum value or the maximum value.	
		0	MMC Receive 128 to 255 Octet Good Bad Packet Counter Interrupt Mask is Disabled
		1	MMC Receive 128 to 255 Octet Good Bad Packet Counter Interrupt Mask is Enabled
12 (R/W)	RX65T127OCTGBPIM	MMC Receive 65 to 127 Octet Good Bad Packet Counter Interrupt Mask. Setting the `EMAC_MMC_RXIMSK.RX65T127OCTGBPIM` bit masks the interrupt when the EMAC_RX65TO127_GB register reaches half of the maximum value or the maximum value.	
		0	MMC Receive 65 to 127 Octet Good Bad Packet Counter Interrupt Mask is Disabled
		1	MMC Receive 65 to 127 Octet Good Bad Packet Counter Interrupt Mask is Enabled

Table 30-248: EMAC_MMC_RXIMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W)	RX64OCTGBPIM	MMC Receive 64 Octet Good Bad Packet Counter Interrupt Mask. Setting the `EMAC_MMC_RXIMSK.RX64OCTGBPIM` bit masks the interrupt when the EMAC_RX64_GB register reaches half of the maximum value or the maximum value.	
		0	MMC Receive 64 Octet Good Bad Packet Counter Interrupt Mask is Disabled
		1	MMC Receive 64 Octet Good Bad Packet Counter Interrupt Mask is Enabled
10 (R/W)	RXOSIZEGPIM	MMC Receive Oversize Good Packet Counter Interrupt Mask. Setting the `EMAC_MMC_RXIMSK.RXOSIZEGPIM` bit masks the interrupt when the EMAC_RX_OVRSZ_PCNT register reaches half of the maximum value or the maximum value.	
		0	MMC Receive Oversize Good Packet Counter Interrupt Mask is Disabled
		1	MMC Receive Oversize Good Packet Counter Interrupt Mask is Enabled
9 (R/W)	RXUSIZEGPIM	MMC Receive Undersize Good Packet Counter Interrupt Mask. Setting the `EMAC_MMC_RXIMSK.RXUSIZEGPIM` bit masks the interrupt when the EMAC_RX_UNDRSZ_PCNT_G register reaches half of the maximum value or the maximum value.	
		0	MMC Receive Undersize Good Packet Counter Interrupt Mask is Disabled
		1	MMC Receive Undersize Good Packet Counter Interrupt Mask is Enabled
8 (R/W)	RXJABERPIM	MMC Receive Jabber Error Packet Counter Interrupt Mask. Setting the `EMAC_MMC_RXIMSK.RXJABERPIM` bit masks the interrupt when the EMAC_RX_JBERR_PCNT register reaches half of the maximum value or the maximum value.	
		0	MMC Receive Jabber Error Packet Counter Interrupt Mask is Disabled
		1	MMC Receive Jabber Error Packet Counter Interrupt Mask is Enabled

Table 30-248: EMAC_MMC_RXIMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	RXRUNTPIM	MMC Receive Runt Packet Counter Interrupt Mask. Setting the `EMAC_MMC_RXIMSK.RXRUNTPIM` bit masks the interrupt when the EMAC_RX_RNTERR_PCNT register reaches half of the maximum value or the maximum value.	
		0	MMC Receive Runt Packet Counter Interrupt Mask is Disabled
		1	MMC Receive Runt Packet Counter Interrupt Mask is Enabled
6 (R/W)	RXALGNERPIM	MMC Receive Alignment Error Packet Counter Interrupt Mask. Setting the `EMAC_MMC_RXIMSK.RXALGNERPIM` bit masks the interrupt when the EMAC_RX_ALGNERR_PCNT register reaches half of the maximum value or the maximum value.	
		0	MMC Receive Alignment Error Packet Counter Interrupt Mask is Disabled
		1	MMC Receive Alignment Error Packet Counter Interrupt Mask is Enabled
5 (R/W)	RXCRCERPIM	MMC Receive CRC Error Packet Counter Interrupt Mask. Setting the `EMAC_MMC_RXIMSK.RXCRCERPIM` bit masks the interrupt when the EMAC_RX_CRCERR_PCNT register reaches half of the maximum value or the maximum value.	
		0	MMC Receive CRC Error Packet Counter Interrupt Mask is Disabled
		1	MMC Receive CRC Error Packet Counter Interrupt Mask is Enabled
4 (R/W)	RXMCGPIM	MMC Receive Multicast Good Packet Counter Interrupt Mask. Setting the `EMAC_MMC_RXIMSK.RXMCGPIM` bit masks the interrupt when the EMAC_RX_MCST_PCNT_G register reaches half of the maximum value or the maximum value.	
		0	MMC Receive Multicast Good Packet Counter Interrupt Mask is Disabled
		1	MMC Receive Multicast Good Packet Counter Interrupt Mask is Enabled

Table 30-248: EMAC_MMC_RXIMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	RXBCGPIM	MMC Receive Broadcast Good Packet Counter Interrupt Mask. Setting the `EMAC_MMC_RXIMSK.RXBCGPIM` bit masks the interrupt when the EMAC_RX_BCERR_PCNT_G register reaches half of the maximum value or the maximum value.	
		0	MMC Receive Broadcast Good Packet Counter Interrupt Mask is Disabled
		1	MMC Receive Broadcast Good Packet Counter Interrupt Mask is Enabled
2 (R/W)	RXGOCTIM	MMC Receive Good Octet Counter Interrupt Mask. Setting the `EMAC_MMC_RXIMSK.RXGOCTIM` bit masks the interrupt when the EMAC_RX_OCNT_G register counter reaches half of the maximum value or the maximum value.	
		0	MMC Receive Good Octet Counter Interrupt Mask is Disabled
		1	MMC Receive Good Octet Counter Interrupt Mask is Enabled
1 (R/W)	RXGBOCTIM	MMC Receive Good Bad Octet Counter Interrupt Mask. Setting the `EMAC_MMC_RXIMSK.RXGBOCTIM` bit masks the interrupt when the EMAC_RX_OCNT_GB register reaches half of the maximum value or the maximum value.	
		0	MMC Receive Good Bad Octet Counter Interrupt Mask is Disabled
		1	MMC Receive Good Bad Octet Counter Interrupt Mask is Enabled
0 (R/W)	RXGBPKTIM	MMC Receive Good Bad Packet Counter Interrupt Mask. Setting the `EMAC_MMC_RXIMSK.RXGBPKTIM` bit masks the interrupt when the EMAC_RX_PCNT_GB register reaches half of the maximum value or the maximum value.	
		0	MMC Receive Good Bad Packet Counter Interrupt Mask is Disabled
		1	MMC Receive Good Bad Packet Counter Interrupt Mask is Enabled

MMC Receive FPE Packet Assembly Error Counter Register

The EMAC_RXPKT_ASERR_CNT register provides the number of MAC frames with reassembly errors on the receiver, due to mismatch in the fragment count value.

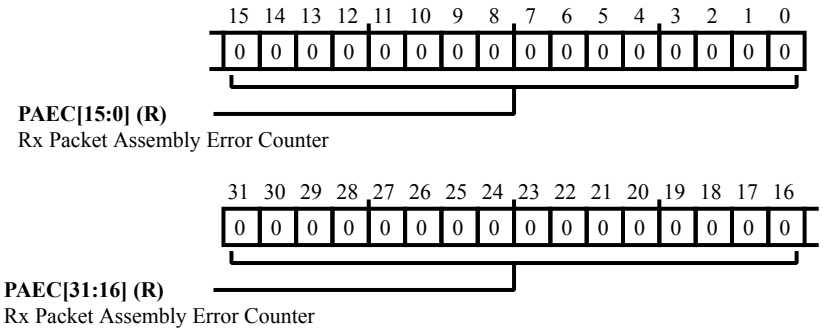

Figure 30-194: EMAC_RXPKT_ASERR_CNT Register Diagram

Table 30-249: EMAC_RXPKT_ASERR_CNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	PAEC	Rx Packet Assembly Error Counter. The EMAC_RXPKT_ASERR_CNT.PAEC field indicates the number of MAC frames with reassembly errors on the receiver, due to mismatch in the Fragment Count value. Exists when any one of the RX/TX MMC counters are enabled during an FPE-enabled configuration.

MMC Receive FPE Packet Assembly Okay Counter Register

The EMAC_RXPKT_ASOK_CNT register provides the number of MAC frames that were successfully reassembled and delivered to MAC.

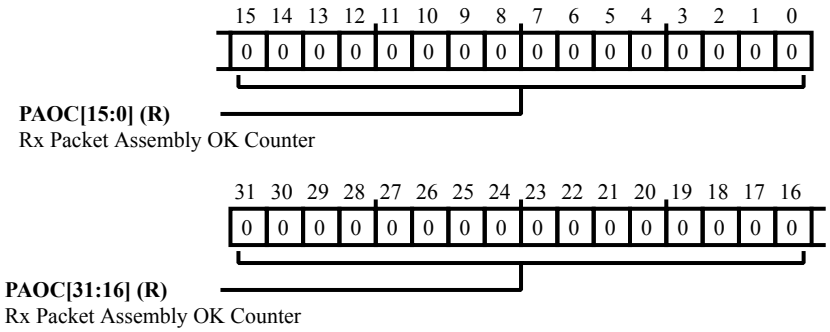

Figure 30-195: EMAC_RXPKT_ASOK_CNT Register Diagram

Table 30-250: EMAC_RXPKT_ASOK_CNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	PAOC	Rx Packet Assembly OK Counter. The EMAC_RXPKT_ASOK_CNT.PAOC field indicates the number of MAC frames that were successfully reassembled and delivered to MAC. Exists when at least one of the RX/TX MMC counters are enabled during an FPE-enabled configuration.

MMC Receive FPE Packet SMD Error Counter Register

The EMAC_RXPKT_SMDERR_CNT register provides the number of received MAC frames rejected due to unknown SMD value and MAC frame fragments rejected due to arriving with an SMD-C when there was no preceding preempted frame.

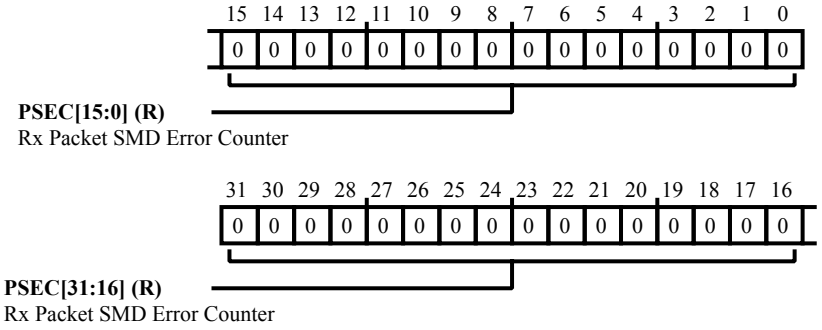

Figure 30-196: EMAC_RXPKT_SMDERR_CNT Register Diagram

Table 30-251: EMAC_RXPKT_SMDERR_CNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	PSEC	Rx Packet SMD Error Counter. The EMAC_RXPKT_SMDERR_CNT.PSEC field indicates the number of MAC frames rejected due to unknown SMD value and MAC frame fragments rejected due to arriving with an SMD-C when there was no preceding preempted frame. Exists when at least one of the RX/TX MMC counters are enabled during an FPE-enabled configuration.

MMC Transmit FPE Packet Fragment Counter Register

The EMAC_TXFPE_FRGMNT_CNT register provides the number of additional mPackets transmitted due to pre-emption.

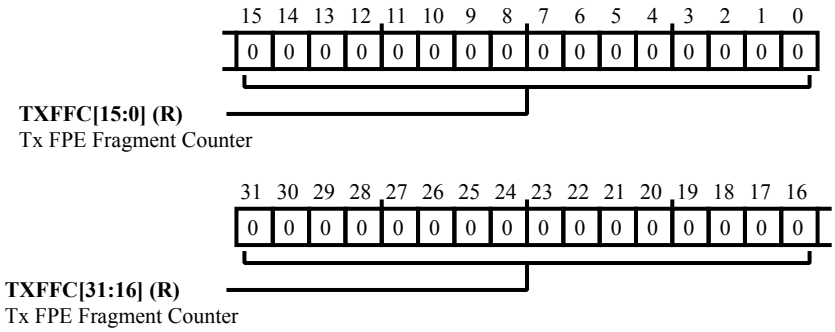

Figure 30-197: EMAC_TXFPE_FRGMNT_CNT Register Diagram

Table 30-252: EMAC_TXFPE_FRGMNT_CNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	TXFFC	Tx FPE Fragment Counter. The EMAC_TXFPE_FRGMNT_CNT.TXFFC field indicates the number of additional mPackets that has been transmitted due to preemption Exists when any one of the RX/TX MMC counters are enabled during an FPE-enabled configuration.

MMC Transmit FPE Hold Request Counter Register

The EMAC_TXHLDRQ_CNT register provides the count of number of times a hold request is given to MAC.

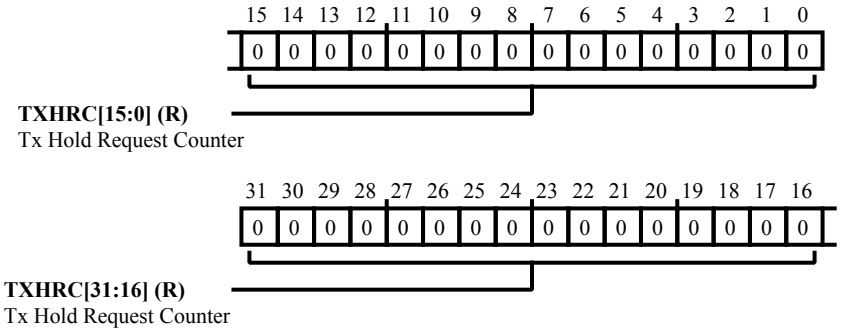

Figure 30-198: EMAC_TXHLDRQ_CNT Register Diagram

Table 30-253: EMAC_TXHLDRQ_CNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	TXHRC	Tx Hold Request Counter. The EMAC_TXHLDRQ_CNT.TXHRC field indicates count of number of a hold request is given to MAC.

MMC Transmit Interrupt Status Register

The EMAC_MMC_TXINT register maintains the interrupts generated from all transmit statistics counters when transmit statistic counters reach half their maximum values (0x8000_0000 for 32 bit counter and 0x8000 for 16 bit counter), and when they cross their maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter).

When Counter Stop Rollover is set, the interrupts are set but the counter remains at all-ones.

The EMAC_MMC_TXINT register is a 32-bit register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read.

The least significant byte lane (bits[7:0]) of the respective counter must be read to clear the interrupt bit.

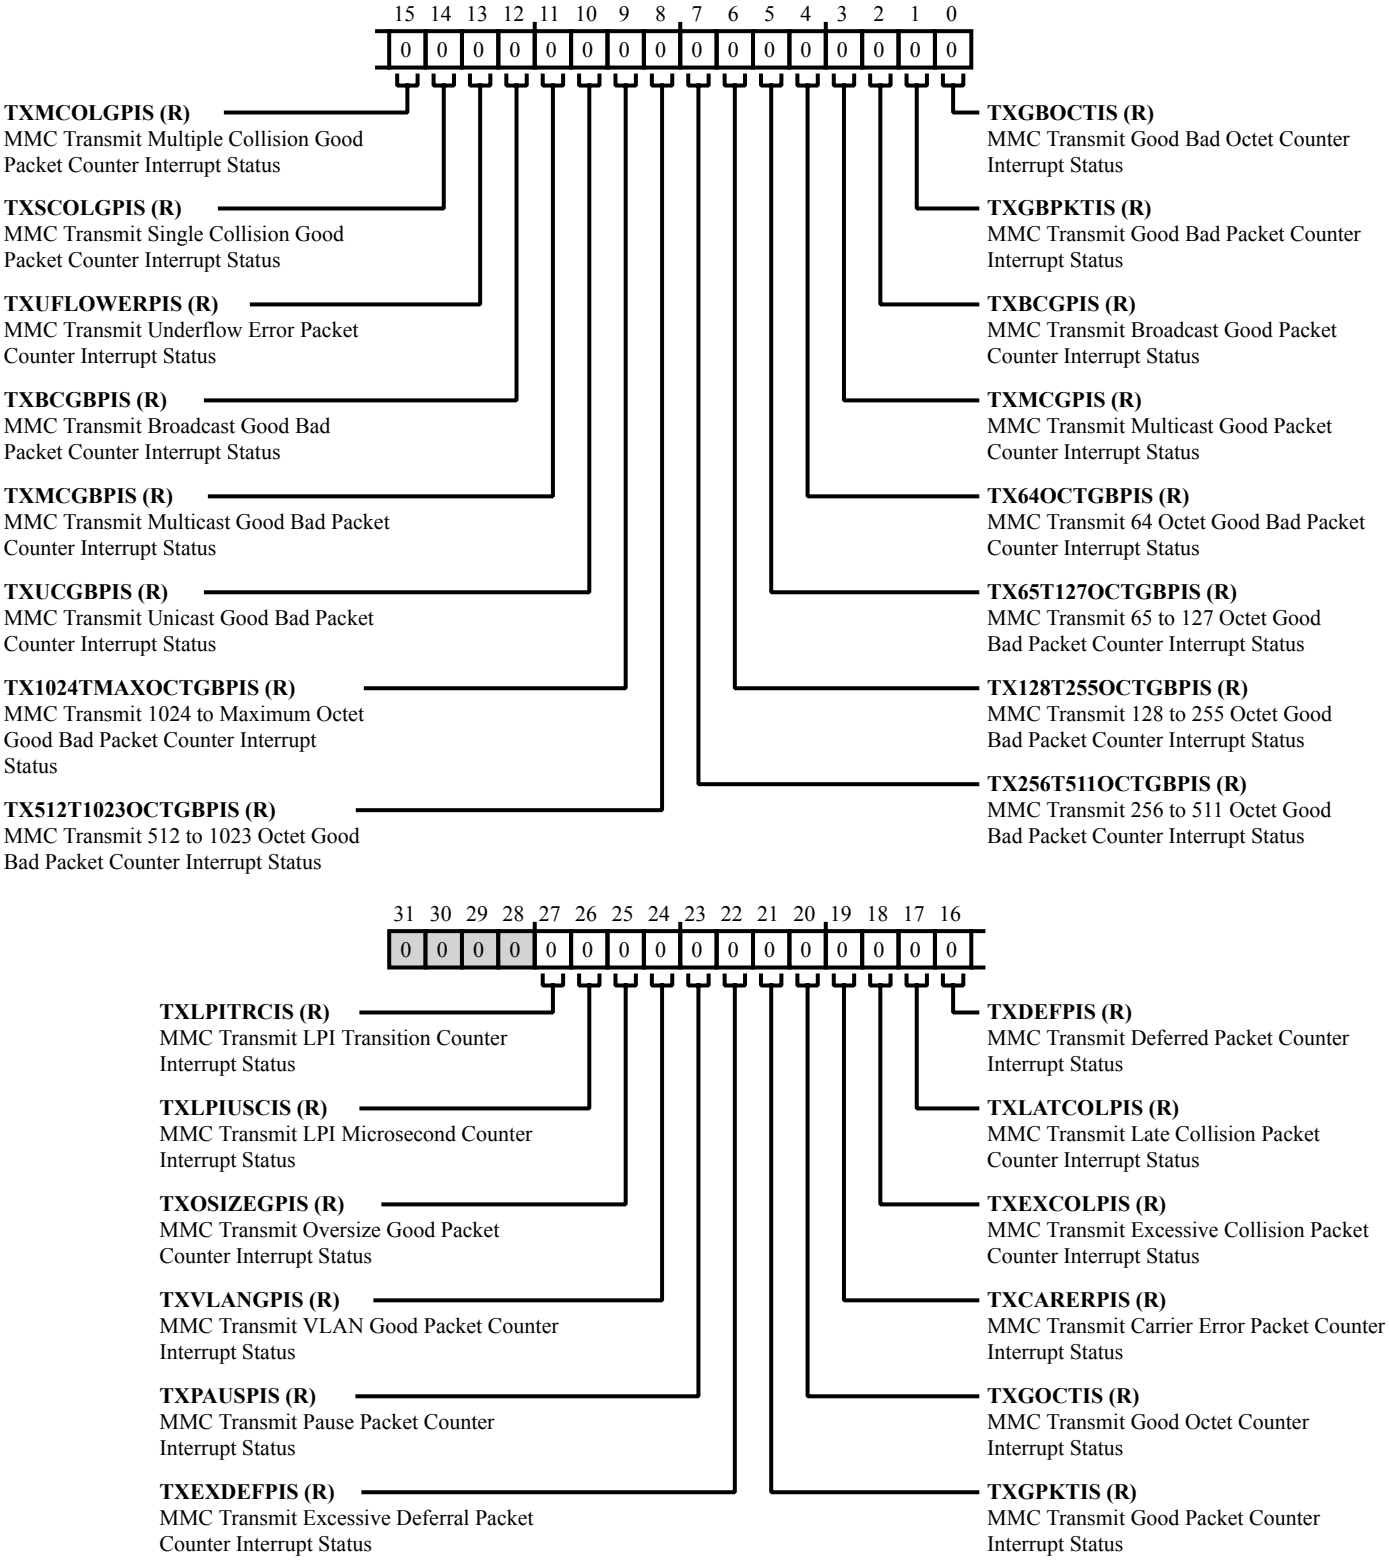

Figure 30-199: EMAC_MMC_TXINT Register Diagram

Table 30-254: EMAC_MMC_TXINT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
27 (R/NW)	TXLPITRCIS	MMC Transmit LPI Transition Counter Interrupt Status. The `EMAC_MMC_TXINT.TXLPITRCIS` bit is set when the EMAC_TX_LPITRAN_CNT register reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Transmit LPI Transition Counter Interrupt Status Not Detected
		1	MMC Transmit LPI Transition Counter Interrupt Status Detected
26 (R/NW)	TXLPIUSCIS	MMC Transmit LPI Microsecond Counter Interrupt Status. The `EMAC_MMC_TXINT.TXLPIUSCIS` bit is set when the EMAC_TX_LPIUSEC_CNT register reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Transmit LPI Microsecond Counter Interrupt Status Not Detected
		1	MMC Transmit LPI Microsecond Counter Interrupt Status Detected
25 (R/NW)	TXOSIZEGPIS	MMC Transmit Oversize Good Packet Counter Interrupt Status. The `EMAC_MMC_TXINT.TXOSIZEGPIS` bit is set when the EMAC_TX_OSIZE_PCNT_G register reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Transmit Oversize Good Packet Counter Interrupt Status Not Detected
		1	MMC Transmit Oversize Good Packet Counter Interrupt Status Detected
24 (R/NW)	TXVLANGPIS	MMC Transmit VLAN Good Packet Counter Interrupt Status. The `EMAC_MMC_TXINT.TXVLANGPIS` bit is set when the EMAC_TX_VLAN_PCNT_G register reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Transmit VLAN Good Packet Counter Interrupt Status Not Detected
		1	MMC Transmit VLAN Good Packet Counter Interrupt Status Detected

Table 30-254: EMAC_MMC_TXINT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
23 (R/NW)	TXPAUSPIS	MMC Transmit Pause Packet Counter Interrupt Status. The `EMAC_MMC_TXINT.TXPAUSPIS` bit is set when the EMAC_TX_PAUSE_PCNT register reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Transmit Pause Packet Counter Interrupt Status Not Detected
		1	MMC Transmit Pause Packet Counter Interrupt Status Detected
22 (R/NW)	TXEXDEFPIS	MMC Transmit Excessive Deferral Packet Counter Interrupt Status. The `EMAC_MMC_TXINT.TXEXDEFPIS` bit is set when the EMAC_TX_EXDFRL_PCNT register reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Transmit Excessive Deferral Packet Counter Interrupt Status Not Detected
		1	MMC Transmit Excessive Deferral Packet Counter Interrupt Status Detected
21 (R/NW)	TXGPKTIS	MMC Transmit Good Packet Counter Interrupt Status. The `EMAC_MMC_TXINT.TXGPKTIS` bit is set when the EMAC_TX_PCNT_G register reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Transmit Good Packet Counter Interrupt Status Not Detected
		1	MMC Transmit Good Packet Counter Interrupt Status Detected
20 (R/NW)	TXGOCTIS	MMC Transmit Good Octet Counter Interrupt Status. The `EMAC_MMC_TXINT.TXGOCTIS` bit is set when the EMAC_TX_OCNT_G register reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Transmit Good Octet Counter Interrupt Status Not Detected
		1	MMC Transmit Good Octet Counter Interrupt Status Detected

Table 30-254: EMAC_MMC_TXINT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
19 (R/NW)	TXCARERPIS	MMC Transmit Carrier Error Packet Counter Interrupt Status. The `EMAC_MMC_TXINT.TXCARERPIS` bit is set when the EMAC_TX_CRERR_PCNT register reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Transmit Carrier Error Packet Counter Interrupt Status Not Detected
		1	MMC Transmit Carrier Error Packet Counter Interrupt Status Detected
18 (R/NW)	TXEXCOLPIS	MMC Transmit Excessive Collision Packet Counter Interrupt Status. The `EMAC_MMC_TXINT.TXEXCOLPIS` bit is set when the EMAC_TX_EXCOL_PCNT register reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Transmit Excessive Collision Packet Counter Interrupt Status Not Detected
		1	MMC Transmit Excessive Collision Packet Counter Interrupt Status Detected
17 (R/NW)	TXLATCOLPIS	MMC Transmit Late Collision Packet Counter Interrupt Status. The `EMAC_MMC_TXINT.TXLATCOLPIS` bit is set when the EMAC_TX_LTCOL_PCNT register reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Transmit Late Collision Packet Counter Interrupt Status Not Detected
		1	MMC Transmit Late Collision Packet Counter Interrupt Status Detected
16 (R/NW)	TXDEFPIS	MMC Transmit Deferred Packet Counter Interrupt Status. The `EMAC_MMC_TXINT.TXDEFPIS` bit is set when the EMAC_TX_DFRD_PCNT register reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Transmit Deferred Packet Counter Interrupt Status Not Detected
		1	MMC Transmit Deferred Packet Counter Interrupt Status Detected

Table 30-254: EMAC_MMC_TXINT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/NW)	TXMCOLGPIS	MMC Transmit Multiple Collision Good Packet Counter Interrupt Status. The `EMAC_MMC_TXINT.TXMCOLGPIS` bit is set when the EMAC_TX_MCST_PCNT_GB register reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Transmit Multiple Collision Good Packet Counter Interrupt Status Not Detected
		1	MMC Transmit Multiple Collision Good Packet Counter Interrupt Status Detected
14 (R/NW)	TXSCOLGPIS	MMC Transmit Single Collision Good Packet Counter Interrupt Status. The `EMAC_MMC_TXINT.TXSCOLGPIS` bit is set when the EMAC_TX_SNGLCOL_PCNT_G register reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Transmit Single Collision Good Packet Counter Interrupt Status Not Detected
		1	MMC Transmit Single Collision Good Packet Counter Interrupt Status Detected
13 (R/NW)	TXUFLOWERPIS	MMC Transmit Underflow Error Packet Counter Interrupt Status. The `EMAC_MMC_TXINT.TXUFLOWERPIS` bit is set when the EMAC_TX_URFL_PCNT register reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Transmit Underflow Error Packet Counter Interrupt Status Not Detected
		1	MMC Transmit Underflow Error Packet Counter Interrupt Status Detected
12 (R/NW)	TXBCGBPIS	MMC Transmit Broadcast Good Bad Packet Counter Interrupt Status. The `EMAC_MMC_TXINT.TXBCGBPIS` bit is set when the EMAC_TX_BCST_PCNT_GB register reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Transmit Broadcast Good Bad Packet Counter Interrupt Status Not Detected
		1	MMC Transmit Broadcast Good Bad Packet Counter Interrupt Status Detected

Table 30-254: EMAC_MMC_TXINT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/NW)	TXMCGBPIS	MMC Transmit Multicast Good Bad Packet Counter Interrupt Status. The bit is set when the EMAC_TX_MCST_PCNT_GB register reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Transmit Multicast Good Bad Packet Counter Interrupt Status Not Detected
		1	MMC Transmit Multicast Good Bad Packet Counter Interrupt Status Detected
10 (R/NW)	TXUCGBPIS	MMC Transmit Unicast Good Bad Packet Counter Interrupt Status. The `EMAC_MMC_TXINT.TXUCGBPIS` bit is set when the EMAC_TX_UCST_PCNT_GB register reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Transmit Unicast Good Bad Packet Counter Interrupt Status Not Detected
		1	MMC Transmit Unicast Good Bad Packet Counter Interrupt Status Detected
9 (R/NW)	TX1024TMAXOCTGBPIS	MMC Transmit 1024 to Maximum Octet Good Bad Packet Counter Interrupt Status. The `EMAC_MMC_TXINT.TX1024TMAXOCTGBPIS` bit is set when the EMAC_TX1024TOMAX_GB register reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Transmit 1024 to Maximum Octet Good Bad Packet Counter Interrupt Status Not Detected
		1	MMC Transmit 1024 to Maximum Octet Good Bad Packet Counter Interrupt Status Detected
8 (R/NW)	TX512T1023OCTGBPIS	MMC Transmit 512 to 1023 Octet Good Bad Packet Counter Interrupt Status. The `EMAC_MMC_TXINT.TX512T1023OCTGBPIS` bit is set when the EMAC_TX512TO1023_GB register reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Transmit 512 to 1023 Octet Good Bad Packet Counter Interrupt Status Not Detected
		1	MMC Transmit 512 to 1023 Octet Good Bad Packet Counter Interrupt Status Detected

Table 30-254: EMAC_MMC_TXINT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/NW)	TX256T511OCTGBPIS	MMC Transmit 256 to 511 Octet Good Bad Packet Counter Interrupt Status. The `EMAC_MMC_TXINT.TX256T511OCTGBPIS` bit is set when the EMAC_TX256TO511_GB register reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Transmit 256 to 511 Octet Good Bad Packet Counter Interrupt Status Not Detected
		1	MMC Transmit 256 to 511 Octet Good Bad Packet Counter Interrupt Status Detected
6 (R/NW)	TX128T255OCTGBPIS	MMC Transmit 128 to 255 Octet Good Bad Packet Counter Interrupt Status. The `EMAC_MMC_TXINT.TX128T255OCTGBPIS` bit is set when the EMAC_TX128TO255_GB register reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Transmit 128 to 255 Octet Good Bad Packet Counter Interrupt Status Not Detected
		1	MMC Transmit 128 to 255 Octet Good Bad Packet Counter Interrupt Status Detected
5 (R/NW)	TX65T127OCTGBPIS	MMC Transmit 65 to 127 Octet Good Bad Packet Counter Interrupt Status. The `EMAC_MMC_TXINT.TX65T127OCTGBPIS` bit is set when the EMAC_TX65TO127_GB register reaches half the maximum value, and also when it reaches the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Transmit 65 to 127 Octet Good Bad Packet Counter Interrupt Status Not Detected
		1	MMC Transmit 65 to 127 Octet Good Bad Packet Counter Interrupt Status Detected
4 (R/NW)	TX64OCTGBPIS	MMC Transmit 64 Octet Good Bad Packet Counter Interrupt Status. The `EMAC_MMC_TXINT.TX64OCTGBPIS` bit is set when the EMAC_TX64_GB register reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Transmit 64 Octet Good Bad Packet Counter Interrupt Status Not Detected
		1	MMC Transmit 64 Octet Good Bad Packet Counter Interrupt Status Detected

Table 30-254: EMAC_MMC_TXINT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/NW)	TXMCGPIS	MMC Transmit Multicast Good Packet Counter Interrupt Status. The `EMAC_MMC_TXINT.TXMCGPIS` bit is set when the EMAC_TX_MCST_PCNT_G register reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Transmit Multicast Good Packet Counter Interrupt Status Not Detected
		1	MMC Transmit Multicast Good Packet Counter Interrupt Status Detected
2 (R/NW)	TXBCGPIS	MMC Transmit Broadcast Good Packet Counter Interrupt Status. The `EMAC_MMC_TXINT.TXBCGPIS` bit is set when the EMAC_TX_BCST_PCNT_G register reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Transmit Broadcast Good Packet Counter Interrupt Status Not Detected
		1	MMC Transmit Broadcast Good Packet Counter Interrupt Status Detected
1 (R/NW)	TXGBPKTIS	MMC Transmit Good Bad Packet Counter Interrupt Status. The `EMAC_MMC_TXINT.TXGBPKTIS` bit is set when the EMAC_TX_PCNT_GB register reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Transmit Good Bad Packet Counter Interrupt Status Not Detected
		1	MMC Transmit Good Bad Packet Counter Interrupt Status Detected
0 (R/NW)	TXGBOCTIS	MMC Transmit Good Bad Octet Counter Interrupt Status. The `EMAC_MMC_TXINT.TXGBOCTIS` bit is set when the EMAC_TX_OCNT_GB register reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	MMC Transmit Good Bad Octet Counter Interrupt Status Not Detected
		1	MMC Transmit Good Bad Octet Counter Interrupt Status Detected

MMC Transmit Interrupt Mask Register

The EMAC_MMC_TXIMSK register maintains the masks for interrupts generated from all transmit statistics counters.

The EMAC_MMC_TXIMSK register maintains the masks for the interrupts generated when the transmit statistic counters reach half of their maximum value or the maximum values. The EMAC_MMC_TXIMSK register is 32 bits wide.

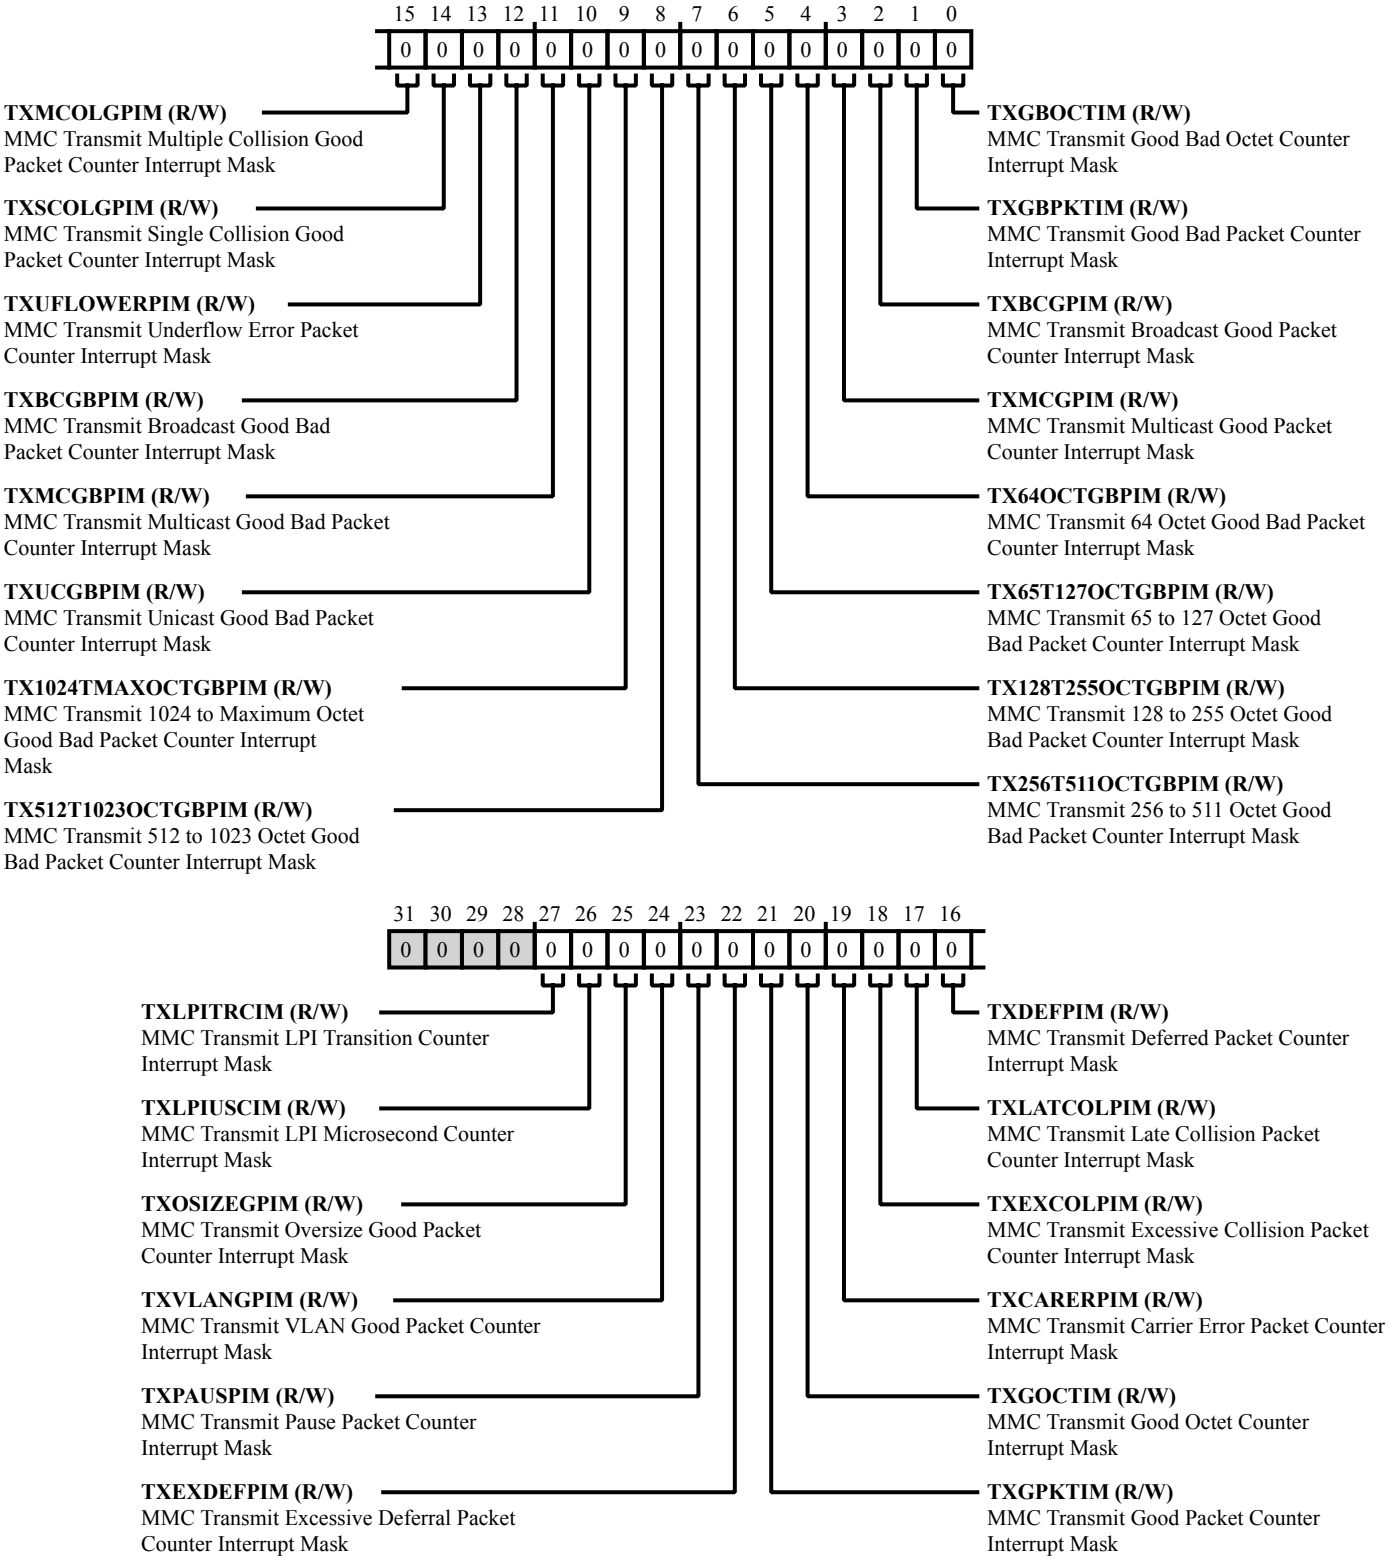

Figure 30-200: EMAC_MMC_TXIMSK Register Diagram

Table 30-255: EMAC_MMC_TXIMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
27 (R/W)	TXLPITRCIM	MMC Transmit LPI Transition Counter Interrupt Mask. Setting the `EMAC_MMC_TXIMSK.TXLPITRCIM` bit masks the interrupt when the EMAC_TX_LPITRAN_CNT counter reaches half of the maximum value or the maximum value.	
		0	MMC Transmit LPI Transition Counter Interrupt Mask is Disabled
		1	MMC Transmit LPI Transition Counter Interrupt Mask is Enabled
26 (R/W)	TXLPIUSCIM	MMC Transmit LPI Microsecond Counter Interrupt Mask. Setting the `EMAC_MMC_TXIMSK.TXLPIUSCIM` bit masks the interrupt when the EMAC_TX_LPIUSEC_CNT counter reaches half of the maximum value or the maximum value.	
		0	MMC Transmit LPI Microsecond Counter Interrupt Mask is Disabled
		1	MMC Transmit LPI Microsecond Counter Interrupt Mask is Enabled
25 (R/W)	TXOSIZEGPIM	MMC Transmit Oversize Good Packet Counter Interrupt Mask. Setting the `EMAC_MMC_TXIMSK.TXOSIZEGPIM` bit masks the interrupt when the EMAC_TX_OSIZE_PCNT_G counter reaches half of the maximum value or the maximum value.	
		0	MMC Transmit Oversize Good Packet Counter Interrupt Mask is Disabled
		1	MMC Transmit Oversize Good Packet Counter Interrupt Mask is Enabled
24 (R/W)	TXVLANGPIM	MMC Transmit VLAN Good Packet Counter Interrupt Mask. Setting the `EMAC_MMC_TXIMSK.TXVLANGPIM` bit masks the interrupt when the EMAC_TX_VLAN_PCNT_G counter reaches half of the maximum value or the maximum value.	
		0	MMC Transmit VLAN Good Packet Counter Interrupt Mask is Disabled
		1	MMC Transmit VLAN Good Packet Counter Interrupt Mask is Enabled

Table 30-255: EMAC_MMC_TXIMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
23 (R/W)	TXPAUSPIM	MMC Transmit Pause Packet Counter Interrupt Mask. Setting the `EMAC_MMC_TXIMSK.TXPAUSPIM` bit masks the interrupt when the EMAC_TX_PAUSE_PCNT counter reaches half of the maximum value or the maximum value.	
		0	MMC Transmit Pause Packet Counter Interrupt Mask is Disabled
		1	MMC Transmit Pause Packet Counter Interrupt Mask is Enabled
22 (R/W)	TXEXDEFPIM	MMC Transmit Excessive Deferral Packet Counter Interrupt Mask. Setting the `EMAC_MMC_TXIMSK.TXEXDEFPIM` bit masks the interrupt when the EMAC_TX_EXDFRL_PCNT counter reaches half of the maximum value or the maximum value.	
		0	MMC Transmit Excessive Deferral Packet Counter Interrupt Mask is Disabled
		1	MMC Transmit Excessive Deferral Packet Counter Interrupt Mask is Enabled
21 (R/W)	TXGPKTIM	MMC Transmit Good Packet Counter Interrupt Mask. Setting the `EMAC_MMC_TXIMSK.TXGPKTIM` bit masks the interrupt when the EMAC_TX_PCNT_G counter reaches half of the maximum value or the maximum value.	
		0	MMC Transmit Good Packet Counter Interrupt Mask is Disabled
		1	MMC Transmit Good Packet Counter Interrupt Mask is Enabled
20 (R/W)	TXGOCTIM	MMC Transmit Good Octet Counter Interrupt Mask. Setting the `EMAC_MMC_TXIMSK.TXGOCTIM` bit masks the interrupt when the EMAC_TX_OCNT_G counter reaches half of the maximum value or the maximum value.	
		0	MMC Transmit Good Octet Counter Interrupt Mask is Disabled
		1	MMC Transmit Good Octet Counter Interrupt Mask is Enabled

Table 30-255: EMAC_MMC_TXIMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
19 (R/W)	TXCARERPIM	MMC Transmit Carrier Error Packet Counter Interrupt Mask. Setting the `EMAC_MMC_TXIMSK.TXCARERPIM` bit masks the interrupt when the EMAC_TX_CRERR_PCNT counter reaches half of the maximum value or the maximum value.	
		0	MMC Transmit Carrier Error Packet Counter Interrupt Mask is Disabled
		1	MMC Transmit Carrier Error Packet Counter Interrupt Mask is Enabled
18 (R/W)	TXEXCOLPIM	MMC Transmit Excessive Collision Packet Counter Interrupt Mask. Setting the `EMAC_MMC_TXIMSK.TXEXCOLPIM` bit masks the interrupt when the EMAC_TX_EXCOL_PCNT counter reaches half of the maximum value or the maximum value.	
		0	MMC Transmit Excessive Collision Packet Counter Interrupt Mask is Disabled
		1	MMC Transmit Excessive Collision Packet Counter Interrupt Mask is Enabled
17 (R/W)	TXLATCOLPIM	MMC Transmit Late Collision Packet Counter Interrupt Mask. Setting the `EMAC_MMC_TXIMSK.TXLATCOLPIM` bit masks the interrupt when the EMAC_TX_LTCOL_PCNT counter reaches half of the maximum value or the maximum value.	
		0	MMC Transmit Late Collision Packet Counter Interrupt Mask is Disabled
		1	MMC Transmit Late Collision Packet Counter Interrupt Mask is Enabled
16 (R/W)	TXDEFPIM	MMC Transmit Deferred Packet Counter Interrupt Mask. Setting the `EMAC_MMC_TXIMSK.TXDEFPIM` bit masks the interrupt when the EMAC_TX_DFRD_PCNT counter reaches half of the maximum value or the maximum value.	
		0	MMC Transmit Deferred Packet Counter Interrupt Mask is Disabled
		1	MMC Transmit Deferred Packet Counter Interrupt Mask is Enabled

Table 30-255: EMAC_MMC_TXIMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	TXMCOLGPIM	MMC Transmit Multiple Collision Good Packet Counter Interrupt Mask. Setting the `EMAC_MMC_TXIMSK.TXMCOLGPIM` bit masks the interrupt when the EMAC_TX_MCOL_PCNT_G counter reaches half of the maximum value or the maximum value.	
		0	MMC Transmit Multiple Collision Good Packet Counter Interrupt Mask is Disabled
		1	MMC Transmit Multiple Collision Good Packet Counter Interrupt Mask is Enabled
14 (R/W)	TXSCOLGPIM	MMC Transmit Single Collision Good Packet Counter Interrupt Mask. Setting the `EMAC_MMC_TXIMSK.TXSCOLGPIM` bit masks the interrupt when the EMAC_TX_SNGLCOL_PCNT_G counter reaches half of the maximum value or the maximum value.	
		0	MMC Transmit Single Collision Good Packet Counter Interrupt Mask is Disabled
		1	MMC Transmit Single Collision Good Packet Counter Interrupt Mask is Enabled
13 (R/W)	TXUFLOWERPIM	MMC Transmit Underflow Error Packet Counter Interrupt Mask. Setting the `EMAC_MMC_TXIMSK.TXUFLOWERPIM` bit masks the interrupt when the EMAC_TX_URFL_PCNT counter reaches half of the maximum value or the maximum value.	
		0	MMC Transmit Underflow Error Packet Counter Interrupt Mask is Disabled
		1	MMC Transmit Underflow Error Packet Counter Interrupt Mask is Enabled
12 (R/W)	TXBCGBPIM	MMC Transmit Broadcast Good Bad Packet Counter Interrupt Mask. Setting the `EMAC_MMC_TXIMSK.TXBCGBPIM` bit masks the interrupt when the EMAC_TX_BCST_PCNT_GB counter reaches half of the maximum value or the maximum value.	
		0	MMC Transmit Broadcast Good Bad Packet Counter Interrupt Mask is Disabled
		1	MMC Transmit Broadcast Good Bad Packet Counter Interrupt Mask is Enabled

Table 30-255: EMAC_MMC_TXIMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W)	TXMCGBPIM	MMC Transmit Multicast Good Bad Packet Counter Interrupt Mask. Setting the `EMAC_MMC_TXIMSK.TXMCGBPIM` bit masks the interrupt when the EMAC_TX_MCST_PCNT_GB counter reaches half of the maximum value or the maximum value.	
		0	MMC Transmit Multicast Good Bad Packet Counter Interrupt Mask is Disabled
		1	MMC Transmit Multicast Good Bad Packet Counter Interrupt Mask is Enabled
10 (R/W)	TXUCGBPIM	MMC Transmit Unicast Good Bad Packet Counter Interrupt Mask. Setting the `EMAC_MMC_TXIMSK.TXUCGBPIM` bit masks the interrupt when the EMAC_TX_UCST_PCNT_GB counter reaches half of the maximum value or the maximum value.	
		0	MMC Transmit Unicast Good Bad Packet Counter Interrupt Mask is Disabled
		1	MMC Transmit Unicast Good Bad Packet Counter Interrupt Mask is Enabled
9 (R/W)	TX1024TMAXOCTGB-PIM	MMC Transmit 1024 to Maximum Octet Good Bad Packet Counter Interrupt Mask. Setting the `EMAC_MMC_TXIMSK.TX1024TMAXOCTGBPIM` bit masks the interrupt when the EMAC_TX1024TOMAX_GB counter reaches half of the maximum value or the maximum value.	
		0	MMC Transmit 1024 to Maximum Octet Good Bad Packet Counter Interrupt Mask is Disabled
		1	MMC Transmit 1024 to Maximum Octet Good Bad Packet Counter Interrupt Mask is Enabled
8 (R/W)	TX512T1023OCTGBPIM	MMC Transmit 512 to 1023 Octet Good Bad Packet Counter Interrupt Mask. Setting the `EMAC_MMC_TXIMSK.TX512T1023OCTGBPIM` bit masks the interrupt when the EMAC_TX512TO1023_GB counter reaches half of the maximum value or the maximum value.	
		0	MMC Transmit 512 to 1023 Octet Good Bad Packet Counter Interrupt Mask is Disabled
		1	MMC Transmit 512 to 1023 Octet Good Bad Packet Counter Interrupt Mask is Enabled

Table 30-255: EMAC_MMC_TXIMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	TX256T511OCTGBPIM	MMC Transmit 256 to 511 Octet Good Bad Packet Counter Interrupt Mask. Setting the `EMAC_MMC_TXIMSK.TX256T511OCTGBPIM` bit masks the interrupt when the EMAC_TX256TO511_GB counter reaches half of the maximum value or the maximum value.	
		0	MMC Transmit 256 to 511 Octet Good Bad Packet Counter Interrupt Mask is Disabled
		1	MMC Transmit 256 to 511 Octet Good Bad Packet Counter Interrupt Mask is Enabled
6 (R/W)	TX128T255OCTGBPIM	MMC Transmit 128 to 255 Octet Good Bad Packet Counter Interrupt Mask. Setting the `EMAC_MMC_TXIMSK.TX128T255OCTGBPIM` bit masks the interrupt when the EMAC_TX128TO255_GB counter reaches half of the maximum value or the maximum value.	
		0	MMC Transmit 128 to 255 Octet Good Bad Packet Counter Interrupt Mask is Disabled
		1	MMC Transmit 128 to 255 Octet Good Bad Packet Counter Interrupt Mask is Enabled
5 (R/W)	TX65T127OCTGBPIM	MMC Transmit 65 to 127 Octet Good Bad Packet Counter Interrupt Mask. Setting the `EMAC_MMC_TXIMSK.TX65T127OCTGBPIM` bit masks the interrupt when the EMAC_TX65TO127_GB counter reaches half of the maximum value or the maximum value.	
		0	MMC Transmit 65 to 127 Octet Good Bad Packet Counter Interrupt Mask is Disabled
		1	MMC Transmit 65 to 127 Octet Good Bad Packet Counter Interrupt Mask is Enabled
4 (R/W)	TX64OCTGBPIM	MMC Transmit 64 Octet Good Bad Packet Counter Interrupt Mask. Setting the `EMAC_MMC_TXIMSK.TX64OCTGBPIM` bit masks the interrupt when the EMAC_TX64_GB counter reaches half of the maximum value or the maximum value.	
		0	MMC Transmit 64 Octet Good Bad Packet Counter Interrupt Mask is Disabled
		1	MMC Transmit 64 Octet Good Bad Packet Counter Interrupt Mask is Enabled

Table 30-255: EMAC_MMC_TXIMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	TXMCGPIM	MMC Transmit Multicast Good Packet Counter Interrupt Mask. Setting the `EMAC_MMC_TXIMSK.TXMCGPIM` bit masks the interrupt when the EMAC_TX_MCST_PCNT_G counter reaches half of the maximum value or the maximum value.	
		0	MMC Transmit Multicast Good Packet Counter Interrupt Mask is Disabled
		1	MMC Transmit Multicast Good Packet Counter Interrupt Mask is Enabled
2 (R/W)	TXBCGPIM	MMC Transmit Broadcast Good Packet Counter Interrupt Mask. Setting the `EMAC_MMC_TXIMSK.TXBCGPIM` bit masks the interrupt when the EMAC_TX_BCST_PCNT_G counter reaches half of the maximum value or the maximum value.	
		0	MMC Transmit Broadcast Good Packet Counter Interrupt Mask is Disabled
		1	MMC Transmit Broadcast Good Packet Counter Interrupt Mask is Enabled
1 (R/W)	TXGBPKTIM	MMC Transmit Good Bad Packet Counter Interrupt Mask. Setting the `EMAC_MMC_TXIMSK.TXGBPKTIM` bit masks the interrupt when the EMAC_TX_PCNT_GB counter reaches half of the maximum value or the maximum value.	
		0	MMC Transmit Good Bad Packet Counter Interrupt Mask is Disabled
		1	MMC Transmit Good Bad Packet Counter Interrupt Mask is Enabled
0 (R/W)	TXGBOCTIM	MMC Transmit Good Bad Octet Counter Interrupt Mask. Setting the `EMAC_MMC_TXIMSK.TXGBOCTIM` bit masks the interrupt when the EMAC_TX_OCNT_GB counter reaches half of the maximum value or the maximum value.	
		0	MMC Transmit Good Bad Octet Counter Interrupt Mask is Disabled
		1	MMC Transmit Good Bad Octet Counter Interrupt Mask is Enabled

EST Control Register

The EMAC_EST_CTL register controls the operation of Enhancements to Scheduled Transmission (EST) (IEEE802.1Qbv).

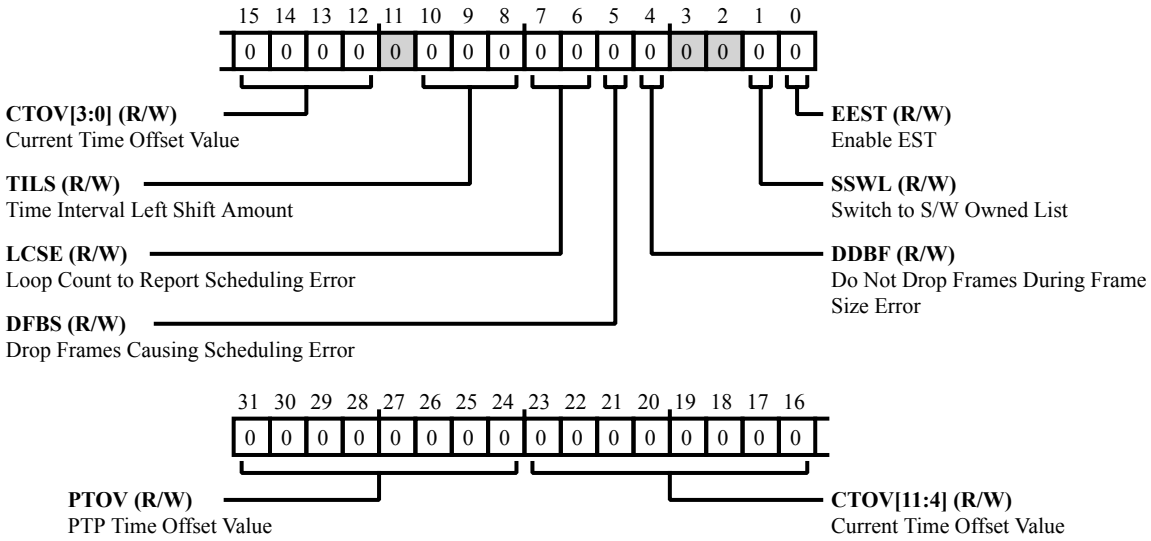

Figure 30-201: EMAC_EST_CTL Register Diagram

Table 30-256: EMAC_EST_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	PTOV	PTP Time Offset Value. The EMAC_EST_CTL.PTOV field indicates the value of the PTP clock period multiplied by 6 in nanoseconds. This value is needed to avoid transmission overruns at the beginning of the installation of a new GCL.
23:12 (R/W)	CTOV	Current Time Offset Value. The EMAC_EST_CTL.CTOV field provides a 12 bit time offset value in nano second that is added to the current time to compensate for all the implementation pipeline delays such as the CDC sync delay, buffering delays, data path delays and so on. This offset helps to ensure that the impact of gate controls is visible on the line exactly at the pre-determined schedule (or as close to the schedule as possible).

Table 30-256: EMAC_EST_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
10:8 (R/W)	TILS	Time Interval Left Shift Amount. The EMAC_EST_CTL.TILS field provides the left shift amount for the programmed time interval values used in the Gate Control Lists. - 000: No left shift needed (equal to x1ns) - 001: Left shift TI by 1 bit (equal to x2ns) - 010: Left shift TI by 2 bits (equal to x4ns) - ... - ... - 100: Left shift TI by 7 bits (equal to x128ns) Based on the configuration one or more bits of this field should be treated as reserved/read-only.	
7:6 (R/W)	LCSE	Loop Count to Report Scheduling Error. The EMAC_EST_CTL.LCSE field indicates a programmable number of GCL list iterations before reporting the EMAC_EST_STAT.HLBS bit.	
		0	4 Iterations
		1	8 Iterations
		2	16 Iterations
		3	32 Iterations
5 (R/W)	DFBS	Drop Frames Causing Scheduling Error. When the EMAC_EST_CTL.DFBS bit is set (=1), frames reported to cause HOL blocking due to not getting scheduled (EMAC_EST_STAT.HLBS) after 4,8,16,32 (based on LCSE field of this register) GCL iterations are dropped.	
		0	Do Not Drop Frames Causing Scheduling Error
		1	Drop Frames Causing Scheduling Error
4 (R/W)	DDBF	Do Not Drop Frames During Frame Size Error. When the EMAC_EST_CTL.DDBF bit is set (=1), frames are not dropped during head-of-line blocking due to a frame size error (EMAC_EST_STAT.HLBF).	
		0	Drop Frames During Frame Size Error
		1	Do Not Drop Frames During Frame Size Error

Table 30-256: EMAC_EST_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W)	SSWL	Switch to S/W Owned List. When set (=1), the EMAC_EST_CTL.SSWL bit indicates that the software has programmed that list that it currently owns (EMAC_EST_STAT.SWOL) and the hardware should switch to the new list based on the new BTR. Hardware clears the EMAC_EST_CTL.SSWL bit when the switch to the EMAC_EST_STAT.SWOL bit happens to indicate the completion of the switch or a BTR error (EMAC_EST_STAT.BTRE = 1). When EMAC_EST_STAT.BTRE = 1, the EMAC_EST_CTL.SSWL bit is cleared, but EMAC_EST_STAT.SWOL is not updated as the switch was not successful. Access restriction applies. Write 1 to set. Self-cleared. Writing 0 has no effect.	
		0	Switch to S/W Owned List is Disabled
		1	Switch to S/W Owned List is Enabled
0 (R/W)	EEST	Enable EST. When set (=1), the EMAC_EST_CTL.EEST bit enables EST. It must be set for the hardware to start processing the gate control lists. When cleared, the gate control list processing is halted and all gates are assumed to be in the Open state. During the toggle from 0 to 1, the gate control list processing starts only after EMAC_EST_CTL.SSWL =1.	
		0	EST is Disabled
		1	EST is Enabled

EST Extended Control Register

The EMAC_EST_EXT_CTL register indicates the number of overhead bytes for EST related scheduling.

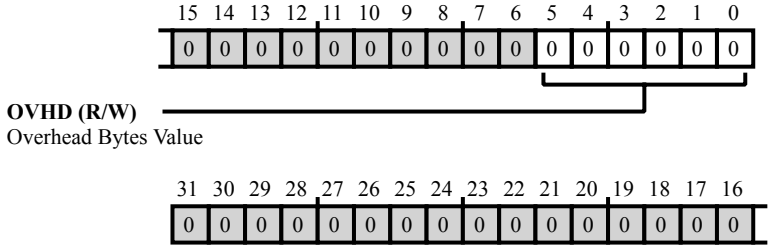

Figure 30-202: EMAC_EST_EXT_CTL Register Diagram

Table 30-257: EMAC_EST_EXT_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
5:0 (R/W)	OVHD	Overhead Bytes Value. The EMAC_EST_EXT_CTL.OVHD field indicates the fixed overhead for every packet to account for EST Scheduler Delay, IPG or EIPG, and Preamble bytes.

EST Frame Size Capture Register

The EMAC_EST_FRMSZ_CAP register captures the frame size and queue number of the first occurrence of the frame size-related error. Upon clearing, it captures the data of immediate next occurrence of a similar error.

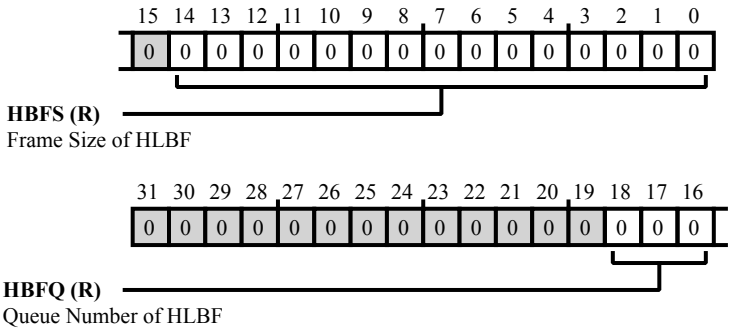

Figure 30-203: EMAC_EST_FRMSZ_CAP Register Diagram

Table 30-258: EMAC_EST_FRMSZ_CAP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
18:16 (R/NW)	HBFQ	Queue Number of HLBF. The EMAC_EST_FRMSZ_CAP.HBFQ field indicates the binary value of the of the first queue (number) experiencing HLBF error (see HLBF field of status register). Value once written is not altered by any subsequent queue errors of similar nature. Once cleared the queue number of the next occurring HLBF error is captured. The width is based on the number of Tx queues configured; remaining bits are read-only. The EMAC_EST_FRMSZ_CAP.HBFQ field is cleared when the EMAC_EST_FRMSZ_ERR register is all zeros.
14:0 (R/NW)	HBFS	Frame Size of HLBF. The EMAC_EST_FRMSZ_CAP.HBFS field indicates the frame size of the dropped frame related to queue number indicated in EMAC_EST_FRMSZ_CAP.HBFQ field. The contents of the register is considered invalid, if the EMAC_EST_FRMSZ_CAP.HBFS field is zero. The EMAC_EST_FRMSZ_CAP.HBFS field cleared when the EMAC_EST_FRMSZ_ERR register is all zeros.

EST Frame Size Error Register

The EMAC_EST_FRMSZ_ERR register provides the one hot encoded queue numbers that are having the frame size-related error.

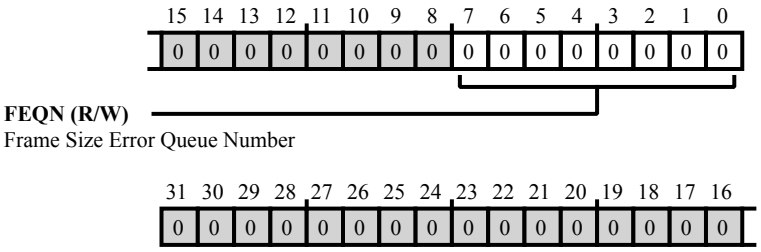

Figure 30-204: EMAC_EST_FRMSZ_ERR Register Diagram

Table 30-259: EMAC_EST_FRMSZ_ERR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	FEQN	Frame Size Error Queue Number. The EMAC_EST_FRMSZ_ERR.FEQN field indicates the one hot encoded queue numbers that have experienced the error described in the HLBF field of status register. Access restriction applies. Self-set to 1 on internal event. Write 1 to clear. Writing 0 has no effect.

EST Gate Control List Control Register

The EMAC_EST_GCL_CTL register provides the control information for reading/writing to the gate control lists.

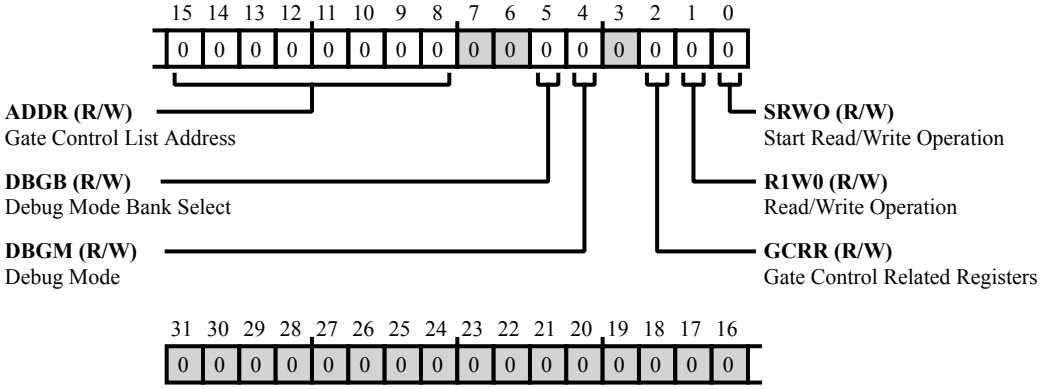

Figure 30-205: EMAC_EST_GCL_CTL Register Diagram

Table 30-260: EMAC_EST_GCL_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:8 (R/W)	ADDR	Gate Control List Address. When set (=1), the EMAC_EST_GCL_CTL.ADDR field indicates the address (row number) of the GCL at which the R/W operation must be performed. By default, the GCL pointed by EMAC_EST_STAT.SWOL is selected for R/W. However, if EMAC_EST_GCL_CTL.DBGM=1, a debug mode access is given to R/W from EMAC_EST_GCL_CTL.DBGB. The width of this field is dependent on DWC_EQOS_EST_DEP; unused bits should be treated as read only. Gate Control List Related Registers Address: (GCRA when GCRR =1). By default, the GCL-related register set pointed by EMAC_EST_STAT.SWOL is selected for R/W. However, if EMAC_EST_GCL_CTL.DBGM=1, debug mode access is given to R/W from EMAC_EST_GCL_CTL.DBGB. Lower 3 bits are only used in this mode, higher order bits are treated as dont care. 000: BTR Low (31:0) 001: BTR High (63:31) 010: CTR Low (31:0) 011: CTR High (39:32) 100: TER (31:0) 101: LLR (8:0) Others: Reserved

Table 30-260: EMAC_EST_GCL_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (R/W)	DBGB	Debug Mode Bank Select. When the EMAC_EST_GCL_CTL.DBGB bit is cleared (=0), it indicates R/W in debug mode is directed to bank 0 (GCL0 and corresponding time-related registers). When set (=1), the EMAC_EST_GCL_CTL.DBGB bit indicates R/W in debug mode should be directed to bank 1 (GCL1 and corresponding time-related registers). This value is used when EMAC_EST_GCL_CTL.DBGB = 1 and overrides by value of SWOL (which is normally used).	
		0	R/W in Debug Mode Should Be Directed to Bank 0
		1	R/W in Debug Mode Should Be Directed to Bank 1
4 (R/W)	DBGM	Debug Mode. When set (=1), the EMAC_EST_GCL_CTL.DBGM bit indicates R/W in debug mode where the memory bank (for GCL and time related registers) is explicitly provided by DBGB value. When the EMAC_EST_GCL_CTL.DBGM bit is cleared (=0), the SWOL bit is used to determine which bank to use.	
		0	Debug Mode is Disabled
		1	Debug Mode is Enabled
2 (R/W)	GCRR	Gate Control Related Registers. When set (=1), the bit indicates that the R/W access is for the GCL related registers (BTR, CTR, TER, LLR) whose address is provided by GCRA. When cleared (=0), the bit indicates that the R/W is directed to GCL from the address provided by GCLA.	
		0	Gate Control Related Registers are Disabled
		1	Gate Control Related Registers are Enabled
1 (R/W)	R1W0	Read/Write Operation. The EMAC_EST_GCL_CTL.R1W0 bit indicates a read or write operation.	
		0	Write Operation
		1	Read Operation

Table 30-260: EMAC_EST_GCL_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	SRWO	Start Read/Write Operation. When set (=1), the bit indicates the start/progress of a read/write operation. When cleared (=0) by hardware, the bit indicates that the read/write operation has completed or an error has occurred (when bit 20 is set). For read operations, data can be read from EMAC_EST_GCL_DAT register after `EMAC_EST_GCL_CTL.SRWO` = 0. For write operations, the EMAC_EST_GCL_DAT register should be programmed with write data before setting the `EMAC_EST_GCL_CTL.SRWO` bit. Access restriction applies. Write 1 to set. Self-cleared. Writing 0 has no effect.	
		0	Start Read/Write Op Disabled
		1	Start Read/Write Op Enabled

EST Gate Control List Data Register

The EMAC_EST_GCL_DAT register holds the read data or write data in case of reads and writes respectively.

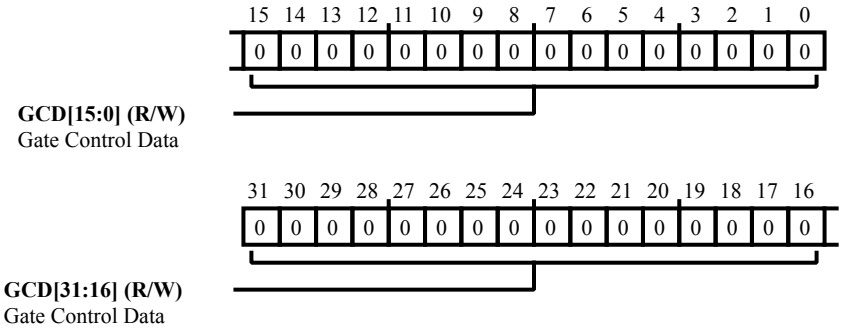

Figure 30-206: EMAC_EST_GCL_DAT Register Diagram

Table 30-261: EMAC_EST_GCL_DAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	GCD	Gate Control Data. The EMAC_EST_GCL_DAT.GCD field contains data corresponding to the address selected in the EMAC_EST_GCL_DAT register. It is used for both read and write operations.

EST Interrupt Enable Register

The EMAC_EST_IEN register implements the interrupt enable bits for the various events that generate an interrupt. Bit positions have a 1-to-1 correlation with the status bit positions in the EMAC_EST_STAT register.

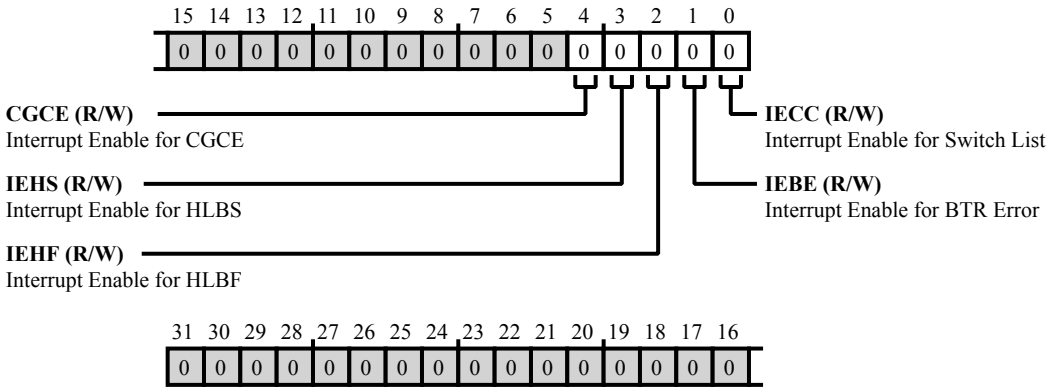

Figure 30-207: EMAC_EST_IEN Register Diagram

Table 30-262: EMAC_EST_IEN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/W)	CGCE	Interrupt Enable for CGCE. When the EMAC_EST_IEN.CGCE bit is set (=1), an interrupt is generated when the constant gate control error occurs and is indicated in the status. When the EMAC_EST_IEN.CGCE bit is cleared (= 0), an interrupt is not generated.	
		0	Interrupt for CGCE is Disabled
		1	Interrupt for CGCE is Enabled
3 (R/W)	IEHS	Interrupt Enable for HLBS. When the EMAC_EST_IEN.IEHS bit is set (=1), an interrupt is generated when the head-of-line blocking due to a scheduling issue and is indicated in the status. When the EMAC_EST_IEN.IEHS bit is cleared (= 0), an interrupt is not generated.	
		0	Interrupt for HLBS is Disabled
		1	Interrupt for HLBS is Enabled
2 (R/W)	IEHF	Interrupt Enable for HLBF. When the EMAC_EST_IEN.IEHF bit is set (=1), an interrupt is generated when the head-of-line blocking due to frame size error occurs and is indicated in the status. When the EMAC_EST_IEN.IEHF bit is cleared (= 0), an interrupt is not generated.	
		0	Interrupt for HLBF is Disabled
		1	Interrupt for HLBF is Enabled

Table 30-262: EMAC_EST_IEN Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W)	IEBE	Interrupt Enable for BTR Error. When the `EMAC_EST_IEN.IEBE` bit is set (=1), an interrupt is generated when the BTR error occurs and is indicated in the status. When the `EMAC_EST_IEN.IEBE` bit is cleared (= 0), an interrupt is not generated.	
		0	Interrupt for BTR Error is Disabled
		1	Interrupt for BTR Error is Enabled
0 (R/W)	IECC	Interrupt Enable for Switch List. When the `EMAC_EST_IEN.IECC` bit is set (=1), an interrupt is generated when the configuration change is successful, and the hardware has switched to the new list. When cleared (= 0), no interrupt is generated.	
		0	Interrupt for Switch List is Disabled
		1	Interrupt for Switch List is Enabled

EST Scheduling Error Register

The EMAC_EST_SCH_ERR register provides the one hot encoded queue numbers that are having the scheduling-related error (timeout).

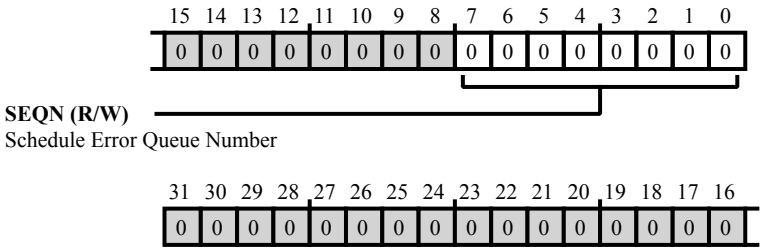

Figure 30-208: EMAC_EST_SCH_ERR Register Diagram

Table 30-263: EMAC_EST_SCH_ERR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	SEQN	Schedule Error Queue Number. The EMAC_EST_SCH_ERR.SEQN field indicates the one hot encoded queue numbers that have experienced error/timeout described in EMAC_EST_STAT.HLBS field. Access restriction applies. Self-set to 1 on internal event. Write 1 to clear. Writing 0 has no effect.

EST Status Register

The EMAC_EST_STAT register provides status information related to Enhancements to Scheduled Transmission (EST) (IEEE802.1Qbv).

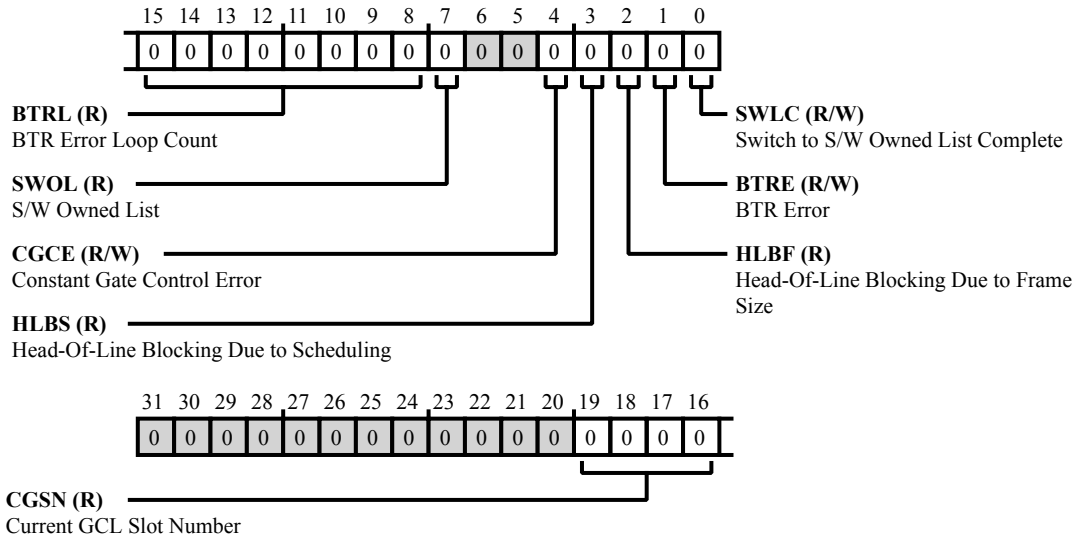

Figure 30-209: EMAC_EST_STAT Register Diagram

Table 30-264: EMAC_EST_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
19:16 (R/NW)	CGSN	Current GCL Slot Number. The EMAC_EST_STAT.CGSN field indicates the slot number of the GCL list. Slot number is a modulo 16 count of the GCL list loops executed so far. Even if a new GCL list is installed, the count is incremental.
15:8 (R/NW)	BTRL	BTR Error Loop Count. The EMAC_EST_STAT.BTRL field provides the minimum count (N) for which the equation Current Time =< New BTR + (N * New Cycle Time) becomes true. N = "11111111" indicates the iterations exceeded the value of 128 and the hardware was not able to update New BTR to be equal to or greater than Current Time. Software intervention is needed to update the new BTR. Value is cleared when EMAC_EST_STAT.BTRE = 0.

Table 30-264: EMAC_EST_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/NW)	SWOL	S/W Owned List. When the EMAC_EST_STAT.SWOL bit is cleared (=0), it indicates that the gate control list number "0" is owned by software. When set (=1), the EMAC_EST_STAT.SWOL bit indicates that Gate Control list "1" is owned by the software. Any reads/writes by the software (using indirect access through GCL_Control) is directed to the list indicated by this value by default. The inverse of this value is treated as HWOL. R/W operations performed by hardware are directed to the list pointed by HWOL by default.	
		0	Gate Control List Number "0" is Owned by Software
		1	Gate Control List Number "1" is Owned by Software
4 (R/W)	CGCE	Constant Gate Control Error. When set (=1), the EMAC_EST_STAT.CGCE bit indicates that an error occurs when the list length (LLR) is 1 and the Cycle Time (CTR) is less than or equal to the programmed Time Interval (TI) value after the optional left shifting. This implies that gates are either always closed or always open based on the Gate Control values; the same effect can be achieved by other simpler (non TSN) programming mechanisms. Since the implementation does not support such a programming an error is reported. Access restriction applies. Self-set to 1 on internal event. Write 1 to clear. Writing 0 has no effect.	
		0	Constant Gate Control Error Not Detected
		1	Constant Gate Control Error Detected
3 (R/NW)	HLBS	Head-Of-Line Blocking Due to Scheduling. When set (=1), the EMAC_EST_STAT.HLBS bit indicates when the frame is not able to win arbitration and get scheduled even after four iterations of the GCL. Indicates to software a potential programming error. The one hot encoded values of the queue numbers that are not able to make progress are indicated in the EMAC_EST_SCH_ERR register. The bit is cleared when the EMAC_EST_SCH_ERR register is all zeros.	
		0	Head-Of-Line Blocking Due to Scheduling Not Detected
		1	Head-Of-Line Blocking Due to Scheduling Detected

Table 30-264: EMAC_EST_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/NW)	HLBF	Head-Of-Line Blocking Due to Frame Size. When set (=1), the EMAC_EST_STAT.HLBF bit indicates HOL Blocking is noticed on one or more queues as a result of none of the time intervals of gate open in the GCL being greater than or equal to the duration needed for frame size (or frame fragment size when preemption is enabled) transmission. The one hot encoded queue numbers that are experiencing HLBF are indicated in the EMAC_EST_FRMSZ_ERR register. Additionally, the first queue number that experienced HLBF along with the frame size is captured in EMAC_EST_FRMSZ_CAP register. The EMAC_EST_STAT.HLBF bit is cleared when EMAC_EST_FRMSZ_ERR register is all zeros.	
		0	Head-Of-Line Blocking Due to Frame Size Not Detected
		1	Head-Of-Line Blocking Due to Frame Size Detected
1 (R/W)	BTRE	BTR Error. When set (=1), the EMAC_EST_STAT.BTRE bit indicates a programming error in the BTR of SWOL where the programmed value is less than current time. If EMAC_EST_STAT.BTRL = "11111111", EMAC_EST_STAT.SWOL is not updated and software should reprogram the BTR to a value greater than current time and then set the SSWL to reinitiate the switch to EMAC_EST_STAT.SWOL. Else, if the value of EMAC_EST_STAT.BTRL < "11111111", the EMAC_EST_STAT.SWOL bit is updated and this field indicates the number of iterations (of + CycleTime) taken by hardware to update the BTR to a value greater than Current Time. Access restriction applies. Self-set to 1 on internal event. Write 1 to clear. Writing 0 has no effect.	
		0	BTR Error Not Detected
		1	BTR Error Detected
0 (R/W)	SWLC	Switch to S/W Owned List Complete. When EMAC_EST_STAT.SWLC= 1, the hardware has successfully switched to the SWOL, and the EMAC_EST_STAT.SWOL bit has been updated to that effect. The EMAC_EST_STAT.SWLC bit is cleared when the EMAC_EST_CTL.SSWL bit transitions from 0 to 1, or on a software write. Access restriction applies. Self-set to 1 on internal event. Write 1 to clear. Writing 0 has no effect.	
		0	Switch to S/W Owned List Complete Not Detected
		1	Switch to S/W Owned List Complete Detected

Frame Preemption Advance Register

The EMAC_FPE_ADV register contains the hold and release advance time.

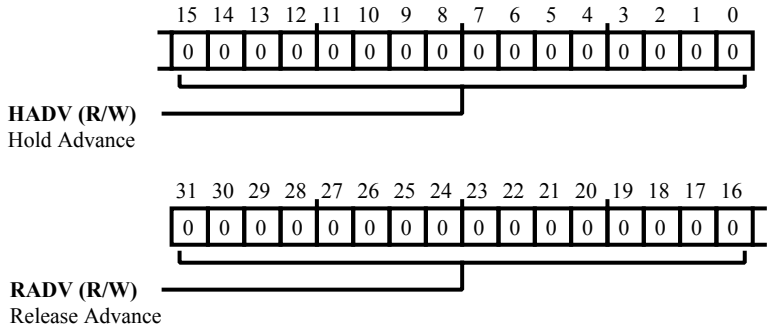

Figure 30-210: EMAC_FPE_ADV Register Diagram

Table 30-265: EMAC_FPE_ADV Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/W)	RADV	Release Advance. The EMAC_FPE_ADV.RADV field indicates the maximum time in nanoseconds that can elapse between issuing a RELEASE to the MAC and the MAC being ready to resume transmission of preemptable frames, in the absence of there being any express frames available for transmission.
15:0 (R/W)	HADV	Hold Advance. The EMAC_FPE_ADV.HADV field indicates the maximum time in nanoseconds that can elapse between issuing a HOLD to the MAC, and the MAC ceasing to transmit any preemptable frame that is in the process of transmission or any preemptable frames that are queued for transmission.

MTL Frame Preemption Control and Status Register

The EMAC_FPE_CTRLSTS register controls the operation of, and provides status for frame preemption (IEEE802.1Qbu/802.3br).

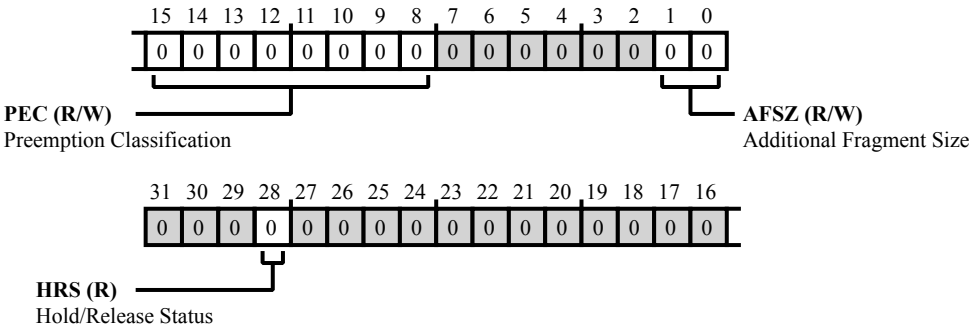

Figure 30-211: EMAC_FPE_CTRLSTS Register Diagram

Table 30-266: EMAC_FPE_CTRLSTS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
28 (R/NW)	HRS	Hold/Release Status. The EMAC_FPE_CTRLSTS.HRS bit indicates whether a set-and-hold MAC operation was last executed and the pMAC is in hold state or a set-and-release MAC operation was last executed and the pMAC is in the release state.	
		0	Release
		1	Hold
15:8 (R/W)	PEC	Preemption Classification. When set (=1), the EMAC_FPE_CTRLSTS.PEC field indicates that the corresponding queue must be classified as preemptable, when '0' queue is classified as express. When both EST (Qbv) and preemption are enabled, queue 0 is always assumed to be preemptable. When EST (Qbv) is enabled, queues categorized as preemptable here are always assumed to be in "Open" state in the Gate Control List.	
1:0 (R/W)	AFSZ	Additional Fragment Size. The EMAC_FPE_CTRLSTS.AFSZ field indicates, in units of 64 bytes, the minimum number of bytes over 64 bytes required in non-final fragments of preempted frames. The minimum non-final fragment size is (AFSZ +1) * 64 bytes.	

MTL Interrupt Status Register

The software driver (application) reads the EMAC_MTL_ISTAT register during interrupt service routine or polling to determine the interrupt status of MTL queues and the MAC.

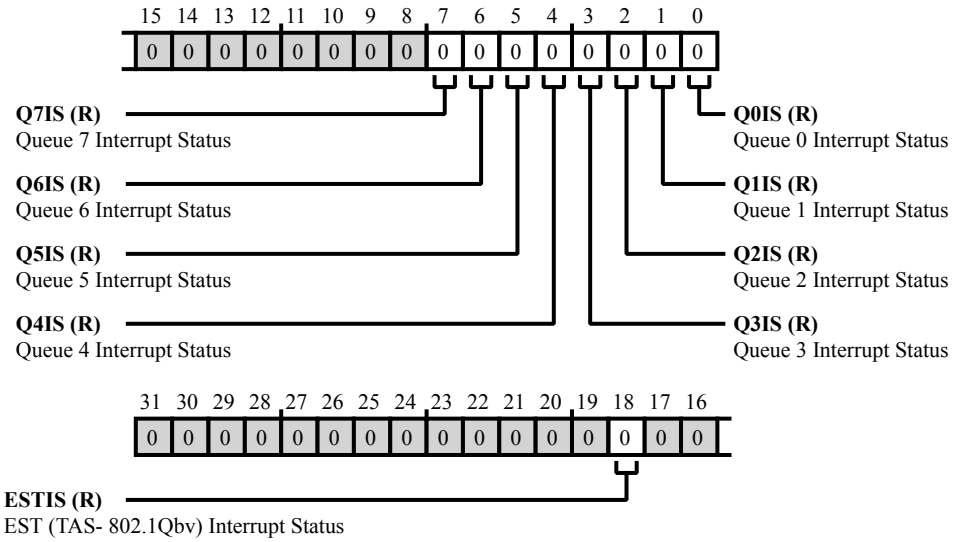

Figure 30-212: EMAC_MTL_ISTAT Register Diagram

Table 30-267: EMAC_MTL_ISTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
18 (R/NW)	ESTIS	EST (TAS- 802.1Qbv) Interrupt Status. The EMAC_MTL_ISTAT.ESTIS bit indicates an interrupt event during the operation of 802.1Qbv. To reset the EMAC_MTL_ISTAT.ESTIS bit, the application must clear the error/event that has caused the Interrupt.	
		0	EST (TAS- 802.1Qbv) Interrupt Status Not Detected
		1	EST (TAS- 802.1Qbv) Interrupt Status Detected
7 (R/NW)	Q7IS	Queue 7 Interrupt Status. The EMAC_MTL_ISTAT.Q7IS bit indicates that there is an interrupt from queue 7. To reset the EMAC_MTL_ISTAT.Q7IS bit, the application must read the EMAC_Q[n]_INT_CTLSTAT register to get the exact cause of the interrupt and clear its source.	
		0	Status Not Detected
		1	Status Detected

Table 30-267: EMAC_MTL_ISTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6 (R/NW)	Q6IS	Queue 6 Interrupt Status. The EMAC_MTL_ISTAT.Q6IS bit indicates that there is an interrupt from queue 6. To reset the EMAC_MTL_ISTAT.Q6IS bit, the application must read the EMAC_Q[n]_INT_CTLSTAT register to get the exact cause of the interrupt and clear its source.	
		0	Status Not Detected
		1	Status Detected
5 (R/NW)	Q5IS	Queue 5 Interrupt Status. The EMAC_MTL_ISTAT.Q5IS bit indicates that there is an interrupt from queue 5. To reset the EMAC_MTL_ISTAT.Q5IS bit, the application must read the EMAC_Q[n]_INT_CTLSTAT register to get the exact cause of the interrupt and clear its source.	
		0	Status Not Detected
		1	Status Detected
4 (R/NW)	Q4IS	Queue 4 Interrupt Status. The EMAC_MTL_ISTAT.Q4IS bit indicates that there is an interrupt from queue 4. To reset the EMAC_MTL_ISTAT.Q4IS bit, the application must read the EMAC_Q[n]_INT_CTLSTAT register to get the exact cause of the interrupt and clear its source.	
		0	Status Not Detected
		1	Status Detected
3 (R/NW)	Q3IS	Queue 3 Interrupt Status. The EMAC_MTL_ISTAT.Q3IS bit indicates that there is an interrupt from queue 3. To reset the EMAC_MTL_ISTAT.Q3IS bit, the application must read the EMAC_Q[n]_INT_CTLSTAT register to get the exact cause of the interrupt and clear its source.	
		0	Status Not Detected
		1	Status Detected
2 (R/NW)	Q2IS	Queue 2 Interrupt Status. The EMAC_MTL_ISTAT.Q2IS bit indicates that there is an interrupt from queue 2. To reset the EMAC_MTL_ISTAT.Q2IS bit, the application must read the EMAC_Q[n]_INT_CTLSTAT register to get the exact cause of the interrupt and clear its source.	
		0	Status Not Detected
		1	Status Detected

Table 30-267: EMAC_MTL_ISTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/NW)	Q1IS	Queue 1 Interrupt Status. The `EMAC_MTL_ISTAT.Q1IS` bit indicates that there is an interrupt from queue 1. To reset the `EMAC_MTL_ISTAT.Q1IS` bit, the application must read the EMAC_Q[n]_INT_CTLSTAT register to get the exact cause of the interrupt and clear its source.	
		0	Status Not Detected
		1	Status Detected
0 (R/NW)	Q0IS	Queue 0 Interrupt Status. The `EMAC_MTL_ISTAT.Q0IS` bit indicates that there is an interrupt from queue 0. To reset the `EMAC_MTL_ISTAT.Q0IS` bit, the application must read the EMAC_Q0_INT_CTLSTAT register to get the exact cause of the interrupt and clear its source.	
		0	Status Not Detected
		1	Status Detected

MTL Operation Mode Register

The EMAC_MTL_OPMODE register establishes the transmit and receive operating modes and commands.

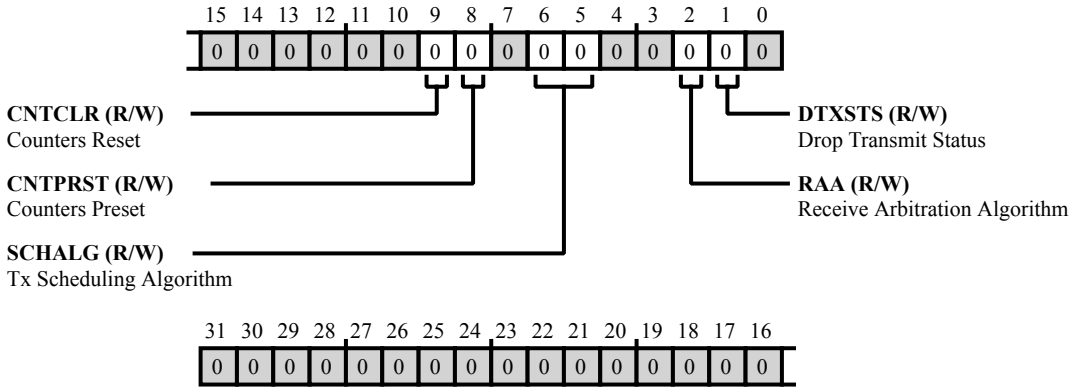

Figure 30-213: EMAC_MTL_OPMODE Register Diagram

Table 30-268: EMAC_MTL_OPMODE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W)	CNTCLR	Counters Reset. When EMAC_MTL_OPMODE.CNTCLR bit = 1, all counters are reset. The EMAC_MTL_OPMODE.CNTCLR bit is cleared automatically after 1 clock cycle. If EMAC_MTL_OPMODE.CNTCLR and EMAC_MTL_OPMODE.CNTPRST are both set (=1), the EMAC_MTL_OPMODE.CNTPRST bit has precedence. Access restriction applies. Write 1 to set. Self-cleared. Writing 0 has no effect.	
		0	Counters are Not Reset
		1	All Counters are Reset
8 (R/W)	CNTPRST	Counters Preset. When set (=1), the EMAC_MTL_OPMODE.CNTPRST bit indicates that the EMAC_TQ[n]_URFL and EMAC_RQ[n]_MSPKTOF_CNT registers are initialized and preset to 12'h7F0. Access restriction applies. Write 1 to set. Self-cleared. Writing 0 has no effect.	
		0	Disable
		1	Enable

Table 30-268: EMAC_MTL_OPMODE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6:5 (R/W)	SCHALG	Tx Scheduling Algorithm. The `EMAC_MTL_OPMODE.SCHALG` field indicates the algorithm for Tx scheduling.	
		0	WRR Algorithm
		1	WFQ Algorithm
		2	DWRR Algorithm
		3	Strict Priority Algorithm
2 (R/W)	RAA	Receive Arbitration Algorithm. The `EMAC_MTL_OPMODE.RAA` bit indicates the arbitration algorithm for the Rx side.	
		0	Strict Priority (SP). Queue 0 has the lowest priority and the last queue has the highest priority.
		1	Weighted Strict Priority (WSP)
1 (R/W)	DTXSTS	Drop Transmit Status. When set, the `EMAC_MTL_OPMODE.DTXSTS` bit indicates that the Tx packet status received from the MAC is dropped in the MTL. When cleared (=0), the packet status is forwarded to the application.	
		0	Disable
		1	Enable

Queue 0 Interrupt Control and Status Register

The EMAC_Q0_INT_CTLSTAT register contains the interrupt enable and status bits for the queue 0 interrupts.

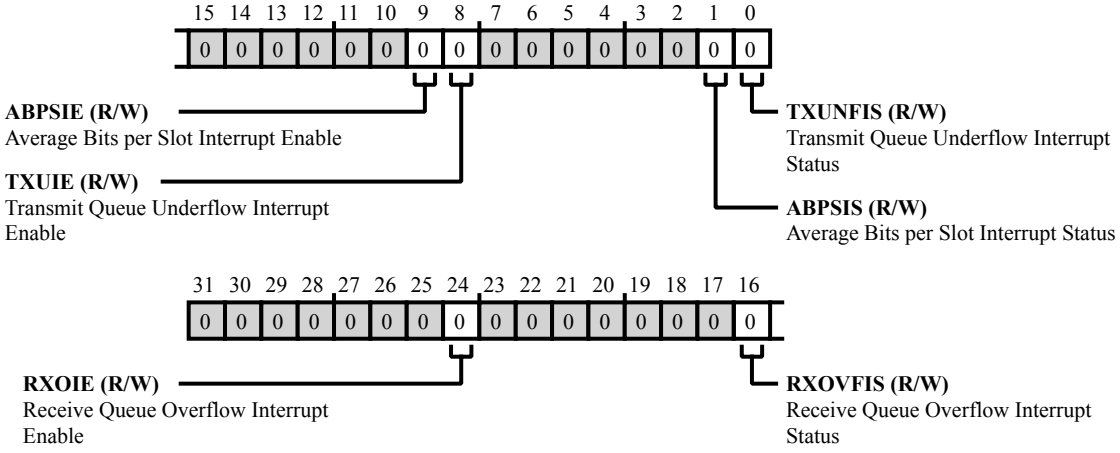

Figure 30-214: EMAC_Q0_INT_CTLSTAT Register Diagram

Table 30-269: EMAC_Q0_INT_CTLSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
24 (R/W)	RXOIE	Receive Queue Overflow Interrupt Enable. When the EMAC_Q0_INT_CTLSTAT.RXOIE bit is set, the Receive Queue Overflow interrupt is enabled. When EMAC_Q0_INT_CTLSTAT.RXOIE = 0, the Receive Queue Overflow interrupt is disabled.	
		0	Receive Queue Overflow Interrupt is Disabled
		1	Receive Queue Overflow Interrupt is Enabled
16 (R/W)	RXOVFIS	Receive Queue Overflow Interrupt Status. The EMAC_Q0_INT_CTLSTAT.RXOVFIS bit indicates that the receive queue had an overflow while receiving the packet. If a partial packet is transferred to the application, the overflow status is set in RDES3[21]. The EMAC_Q0_INT_CTLSTAT.RXOVFIS bit is cleared when the application writes 1 to the EMAC_Q0_INT_CTLSTAT.RXOVFIS bit. Access restriction applies. Self-set to 1 on internal event. Write 1 to clear. Writing 0 has no effect.	
		0	Receive Queue Overflow Interrupt Status Not Detected
		1	Receive Queue Overflow Interrupt Status Detected

Table 30-269: EMAC_Q0_INT_CTLSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W)	ABPSIE	Average Bits per Slot Interrupt Enable. When the EMAC_Q0_INT_CTLSTAT.ABPSIE bit is set, the MAC asserts the EMAC_STAT or EMAC_MAC interrupt when the average bits per slot status is updated. When the EMAC_Q0_INT_CTLSTAT.ABPSIE bit is cleared, the interrupt is not asserted for such an event.	
		0	Average Bits per Slot Interrupt is Disabled
		1	Average Bits per Slot Interrupt is Enabled
8 (R/W)	TXUIE	Transmit Queue Underflow Interrupt Enable. When the EMAC_Q0_INT_CTLSTAT.TXUIE bit is set, the Transmit Queue Underflow interrupt is enabled. When EMAC_Q0_INT_CTLSTAT.TXUIE = 0, the Transmit Queue Underflow interrupt is disabled.	
		0	Transmit Queue Underflow Interrupt Status is Disabled
		1	Transmit Queue Underflow Interrupt Status is Enabled
1 (R/W)	ABPSIS	Average Bits per Slot Interrupt Status. When set, the EMAC_Q0_INT_CTLSTAT.ABPSIS bit indicates that the MAC has updated the ABS value. The EMAC_Q0_INT_CTLSTAT.ABPSIS bit is cleared when the application writes 1 to the EMAC_Q0_INT_CTLSTAT.ABPSIS bit. Access restriction applies. Self-set to 1 on internal event. Write 1 to clear. Writing 0 has no effect.	
		0	Average Bits per Slot Interrupt Status Not Detected
		1	Average Bits per Slot Interrupt Status Detected
0 (R/W)	TXUNFIS	Transmit Queue Underflow Interrupt Status. The EMAC_Q0_INT_CTLSTAT.TXUNFIS bit indicates that the transmit queue had an underflow while transmitting the packet. Transmission is suspended and an Underflow Error TDES3[2] is set. The EMAC_Q0_INT_CTLSTAT.TXUNFIS bit is cleared when the application writes 1 to the EMAC_Q0_INT_CTLSTAT.TXUNFIS bit. Access restriction applies. Self-set to 1 on internal event. Write 1 to clear. Writing 0 has no effect.	
		0	Transmit Queue Underflow Interrupt Status Not Detected
		1	Transmit Queue Underflow Interrupt Status Detected

Queue n Interrupt Control and Status Register

The EMAC_Q[n]_INT_CTLSTAT register contains the interrupt enable and status bits for the queue 1 interrupts.

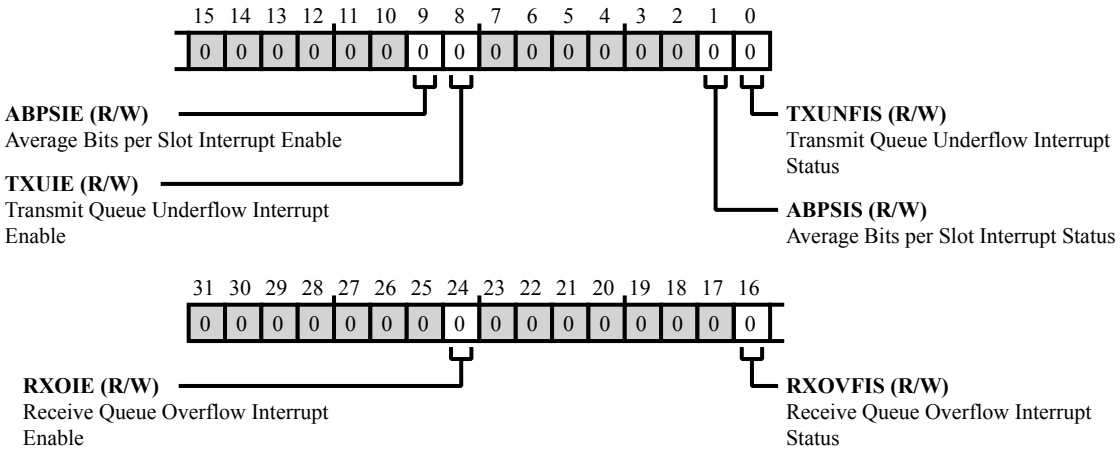

Figure 30-215: EMAC_Q[n]_INT_CTLSTAT Register Diagram

Table 30-270: EMAC_Q[n]_INT_CTLSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
24 (R/W)	RXOIE	Receive Queue Overflow Interrupt Enable. When the EMAC_Q[n]_INT_CTLSTAT.RXOIE bit is set, the receive queue overflow interrupt interrupt is enabled. When EMAC_Q[n]_INT_CTLSTAT.RXOIE = 0, the receive queue overflow interrupt is disabled.	
		0	Disabled
		1	Enabled
16 (R/W)	RXOVFIS	Receive Queue Overflow Interrupt Status. The EMAC_Q[n]_INT_CTLSTAT.RXOVFIS bit indicates that the receive queue had an overflow while receiving the packet. If a partial packet is transferred to the application, the overflow status is set in RDES3[21]. The EMAC_Q[n]_INT_CTLSTAT.RXOVFIS bit is cleared when the application writes 1 to the EMAC_Q[n]_INT_CTLSTAT.RXOVFIS bit. Access restriction applies. Self-set to 1 on internal event. Write 1 to clear. Writing 0 has no effect.	
		0	Status Not Detected
		1	Status Detected

Table 30-270: EMAC_Q[n]_INT_CTLSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W)	ABPSIE	Average Bits per Slot Interrupt Enable. When the EMAC_Q[n]_INT_CTLSTAT.ABPSIE bit is set, the MAC asserts the EMAC_STAT or EMAC_MAC interrupt when the average bits per slot status is updated. When the EMAC_Q[n]_INT_CTLSTAT.ABPSIE bit is cleared, the interrupt is not asserted for such an event.	
		0	Disabled
		1	Enabled
8 (R/W)	TXUIE	Transmit Queue Underflow Interrupt Enable. When the EMAC_Q[n]_INT_CTLSTAT.TXUIE bit is set, the transmit queue underflow interrupt is enabled. When EMAC_Q[n]_INT_CTLSTAT.TXUIE = 0, the transmit queue underflow interrupt is disabled.	
		0	Disabled
		1	Enabled
1 (R/W)	ABPSIS	Average Bits per Slot Interrupt Status. When set, the EMAC_Q[n]_INT_CTLSTAT.ABPSIS bit indicates that the MAC has updated the ABS value. The EMAC_Q[n]_INT_CTLSTAT.ABPSIS bit is cleared when the application writes 1 to the EMAC_Q[n]_INT_CTLSTAT.ABPSIS bit. Access restriction applies. Self-set to 1 on internal event. Write 1 to clear. Writing 0 has no effect.	
		0	Status Not Detected
		1	Status Detected
0 (R/W)	TXUNFIS	Transmit Queue Underflow Interrupt Status. The EMAC_Q[n]_INT_CTLSTAT.TXUNFIS bit indicates that the transmit queue had an underflow while transmitting the packet. Transmission is suspended and an Underflow Error TDES3[2] is set. The EMAC_Q[n]_INT_CTLSTAT.TXUNFIS bit is cleared when the application writes 1 to the EMAC_Q[n]_INT_CTLSTAT.TXUNFIS bit. Access restriction applies. Self-set to 1 on internal event. Write 1 to clear. Writing 0 has no effect.	
		0	Status Not Detected
		1	Status Detected

Receive Queue Control Register

The EMAC_RQ0_CTL register controls the receive arbitration and passing of received packets to the application.

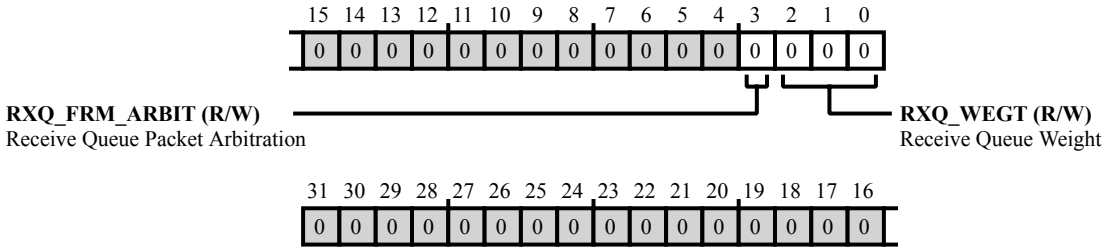

Figure 30-216: EMAC_RQ0_CTL Register Diagram

Table 30-271: EMAC_RQ0_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	RXQ_FRM_ARBIT	Receive Queue Packet Arbitration. When the EMAC_RQ0_CTL.RXQ_FRM_ARBIT bit is set, the EMAC module drives the packet data to the ARI interface such that the entire packet data of currently-selected queue is transmitted before switching to other queue. When EMAC_RQ0_CTL.RXQ_FRM_ARBIT = 0, the EMAC module drives the packet data to the ARI interface such that the following amount of data of currently-selected queue is transmitted before switching to other queue: - PBL amount of data or - Complete data of a packet The status and the time stamp are not a part of the PBL data. Therefore, the EMAC module drives the complete status (including time stamp status) during first PBL request for the packet (in store-and-forward mode) or the last PBL request for the packet (in threshold mode).	
		0	Receive Queue Packet Arbitration is Disabled
		1	Receive Queue Packet Arbitration is Enabled

Table 30-271: EMAC_RQ0_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
2:0 (R/W)	RXQ_WEGT	Receive Queue Weight. The `EMAC_RQ0_CTL.RXQ_WEGT` field indicates the weight assigned to the Rx queue 0. The field must be programmed with one value less than the required weight, that is, reset value of 0 indicates weight of 1, value of 1 indicates weight of 2, and so on. The weight is used as the number of continuous PBL or packets requests (depending on the RXQ_FRM_ARBIT) allocated to the queue in one arbitration cycle. Note: The change in value of RXQ_WEGT takes effect only after the completion of current service round or when there is change from RAA=SP to RAA=WSP algorithm. This approach is taken so that there is smooth transition. For the RXQ_WEGT value to take effect at the start, the EMAC_RQ[n]_CTL registers must be programmed before the EMAC_MTL_OPMODE register.

Receive Queue 0 Debug Register

The EMAC_RQ0_DBG register gives the debug status of various blocks related to the receive queue.

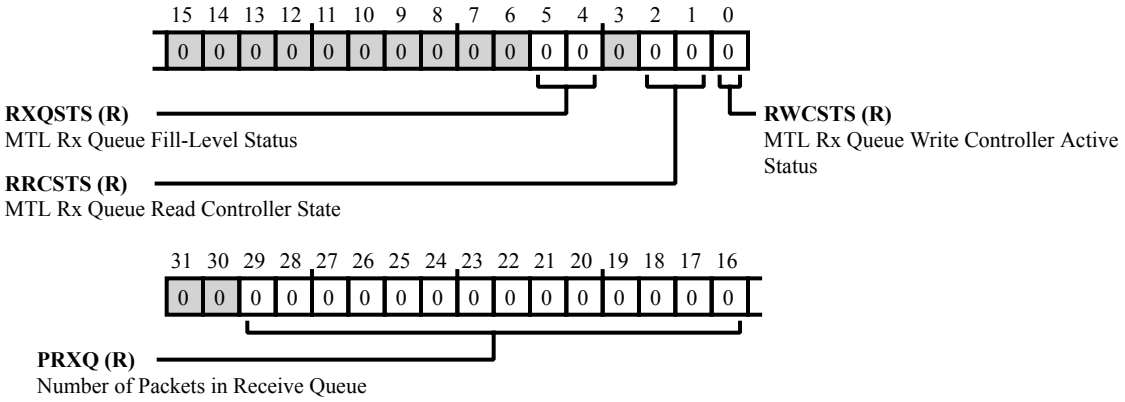

Figure 30-217: EMAC_RQ0_DBG Register Diagram

Table 30-272: EMAC_RQ0_DBG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
29:16 (R/NW)	PRXQ	Number of Packets in Receive Queue. The EMAC_RQ0_DBG.PRXQ field indicates the current number of packets in the Rx queue. The theoretical maximum value for this field is 256KB/16B = 16K Packets, that is, Max_Queue_Size/Min_Packet_Size.	
5:4 (R/NW)	RXQSTS	MTL Rx Queue Fill-Level Status. The EMAC_RQ0_DBG.RXQSTS field gives the status of the fill-level of the Rx queue:	
		0	Rx Queue Empty
		1	Rx Queue Fill-level Below Flow-control Deactivate Threshold
		2	Rx Queue Fill-level Above Flow-control Activate Threshold
		3	Rx Queue Full
2:1 (R/NW)	RRCSTS	MTL Rx Queue Read Controller State. The EMAC_RQ0_DBG.RRCSTS field gives the state of the Rx queue read controller:	
		0	Idle State
		1	Reading Packet Data
		2	Reading Packet Status (or Timestamp)
		3	Flushing the Packet Data and Status

Table 30-272: EMAC_RQ0_DBG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/NW)	RWCSTS	MTL Rx Queue Write Controller Active Status. When high, the `EMAC_RQ0_DBG.RWCSTS` bit indicates that the MTL Rx queue Write controller is active, and it is transferring a received packet to the Rx queue.	
		0	MTL Rx Queue Write Controller Active Status Not Detected
		1	MTL Rx Queue Write Controller Active Status Detected

Receive Queue 0 Missed Packet and Overflow Counter Register

The EMAC_RQ0_MSPKTOF_CNT register contains the counter for packets missed because of receive queue packet flush and packets discarded because of receive queue overflow.

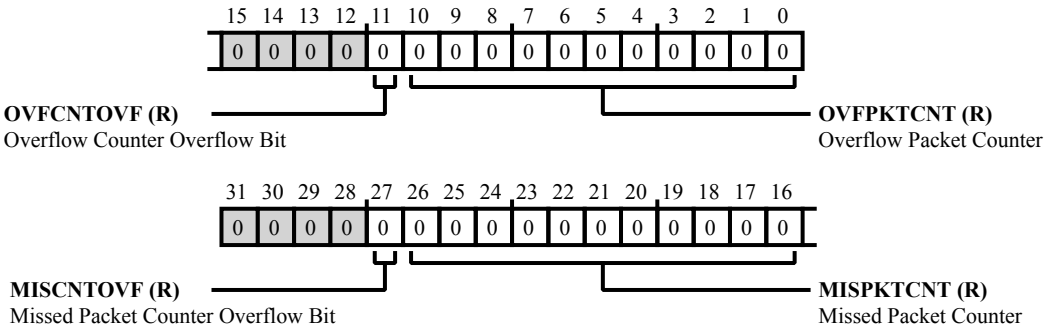

Figure 30-218: EMAC_RQ0_MSPKTOF_CNT Register Diagram

Table 30-273: EMAC_RQ0_MSPKTOF_CNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
27 (R/NW)	MISCNTOVF	Missed Packet Counter Overflow Bit. When set, the EMAC_RQ0_MSPKTOF_CNT.MISCNTOVF bit indicates that the Rx Queue Missed Packet Counter crossed the maximum limit. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	Missed Packet Counter Overflow Not Detected
		1	Missed Packet Counter Overflow Detected
26:16 (R/NW)	MISPKTCNT	Missed Packet Counter. The EMAC_RQ0_MSPKTOF_CNT.MISPKTCNT field indicates the number of packets missed by the EMAC module because the application asserted EMAC_DMA[n]_RXCTL.RPF for this queue. This counter is incremented by 1 when the DMA discards the packet because of buffer unavailability. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
11 (R/NW)	OVFCNTOVF	Overflow Counter Overflow Bit. When set, the EMAC_RQ0_MSPKTOF_CNT.OVFCNTOVF bit indicates that the Rx Queue Overflow Packet Counter field crossed the maximum limit. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	Overflow Counter Overflow Not Detected
		1	Overflow Counter Overflow Detected

Table 30-273: EMAC_RQ0_MSPKTOF_CNT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
10:0 (R/NW)	OVFPKTCNT	Overflow Packet Counter. The `EMAC_RQ0_MSPKTOF_CNT.OVFPKTCNT` field indicates the number of packets discarded by the EMAC module because of receive queue overflow. This counter is incremented each time the EMAC module discards an incoming packet because of overflow. Access restriction applies. Clears on read. Self-set to 1 on internal event.

Receive Queue 0 Operation Mode Register

The EMAC_RQ0_OPMODE register establishes the receive queue operating modes and command.

The RFA and RFD fields are not backward compatible with the RFA and RFD fields of 4.00a release.

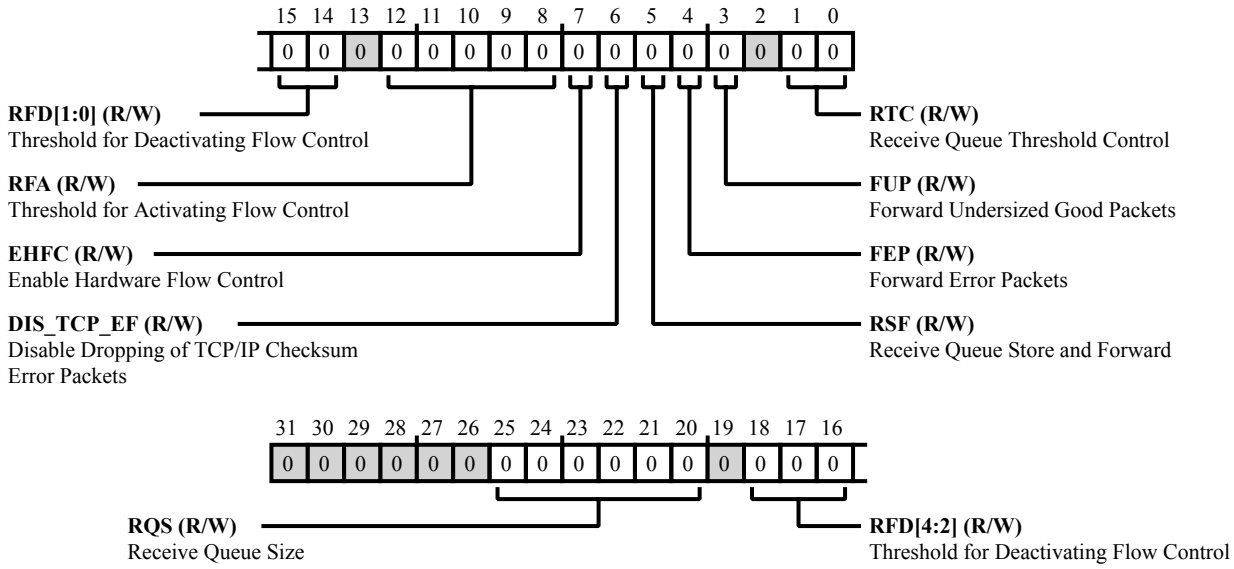

Figure 30-219: EMAC_RQ0_OPMODE Register Diagram

Table 30-274: EMAC_RQ0_OPMODE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
25:20 (R/W)	RQS	Receive Queue Size. The EMAC_RQ0_OPMODE.RQS field indicates the size of the allocated receive queues in blocks of 256 bytes. The field is read-write only if the number of Rx queues more than one, the reset value is 0x0 and indicates size of 256 bytes. For example, the value of 0x0 = 256 bytes, 0x1 = 512 bytes and so on. So, program RQS [5:0] = 6'b001111 to allocate queue size of 4096 (4K) bytes. In general, the size of the queue = (RQS+1)*256 bytes. When the number of Rx queues is one, the field is read-only and the configured RX FIFO size in blocks of 256 bytes is reflected in the reset value.

Table 30-274: EMAC_RQ0_OPMODE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
18:14 (R/W)	RFD	Threshold for Deactivating Flow Control. The EMAC_RQ0_OPMODE.RFD field indicates the threshold (fill-level of Rx queue) at which the flow control is deasserted after activation. It is valid in half-duplex and full-duplex mode). 0: Full minus 1 KB, that is, FULL 1 KB 1: Full minus 1.5 KB, that is, FULL 1.5 KB 2: Full minus 2 KB, that is, FULL 2 KB 3: Full minus 2.5 KB, that is, FULL 2.5 KB ... 30: Full minus 16 KB, that is, FULL 16 KB 31: Full minus 16.5 KB, that is, FULL 16.5 KB The deassertion is effective only after flow control is asserted. Note: The value must be programmed in such a way to make sure that the threshold is a positive number. When the EMAC_RQ0_OPMODE.EHFC bit is set (=1), these values are applicable only when the Rx queue size determined by the EMAC_RQ0_OPMODE.RQS field, is equal to or greater than 4 KB. For a given queue size, the values ranges between 0 and the encoding for FULL minus (QSIZE - 0.5 KB) and all other values are illegal. Here the term FULL and QSIZE refers to the queue size determined by the EMAC_RQ0_OPMODE.RQS field.	
12:8 (R/W)	RFA	Threshold for Activating Flow Control. The EMAC_RQ0_OPMODE.RFA field indicates the threshold (fill-level of Rx queue) at which the flow control is activated. It is valid in half-duplex and full-duplex mode). For more information on encoding for this field, see RFD.	
7 (R/W)	EHFC	Enable Hardware Flow Control. When the EMAC_RQ0_OPMODE.EHFC bit is set, the flow control signal operation, based on the fill-level of Rx queue, is enabled. When cleared (=0), the flow control operation is disabled.	
		0	Hardware Flow Control is Disabled
		1	Hardware Flow Control is Enabled

Table 30-274: EMAC_RQ0_OPMODE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6 (R/W)	DIS_TCP_EF	Disable Dropping of TCP/IP Checksum Error Packets. When the EMAC_RQ0_OPMODE.DIS_TCP_EF bit is set, the MAC does not drop the packets which only have the errors detected by the receive checksum offload engine. Such packets have errors only in the encapsulated payload. There are no errors (including FCS error) in the Ethernet packet received by the MAC. When EMAC_RQ0_OPMODE.DIS_TCP_EF = 0, all error packets are dropped if EMAC_RQ0_OPMODE.FEP = 0.	
		0	Dropping of TCP/IP Checksum Error Packets is Enabled
		1	Dropping of TCP/IP Checksum Error Packets is Disabled
5 (R/W)	RSF	Receive Queue Store and Forward. When the EMAC_RQ0_OPMODE.RSF bit is set, the EMAC module reads a packet from the Rx queue only after the complete packet has been written to it, ignoring the EMAC_RQ0_OPMODE.RTC field. When EMAC_RQ0_OPMODE.RSF = 0, the Rx queue operates in the threshold (cut-through) mode, subject to the threshold specified by the EMAC_RQ0_OPMODE.RTC field.	
		0	Receive Queue Store and Forward is Disabled
		1	Receive Queue Store and Forward is Enabled
4 (R/W)	FEP	Forward Error Packets. When EMAC_RQ0_OPMODE.FEP = 0, the Rx queue drops packets with error status (CRC error, GMII_ER, watchdog timeout, or overflow). However, if the start byte (write) pointer of a packet is already transferred to the read controller side (in threshold mode), the packet is not dropped. When the EMAC_RQ0_OPMODE.FEP bit is set, all packets except the runt error packets are forwarded to the application or DMA. If the EMAC_RQ0_OPMODE.RSF = 1 and the Rx queue overflows when a partial packet is written, the packet is dropped irrespective of the setting of the EMAC_RQ0_OPMODE.FEP bit. However, if the EMAC_RQ0_OPMODE.RSF = 0 and the Rx queue overflows when a partial packet is written, a partial packet might be forwarded to the application or DMA.	
		0	Forward Error Packets is Disabled
		1	Forward Error Packets is Enabled

Table 30-274: EMAC_RQ0_OPMODE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	FUP	Forward Undersized Good Packets. When the EMAC_RQ0_OPMODE.FUP bit is set, the Rx queue forwards the undersized good packets (packets with no error and length less than 64 bytes), including pad-bytes and CRC. When EMAC_RQ0_OPMODE.FUP = 0, the Rx queue drops all packets of less than 64 bytes, unless a packet is already transferred because of the lower value of Rx threshold, for example, RTC = 01.	
		0	Forward Undersized Good Packets is Disabled
		1	Forward Undersized Good Packets is Enabled
1:0 (R/W)	RTC	Receive Queue Threshold Control. The EMAC_RQ0_OPMODE.RTC field indicates the threshold level of the MTL Rx queue (in bytes). The received packet is transferred to the application or DMA when the packet size within the MTL Rx queue is larger than the threshold. In addition, full packets with length less than the threshold are automatically transferred. The EMAC_RQ0_OPMODE.RTC field is valid only when EMAC_RQ0_OPMODE.RSF = 0. The EMAC_RQ0_OPMODE.RTC field is ignored when EMAC_RQ0_OPMODE.RSF = 1.	
		0	64
		1	32
		2	96
		3	128

Receive Queue n Control Register

The EMAC_RQ[n]_CTL register controls the receive arbitration and passing of received packets to the application.

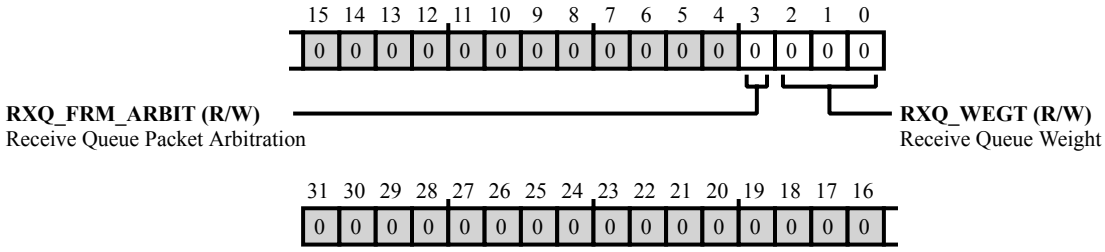

Figure 30-220: EMAC_RQ[n]_CTL Register Diagram

Table 30-275: EMAC_RQ[n]_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	RXQ_FRM_ARBIT	Receive Queue Packet Arbitration. When the EMAC_RQ[n]_CTL.RXQ_FRM_ARBIT bit is set, the EMAC module drives the packet data to the ARI interface such that the entire packet data of currently-selected queue is transmitted before switching to other queue. When EMAC_RQ[n]_CTL.RXQ_FRM_ARBIT = 0, the EMAC module drives the packet data to the ARI interface such that the following amount of data of currently-selected queue is transmitted before switching to other queue: - PBL amount of data or - Complete data of a packet The status and the time stamp are not a part of the PBL data. Therefore, the EMAC module drives the complete status (including time stamp status) during first PBL request for the packet (in store-and-forward mode) or the last PBL request for the packet (in threshold mode).	
		0	Disabled
		1	Enabled

Table 30-275: EMAC_RQ[n]_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
2:0 (R/W)	RXQ_WEGT	Receive Queue Weight. The `EMAC_RQ[n]_CTL.RXQ_WEGT` field indicates the weight assigned to the Rx queue 0. The `EMAC_RQ[n]_CTL.RXQ_WEGT` field needs to be programmed with one value less than the required weight. For example, a reset value of 0 indicates a weight of 1, a value of 1 indicates weight of 2, and so on. The weight is used as the number of continuous PBL or packets requests (depending on the RXQ_FRM_ARBIT) allocated to the queue in one arbitration cycle. Note: The change in value of RXQ_WEGT takes effect only after the completion of current service round or when there is change from RAA=SP to RAA=WSP algorithm. This approach is taken so that there is smooth transition. For the RXQ_WEGT value to take effect at the start, the EMAC_RQ[n]_CTL registers must be programmed before the EMAC_MTL_OPMODE register.

Receive Queue n Debug Register

The EMAC_RQ[n]_DBG register gives the debug status of various blocks related to the receive queue.

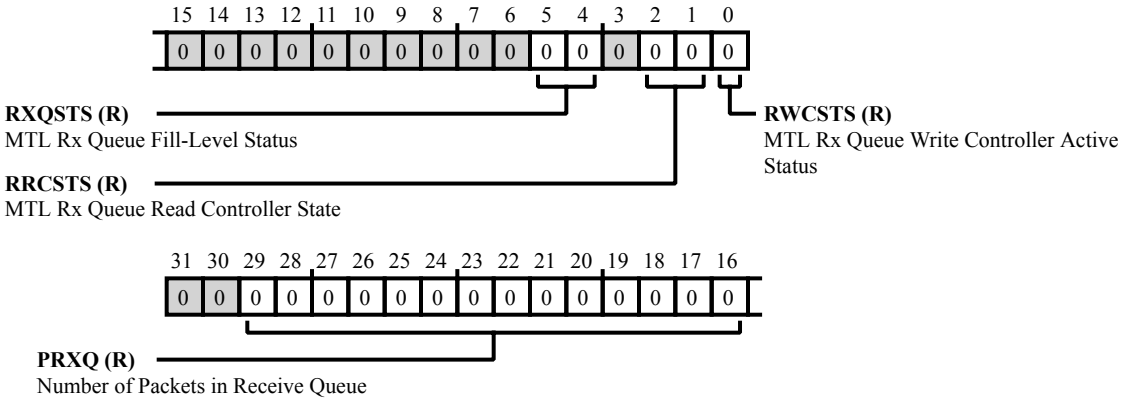

Figure 30-221: EMAC_RQ[n]_DBG Register Diagram

Table 30-276: EMAC_RQ[n]_DBG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
29:16 (R/NW)	PRXQ	Number of Packets in Receive Queue. The EMAC_RQ[n]_DBG.PRXQ field indicates the current number of packets in the Rx queue. The theoretical maximum value for this field is 256KB/16B = 16K packets, that is, Max_Queue_Size/Min_Packet_Size.	
5:4 (R/NW)	RXQSTS	MTL Rx Queue Fill-Level Status. The EMAC_RQ[n]_DBG.RXQSTS field gives the status of the fill-level of the Rx queue:	
		0	Empty
		1	Below Flow Control Deactivate Threshold
		2	Above Flow Control Activate Threshold
		3	Full
2:1 (R/NW)	RRCSTS	MTL Rx Queue Read Controller State. The EMAC_RQ[n]_DBG.RRCSTS field gives the state of the Rx queue read controller.	
		0	Idle State
		1	Reading Packet Data
		2	Reading Packet Status (or Time Stamp)
		3	Flushing the Packet Data and Status

Table 30-276: EMAC_RQ[n]_DBG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/NW)	RWCSTS	MTL Rx Queue Write Controller Active Status. When high, the `EMAC_RQ[n]_DBG.RWCSTS` bit indicates that the MTL Rx queue write controller is active, and it is transferring a received packet to the Rx queue.	
		0	Status Not Detected
		1	Status Detected

Receive Queue n Missed Packet and Overflow Counter Register

The EMAC_RQ[n]_MSPKTOF_CNT register contains the counter for packets missed because of receive queue packet flush and packets discarded because of receive queue overflow.

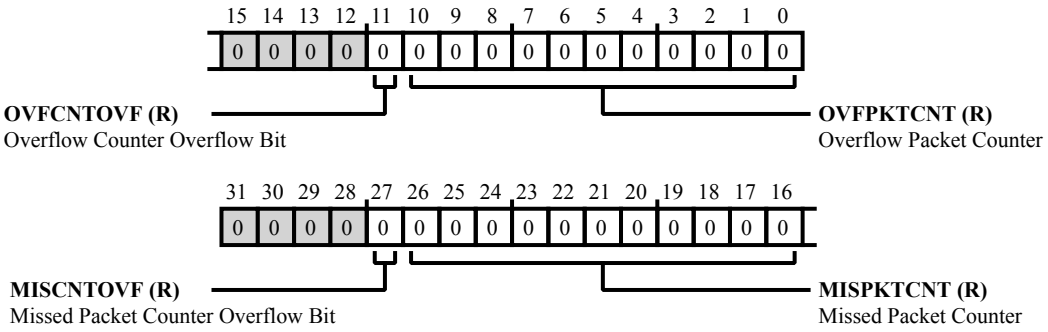

Figure 30-222: EMAC_RQ[n]_MSPKTOF_CNT Register Diagram

Table 30-277: EMAC_RQ[n]_MSPKTOF_CNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
27 (R/NW)	MISCNTOVF	Missed Packet Counter Overflow Bit. When set, the EMAC_RQ[n]_MSPKTOF_CNT.MISCNTOVF bit indicates that the Rx queue missed packet counter crossed the maximum limit. Access restriction applies. Clears (=0) on read. Self-set to 1 on internal event.	
		0	Overflow Not Detected
		1	Overflow Detected
26:16 (R/NW)	MISPKTCNT	Missed Packet Counter. The EMAC_RQ[n]_MSPKTOF_CNT.MISPKTCNT field indicates the number of packets missed by the EMAC module because the application asserted EMAC_DMA[n]_RXCTL.RPF for this queue. This counter is incremented by 1 when the DMA discards the packet because of buffer unavailability. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
11 (R/NW)	OVFCNTOVF	Overflow Counter Overflow Bit. When set, the EMAC_RQ[n]_MSPKTOF_CNT.OVFCNTOVF bit indicates that the Rx queue overflow packet counter field crossed the maximum limit. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	Overflow Not Detected
		1	Overflow Detected

Table 30-277: EMAC_RQ[n]_MSPKTOF_CNT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
10:0 (R/NW)	OVFPKTCNT	Overflow Packet Counter. The `EMAC_RQ[n]_MSPKTOF_CNT.OVFPKTCNT` field indicates the number of packets discarded by the EMAC module because of receive queue overflow. This counter is incremented each time the EMAC module discards an incoming packet because of overflow. Access restriction applies. Clears on read. Self-set to 1 on internal event.

Receive Queue n Operation Mode Register

The EMAC_RQ[n]_OPMODE register establishes the receive queue operating modes and command.

The RFA and RFD fields are not backward compatible with the RFA and RFD fields of 4.00a release

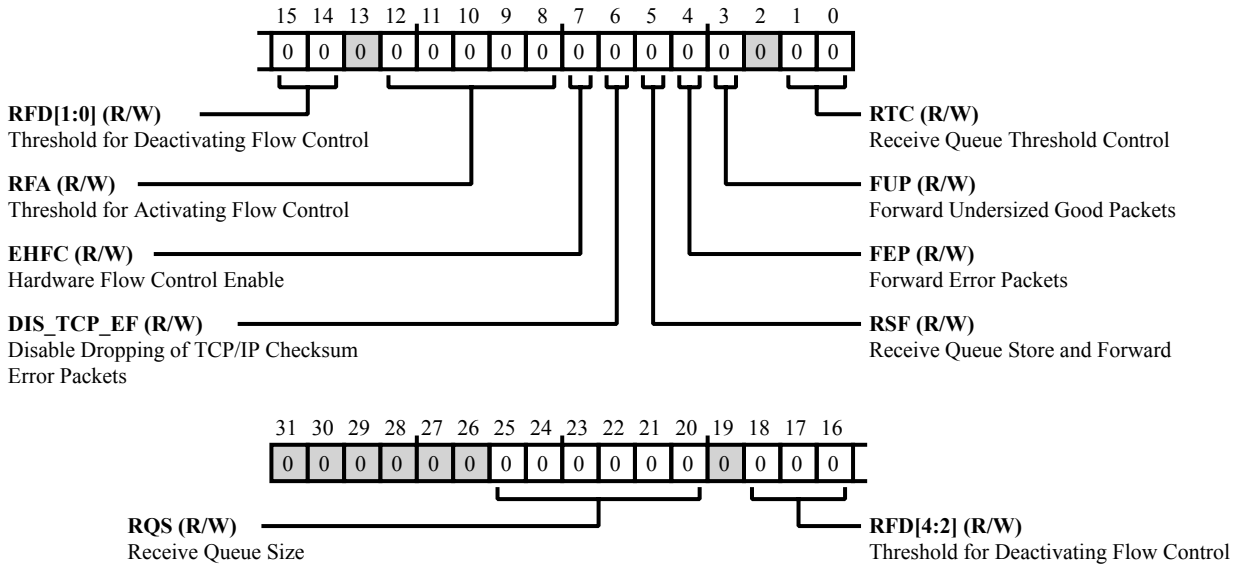

Figure 30-223: EMAC_RQ[n]_OPMODE Register Diagram

Table 30-278: EMAC_RQ[n]_OPMODE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
25:20 (R/W)	RQS	Receive Queue Size. The EMAC_RQ[n]_OPMODE.RQS field indicates the size of the allocated receive queues in blocks of 256 bytes. The field is read-write only if the number of Rx queues is more than one; the reset value is 0x0 and indicates size of 256 bytes. For example, a value of 0x0 = 256 bytes, 0x1 = 512 bytes and so on. Program RQS [5:0] = 6'b001111 to allocate queue size of 4096 (4K) bytes. In general, the size of the queue = (RQS +1)*256 bytes. When the number of Rx queues is one, the field is read-only and the configured RX FIFO size in blocks of 256 bytes is reflected in the reset value.

Table 30-278: EMAC_RQ[n]_OPMODE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
18:14 (R/W)	RFD	Threshold for Deactivating Flow Control. The EMAC_RQ[n]_OPMODE.RFD field indicates the threshold (fill-level of Rx queue) at which the flow control is deasserted after activation (in half-duplex and full-duplex modes): - 0: Full minus 1 KB, that is, FULL 1 KB - 1: Full minus 1.5 KB, that is, FULL 1.5 KB - 2: Full minus 2 KB, that is, FULL 2 KB - 3: Full minus 2.5 KB, that is, FULL 2.5 KB - ... - 30: Full minus 16 KB, that is, FULL 16 KB - 31: Full minus 16.5 KB, that is, FULL 16.5 KB The deassertion is effective only after flow control is asserted. Note: The value must be programmed in such a way to make sure that the threshold is a positive number. When EMAC_RQ[n]_OPMODE.EHFC =1, these values are applicable only when the Rx queue size determined by the EMAC_RQ[n]_OPMODE.RQS field, is equal to or greater than 4 KB. For a given queue size, the values ranges between 0 and the encoding for FULL minus (QSIZE - 0.5 KB) and all other values are illegal. Here, the term FULL and QSIZE refers to the queue size determined by the EMAC_RQ[n]_OPMODE.RQS field.	
12:8 (R/W)	RFA	Threshold for Activating Flow Control. The EMAC_RQ[n]_OPMODE.RFA field indicates the threshold (fill-level of Rx queue) at which the flow control is activated (in half-duplex and full-duplex modes). For more information on encoding for this field, see RFD.	
7 (R/W)	EHFC	Hardware Flow Control Enable. When the EMAC_RQ[n]_OPMODE.EHFC bit is set (=1), the flow control signal operation, based on the fill-level of Rx queue, is enabled. When cleared (=0), the flow control operation is disabled.	
		0	Disabled
		1	Enabled

Table 30-278: EMAC_RQ[n]_OPMODE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6 (R/W)	DIS_TCP_EF	Disable Dropping of TCP/IP Checksum Error Packets. When the EMAC_RQ[n]_OPMODE.DIS_TCP_EF bit is set (=1), the MAC does not drop the packets which only have the errors detected by the receive checksum offload engine. Such packets have errors only in the encapsulated payload. There are no errors (including FCS error) in the Ethernet packet received by the MAC. When EMAC_RQ[n]_OPMODE.DIS_TCP_EF = 0, all error packets are dropped if EMAC_RQ[n]_OPMODE.FEP = 0.	
		0	Enabled
		1	Disabled
5 (R/W)	RSF	Receive Queue Store and Forward. When the EMAC_RQ[n]_OPMODE.RSF bit is set (=1), the EMAC module reads a packet from the Rx queue only after the complete packet has been written to it, ignoring the EMAC_RQ[n]_OPMODE.RTC field. When EMAC_RQ[n]_OPMODE.RSF = 0, the Rx queue operates in the threshold (cut-through) mode, subject to the threshold specified by the EMAC_RQ[n]_OPMODE.RTC field.	
		0	Disabled
		1	Enabled
4 (R/W)	FEP	Forward Error Packets. When EMAC_RQ[n]_OPMODE.FEP = 0, the Rx queue drops packets with error status (CRC error, GMII_ER, watchdog timeout, or overflow). However, if the start byte (write) pointer of a packet is already transferred to the read controller side (in threshold mode), the packet is not dropped. When the EMAC_RQ[n]_OPMODE.FEP bit is set, all packets except the runt error packets are forwarded to the application or DMA. If the RSF bit is set and the Rx queue overflows when a partial packet is written, the packet is dropped irrespective of the setting of the EMAC_RQ[n]_OPMODE.FEP bit. However, if the RSF bit is reset and the Rx queue overflows when a partial packet is written, a partial packet might be forwarded to the application or DMA.	
		0	Disabled
		1	Enabled

Table 30-278: EMAC_RQ[n]_OPMODE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	FUP	Forward Undersized Good Packets. When the EMAC_RQ[n]_OPMODE.FUP bit is set, the Rx queue forwards the undersized good packets (packets with no error and length less than 64 bytes), including pad-bytes and CRC. When EMAC_RQ[n]_OPMODE.FUP = 0, the Rx queue drops all packets of less than 64 bytes, unless a packet is already transferred because of the lower value of Rx threshold, for example, RTC = 01.	
		0	Disabled
		1	Enabled
1:0 (R/W)	RTC	Receive Queue Threshold Control. The EMAC_RQ[n]_OPMODE.RTC field indicates the threshold level of the MTL Rx queue (in bytes). The received packet is transferred to the application or DMA when the packet size within the MTL Rx queue is larger than the threshold. In addition, full packets with length less than the threshold are automatically transferred. The EMAC_RQ[n]_OPMODE.RTC field is valid only when the RSF bit is zero. The EMAC_RQ[n]_OPMODE.RTC field is ignored when the RSF bit is set (=1).	
		0	64
		1	32
		2	96
		3	128

Receive Queue to DMA Channel Mapping Register 0

The EMAC_RXQ_DMA_MAP0 register is reserved in EQOS-CORE and EQOS-MTL configurations.

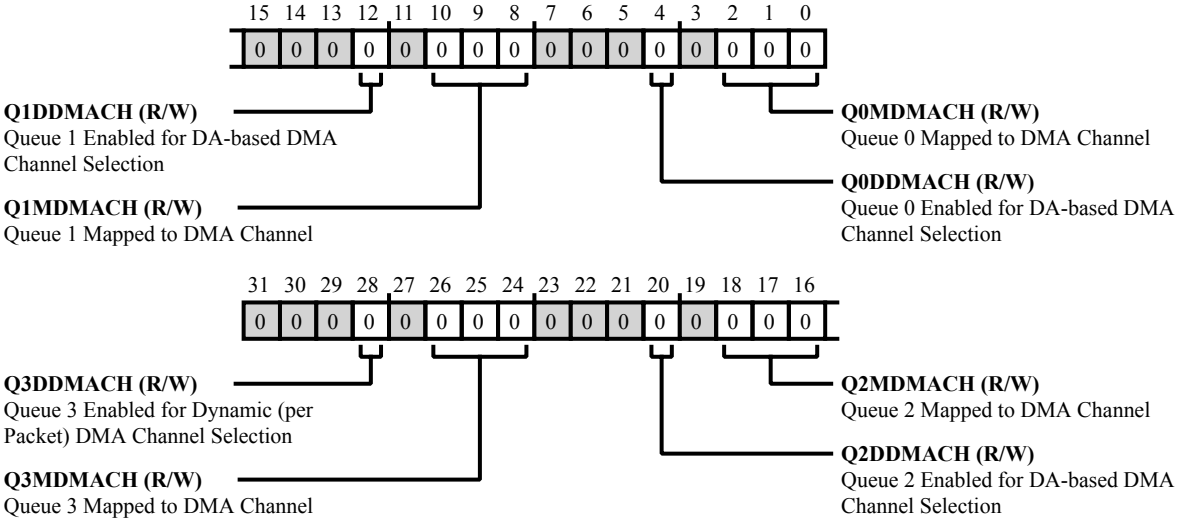

Figure 30-224: EMAC_RXQ_DMA_MAP0 Register Diagram

Table 30-279: EMAC_RXQ_DMA_MAP0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
28 (R/W)	Q3DDMACH	Queue 3 Enabled for Dynamic (per Packet) DMA Channel Selection. When set, the EMAC_RXQ_DMA_MAP0.Q3DDMACH bit indicates that the packets received in queue 3 are routed to a particular DMA channel as decided in the MAC receiver based on the DMA channel number programmed in the L3-L4 filter registers, or the Ethernet DA address. When cleared (=0), the EMAC_RXQ_DMA_MAP0.Q3DDMACH bit indicates that the packets received in queue 3 are routed to the DMA channel programmed in the EMAC_RXQ_DMA_MAP0.Q3MDMACH field.	
		0	Disable
		1	Enable
26:24 (R/W)	Q3MDMACH	Queue 3 Mapped to DMA Channel. The EMAC_RXQ_DMA_MAP0.Q3MDMACH field controls the routing of the received packet in queue 3 to the DMA channel. The EMAC_RXQ_DMA_MAP0.Q3MDMACH field is valid when the EMAC_RXQ_DMA_MAP0.Q3DDMACH field is reset. Note: The width of this field depends on the number of RX DMA channels and not all the values might be valid in some configurations. For example, if the number of RX DMA channels selected is 2, only 000 and 001 are valid, the others are reserved

MTL Time Based Scheduling Control Register

The EMAC_TBS_CTRL register controls the operation of Time-Based Scheduling (TBS).

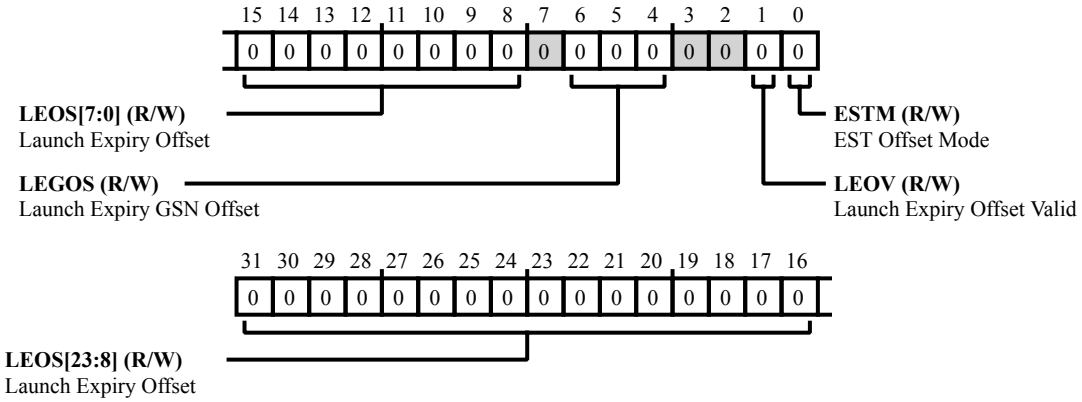

Figure 30-226: EMAC_TBS_CTRL Register Diagram

Table 30-281: EMAC_TBS_CTRL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:8 (R/W)	LEOS	Launch Expiry Offset. The field contains the value in units of 256 nanoseconds that must be added to the launch time to compute the launch expiry time. The value is valid only when EMAC_TBS_CTRL.LEOV = 1. The max value, 999,999,999 ns, should be smaller than the CTR-1 value when ESTM mode is enabled, because this value is a modulo CTR value.	
6:4 (R/W)	LEGOS	Launch Expiry GSN Offset. The EMAC_TBS_CTRL.LEGOS field indicates the number GSN slots that must be added to the launch GSN to compute the launch expiry time. The value is valid only when EMAC_TBS_CTRL.LEOV = 1.	
1 (R/W)	LEOV	Launch Expiry Offset Valid. When set (=1), the EMAC_TBS_CTRL.LEOV bit indicates that the EMAC_TBS_CTRL.LEOS field is valid. When not set, it indicates that the launch expiry offset is invalid and the MTL must not check for launch expiry time.	
		0	LEOS Field is Invalid
		1	LEOS Field is Valid

Table 30-281: EMAC_TBS_CTRL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	ESTM	EST Offset Mode. When the `EMAC_TBS_CTRL.ESTM` bit is set, the launch time value used in time based scheduling is interpreted as an EST offset value and is added to the Base Time Register (BTR) of the current list. When cleared (=0), the launch time value is used as an absolute value that should be compared with the system time [39:8].	
		0	Disabled
		1	Enabled

Transmit Queue 0 Debug Register

The EMAC_TQ0_DBG register gives the debug status of various blocks related to the transmit queue.

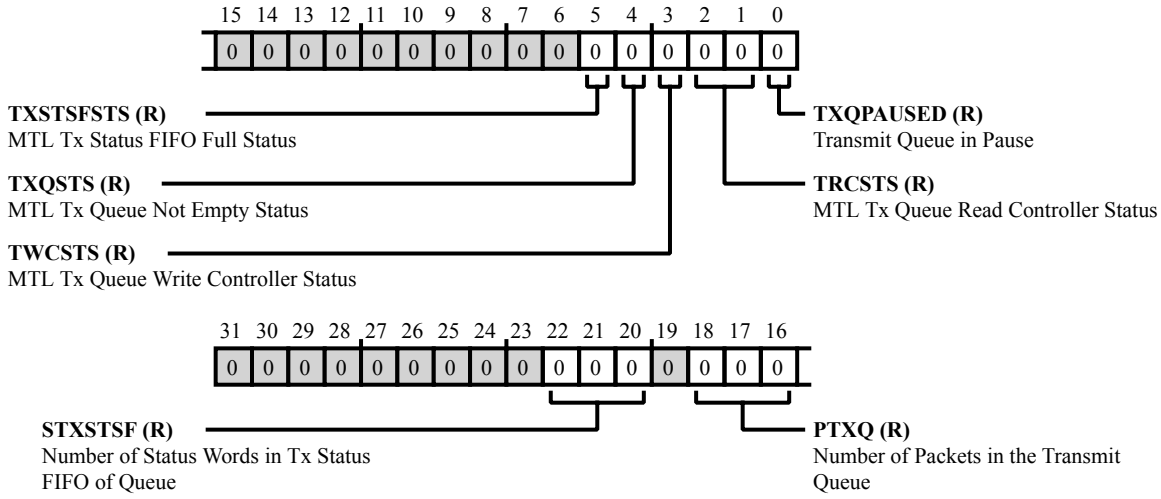

Figure 30-227: EMAC_TQ0_DBG Register Diagram

Table 30-282: EMAC_TQ0_DBG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
22:20 (R/NW)	STXSTSF	Number of Status Words in Tx Status FIFO of Queue. The EMAC_TQ0_DBG.STXSTSF field indicates the current number of status in the Tx status FIFO of this queue. When EMAC_MTL_OPMODE.DTXSTS = 1, this field does not reflect the number of status words in Tx status FIFO.	
18:16 (R/NW)	PTXQ	Number of Packets in the Transmit Queue. The EMAC_TQ0_DBG.PTXQ field indicates the current number of packets in the Tx queue. When EMAC_MTL_OPMODE.DTXSTS = 1, this field does not reflect the number of packets in the transmit queue.	
5 (R/NW)	TXSTSFSTS	MTL Tx Status FIFO Full Status. When set (=1), the EMAC_TQ0_DBG.TXSTSFSTS bit indicates that the MTL Tx status FIFO is full. Therefore, the MTL cannot accept any more packets for transmission.	
		0	MTL Tx Status FIFO Full Status is Not Detected
		1	MTL Tx Status FIFO Full Status is Detected

Table 30-282: EMAC_TQ0_DBG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/NW)	TXQSTS	MTL Tx Queue Not Empty Status. When the EMAC_TQ0_DBG.TXQSTS bit is set (=1), it indicates that the MTL Tx queue is not empty and some data is left for transmission.	
		0	MTL Tx Queue Not Empty Status is Not Detected
		1	MTL Tx Queue Not Empty Status is Detected
3 (R/NW)	TWCSTS	MTL Tx Queue Write Controller Status. When set (=1), the EMAC_TQ0_DBG.TWCSTS bit indicates that the MTL Tx queue write controller is active, and it is transferring the data to the Tx queue.	
		0	MTL Tx Queue Write Controller Status is Not Detected
		1	MTL Tx Queue Write Controller Status is Detected
2:1 (R/NW)	TRCSTS	MTL Tx Queue Read Controller Status. The EMAC_TQ0_DBG.TRCSTS field indicates the state of the Tx queue read controller:	
		0	Idle State
		1	Read State (Transferring Data to the MAC Transmitter)
		2	Waiting for Pending Tx Status from the MAC Transmitter
		3	Flushing the Tx Queue Because of the Packet Abort Request from the MAC
0 (R/NW)	TXQPAUSED	Transmit Queue in Pause. When the EMAC_TQ0_DBG.TXQPAUSED bit is set (=1) and the Rx flow control is enabled, it indicates that the Tx queue is in the Pause condition (in the full-duplex only mode) because of the following: Reception of the PFC packet for the priorities assigned to the Tx queue when PFC is enabled. Reception of 802.3x Pause packet when PFC is disabled.	
		0	Transmit Queue in Pause Status is Not Detected
		1	Transmit Queue in Pause Status is Detected

Transmit Queue 0 ETS Status Register

The EMAC_TQ0_ETS_STAT register provides the average traffic transmitted in queue 0.

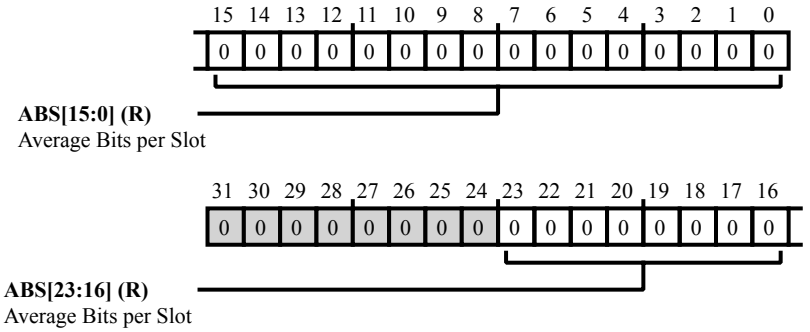

Figure 30-228: EMAC_TQ0_ETS_STAT Register Diagram

Table 30-283: EMAC_TQ0_ETS_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
23:0 (R/NW)	ABS	Average Bits per Slot. The EMAC_TQ0_ETS_STAT.ABS field contains the average transmitted bits per slot. When the DCB operation is enabled for queue 0, this field is computed over every 10 million bit times slot (4 ms in 2500 Mbps; 10 ms in 1000 Mbps; 100 ms in 100 Mbps). The maximum value is 0x989680.

Transmit Queue 0 Operation Mode Register

The EMAC_TQ0_OPMODE register establishes the transmit queue operating modes and commands.

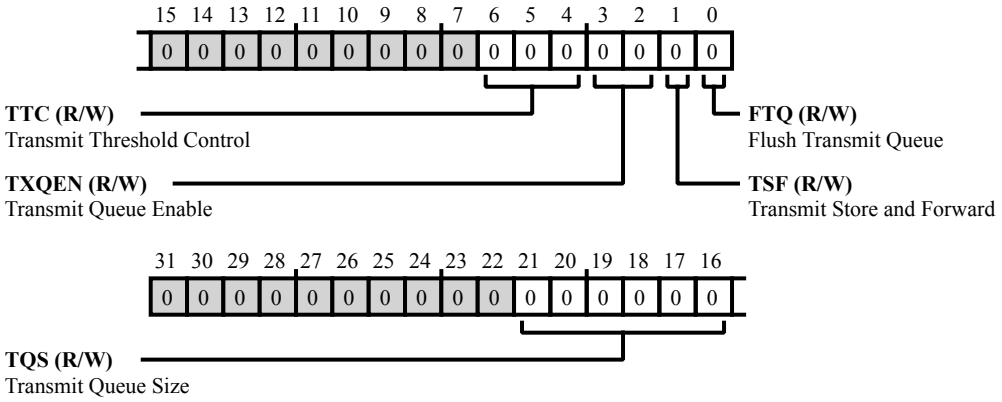

Figure 30-229: EMAC_TQ0_OPMODE Register Diagram

Table 30-284: EMAC_TQ0_OPMODE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
21:16 (R/W)	TQS	Transmit Queue Size. The EMAC_TQ0_OPMODE.TQS field indicates the size of the allocated transmit queues in blocks of 256 bytes. The field is read-write only if the number of Tx queues more than one, the reset value is 0x0 and indicates size of 256 bytes. For example, a value of 0x0 = 256 bytes, 0x1 = 512 bytes and so on. So, program TQS [5:0] = 6'b001111 to allocate queue size of 4096 (4K) bytes. In general, the size of the queue = (TQS+1)*256 bytes. When the number of Tx queues is one, the field is read-only and the configured TX FIFO size in blocks of 256 bytes is reflected in the reset value.	
6:4 (R/W)	TTC	Transmit Threshold Control. These bits control the threshold level of the MTL Tx queue. The transmission starts when the packet size within the MTL Tx queue is larger than the threshold. In addition, full packets with length less than the threshold are also transmitted. These bits are used only when the TSF bit is reset.	
		0	32
		1	64
		2	96
		3	128
		4	192
		5	256
		6	384

Table 30-284: EMAC_TQ0_OPMODE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		7	512
3:2 (R/W)	TXQEN	Transmit Queue Enable. The EMAC_TQ0_OPMODE.TXQEN field is used to enable/disable the transmit queue 0. The EMAC_TQ0_OPMODE.TXQEN field is read Only in Single queue configurations and read write in multiple queue configurations. Note: In multiple Tx queues configuration, all the queues are disabled by default. Enable the Tx queue by programming this field.	
		0	Not Enabled
		1	Enable in AV Mode (Reserved in Non-AV)
		2	Enabled
		3	Reserved
1 (R/W)	TSF	Transmit Store and Forward. When the EMAC_TQ0_OPMODE.TSF bit is set, the transmission starts when a full packet resides in the MTL Tx queue. When the EMAC_TQ0_OPMODE.TSF bit is set, the EMAC_TQ0_OPMODE.TTC field is ignored. The EMAC_TQ0_OPMODE.TSF bit should be changed only when the transmission is stopped.	
		0	Transmit Store and Forward is Disabled
		1	Transmit Store and Forward is Enabled
0 (R/W)	FTQ	Flush Transmit Queue. When the EMAC_TQ0_OPMODE.FTQ bit is set, the Tx queue controller logic is reset to its default values. Therefore, all the data in the Tx queue is lost or flushed. The EMAC_TQ0_OPMODE.FTQ bit is internally reset when the flushing operation is complete. Until EMAC_TQ0_OPMODE.FTQ = 0, do not write to the EMAC_TQ[n]_OPMODE register. The data which is already accepted by the MAC transmitter is not flushed. It is scheduled for transmission and results in underflow and runt packet transmission. Note: The flush operation is complete only when the Tx queue is empty and the application has accepted the pending Tx Status of all transmitted packets. To complete this flush operation, the PHY Tx clock (clk_tx_i) should be active. Access restriction applies. Write 1 to set. Self-cleared. Writing 0 has no effect.	
		0	Flush Transmit Queue is Disabled
		1	Flush Transmit Queue is Enabled

Transmit Queue 0 IdleSlopeCredit, Quantum or Weights Register

The EMAC_TQ0_QTMWGT register contains the quantum value for Deficit Weighted Round Robin (DWRR), weights for the Weighted Round Robin (WRR), and Weighted Fair Queuing (WFQ) for queue 0.

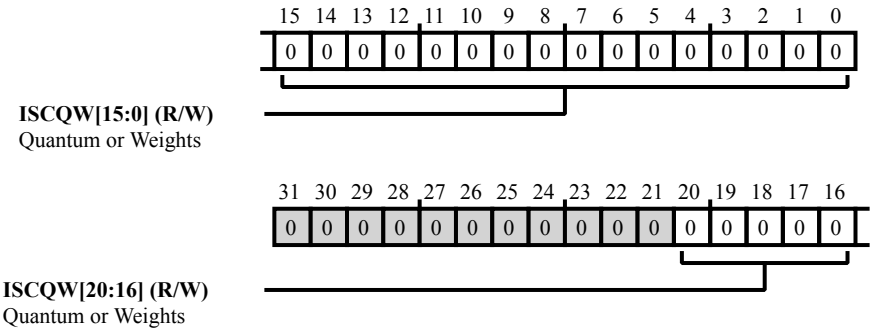

Figure 30-230: EMAC_TQ0_QTMWGT Register Diagram

Table 30-285: EMAC_TQ0_QTMWGT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
20:0 (R/W)	ISCQW	Quantum or Weights. When the DCB operation is enabled with DWRR algorithm for queue 0 traffic, the EMAC_TQ0_QTMWGT.ISCQW field contains the quantum value in bytes to be added to credit during every queue scanning cycle. The maximum value is 0x1312D0 bytes. When DCB operation is enabled with WFQ algorithm for queue 0 traffic, the EMAC_TQ0_QTMWGT.ISCQW field contains the weight for this queue. The maximum value is 0x3FFF where weight of 0 indicates 100% bandwidth. Bits[20:14] must be written to zero. The higher the programmed weights lesser the bandwidth allocated for the particular transmit queue. This is because the weights are used to compute the packet finish time (weights * packet_size). Lesser the finish time, higher the probability of the packet getting scheduled first and using more bandwidth. When DCB operation or generic queuing operation is enabled with WRR algorithm for queue 0 traffic, this field contains the weight for this queue. The maximum value is 0x64. Bits [20:7] must be written to zero.

Transmit Queue 0 Underflow Packet Counter Register

The EMAC_TQ0_URFL register contains the counter for packets aborted because of transmit queue underflow and packets missed because of receive queue packet flush.

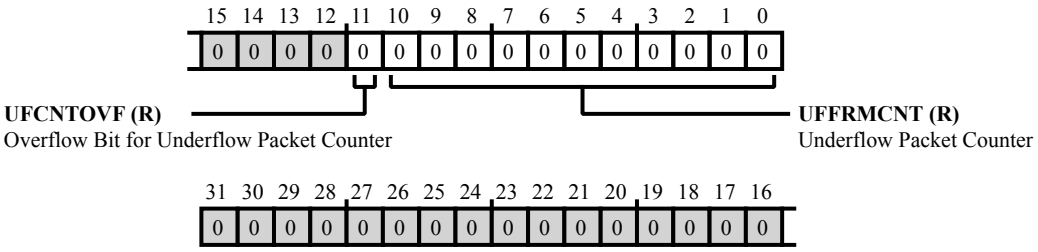

Figure 30-231: EMAC_TQ0_URFL Register Diagram

Table 30-286: EMAC_TQ0_URFL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/NW)	UFCNTOVF	Overflow Bit for Underflow Packet Counter. The EMAC_TQ0_URFL.UFCNTOVF bit is set every time the Tx queue Underflow Packet Counter field overflows, that is, it has crossed the maximum count. In such a scenario, the overflow packet counter is reset to all-zeros and the EMAC_TQ0_URFL.UFCNTOVF bit indicates that the rollover happened. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	Overflow Not Detected for Underflow Packet Counter
		1	Overflow Detected for Underflow Packet Counter
10:0 (R/NW)	UFFRMCNT	Underflow Packet Counter. The EMAC_TQ0_URFL.UFFRMCNT field indicates the number of packets aborted by the controller because of Tx queue underflow. This counter is incremented each time the MAC aborts outgoing packet because of underflow. Access restriction applies. Clears on read. Self-set to 1 on internal event.	

Transmit Queue n Debug Register

The EMAC_TQ[n]_DBG register gives the debug status of various blocks related to the transmit queue.

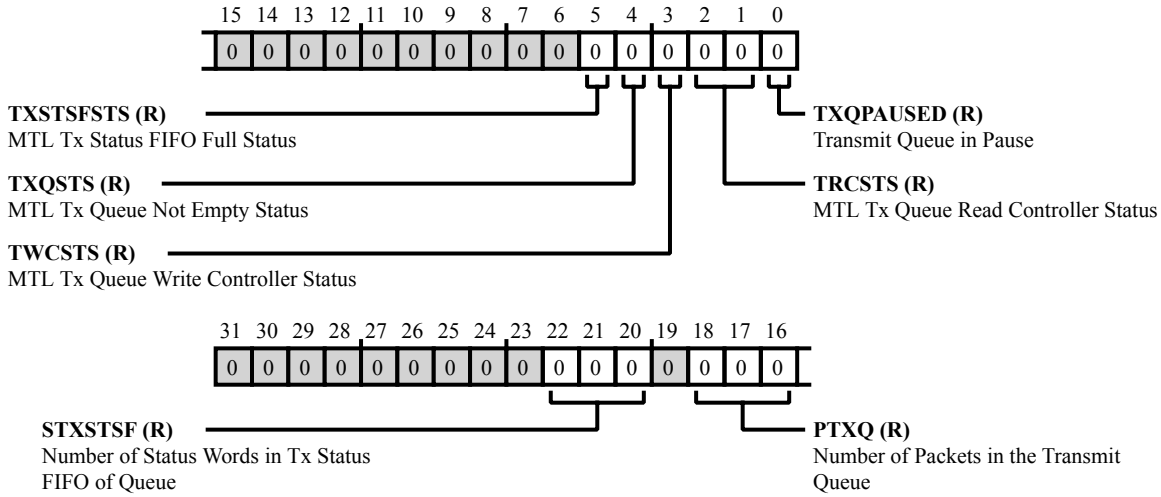

Figure 30-232: EMAC_TQ[n]_DBG Register Diagram

Table 30-287: EMAC_TQ[n]_DBG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
22:20 (R/NW)	STXSTSF	Number of Status Words in Tx Status FIFO of Queue. The EMAC_TQ[n]_DBG.STXSTSF field indicates the current number of status in the Tx Status FIFO of this queue. When EMAC_MTL_OPMODE.DTXSTS = 1, this field does not reflect the number of status words in Tx Status FIFO.	
18:16 (R/NW)	PTXQ	Number of Packets in the Transmit Queue. The EMAC_TQ[n]_DBG.PTXQ field indicates the current number of packets in the Tx queue. When EMAC_MTL_OPMODE.DTXSTS = 1, the field does not reflect the number of packets in the transmit queue.	
5 (R/NW)	TXSTSFSTS	MTL Tx Status FIFO Full Status. When set (=1), the EMAC_TQ[n]_DBG.TXSTSFSTS bit indicates that the MTL Tx status FIFO is full. Therefore, the MTL cannot accept any more packets for transmission.	
		0	Status Not Detected
		1	Status Detected

Table 30-287: EMAC_TQ[n]_DBG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/NW)	TXQSTS	MTL Tx Queue Not Empty Status. When the `EMAC_TQ[n]_DBG.TXQSTS` bit is set (=1), it indicates that the MTL Tx queue is not empty and some data is left for transmission.	
		0	Status Not Detected
		1	Status Detected
3 (R/NW)	TWCSTS	MTL Tx Queue Write Controller Status. When set (=1), the `EMAC_TQ[n]_DBG.TWCSTS` bit indicates that the MTL Tx queue write controller is active (status detected), and it is transferring the data to the Tx queue.	
		0	Status Not Detected
		1	Status Detected
2:1 (R/NW)	TRCSTS	MTL Tx Queue Read Controller Status. The `EMAC_TQ[n]_DBG.TRCSTS` field indicates the state of the Tx queue read controller.	
		0	Idle State
		1	Read State (Transferring data to the MAC transmitter)
		2	Wait for pending Tx status from the MAC transmitter
		3	Flush the Tx queue because of the packet abort request from the MAC
0 (R/NW)	TXQPAUSED	Transmit Queue in Pause. When the `EMAC_TQ[n]_DBG.TXQPAUSED` bit is set (=1) and the Rx flow control is enabled, it indicates that the Tx queue is in the pause condition (in the full-duplex only mode) because of the following: - Reception of the PFC packet for the priorities assigned to the Tx queue, when PFC is enabled. - Reception of the 802.3x pause packet, when PFC is disabled.	
		0	Transmit Queue in Pause Status is Not Detected
		1	Transmit Queue in Pause Status is Detected

Transmit Queue n ETS Control Register

The EMAC_TQ[n]_ETS_CTL register controls the enhanced transmission selection operation.

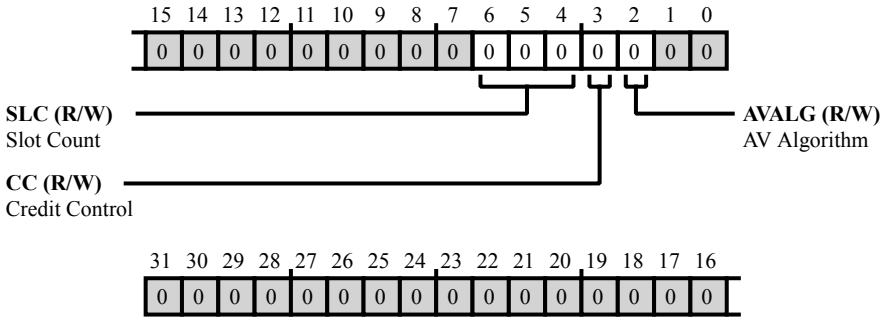

Figure 30-233: EMAC_TQ[n]_ETS_CTL Register Diagram

Table 30-288: EMAC_TQ[n]_ETS_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
6:4 (R/W)	SLC	Slot Count. If the credit-based shaper algorithm is enabled, the software can program the EMAC_TQ[n]_ETS_CTL.SLC field (of a duration programmed in EMAC_DMA[n]_SFN_CTLSTAT register). The average transmitted bits per slot must be computed for the queue; it is provided in the EMAC_TQ[n]_ETS_STAT register.	
		0	1 Slot
		1	2 Slots
		2	4 Slots
		3	8 Slots
		4	16 Slots
		5	Reserved
3 (R/W)	CC	Credit Control. When the EMAC_TQ[n]_ETS_CTL.CC bit is set, the accumulated credit parameter in the credit-based shaper algorithm logic is not reset to zero when there is positive credit and no packet to transmit in channel 1. The credit accumulates even when there is no packet waiting in channel 1 and another channel is transmitting. When EMAC_TQ[n]_ETS_CTL.CC = 0, the accumulated credit parameter in the credit-based shaper algorithm logic is set to zero when there is positive credit and no packet to transmit in channel 1. When there is no packet waiting in channel 1 and other channel is transmitting, no credit is accumulated.	
		0	Credit Control is Disabled
		1	Credit Control is Enabled

Table 30-288: EMAC_TQ[n]_ETS_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W)	AVALG	AV Algorithm. When queue 1 is programmed for AV, the `EMAC_TQ[n]_ETS_CTL.AVALG` field configures the scheduling algorithm for the queue. The `EMAC_TQ[n]_ETS_CTL.AVALG` bit when set, a credit-based shaper algorithm (CBS) is selected for queue 1 traffic. When cleared (=0), strict priority is selected.	
		0	CBS Algorithm is Disabled
		1	CBS Algorithm is Enabled

Transmit Queue n ETS Status Register

The EMAC_TQ[n]_ETS_STAT register provides the average traffic transmitted in queue 1.

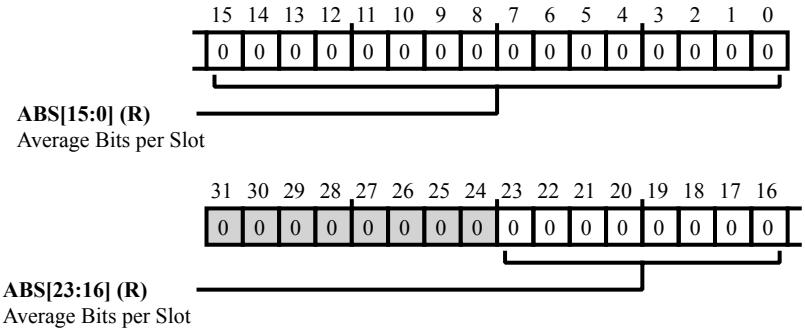

Figure 30-234: EMAC_TQ[n]_ETS_STAT Register Diagram

Table 30-289: EMAC_TQ[n]_ETS_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
23:0 (R/NW)	ABS	Average Bits per Slot. The EMAC_TQ[n]_ETS_STAT.ABS field contains the average transmitted bits per slot. If AV operation is enabled, the EMAC_TQ[n]_ETS_STAT.ABS field is computed over the number of slots, programmed in EMAC_TQ[n]_ETS_CTL.SLC. The maximum value of this field is 0x6_4000 in 100 Mbps, 0x3E_8000 in 1000 Mbps and 9C_4000 in 2500 Mbps mode respectively. When the DCB operation is enabled for queue, the EMAC_TQ[n]_ETS_STAT.ABS field is computed over every 10 million bit times slot (4 ms in 2500 Mbps; 10 ms in 1000 Mbps; 100 ms in 100 Mbps). The maximum value is 0x989680.

Transmit Queue n CBS HiCredit Register

The EMAC_TQ[n]_HICRDT register contains the HiCredit value required for the credit-based shaper algorithm for the queue.

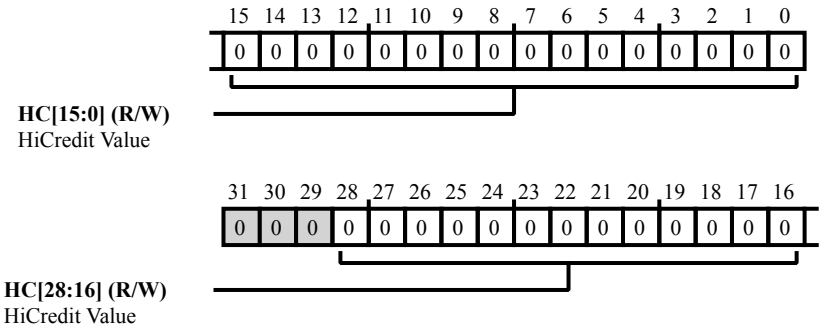

Figure 30-235: EMAC_TQ[n]_HICRDT Register Diagram

Table 30-290: EMAC_TQ[n]_HICRDT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
28:0 (R/W)	HC	HiCredit Value. When the AV feature is enabled, the EMAC_TQ[n]_HICRDT.HC field contains the hiCredit value required for the credit-based shaper algorithm. This is the maximum value that can be accumulated in the credit parameter. It is specified in bits scaled by 1,024. The maximum value is maxInterferenceSize, that is, best-effort maximum packet size (16,384 bytes or 131,072 bits). The value to be specified is 131,072 * 1,024 = 134,217,728 or 0x0800_0000.

Transmit Queue n CBS LoCredit Register

The EMAC_TQ[n]_LOCRDT register contains the loCredit value required for the credit-based shaper algorithm for the queue.

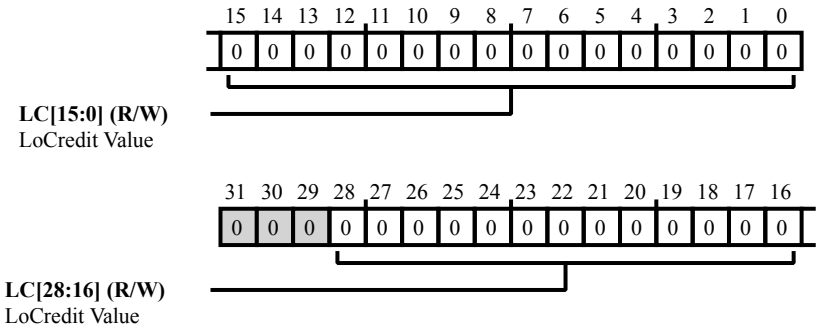

Figure 30-236: EMAC_TQ[n]_LOCRDT Register Diagram

Table 30-291: EMAC_TQ[n]_LOCRDT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
28:0 (R/W)	LC	LoCredit Value. When the AV operation is enabled, the EMAC_TQ[n]_LOCRDT.LC field contains the loCredit value required for the credit-based shaper algorithm. This is the minimum value that can be accumulated in the credit parameter. It is specified in bits scaled by 1,024. The maximum value to be programmed corresponds to twice the maxFrame-Size transmitted from this queue. If the maxFrameSize is 8192 bytes, then (8192*2) * 8 * 1024 = 134,217,728 or 0x0800_0000. Because it is a negative value, the programmed value is the 2's complement of the value, that is, 0x1800_0000.

Transmit Queue n Operation Mode Register

The EMAC_TQ[n]_OPMODE register establishes the transmit queue operating modes and commands.

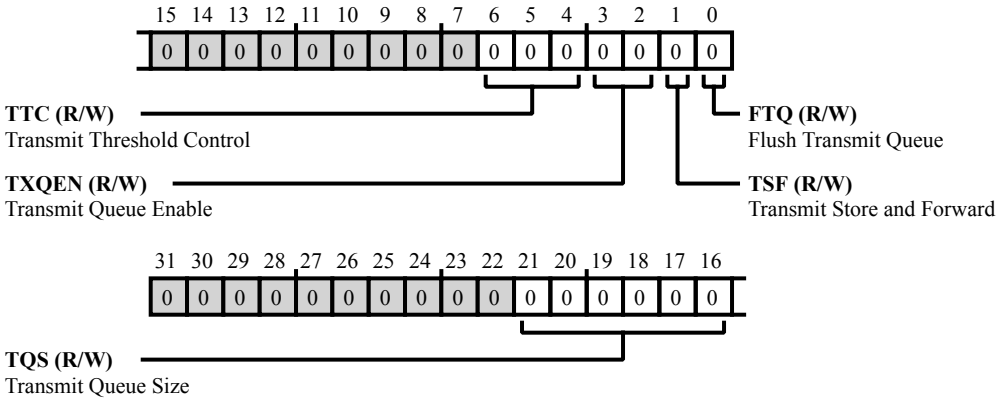

Figure 30-237: EMAC_TQ[n]_OPMODE Register Diagram

Table 30-292: EMAC_TQ[n]_OPMODE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
21:16 (R/W)	TQS	Transmit Queue Size. The EMAC_TQ[n]_OPMODE.TQS field indicates the size of the allocated transmit queues in blocks of 256 bytes. The EMAC_TQ[n]_OPMODE.TQS field is read-write only if the number of Tx queues more than one; the reset value is 0x0 and indicates size of 256 bytes. For example, a value of 0x0 = 256 bytes, 0x1 = 512 bytes and so on. Program TQS [5:0] = 6'b001111 to allocate queue size of 4096 (4K) bytes. In general, the size of the queue = (TQS+1)*256 bytes. When the number of Tx queues is one, the EMAC_TQ[n]_OPMODE.TQS field is read-only and the configured TX FIFO size in blocks of 256 bytes is reflected in the reset value.	
6:4 (R/W)	TTC	Transmit Threshold Control. The EMAC_TQ[n]_OPMODE.TTC field controls the threshold level of the MTL Tx queue. The transmission starts when the packet size within the MTL Tx queue is larger than the threshold. In addition, full packets with length less than the threshold are also transmitted. The EMAC_TQ[n]_OPMODE.TTC field is used only when EMAC_TQ[n]_OPMODE.TSF = 0.	
		0	32
		1	64
		2	96
		3	128
		4	192

Table 30-292: EMAC_TQ[n]_OPMODE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		5	256
		6	384
		7	512
3:2 (R/W)	TXQEN	Transmit Queue Enable. The `EMAC_TQ[n]_OPMODE.TXQEN` field is used to enable/disable the transmit queue 0. Note: In multiple Tx queues configuration, all the queues are disabled by default. Enable the Tx queue by programming this field.	
		0	Not Enabled
		1	Enable in AV Mode (Reserved in Non-AV)
		2	Enabled
		3	Reserved
1 (R/W)	TSF	Transmit Store and Forward. When the `EMAC_TQ[n]_OPMODE.TSF` bit is set, the transmission starts when a full packet resides in the MTL Tx queue. When the `EMAC_TQ[n]_OPMODE.TSF` bit is set, the TTC values specified in bits[6:4] of this register are ignored. The `EMAC_TQ[n]_OPMODE.TSF` bit should be changed only when the transmission is stopped.	
		0	Transmit Store and Forward is Disabled
		1	Transmit Store and Forward is Enabled
0 (R/W)	FTQ	Flush Transmit Queue. When the `EMAC_TQ[n]_OPMODE.FTQ` bit is set, the Tx queue controller logic is reset to its default values. Therefore, all the data in the Tx queue is lost or flushed. The `EMAC_TQ[n]_OPMODE.FTQ` bit is internally reset when the flushing operation is complete. Until EMAC_TQ[0]_OPMODE= 0, do not write to the EMAC_TQ[1]_OPMODE register. The data which is already accepted by the MAC transmitter is not flushed. It is scheduled for transmission and results in underflow and runt packet transmission. Note: The flush operation is complete only when the Tx queue is empty and the application has accepted the pending Tx Status of all transmitted packets. To complete this flush operation, the PHY Tx clock (clk_tx_i) should be active. Access restriction applies. Write 1 to set. Self-cleared. Writing 0 has no effect.	
		0	Flush Transmit Queue is Disabled
		1	Flush Transmit Queue is Enabled

Transmit Queue n IdleSlopeCredit, Quantum or Weights Register

The EMAC_TQ[n]_QTMWGT register provides the average traffic transmitted in queue 1.

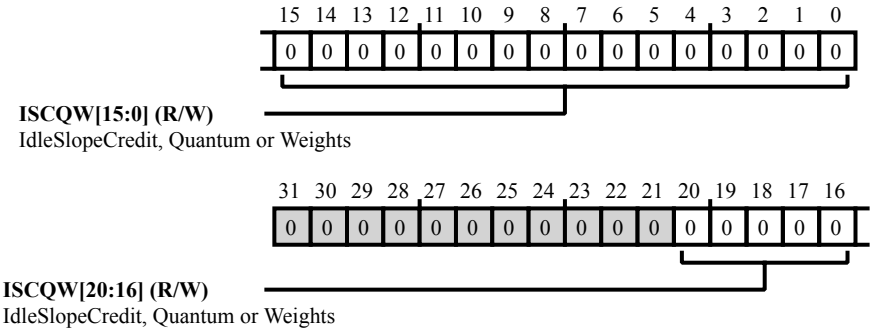

Figure 30-238: EMAC_TQ[n]_QTMWGT Register Diagram

Table 30-293: EMAC_TQ[n]_QTMWGT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
20:0 (R/W)	ISCQW	IdleSlopeCredit, Quantum or Weights. When AV feature is enabled, the `EMAC_TQ[n]_QTMWGT.ISCQW` field contains the idleSlopeCredit value required for the credit-based shaper algorithm for queue 1. This is the rate of change of credit in bits per cycle (40 ns for 100 Mbps; 8 ns for 1000 Mbps; 3.2 ns for 2500 Mbps) when the credit is increasing. The software should program the `EMAC_TQ[n]_QTMWGT.ISCQW` field with computed credit in bits per cycle scaled by 1,024. The maximum value is portTransmitRate, that is, 0x2000 in 1000/2500 Mbps mode and 0x1000 in 100 Mbps mode. Bits[20:14] must be written to zero. Quantum When the DCB operation is enabled with DWRR algorithm for queue 1 traffic, the `EMAC_TQ[n]_QTMWGT.ISCQW` field field contains the quantum value in bytes to be added to credit during every queue scanning cycle. The maximum value is 0x1312D0 bytes. Weights When DCB operation is enabled with WFQ algorithm for queue 1 traffic, the `EMAC_TQ[n]_QTMWGT.ISCQW` field contains the weight for this queue. The maximum value is 0x3FFF where weight of 0 indicates 100% bandwidth. Bits[20:14] must be written to zero. When DCB operation or generic queuing operation is enabled with WRR algorithm for queue 1 traffic, the `EMAC_TQ[n]_QTMWGT.ISCQW` field contains the weight for this queue. The maximum value is 0x64. Bits [20:7] must be written to zero. Note 1: In multiple queue configuration this field in respective per queue register must be programmed to some non-zero value when multiple queues are enabled or single queue other than Q0 is enabled. The `EMAC_TQ[n]_QTMWGT.ISCQW` field need not be programmed when only Q0 is enabled. In general, when WRR algorithm is selected a non-zero value must be programmed on both receive and transmit. In receive, the register is EMAC_MTL_OPMODE register. Note 2: For WFQ algorithm, higher the programmed weights lesser the bandwidth allocated for that transmit queue. The finish time is not a function of particular packet alone but it is as per the formula: (previous_finish_time of particular transmit queue + (weights*packet_size)) Note 3: The weights programmed do not correspond to the number of packets but the fraction of bandwidth or time allocated for particular queue with respect to total BW or time.

Transmit Queue n SendSlopeCredit Register

The EMAC_TQ[n]_SSCRDT register contains the sendSlope credit value required for the credit-based shaper algorithm for the queue.

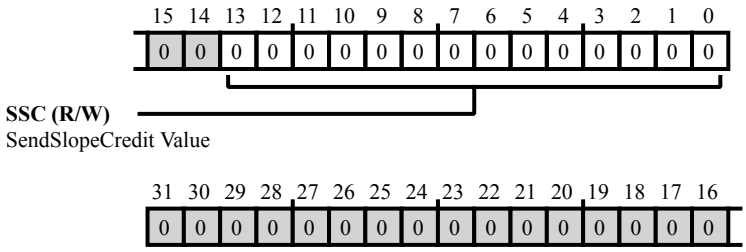

Figure 30-239: EMAC_TQ[n]_SSCRDT Register Diagram

Table 30-294: EMAC_TQ[n]_SSCRDT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
13:0 (R/W)	SSC	SendSlopeCredit Value. When AV operation is enabled, the EMAC_TQ[n]_SSCRDT.SSC field contains the sendSlopeCredit value required for credit-based shaper algorithm for queue 1. This is the rate of change of credit in bits per cycle (40 ns, 8 ns and 3.2 ns for 100 Mbps, 1000 Mbps and 2500 Mbps respectively) when the credit is decreasing. The software should program this field with computed credit in bits per cycle scaled by 1,024. The maximum value is portTransmitRate, that is, 0x2000 in 1000/2500 Mbps mode and 0x1000 in 100 Mbps mode. The EMAC_TQ[n]_SSCRDT.SSC field should be programmed with absolute sendSlopeCredit value. The credit-based shaper logic subtracts it from the accumulated credit when channel 1 is selected for transmission.

Transmit Queue n Underflow Packet Counter Register

The EMAC_TQ[n]_URFL register contains the counter for packets aborted because of transmit queue underflow and packets missed because of receive queue packet flush.

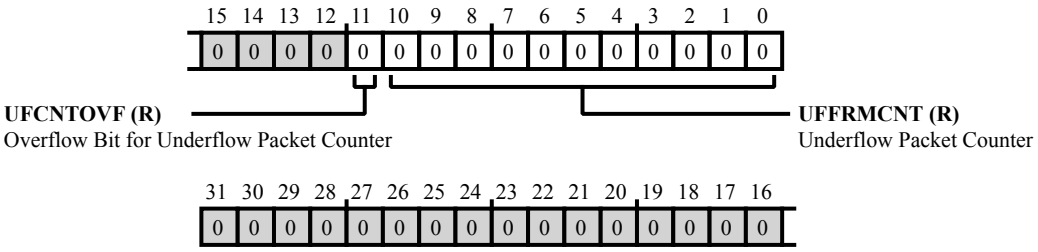

Figure 30-240: EMAC_TQ[n]_URFL Register Diagram

Table 30-295: EMAC_TQ[n]_URFL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/NW)	UFCNTOVF	Overflow Bit for Underflow Packet Counter. The EMAC_TQ[n]_URFL.UFCNTOVF bit is set every time the Tx queue underflow packet counter field overflows, that is, it has crossed the maximum count. In such a scenario, the overflow packet counter is reset to all-zeros and the EMAC_TQ[n]_URFL.UFCNTOVF bit indicates that the rollover happened. Access restriction applies. Clears on read. Self-set to 1 on internal event.	
		0	Overflow Not Detected for Underflow Packet Counter
		1	Overflow Detected for Underflow Packet Counter
10:0 (R/NW)	UFFRMCNT	Underflow Packet Counter. The EMAC_TQ[n]_URFL.UFFRMCNT field indicates the number of packets aborted by the controller because of Tx queue underflow. This counter is incremented each time the MAC aborts outgoing packet because of underflow. Access restriction applies. Clears on read. Self-set to 1 on internal event.	

Receive ICMP Error Octets Counter Register

The EMAC_RXICMP_ERR_OCNT register provides the number of bytes received by the EMAC module in a ICMP segment that had checksum errors. This counter does not count IP header bytes.

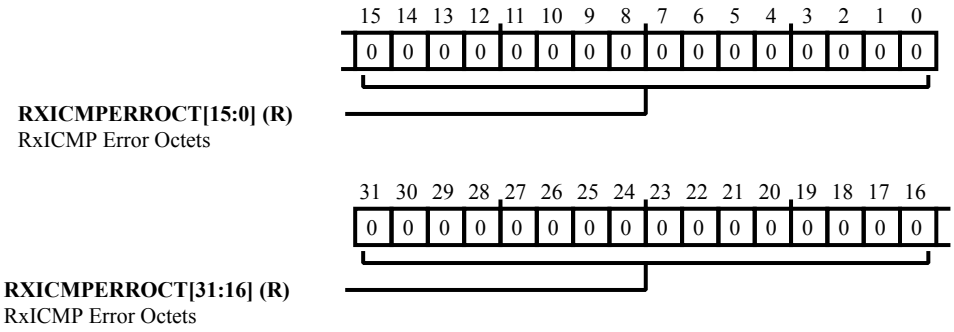

Figure 30-241: EMAC_RXICMP_ERR_OCNT Register Diagram

Table 30-296: EMAC_RXICMP_ERR_OCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	RXICMPERROCT	RxICMP Error Octets. The EMAC_RXICMP_ERR_OCNT.RXICMPERROCT field indicates the number of bytes received in a ICMP segment that had checksum errors. This counter does not count IP header bytes.

Receive ICMP Error Packets Counter Register

The EMAC_RXICMP_ERR_PCNT register provides the number of good IP datagrams received by the EMAC module whose ICMP payload has a checksum error.

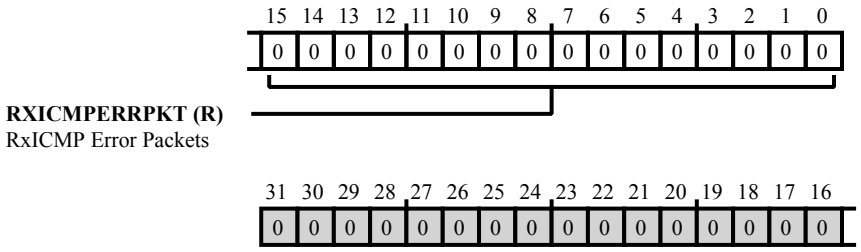

Figure 30-242: EMAC_RXICMP_ERR_PCNT Register Diagram

Table 30-297: EMAC_RXICMP_ERR_PCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	RXICMPERRPKT	RxICMP Error Packets. The EMAC_RXICMP_ERR_PCNT.RXICMPERRPKT field indicates the number of good IP datagrams received whose ICMP payload has a checksum error.

Receive ICMP Good Octets Counter Register

The EMAC_RXICMP_OCNT_G register provides the number of bytes received by the EMAC module in a good ICMP segment. This counter does not count IP header bytes.

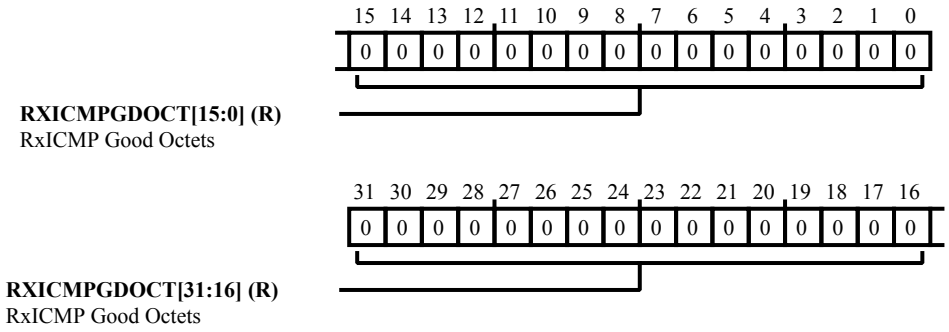

Figure 30-243: EMAC_RXICMP_OCNT_G Register Diagram

Table 30-298: EMAC_RXICMP_OCNT_G Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	RXICMPGDOCT	RxICMP Good Octets. The EMAC_RXICMP_OCNT_G.RXICMPGDOCT field indicates the number of bytes received in a good ICMP segment. This counter does not count IP header bytes.

Receive ICMP Good Packets Counter Register

The EMAC_RXICMP_PCNT_G register provides the number of good IP datagrams received by the EMAC module with a good ICMP payload.

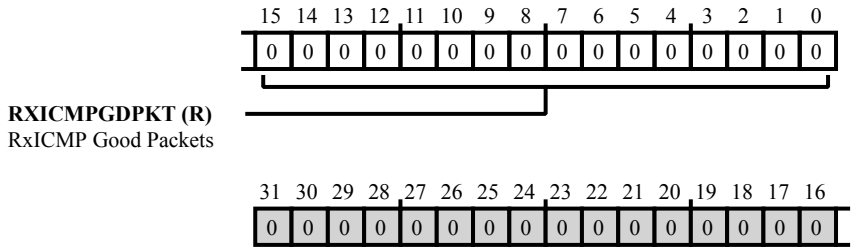

Figure 30-244: EMAC_RXICMP_PCNT_G Register Diagram

Table 30-299: EMAC_RXICMP_PCNT_G Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	RXICMPGDPKT	RxICMP Good Packets. The EMAC_RXICMP_PCNT_G.RXICMPGDPKT field indicates the number of good IP datagrams received with a good ICMP payload.

Receive IPv4 Fragmented Octets Counter Register

The EMAC_RXIPV4_FRGMT_OCNT register provides the number of bytes received by the EMAC module in fragmented IPv4 datagrams. The value in the Length field of IPv4 header is used to update this counter. (Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.)

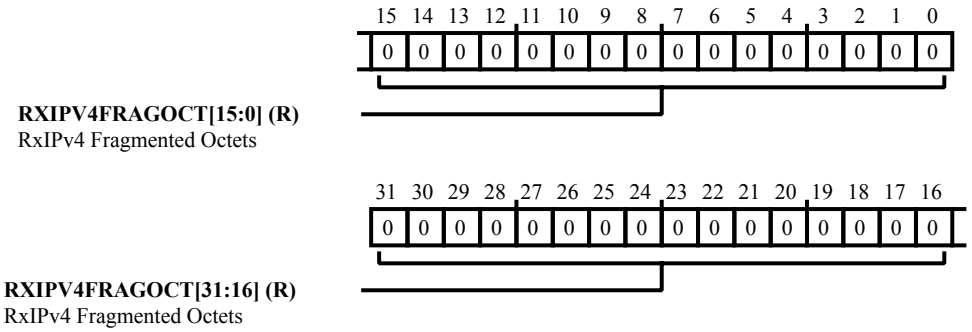

Figure 30-245: EMAC_RXIPV4_FRGMT_OCNT Register Diagram

Table 30-300: EMAC_RXIPV4_FRGMT_OCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	RXIPV4FRAGOCT	RxIPv4 Fragmented Octets. The EMAC_RXIPV4_FRGMT_OCNT.RXIPV4FRAGOCT field indicates the number of bytes received in fragmented IPv4 datagrams. The value in the Length field of IPv4 header is used to update this counter. (Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.)

Receive IPv4 Fragmented Packets Counter Register

The EMAC_RXIPV4_FRGMT_PCNT register provides the number of good IPv4 datagrams received by the EMAC module with fragmentation.

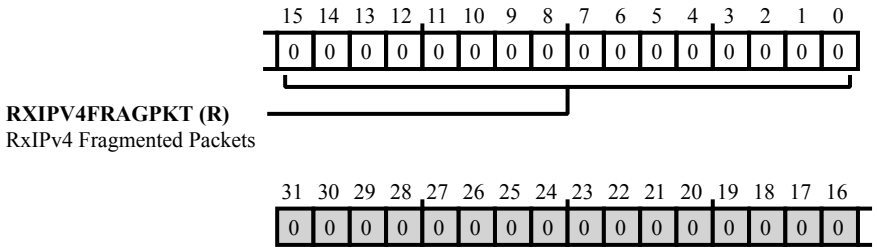

Figure 30-246: EMAC_RXIPV4_FRGMT_PCNT Register Diagram

Table 30-301: EMAC_RXIPV4_FRGMT_PCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	RXIPV4FRAGPKT	RxIPv4 Fragmented Packets. The EMAC_RXIPV4_FRGMT_PCNT.RXIPV4FRAGPKT field indicates the number of good IPv4 datagrams received with fragmentation.

Receive IPv4 Good Octets Counter Register

The EMAC_RXIPV4_OCNT_G register provides the number of bytes received by the EMAC module in good IPv4 datagrams encapsulating TCP, UDP, or ICMP data. (Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.)

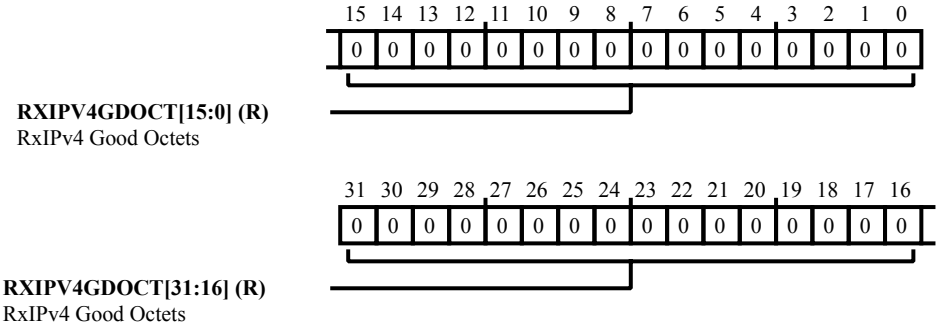

Figure 30-247: EMAC_RXIPV4_OCNT_G Register Diagram

Table 30-302: EMAC_RXIPV4_OCNT_G Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	RXIPV4GDOCT	RxIPv4 Good Octets. The EMAC_RXIPV4_OCNT_G.RXIPV4GDOCT field indicates the number of bytes received in good IPv4 datagrams encapsulating TCP, UDP, or ICMP data. (Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.)

Receive IPv4 Good Packets Counter Register

The EMAC_RXIPV4_PCNT_G register provides the number of good IPv4 datagrams received by the EMAC module with the TCP, UDP, or ICMP payload.

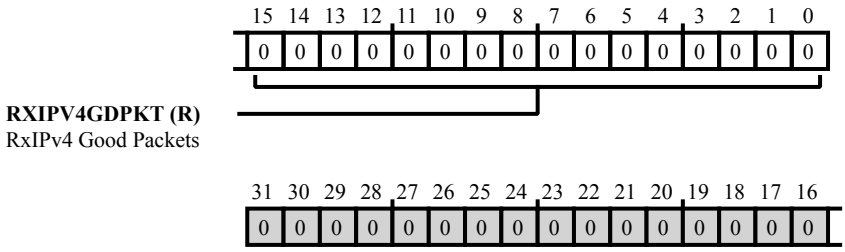

Figure 30-248: EMAC_RXIPV4_PCNT_G Register Diagram

Table 30-303: EMAC_RXIPV4_PCNT_G Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	RXIPV4GDPKT	RxIPv4 Good Packets. The EMAC_RXIPV4_PCNT_G.RXIPV4GDPKT field indicates the number of good IPv4 datagrams received with the TCP, UDP, or ICMP payload.

Receive IPv4 Header Error Octets Counter Register

The EMAC_RXIPV4_HDRERR_OCNT register provides the number of bytes received by the EMAC module in IPv4 datagrams with header errors (checksum, length, version mismatch). The value in the Length field of IPv4 header is used to update this counter. (Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.)

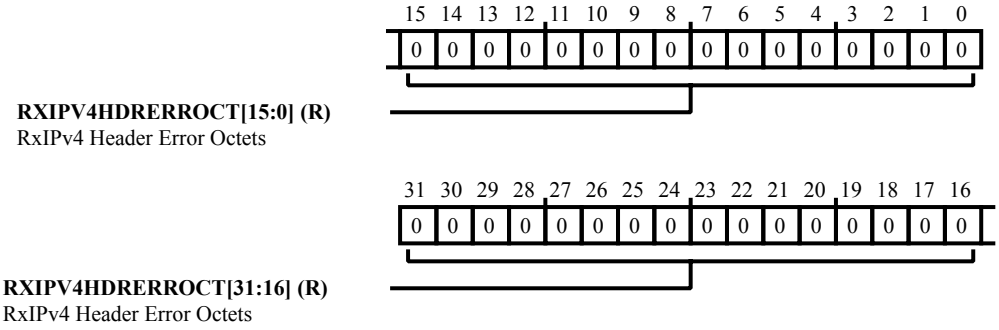

Figure 30-249: EMAC_RXIPV4_HDRERR_OCNT Register Diagram

Table 30-304: EMAC_RXIPV4_HDRERR_OCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	RXIPV4HDRERROCT	RxIPv4 Header Error Octets. The EMAC_RXIPV4_HDRERR_OCNT.RXIPV4HDRERROCT field indicates the number of bytes received in IPv4 datagrams with header errors (checksum, length, version mismatch). The value in the Length field of IPv4 header is used to update this counter. (Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.)

Receive IPv4 Header Error Packets Counter Register

The EMAC_RXIPV4_HDRERR_PCNT register provides the number of IPv4 datagrams received by the EMAC module with header (checksum, length, or version mismatch) errors.

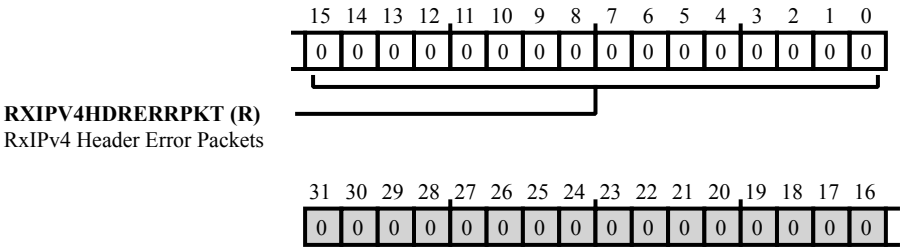

Figure 30-250: EMAC_RXIPV4_HDRERR_PCNT Register Diagram

Table 30-305: EMAC_RXIPV4_HDRERR_PCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	RXIPV4HDRERRPKT	RxIPv4 Header Error Packets. The EMAC_RXIPV4_HDRERR_PCNT.RXIPV4HDRERRPKT field indicates the number of IPv4 datagrams received with header (checksum, length, or version mismatch) errors.

Receive IPv4 Payload Octets Counter Register

The EMAC_RXIPV4_PYLD_OCNT register provides the number of bytes received by the EMAC module in IPv4 datagrams that did not have a TCP, UDP, or ICMP payload. The value in the Length field of IPv4 header is used to update this counter. (Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.)

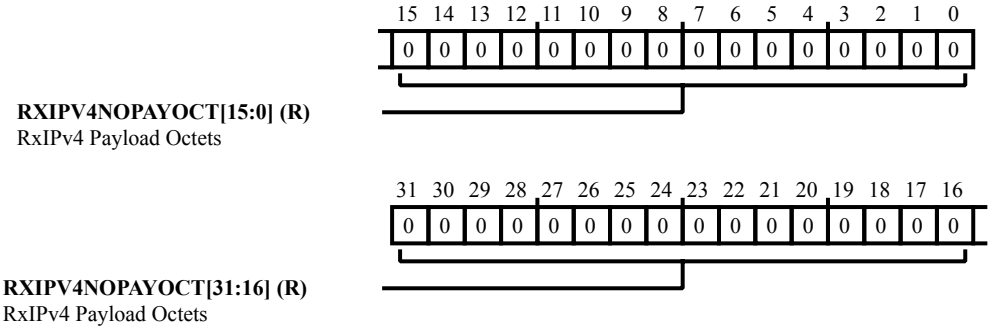

Figure 30-251: EMAC_RXIPV4_PYLD_OCNT Register Diagram

Table 30-306: EMAC_RXIPV4_PYLD_OCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	RXIPV4NOPAYOCT	RxIPv4 Payload Octets. The EMAC_RXIPV4_PYLD_OCNT.RXIPV4NOPAYOCT field indicates the number of bytes received in IPv4 datagrams that did not have a TCP, UDP, or ICMP payload. The value in the Length field of IPv4 header is used to update this counter. (Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.)

Receive IPv4 Payload Packets Counter Register

The EMAC_RXIPV4_PYLD_PCNT register provides the number of IPv4 datagram packets received by EMAC module that did not have a TCP, UDP, or ICMP payload.

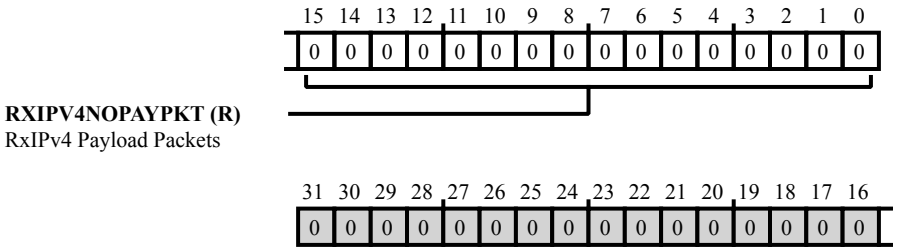

Figure 30-252: EMAC_RXIPV4_PYLD_PCNT Register Diagram

Table 30-307: EMAC_RXIPV4_PYLD_PCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	RXIPV4NOPAYPKT	RxIPv4 Payload Packets. The EMAC_RXIPV4_PYLD_PCNT.RXIPV4NOPAYPKT field indicates the number of IPv4 datagram packets received that did not have a TCP, UDP, or ICMP payload.

Receive IPv4 UDP Checksum Disable Octets Counter Register

The EMAC_RXIPV4_UDPCSD_OCNT register provides the number of bytes received by the EMAC module in a UDP segment that had the UDP checksum disabled. This counter does not count IP Header bytes. (Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.)

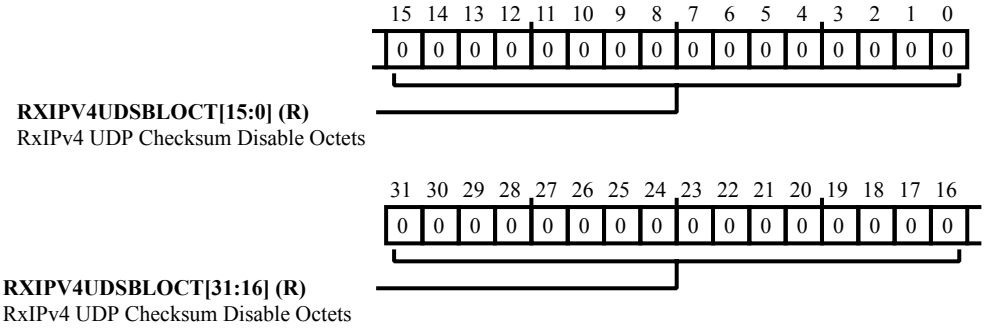

Figure 30-253: EMAC_RXIPV4_UDPCSD_OCNT Register Diagram

Table 30-308: EMAC_RXIPV4_UDPCSD_OCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	RXIPV4UDSBLOCT	RxIPv4 UDP Checksum Disable Octets. The EMAC_RXIPV4_UDPCSD_OCNT.RXIPV4UDSBLOCT field indicates the number of bytes received in a UDP segment that had the UDP checksum disabled. This counter does not count IP Header bytes. (Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.)

Receive IPv4 UDP Checksum Disable Packets Counter Register

The EMAC_RXIPV4_UDPCSD_PCNT register provides the number of good IPv4 datagrams received by the EMAC module that had a UDP payload with checksum disabled.

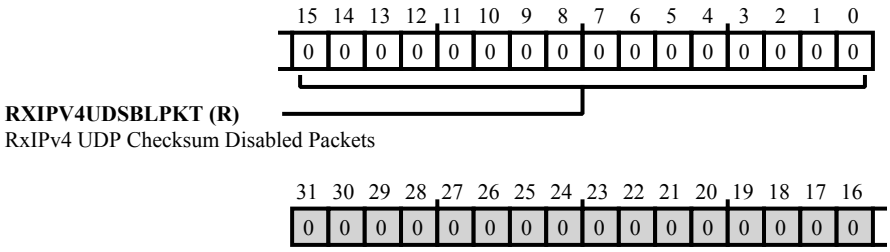

Figure 30-254: EMAC_RXIPV4_UDPCSD_PCNT Register Diagram

Table 30-309: EMAC_RXIPV4_UDPCSD_PCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	RXIPV4UDSBLPKT	RxIPv4 UDP Checksum Disabled Packets. The EMAC_RXIPV4_UDPCSD_PCNT.RXIPV4UDSBLPKT field indicates the number of good IPv4 datagrams received that had a UDP payload with checksum disabled.

Receive IPv6 Good Octets Counter Register

The EMAC_RXIPV6_OCNT_G register provides the number of bytes received by the EMAC module in good IPv6 datagrams encapsulating TCP, UDP, or ICMP data. (Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.)

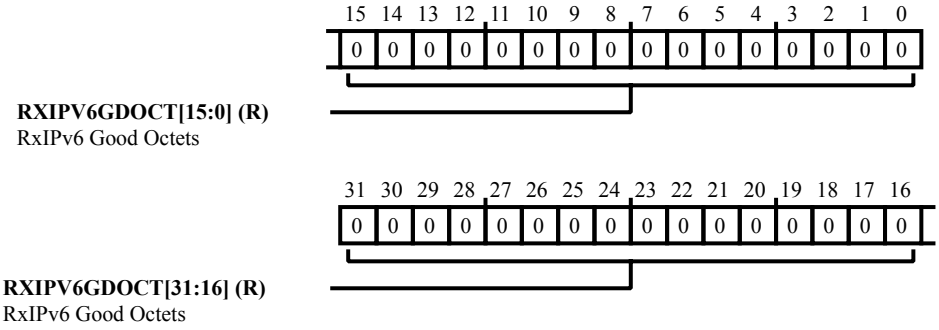

Figure 30-255: EMAC_RXIPV6_OCNT_G Register Diagram

Table 30-310: EMAC_RXIPV6_OCNT_G Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	RXIPV6GDOCT	RxIPv6 Good Octets. The EMAC_RXIPV6_OCNT_G.RXIPV6GDOCT field indicates the number of bytes received in good IPv6 datagrams encapsulating TCP, UDP, or ICMP data. (Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.)

Receive IPv6 Good Packets Counter Register

The EMAC_RXIPV6_PCNT_G register provides the number of good IPv6 datagrams received by the EMAC module with the TCP, UDP, or ICMP payload.

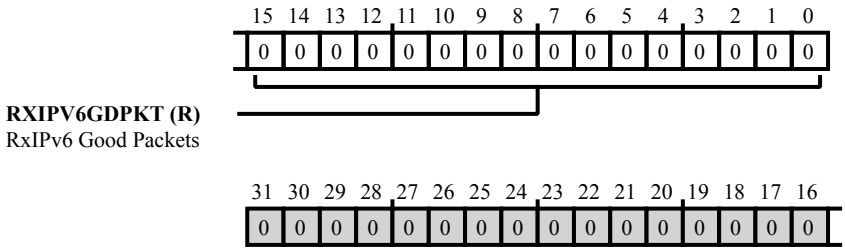

Figure 30-256: EMAC_RXIPV6_PCNT_G Register Diagram

Table 30-311: EMAC_RXIPV6_PCNT_G Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	RXIPV6GDPKT	RxIPv6 Good Packets. The EMAC_RXIPV6_PCNT_G.RXIPV6GDPKT field indicates the number of good IPv6 datagrams received with the TCP, UDP, or ICMP payload.

Receive IPv6 Header Error Octets Counter Register

The EMAC_RXIPV6_HDRERR_OCNT register provides the number of bytes received by the EMAC module in IPv6 datagrams with header errors (length, version mismatch). The value in the Length field of IPv6 header is used to update this counter. (Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.)

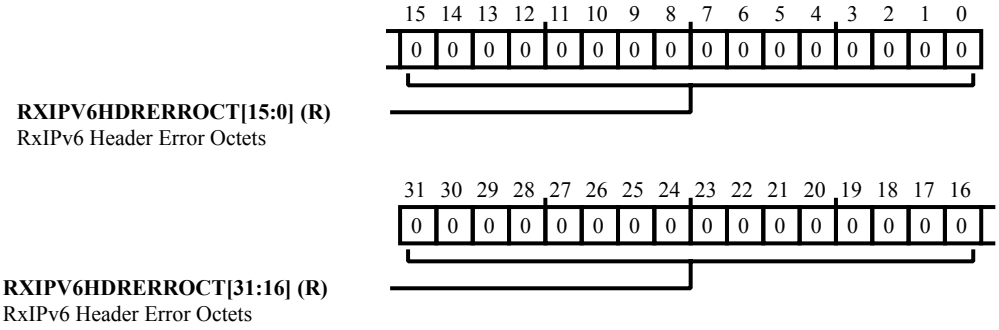

Figure 30-257: EMAC_RXIPV6_HDRERR_OCNT Register Diagram

Table 30-312: EMAC_RXIPV6_HDRERR_OCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	RXIPV6HDRERROCT	RxIPv6 Header Error Octets. The EMAC_RXIPV6_HDRERR_OCNT.RXIPV6HDRERROCT field indicates the number of bytes received in IPv6 datagrams with header errors (length, version mismatch). The value in the Length field of IPv6 header is used to update this counter. (Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.)

Receive IPv6 Header Error Packets Counter Register

The EMAC_RXIPV6_HDRERR_PCNT register provides the number of IPv6 datagrams received by the EMAC module with header (length or version mismatch) errors.

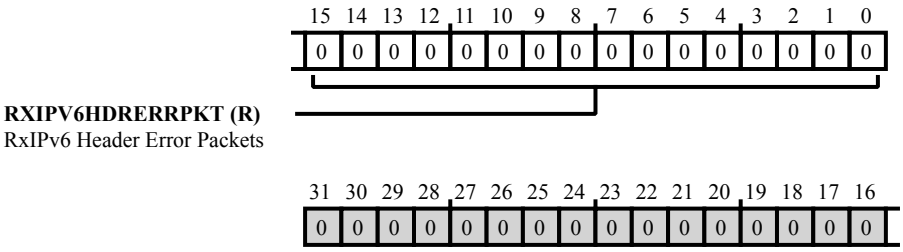

Figure 30-258: EMAC_RXIPV6_HDRERR_PCNT Register Diagram

Table 30-313: EMAC_RXIPV6_HDRERR_PCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	RXIPV6HDRERRPKT	RxIPv6 Header Error Packets. The EMAC_RXIPV6_HDRERR_PCNT.RXIPV6HDRERRPKT field indicates the number of IPv6 datagrams received with header (length or version mismatch) errors.

Receive IPv6 Payload Octets Counter Register

The EMAC_RXIPV6_PYLD_OCNT register provides the number of bytes received by the EMAC module in IPv6 datagrams that did not have a TCP, UDP, or ICMP payload. The value in the Length field of IPv6 header is used to update this counter. (Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.)

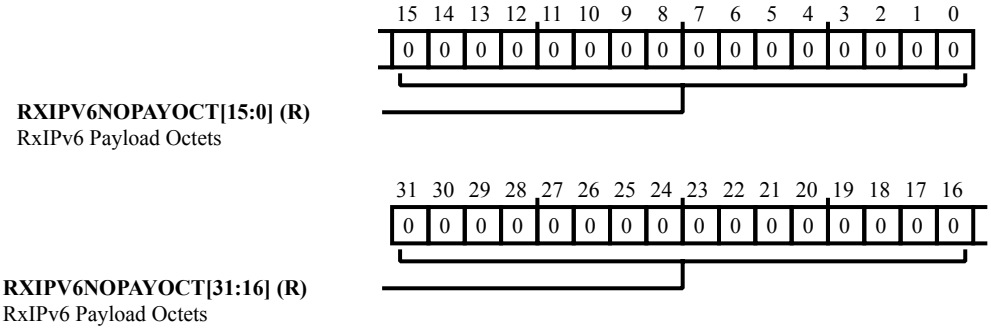

Figure 30-259: EMAC_RXIPV6_PYLD_OCNT Register Diagram

Table 30-314: EMAC_RXIPV6_PYLD_OCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	RXIPV6NOPAYOCT	RxIPv6 Payload Octets. The EMAC_RXIPV6_PYLD_OCNT.RXIPV6NOPAYOCT field indicates the number of bytes received in IPv6 datagrams that did not have a TCP, UDP, or ICMP payload. The value in the Length field of IPv6 header is used to update this counter. (Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.)

Receive IPv6 Payload Packets Counter Register

The EMAC_RXIPV6_PYLD_PCNT register provides the number of IPv6 datagram packets received by the EMAC module that did not have a TCP, UDP, or ICMP payload. This includes all IPv6 datagrams with fragmentation or security extension headers.

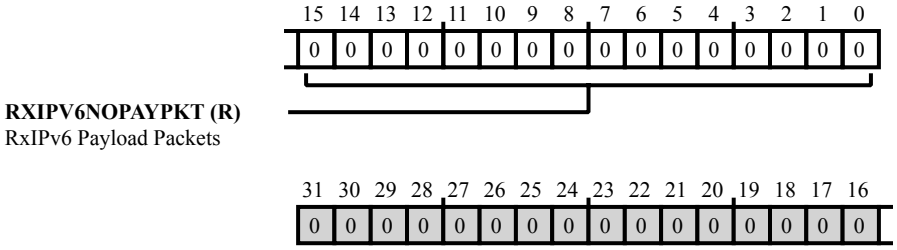

Figure 30-260: EMAC_RXIPV6_PYLD_PCNT Register Diagram

Table 30-315: EMAC_RXIPV6_PYLD_PCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	RXIPV6NOPAYPKT	RxIPv6 Payload Packets. The EMAC_RXIPV6_PYLD_PCNT.RXIPV6NOPAYPKT field indicates the number of IPv6 datagram packets received that did not have a TCP, UDP, or ICMP payload. This includes all IPv6 datagrams with fragmentation or security extension headers.

Receive TCP Error Octets Counter Register

The EMAC_RXTCP_ERR_OCNT register provides the number of bytes received by the EMAC module in a TCP segment that had checksum errors. This counter does not count IP header bytes.

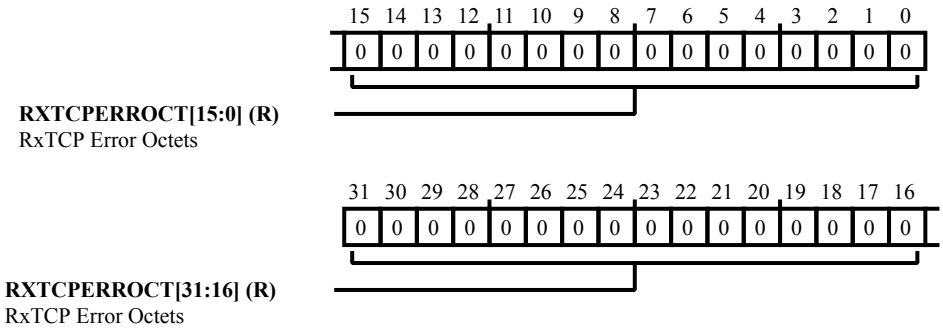

Figure 30-261: EMAC_RXTCP_ERR_OCNT Register Diagram

Table 30-316: EMAC_RXTCP_ERR_OCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	RXTCPERROCT	RxTCP Error Octets. The EMAC_RXTCP_ERR_OCNT.RXTCPERROCT field indicates the number of bytes received in a TCP segment that had checksum errors. This counter does not count IP header bytes.

Receive TCP Error Packets Counter Register

The EMAC_RXTCP_ERR_PCNT register provides the number of good IP datagrams received by the EMAC module whose TCP payload has a checksum error.

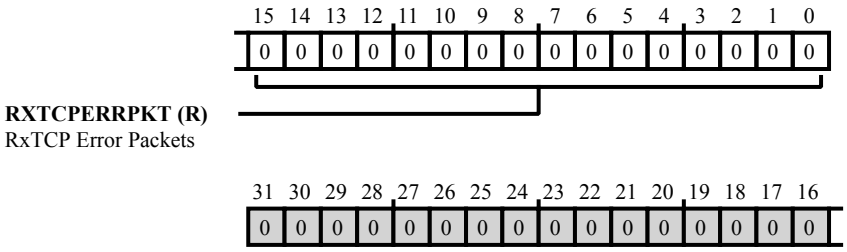

Figure 30-262: EMAC_RXTCP_ERR_PCNT Register Diagram

Table 30-317: EMAC_RXTCP_ERR_PCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	RXTCPERRPKT	RxTCP Error Packets. The EMAC_RXTCP_ERR_PCNT.RXTCPERRPKT field indicates the number of good IP datagrams received whose TCP payload has a checksum error.

Receive TCP Good Octets Counter Register

The EMAC_RXTCP_OCNT_G register provides the number of bytes received by the EMAC module in a good TCP segment. This counter does not count IP header bytes.

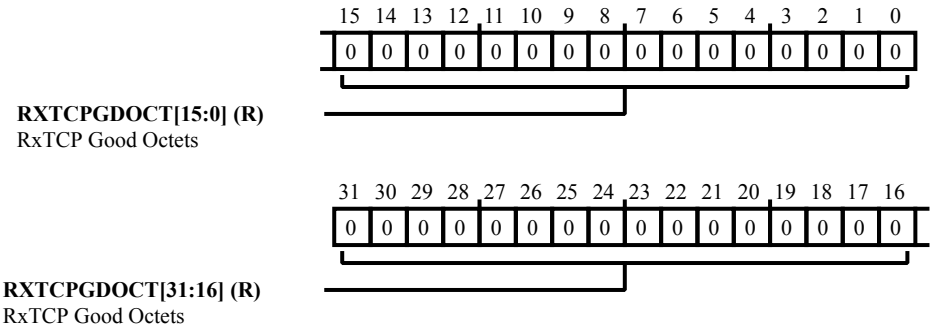

Figure 30-263: EMAC_RXTCP_OCNT_G Register Diagram

Table 30-318: EMAC_RXTCP_OCNT_G Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	RXTCPGDOCT	RxTCP Good Octets. The EMAC_RXTCP_OCNT_G.RXTCPGDOCT field indicates the number of bytes received in a good TCP segment. This counter does not count IP header bytes.

Receive TCP Good Packets Counter Register

The EMAC_RXTCP_PCNT_G register provides the number of good IP datagrams received by the EMAC module with a good TCP payload.

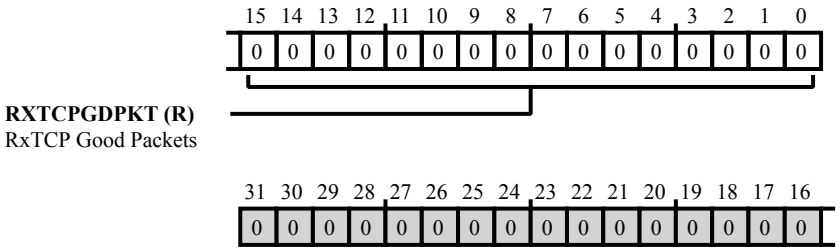

Figure 30-264: EMAC_RXTCP_PCNT_G Register Diagram

Table 30-319: EMAC_RXTCP_PCNT_G Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	RXTCPGDPKT	RxTCP Good Packets. The EMAC_RXTCP_PCNT_G.RXTCPGDPKT field indicates the number of good IP datagrams received with a good TCP payload.

Receive UDP Error Octets Counter Register

The EMAC_RXUDP_ERR_OCNT register provides the number of bytes received by the EMAC module in a UDP segment that had checksum errors. This counter does not count IP header bytes.

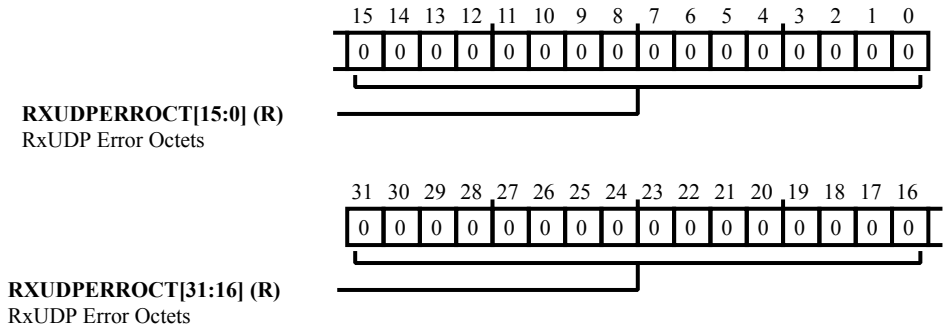

Figure 30-265: EMAC_RXUDP_ERR_OCNT Register Diagram

Table 30-320: EMAC_RXUDP_ERR_OCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	RXUDPERROCT	RxUDP Error Octets. The EMAC_RXUDP_ERR_OCNT.RXUDPERROCT field indicates the number of bytes received in a UDP segment that had checksum errors. This counter does not count IP header bytes.

Receive UDP Error Packets Counter Register

The EMAC_RXUDP_ERR_PCNT register provides the number of good IP datagrams received by the EMAC module whose UDP payload has a checksum error.

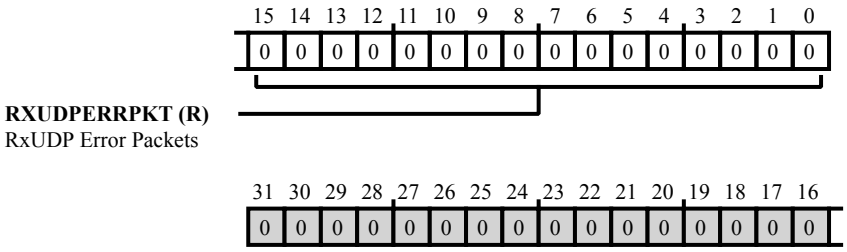

Figure 30-266: EMAC_RXUDP_ERR_PCNT Register Diagram

Table 30-321: EMAC_RXUDP_ERR_PCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	RXUDPERRPKT	RxUDP Error Packets. The EMAC_RXUDP_ERR_PCNT.RXUDPERRPKT field indicates the number of good IP datagrams received whose UDP payload has a checksum error.

Receive UDP Good Octets Counter Register

The EMAC_RXUDP_OCNT_G register provides the number of bytes received by the EMAC module in a good UDP segment. This counter does not count IP header bytes.

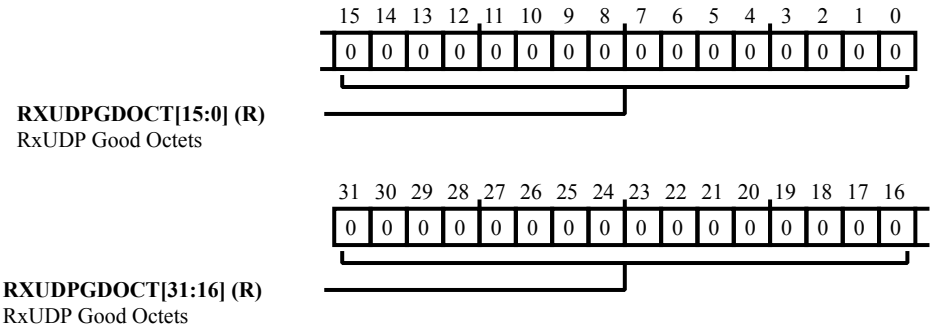

Figure 30-267: EMAC_RXUDP_OCNT_G Register Diagram

Table 30-322: EMAC_RXUDP_OCNT_G Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	RXUDPGDOCT	RxUDP Good Octets. The EMAC_RXUDP_OCNT_G.RXUDPGDOCT field indicates the number of bytes received in a good UDP segment. This counter does not count IP header bytes.

Receive UDP Good Packets Counter Register

The EMAC_RXUDP_PCNT_G register provides the number of good IP datagrams received by the EMAC module with a good UDP payload. This counter is not updated when the EMAC_RXIPV4_UDPCSD_PCNT counter is incremented.

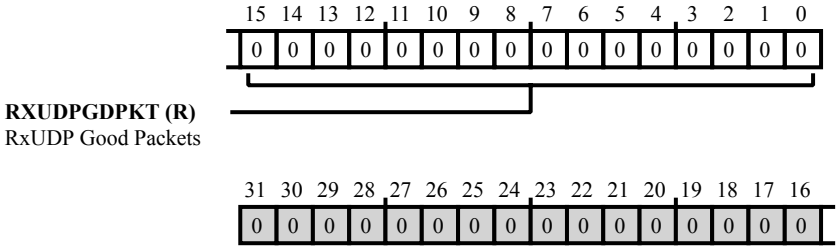

Figure 30-268: EMAC_RXUDP_PCNT_G Register Diagram

Table 30-323: EMAC_RXUDP_PCNT_G Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	RXUDPGDPKT	RxUDP Good Packets. The EMAC_RXUDP_PCNT_G.RXUDPGDPKT field indicates the number of good IP datagrams received with a good UDP payload. This counter is not updated when the EMAC_RXIPV4_UDPCSD_PCNT counter is incremented.

Receive 1024 - Maximum Octets Packets Good Bad Counter Register

The EMAC_RX1024TOMAX_GB register provides the number of good and bad packets received by the EMAC module with length between 1024 and maxsize (inclusive) bytes, exclusive of the preamble.

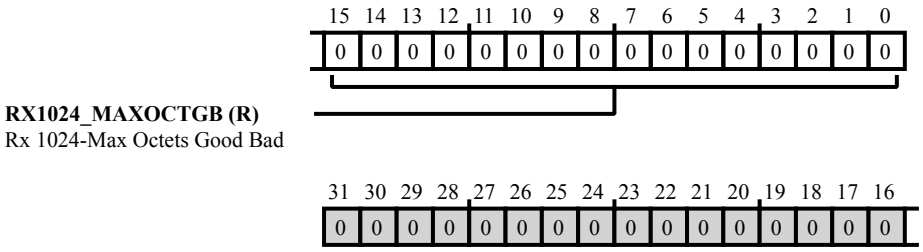

Figure 30-269: EMAC_RX1024TOMAX_GB Register Diagram

Table 30-324: EMAC_RX1024TOMAX_GB Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	RX1024_MAXOCTGB	Rx 1024-Max Octets Good Bad. The EMAC_RX1024TOMAX_GB.RX1024_MAXOCTGB field indicates the number of good and bad packets received with a length between 1024 and maxsize (inclusive) bytes, exclusive of the preamble.

Receive 128 - 255 Octets Packets Good Bad Counter Register

The EMAC_RX128TO255_GB register provides the number of good and bad packets received by the EMAC module with length between 128 and 255 (inclusive) bytes, exclusive of the preamble.

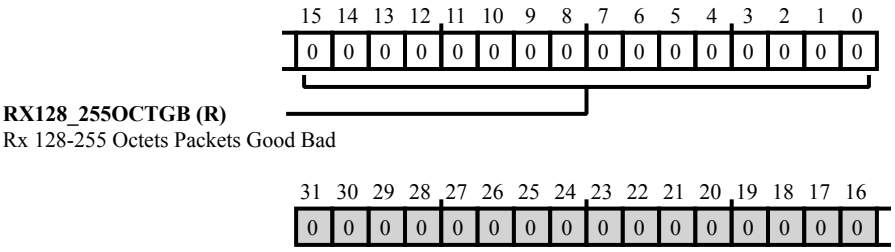

Figure 30-270: EMAC_RX128TO255_GB Register Diagram

Table 30-325: EMAC_RX128TO255_GB Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	RX128_255OCTGB	Rx 128-255 Octets Packets Good Bad. The EMAC_RX128TO255_GB.RX128_255OCTGB field indicates the number of good and bad packets received with length between 128 and 255 (inclusive) bytes, exclusive of the preamble.

Receive 256 - 511 Octets Packets Good Bad Counter Register

The EMAC_RX256TO511_GB register provides the number of good and bad packets received by the EMAC module with length between 256 and 511 (inclusive) bytes, exclusive of the preamble.

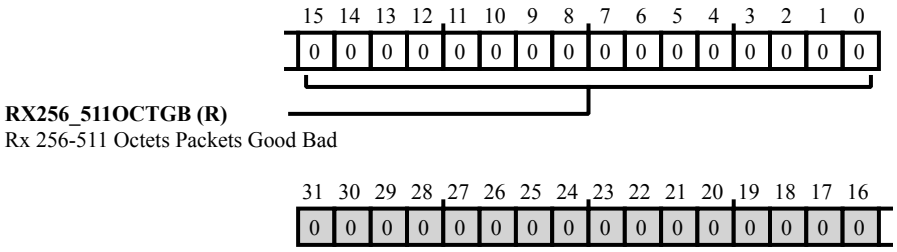

Figure 30-271: EMAC_RX256TO511_GB Register Diagram

Table 30-326: EMAC_RX256TO511_GB Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	RX256_511OCTGB	Rx 256-511 Octets Packets Good Bad. The EMAC_RX256TO511_GB.RX256_511OCTGB field indicates the number of good and bad packets received with length between 256 and 511 (inclusive) bytes, exclusive of the preamble.

Receive 512 - 1023 Octets Packets Good Bad Counter Register

The EMAC_RX512TO1023_GB register provides the number of good and bad packets received by the EMAC module with length between 512 and 1023 (inclusive) bytes, exclusive of the preamble.

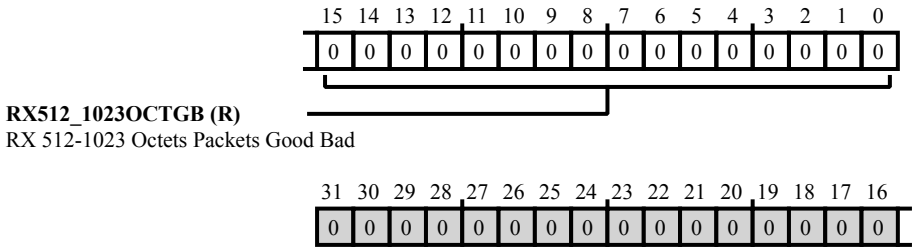

Figure 30-272: EMAC_RX512TO1023_GB Register Diagram

Table 30-327: EMAC_RX512TO1023_GB Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	RX512_1023OCTGB	RX 512-1023 Octets Packets Good Bad. The EMAC_RX512TO1023_GB.RX512_1023OCTGB field indicates the number of good and bad packets received with length between 512 and 1023 (inclusive) bytes, exclusive of the preamble.

Receive 64 Octets Packets Good Bad Counter Register

The EMAC_RX64_GB register provides the number of good and bad packets received by the EMAC module with length 64 bytes, exclusive of the preamble.

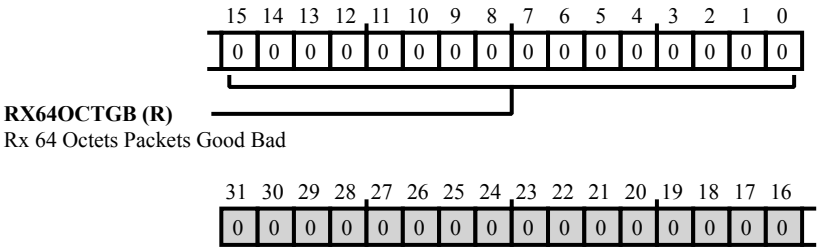

Figure 30-273: EMAC_RX64_GB Register Diagram

Table 30-328: EMAC_RX64_GB Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	RX64OCTGB	Rx 64 Octets Packets Good Bad. The EMAC_RX64_GB.RX64OCTGB field indicates the number of good and bad packets received with length 64 bytes, exclusive of the preamble.

Receive 65 - 127 Octets Packets Good Bad Counter Register

The EMAC_RX65TO127_GB register provides the number of good and bad packets received by the EMAC module with length between 65 and 127 (inclusive) bytes, exclusive of the preamble.

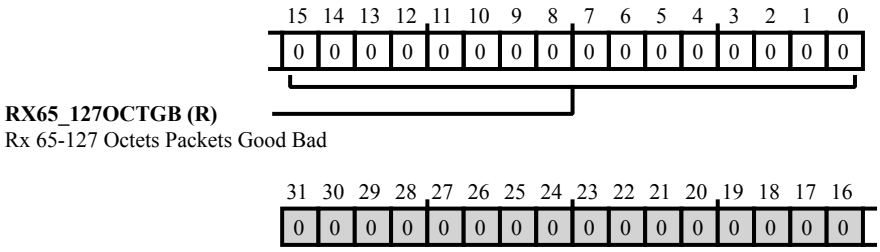

Figure 30-274: EMAC_RX65TO127_GB Register Diagram

Table 30-329: EMAC_RX65TO127_GB Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	RX65_127OCTGB	Rx 65-127 Octets Packets Good Bad. The EMAC_RX65TO127_GB.RX65_127OCTGB field indicates the number of good and bad packets received with length between 65 and 127 (inclusive) bytes, exclusive of the preamble.

Receive Alignment Error Packets Counter Register

The EMAC_RX_ALGNERR_PCNT register provides the number of packets received by the EMAC module with alignment (dribble) error. It is valid only in 10/100 mode.

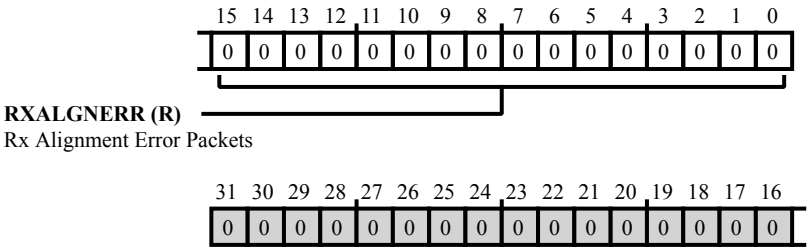

Figure 30-275: EMAC_RX_ALGNERR_PCNT Register Diagram

Table 30-330: EMAC_RX_ALGNERR_PCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	RXALGNERR	Rx Alignment Error Packets. The EMAC_RX_ALGNERR_PCNT.RXALGNERR field indicates the number of packets received with alignment (dribble) error. It is valid only in 10/100 mode.

Receive Broadcast Packets Good Counter Register

The EMAC_RX_BCERR_PCNT_G register provides the number of good broadcast packets received by the EMAC module.

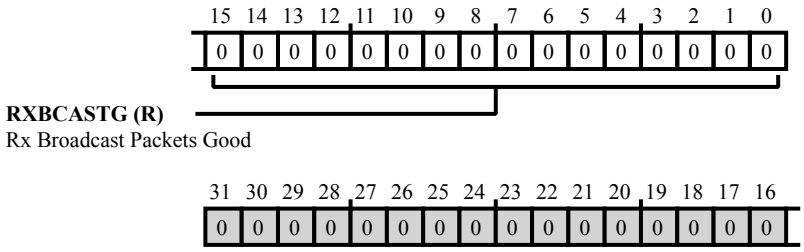

Figure 30-276: EMAC_RX_BCERR_PCNT_G Register Diagram

Table 30-331: EMAC_RX_BCERR_PCNT_G Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	RXBCASTG	Rx Broadcast Packets Good. The EMAC_RX_BCERR_PCNT_G.RXBCASTG field indicates the number of good broadcast packets received.

Receive CRC Error Packets Counter Register

The EMAC_RX_CRCERR_PCNT register provides the number of packets received by the EMAC module with CRC error.

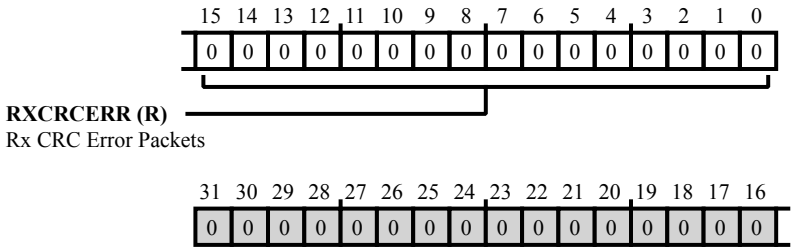

Figure 30-277: EMAC_RX_CRCERR_PCNT Register Diagram

Table 30-332: EMAC_RX_CRCERR_PCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	RXCRCERR	Rx CRC Error Packets. The EMAC_RX_CRCERR_PCNT.RXCRCERR field indicates the number of packets received with CRC error.

Receive Control Packets Good Counter Register

The EMAC_RX_CTL_PCNT_G register provides the number of good control packets received by the EMAC module.

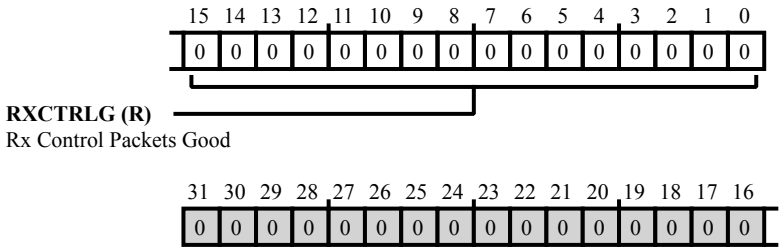

Figure 30-278: EMAC_RX_CTL_PCNT_G Register Diagram

Table 30-333: EMAC_RX_CTL_PCNT_G Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	RXCTRLG	Rx Control Packets Good. The EMAC_RX_CTL_PCNT_G.RXCTRLG field indicates the number of good control packets received.

Receive FIFO Overflow Packets Counter Register

The EMAC_RX_FIFOOVFL_PCNT register provides the number of missed received packets because of FIFO overflow in the EMAC module.

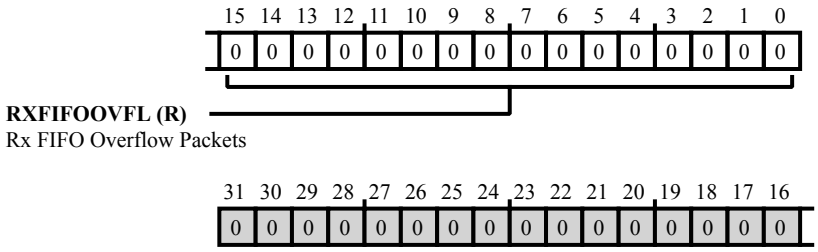

Figure 30-279: EMAC_RX_FIFOOVFL_PCNT Register Diagram

Table 30-334: EMAC_RX_FIFOOVFL_PCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	RXFIFOOVFL	Rx FIFO Overflow Packets. The EMAC_RX_FIFOOVFL_PCNT.RXFIFOOVFL field indicates the number of missed received packets because of FIFO overflow.

Receive Jabber Error Packets Counter Register

The EMAC_RX_JBERR_PCNT register provides the number of giant packets received by the EMAC module with length (including CRC) greater than 1,518 bytes (1,522 bytes for VLAN tagged) and with CRC error. When jumbo packet mode is enabled (EMAC_MAC_CFG.JE = 1), packets of length greater than 9,018 bytes (9,022 bytes for VLAN tagged) are considered as giant packets.

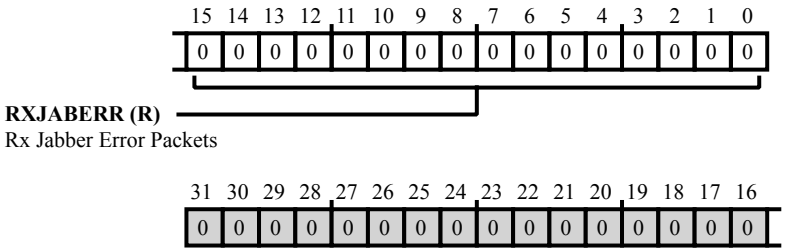

Figure 30-280: EMAC_RX_JBERR_PCNT Register Diagram

Table 30-335: EMAC_RX_JBERR_PCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	RXJABERR	Rx Jabber Error Packets. The EMAC_RX_JBERR_PCNT.RXJABERR field indicates the number of giant packets received with length (including CRC) greater than 1,518 bytes (1,522 bytes for VLAN tagged) and with CRC error. If jumbo packet mode is enabled (EMAC_MAC_CFG.JE = 1), packets of length greater than 9,018 bytes (9,022 bytes for VLAN tagged) are considered as giant packets.

Receive LPI Transition Counter Register

The EMAC_RX_LPITRAN_CNT register provides the number of times the EMAC module has entered Rx LPI.

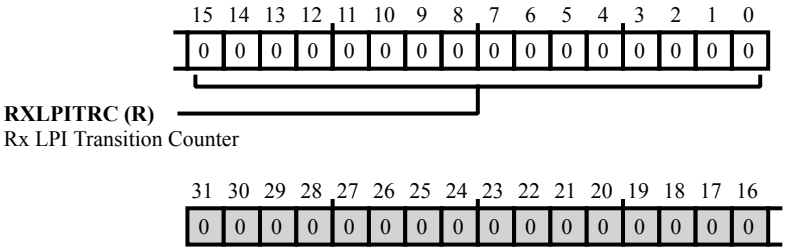

Figure 30-281: EMAC_RX_LPITRAN_CNT Register Diagram

Table 30-336: EMAC_RX_LPITRAN_CNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	RXLPITRC	Rx LPI Transition Counter. The EMAC_RX_LPITRAN_CNT.RXLPITRC field indicates the number of times Rx LPI entry has occurred.

Receive LPI Microseconds Counter Register

The EMAC_RX_LPIUSEC_CNT register provides the number of microseconds Rx LPI is sampled by the EMAC module.

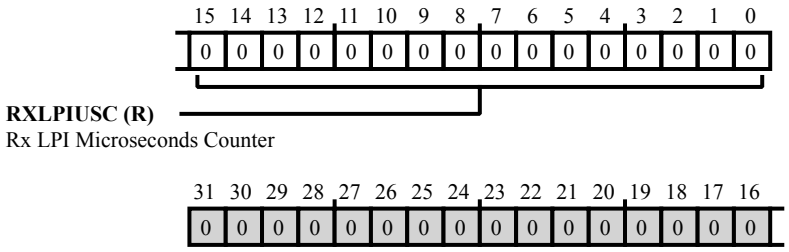

Figure 30-282: EMAC_RX_LPIUSEC_CNT Register Diagram

Table 30-337: EMAC_RX_LPIUSEC_CNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	RXLPIUSC	Rx LPI Microseconds Counter. The EMAC_RX_LPIUSEC_CNT.RXLPIUSC field indicates the number of microseconds Rx LPI is asserted. For every Rx LPI entry and exit, the timer value can have an error of +/- 1 microsecond.

Receive Length Error Packets Counter Register

The EMAC_RX_LENERR_PCNT register provides the number of packets received by the EMAC module with length error (Length Type field not equal to packet size), for all packets with valid length field.

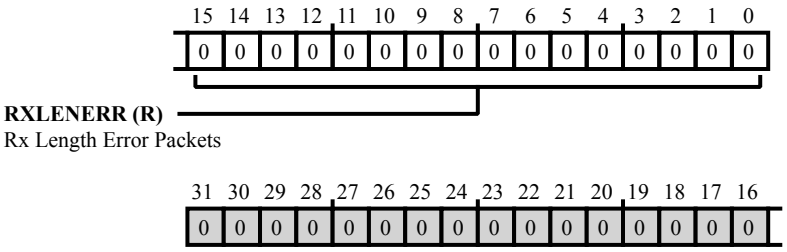

Figure 30-283: EMAC_RX_LENERR_PCNT Register Diagram

Table 30-338: EMAC_RX_LENERR_PCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	RXLENERR	Rx Length Error Packets. The EMAC_RX_LENERR_PCNT.RXLENERR field indicates the number of packets received with length error (length type field not equal to packet size), for all packets with valid length field.

Receive Multicast Packets Good Counter Register

The EMAC_RX_MCST_PCNT_G register provides the number of good multicast packets received by the EMAC module.

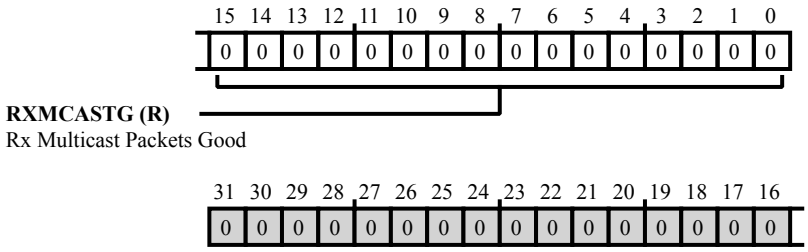

Figure 30-284: EMAC_RX_MCST_PCNT_G Register Diagram

Table 30-339: EMAC_RX_MCST_PCNT_G Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	RXMCASTG	Rx Multicast Packets Good. The EMAC_RX_MCST_PCNT_G.RXMCASTG field indicates the number of good multicast packets received.

Receive Octet Good Counter Register

The EMAC_RX_OCNT_G register provides the number of bytes received by the EMAC module, exclusive of preamble, only in good packets.

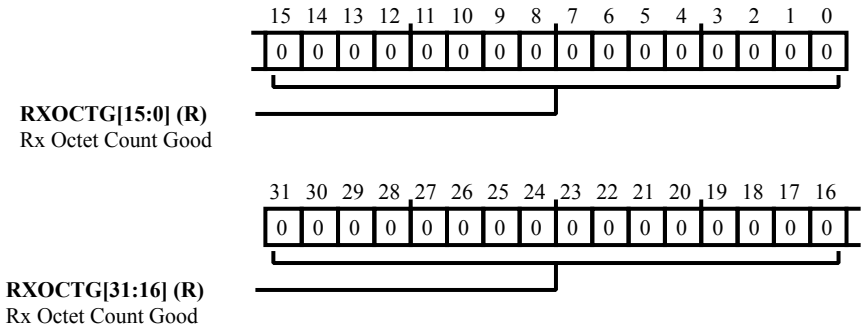

Figure 30-285: EMAC_RX_OCNT_G Register Diagram

Table 30-340: EMAC_RX_OCNT_G Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	RXOCTG	Rx Octet Count Good. The EMAC_RX_OCNT_G.RXOCTG field indicates the number of bytes received, exclusive of preamble, only in good packets.

Receive Octet Good Bad Counter Register

The EMAC_RX_OCNT_GB register provides the number of bytes received by the EMAC module, exclusive of preamble, in good and bad packets.

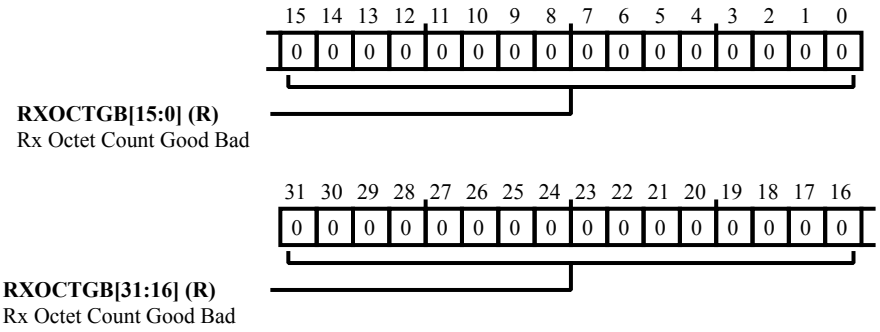

Figure 30-286: EMAC_RX_OCNT_GB Register Diagram

Table 30-341: EMAC_RX_OCNT_GB Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	RXOCTGB	Rx Octet Count Good Bad. The EMAC_RX_OCNT_GB.RXOCTGB field indicates the number of bytes received, exclusive of preamble, in good and bad packets.

Receive Out of Range Type Packets Counter Register

The EMAC_RX_ORTYPE_PCNT register provides the number of packets received by the EMAC module with length field not equal to the valid packet size (greater than 1,500 but less than 1,536).

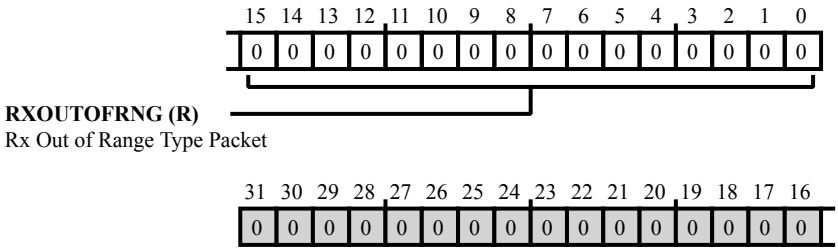

Figure 30-287: EMAC_RX_ORTYPE_PCNT Register Diagram

Table 30-342: EMAC_RX_ORTYPE_PCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	RXOUTOFRNG	Rx Out of Range Type Packet. The EMAC_RX_ORTYPE_PCNT.RXOUTOFRNG field indicates the number of packets received with length field not equal to the valid packet size (greater than 1,500 but less than 1,536).

Receive Oversize Packets Good Counter Register

The EMAC_RX_OVRSZ_PCNT register provides the number of packets received by the EMAC module without errors, with length greater than the max size (1,518 bytes or 1,522 bytes for VLAN tagged packets; 2000 bytes when EMAC_MAC_CFG MAC.S2KP = 1).

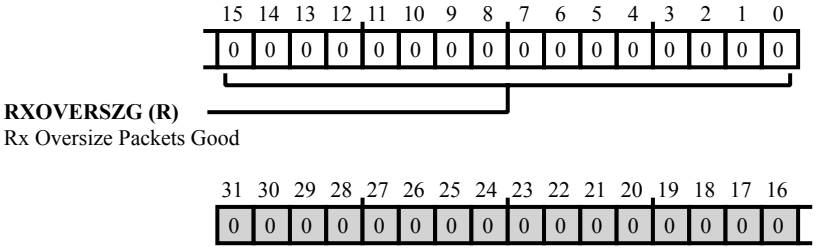

Figure 30-288: EMAC_RX_OVRSZ_PCNT Register Diagram

Table 30-343: EMAC_RX_OVRSZ_PCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	RXOVERSZG	Rx Oversize Packets Good. The EMAC_RX_OVRSZ_PCNT.RXOVERSZG field indicates the number of packets received without errors, with length greater than the maxsize (1,518 bytes or 1,522 bytes for VLAN tagged packets; 2000 bytes when EMAC_MAC_CFG MAC.S2KP = 1).

Receive Packets Good Bad Counter Register

The EMAC_RX_PCNT_GB register provides the number of good and bad packets received by the EMAC module.

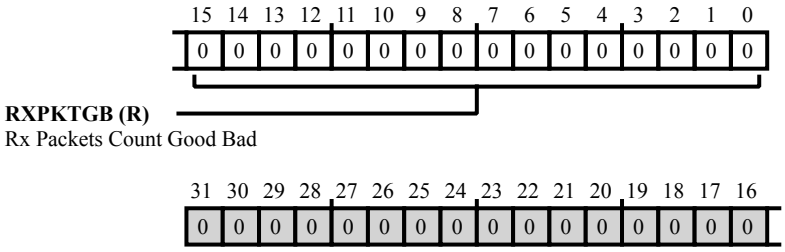

Figure 30-289: EMAC_RX_PCNT_GB Register Diagram

Table 30-344: EMAC_RX_PCNT_GB Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	RXPKTGB	Rx Packets Count Good Bad. The EMAC_RX_PCNT_GB.RXPKTGB field indicates the number of good and bad packets received.

Receive Pause Packets Counter Register

The EMAC_RX_PAUSE_PCNT register provides the number of good and valid Pause packets received by the EMAC module.

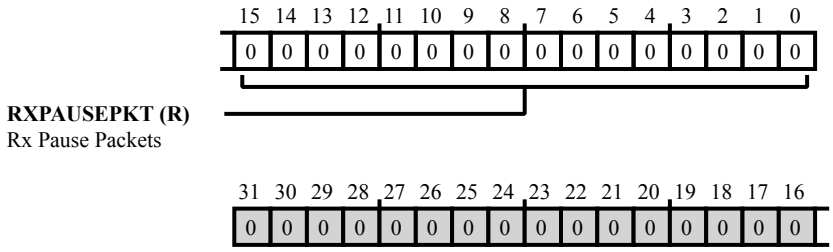

Figure 30-290: EMAC_RX_PAUSE_PCNT Register Diagram

Table 30-345: EMAC_RX_PAUSE_PCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	RXPAUSEPKT	Rx Pause Packets. The EMAC_RX_PAUSE_PCNT.RXPAUSEPKT field indicates the number of good and valid Pause packets received.

Receive Error Packets Counter Register

The EMAC_RX_ERR_PCNT register provides the number of packets received by the EMAC module with receive error or packet extension error on the GMII or MII interface.

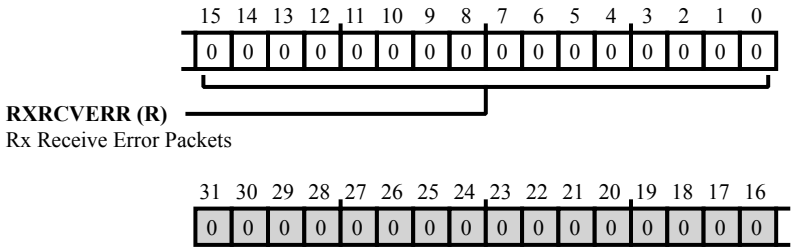

Figure 30-291: EMAC_RX_ERR_PCNT Register Diagram

Table 30-346: EMAC_RX_ERR_PCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	RXRCVERR	Rx Receive Error Packets. The EMAC_RX_ERR_PCNT.RXRCVERR field indicates the number of packets received with Receive error or Packet Extension error on the GMII or MII interface.

Receive Runt Error Packets Counter Register

The EMAC_RX_RNTERR_PCNT register provides the number of packets received by the EMAC module with runt (length less than 64 bytes and CRC error) error.

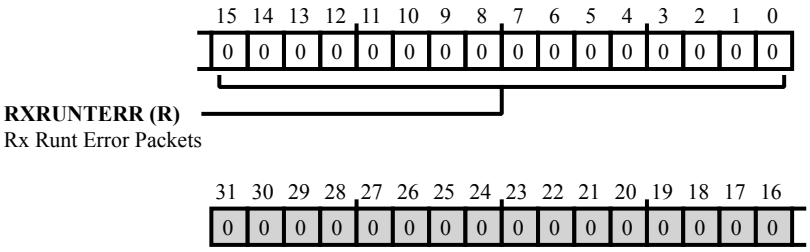

Figure 30-292: EMAC_RX_RNTERR_PCNT Register Diagram

Table 30-347: EMAC_RX_RNTERR_PCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	RXRUNTERR	Rx Runt Error Packets. The EMAC_RX_RNTERR_PCNT.RXRUNTERR field indicates the number of packets received with runt (length less than 64 bytes and CRC error) error.

Receive Undersize Packets Good Counter Register

The EMAC_RX_UNDRSZ_PCNT_G register provides the number of packets received by the EMAC module with length less than 64 bytes, without any errors.

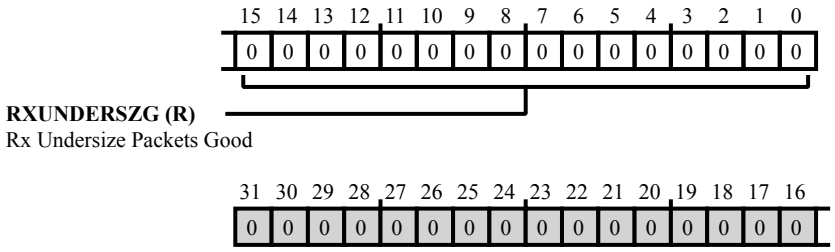

Figure 30-293: EMAC_RX_UNDRSZ_PCNT_G Register Diagram

Table 30-348: EMAC_RX_UNDRSZ_PCNT_G Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	RXUNDERSZG	Rx Undersize Packets Good. The EMAC_RX_UNDRSZ_PCNT_G.RXUNDERSZG field indicates the number of packets received with length less than 64 bytes, without any errors.

Receive Unicast Packets Good Counter Register

The EMAC_RX_UCST_PCNT_G register provides the number of good unicast packets received by the EMAC module.

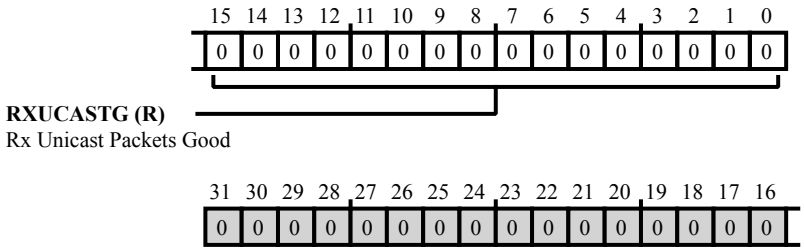

Figure 30-294: EMAC_RX_UCST_PCNT_G Register Diagram

Table 30-349: EMAC_RX_UCST_PCNT_G Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	RXUCASTG	Rx Unicast Packets Good. The EMAC_RX_UCST_PCNT_G.RXUCASTG field indicates the number of good unicast packets received.

Receive VLAN Packets Good Bad Counter Register

The EMAC_RX_VLAN_PCNT_GB register provides the number of good and bad VLAN packets received by the EMAC module.

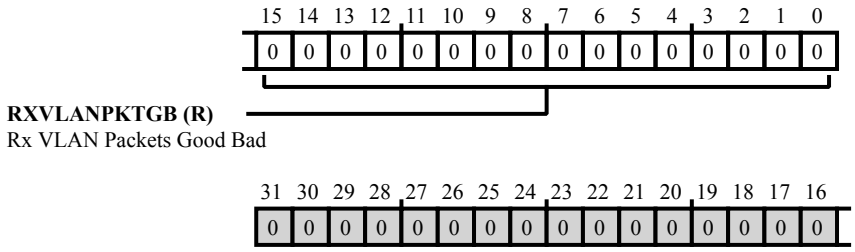

Figure 30-295: EMAC_RX_VLAN_PCNT_GB Register Diagram

Table 30-350: EMAC_RX_VLAN_PCNT_GB Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	RXVLANPKTGB	Rx VLAN Packets Good Bad. The EMAC_RX_VLAN_PCNT_GB.RXVLANPKTGB field indicates the number of good and bad VLAN packets received.

Receive Watchdog Error Packets Counter Register

The EMAC_RX_WDTERR_PCNT register provides the number of packets received by the EMAC module with error because of watchdog timeout error (packets with a data load larger than 2,048 bytes (when EMAC_MAC_CFG.JE and EMAC_MAC_CFG.WD = 0), 10,240 bytes (EMAC_MAC_CFG.JE = 1 and EMAC_MAC_CFG.WD = 0), 16,384 bytes (when EMAC_MAC_CFG.WD = 1) or the value programmed in the EMAC_WDT_TMOUT register).

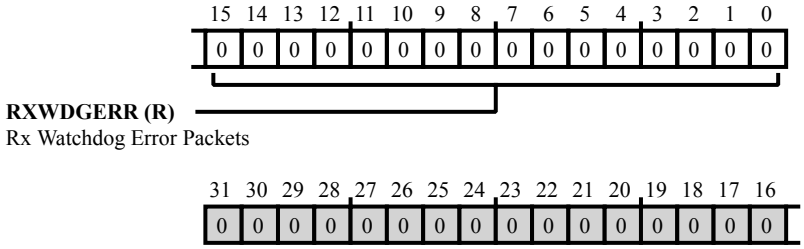

Figure 30-296: EMAC_RX_WDTERR_PCNT Register Diagram

Table 30-351: EMAC_RX_WDTERR_PCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	RXWDGERR	Rx Watchdog Error Packets. The EMAC_RX_WDTERR_PCNT.RXWDGERR field indicates the number of packets received with error because of watchdog timeout error (packets with a data load larger than 2,048 bytes (when EMAC_MAC_CFG MAC.JE = 0 and EMAC_MAC_CFG MAC.WD = 0), 10,240 bytes (when EMAC_MAC_CFG MAC.JE = 1 and EMAC_MAC_CFG MAC.WD = 0), 16,384 bytes (when EMAC_MAC_CFG MAC.WD = 1) or the value programmed in the EMAC_WDT_TMOUT register).

Transmit 1024-Max Octets Packets Good Bad Counter Register

The EMAC_TX1024TOMAX_GB register provides the number of good and bad packets transmitted by the EMAC module with length 1024 to maxsize (inclusive) bytes, exclusive of preamble and retried packets.

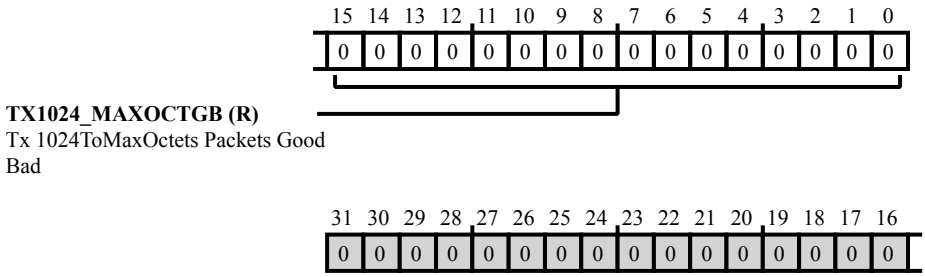

Figure 30-297: EMAC_TX1024TOMAX_GB Register Diagram

Table 30-352: EMAC_TX1024TOMAX_GB Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	TX1024_MAXOCTGB	Tx 1024ToMaxOctets Packets Good Bad. The EMAC_TX1024TOMAX_GB.TX1024_MAXOCTGB field indicates the number of good and bad packets transmitted with length between 1024 and maxsize (inclusive) bytes, exclusive of preamble and retried packets.

Transmit 128-255 Octets Packets Good Bad Counter Register

The EMAC_TX128TO255_GB register provides the number of good and bad packets transmitted by the EMAC module with length between 128 to 255 (inclusive) bytes, exclusive of preamble and retried packets.

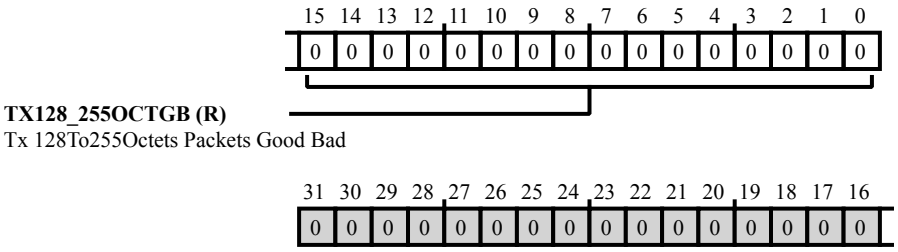

Figure 30-298: EMAC_TX128TO255_GB Register Diagram

Table 30-353: EMAC_TX128TO255_GB Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	TX128_255OCTGB	Tx 128To255Octets Packets Good Bad. The EMAC_TX128TO255_GB.TX128_255OCTGB field indicates the number of good and bad packets transmitted with length between 128 and 255 (inclusive) bytes, exclusive of preamble and retried packets.

Transmit 256-511 Octets Packets Good Bad Counter Register

The EMAC_TX256TO511_GB register provides the number of good and bad packets transmitted by the EMAC module with length between 256 to 511 (inclusive) bytes, exclusive of preamble and retried packets.

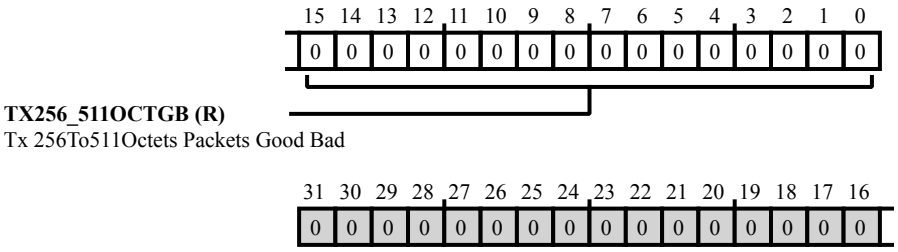

Figure 30-299: EMAC_TX256TO511_GB Register Diagram

Table 30-354: EMAC_TX256TO511_GB Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	TX256_511OCTGB	Tx 256To511Octets Packets Good Bad. The EMAC_TX256TO511_GB.TX256_511OCTGB field indicates the number of good and bad packets transmitted with length between 256 and 511 (inclusive) bytes, exclusive of preamble and retried packets.

Transmit 512-1023 Octets Packets Good Bad Counter Register

The EMAC_TX512TO1023_GB register provides the number of good and bad packets transmitted by the EMAC module with length 512 to 1023 (inclusive) bytes, exclusive of preamble and retried packets.

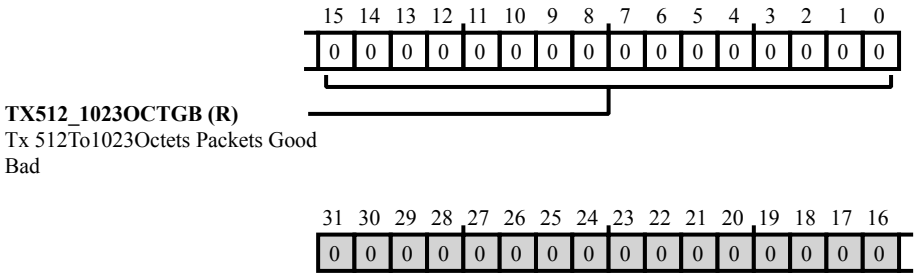

Figure 30-300: EMAC_TX512TO1023_GB Register Diagram

Table 30-355: EMAC_TX512TO1023_GB Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	TX512_1023OCTGB	Tx 512To1023Octets Packets Good Bad. The EMAC_TX512TO1023_GB.TX512_1023OCTGB field indicates the number of good and bad packets transmitted with length between 512 and 1023 (inclusive) bytes, exclusive of preamble and retried packets.

Transmit 64 Octets Packets Good Bad Counter Register

The EMAC_TX64_GB register provides the number of good and bad packets transmitted by the EMAC module with length 64 bytes, exclusive of preamble and retried packets.

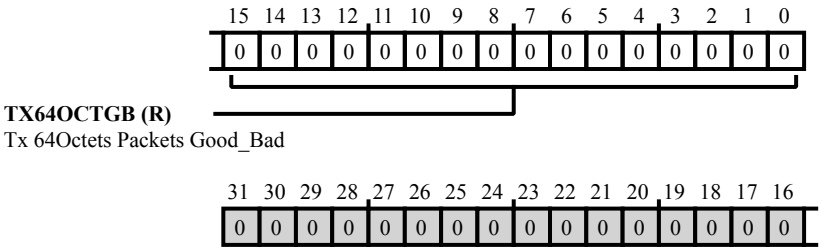

Figure 30-301: EMAC_TX64_GB Register Diagram

Table 30-356: EMAC_TX64_GB Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	TX64OCTGB	Tx 64Octets Packets Good_Bad. The EMAC_TX64_GB.TX64OCTGB field indicates the number of good and bad packets transmitted with length 64 bytes, exclusive of preamble and retried packets.

Transmit 65-127 Octets Packets Good Bad Counter Register

The EMAC_TX65TO127_GB register provides the number of good and bad packets transmitted by the EMAC module with length between 65 and 127 (inclusive) bytes, exclusive of preamble and retried packets.

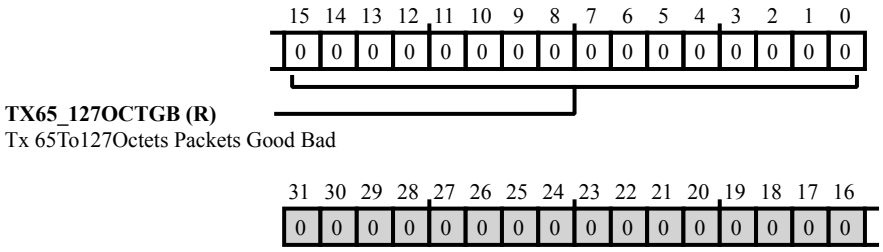

Figure 30-302: EMAC_TX65TO127_GB Register Diagram

Table 30-357: EMAC_TX65TO127_GB Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	TX65_127OCTGB	Tx 65To127Octets Packets Good Bad. The EMAC_TX65TO127_GB.TX65_127OCTGB field indicates the number of good and bad packets transmitted with length between 65 and 127 (inclusive) bytes, exclusive of preamble and retried packets.

Transmit Broadcast Packets Good Counter Register

The EMAC_TX_BCST_PCNT_G register provides the number of good broadcast packets transmitted by the EMAC module.

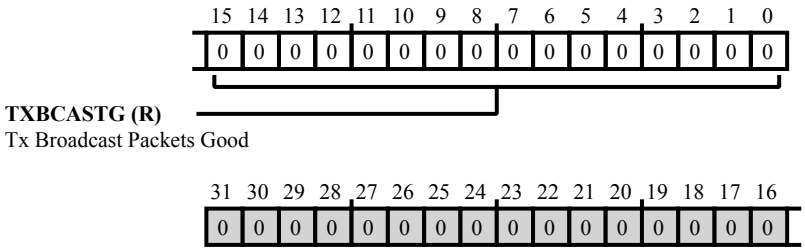

Figure 30-303: EMAC_TX_BCST_PCNT_G Register Diagram

Table 30-358: EMAC_TX_BCST_PCNT_G Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	TXBCASTG	Tx Broadcast Packets Good. The EMAC_TX_BCST_PCNT_G.TXBCASTG field indicates the number of good broadcast packets transmitted.

Transmit Broadcast Packets Good Bad Counter Register

The EMAC_TX_BCST_PCNT_GB register provides the number of good and bad broadcast packets transmitted by the EMAC module.

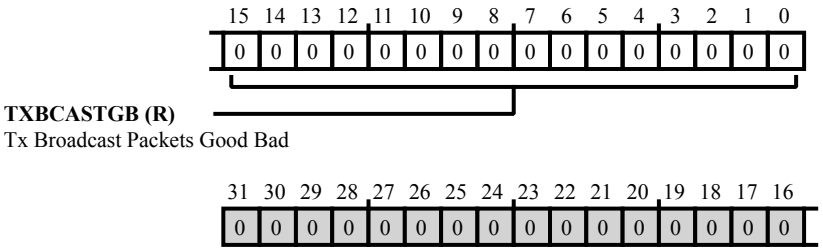

Figure 30-304: EMAC_TX_BCST_PCNT_GB Register Diagram

Table 30-359: EMAC_TX_BCST_PCNT_GB Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	TXBCASTGB	Tx Broadcast Packets Good Bad. The EMAC_TX_BCST_PCNT_GB.TXBCASTGB field indicates the number of good and bad broadcast packets transmitted.

Transmit Carrier Error Packets Counter Register

The EMAC_TX_CRERR_PCNT register provides the number of packets aborted by the EMAC module because of carrier sense error (no carrier or loss of carrier).

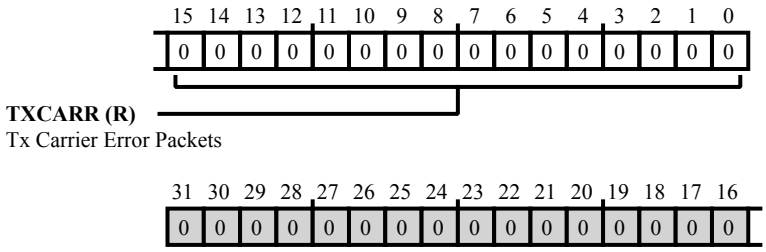

Figure 30-305: EMAC_TX_CRERR_PCNT Register Diagram

Table 30-360: EMAC_TX_CRERR_PCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	TXCARR	Tx Carrier Error Packets. The EMAC_TX_CRERR_PCNT.TXCARR field indicates the number of packets aborted because of carrier sense error (no carrier or loss of carrier).

Transmit Deferred Packets Counter Register

The EMAC_TX_DFRD_PCNT register provides the number of successfully transmitted by the EMAC module after a deferral in the half-duplex mode.

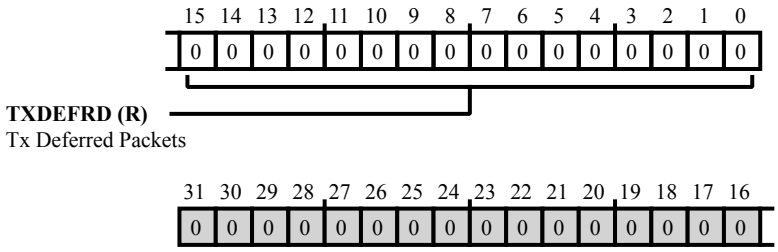

Figure 30-306: EMAC_TX_DFRD_PCNT Register Diagram

Table 30-361: EMAC_TX_DFRD_PCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	TXDEFRD	Tx Deferred Packets. The EMAC_TX_DFRD_PCNT.TXDEFRD field indicates the number of successfully transmitted after a deferral in the half-duplex mode.

Transmit Excessive Collision Packets Counter Register

The EMAC_TX_EXCOL_PCNT register provides the number of packets aborted by the EMAC module because of excessive (16) collision errors.

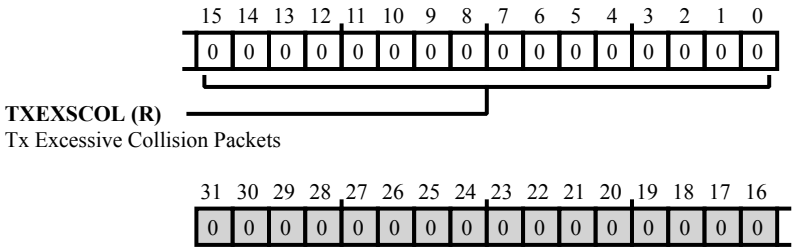

Figure 30-307: EMAC_TX_EXCOL_PCNT Register Diagram

Table 30-362: EMAC_TX_EXCOL_PCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	TXEXSCOL	Tx Excessive Collision Packets. The EMAC_TX_EXCOL_PCNT.TXEXSCOL field indicates the number of packets aborted because of excessive (16) collision errors.

Transmit Excessive Deferral Error Counter Register

The EMAC_TX_EXDFRL_PCNT register provides the number of packets aborted by the EMAC module because of excessive deferral error (deferred for more than two max-sized packet times).

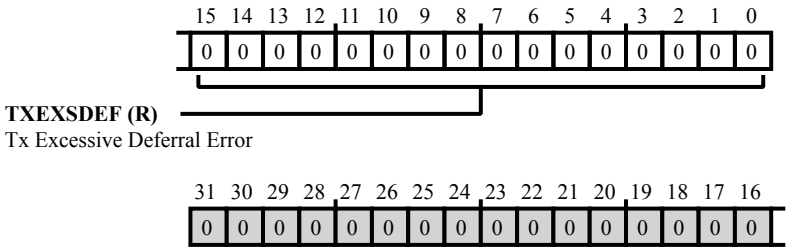

Figure 30-308: EMAC_TX_EXDFRL_PCNT Register Diagram

Table 30-363: EMAC_TX_EXDFRL_PCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	TXEXSDEF	Tx Excessive Deferral Error. The EMAC_TX_EXDFRL_PCNT.TXEXSDEF field indicates the number of packets aborted because of excessive deferral error (deferred for more than two max-sized packet times).

Transmit LPI Transition Counter Register

The EMAC_TX_LPITRAN_CNT register provides the number of times the EMAC module has entered Tx LPI.

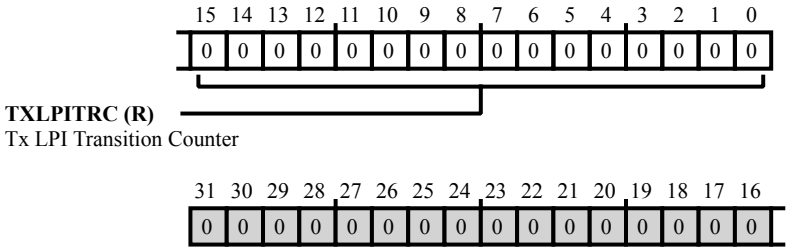

Figure 30-309: EMAC_TX_LPITRAN_CNT Register Diagram

Table 30-364: EMAC_TX_LPITRAN_CNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	TXLPITRC	Tx LPI Transition Counter. The EMAC_TX_LPITRAN_CNT.TXLPITRC field indicates the number of times Tx LPI entry has occurred. Even if Tx LPI entry occurs in automate mode (EMAC_LPI_CTLSTAT.LPITXA = 1), the counter increments.

Transmit LPI Microseconds Counter Register

The EMAC_TX_LPIUSEC_CNT register provides the number of microseconds Tx LPI is asserted by the EMAC module.

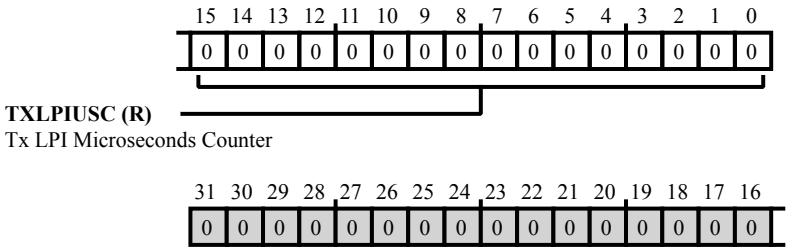

Figure 30-310: EMAC_TX_LPIUSEC_CNT Register Diagram

Table 30-365: EMAC_TX_LPIUSEC_CNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	TXLPIUSC	Tx LPI Microseconds Counter. The EMAC_TX_LPIUSEC_CNT.TXLPIUSC field indicates the number of microseconds Tx LPI is asserted. For every Tx LPI entry and exit, the timer value can have an error of +/- 1 microsecond.

Transmit Late Collision Packets Counter Register

The EMAC_TX_LTCOL_PCNT register provides the number of packets aborted by the EMAC module because of late collision error.

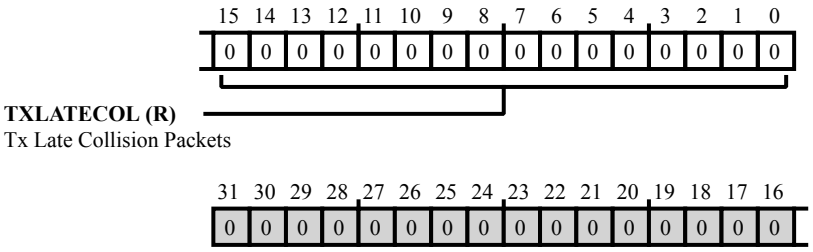

Figure 30-311: EMAC_TX_LTCOL_PCNT Register Diagram

Table 30-366: EMAC_TX_LTCOL_PCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	TXLATECOL	Tx Late Collision Packets. The EMAC_TX_LTCOL_PCNT.TXLATECOL field indicates the number of packets aborted because of late collision error.

Transmit Multicast Packets Good Counter Register

The EMAC_TX_MCST_PCNT_G register provides the number of good multicast packets transmitted by the EMAC module.

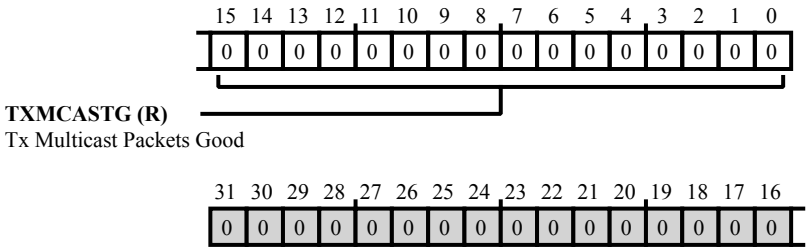

Figure 30-312: EMAC_TX_MCST_PCNT_G Register Diagram

Table 30-367: EMAC_TX_MCST_PCNT_G Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	TXMCASTG	Tx Multicast Packets Good. The EMAC_TX_MCST_PCNT_G.TXMCASTG field indicates the number of good multicast packets transmitted.

Transmit Multicast Packets Good Bad Counter Register

The EMAC_TX_MCST_PCNT_GB register provides the number of good and bad multicast packets transmitted by the EMAC module.

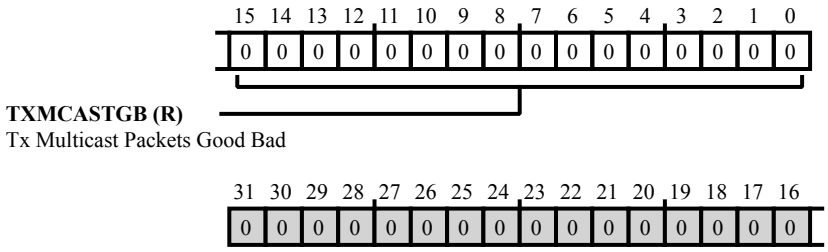

Figure 30-313: EMAC_TX_MCST_PCNT_GB Register Diagram

Table 30-368: EMAC_TX_MCST_PCNT_GB Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	TXMCASTGB	Tx Multicast Packets Good Bad. The EMAC_TX_MCST_PCNT_GB.TXMCASTGB field indicates the number of good and bad multicast packets transmitted.

Transmit Multiple Collision Packets Good Counter Register

The EMAC_TX_MCOL_PCNT_G register provides the number of successfully transmitted packets by the EMAC module after multiple collisions in the half-duplex mode.

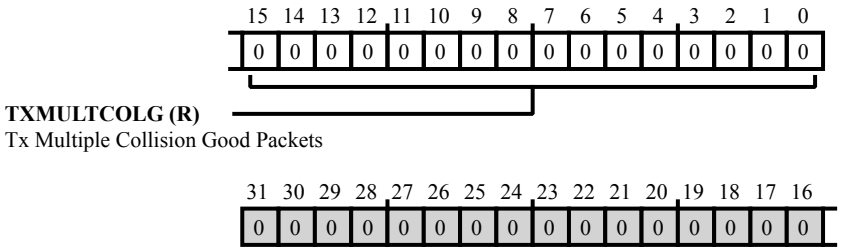

Figure 30-314: EMAC_TX_MCOL_PCNT_G Register Diagram

Table 30-369: EMAC_TX_MCOL_PCNT_G Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	TXMULTCOLG	Tx Multiple Collision Good Packets. The EMAC_TX_MCOL_PCNT_G.TXMULTCOLG field indicates the number of successfully transmitted packets after multiple collisions in the half-duplex mode.

Transmit Osize Packets Good Counter Register

The EMAC_TX_OSIZE_PCNT_G register provides the number of packets transmitted by the EMAC module without errors and with length greater than the maxsize (1,518 or 1,522 bytes for VLAN tagged packets; 2000 bytes if enabled in EMAC_MAC_CFG.S2KP).

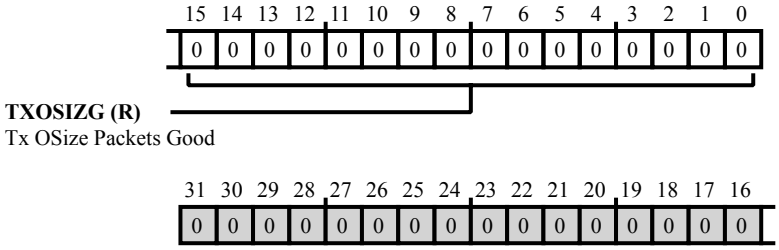

Figure 30-315: EMAC_TX_OSIZE_PCNT_G Register Diagram

Table 30-370: EMAC_TX_OSIZE_PCNT_G Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	TXOSIZG	Tx OSize Packets Good. The EMAC_TX_OSIZE_PCNT_G.TXOSIZG field indicates the number of packets transmitted without errors and with length greater than the maxsize (1,518 or 1,522 bytes for VLAN tagged packets; 2000 bytes when EMAC_MAC_CFG MAC.S2KP = 1).

Transmit Octet Good Counter Register

The EMAC_TX_OCNT_G register provides the number of bytes transmitted by the EMAC module, exclusive of preamble, only in good packets.

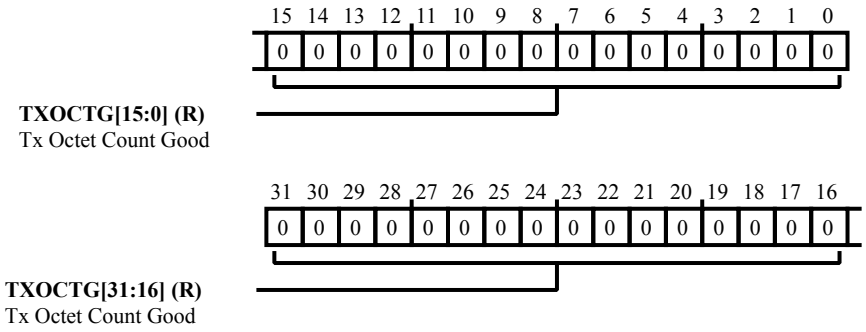

Figure 30-316: EMAC_TX_OCNT_G Register Diagram

Table 30-371: EMAC_TX_OCNT_G Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	TXOCTG	Tx Octet Count Good. The EMAC_TX_OCNT_G.TXOCTG field indicates the number of bytes transmitted, exclusive of preamble, only in good packets.

Transmit Octet Good Bad Counter Register

The EMAC_TX_OCNT_GB register provides the number of bytes transmitted by the EMAC module, exclusive of preamble and retried bytes, in good and bad packets.

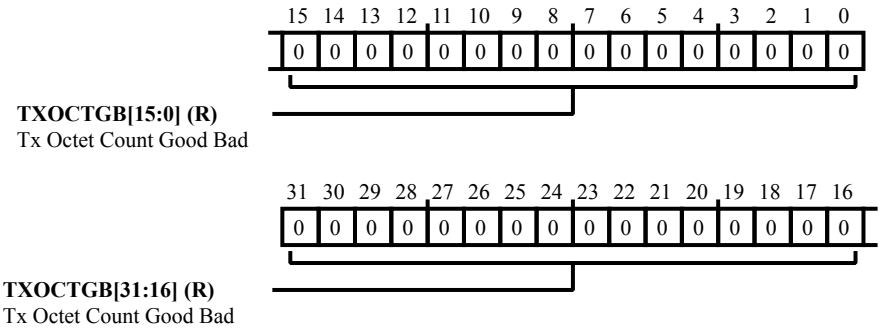

Figure 30-317: EMAC_TX_OCNT_GB Register Diagram

Table 30-372: EMAC_TX_OCNT_GB Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	TXOCTGB	Tx Octet Count Good Bad. The EMAC_TX_OCNT_GB.TXOCTGB field indicates the number of bytes transmitted, exclusive of preamble and retried bytes, in good and bad packets.

Transmit Packet Good Counter Register

The EMAC_TX_PCNT_G register provides the number of good packets transmitted by the EMAC module.

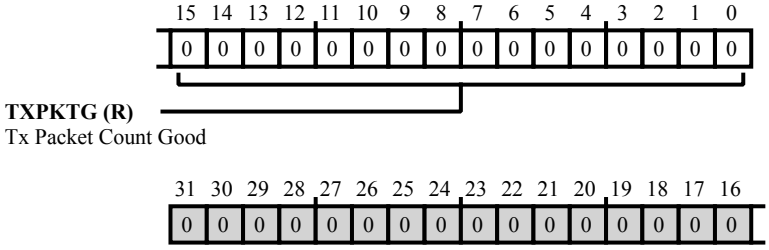

Figure 30-318: EMAC_TX_PCNT_G Register Diagram

Table 30-373: EMAC_TX_PCNT_G Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	TXPKTG	Tx Packet Count Good. The EMAC_TX_PCNT_G.TXPKTG field indicates the number of good packets transmitted.

Transmit Packet Good Bad Counter Register

The EMAC_TX_PCNT_GB register provides the number of good and bad packets transmitted by the EMAC module, exclusive of retried packets.

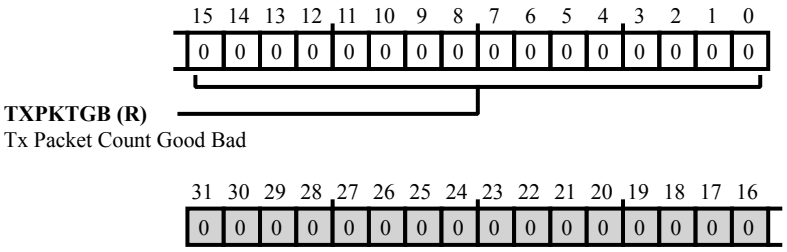

Figure 30-319: EMAC_TX_PCNT_GB Register Diagram

Table 30-374: EMAC_TX_PCNT_GB Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	TXPKTGB	Tx Packet Count Good Bad. The EMAC_TX_PCNT_GB.TXPKTGB field indicates the number of good and bad packets transmitted, exclusive of retried packets.

Transmit Pause Packets Counter Register

The EMAC_TX_PAUSE_PCNT register provides the number of good pause packets transmitted by the EMAC module.

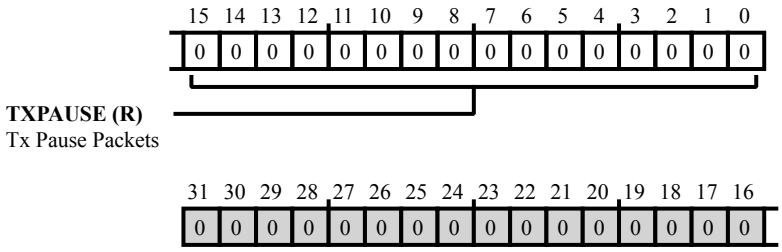

Figure 30-320: EMAC_TX_PAUSE_PCNT Register Diagram

Table 30-375: EMAC_TX_PAUSE_PCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	TXPAUSE	Tx Pause Packets. The EMAC_TX_PAUSE_PCNT.TXPAUSE field indicates the number of good Pause packets transmitted.

Transmit Single Collision Packets Good Counter Register

The EMAC_TX_SNGLCOL_PCNT_G register provides the number of successfully transmitted packets by the EMAC module after a single collision in the half-duplex mode.

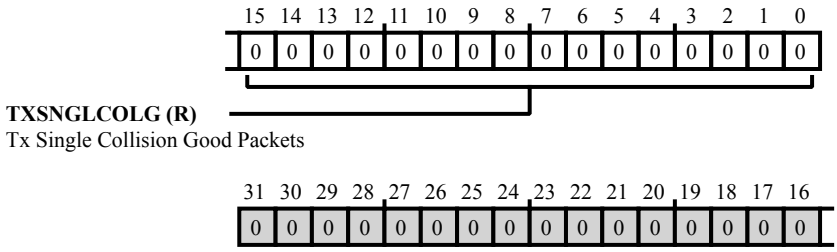

Figure 30-321: EMAC_TX_SNGLCOL_PCNT_G Register Diagram

Table 30-376: EMAC_TX_SNGLCOL_PCNT_G Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	TXSNGLCOLG	Tx Single Collision Good Packets. The EMAC_TX_SNGLCOL_PCNT_G.TXSNGLCOLG field indicates the number of successfully transmitted packets after a single collision in the half-duplex mode.

Transmit Underflow Error Packets Counter Register

The EMAC_TX_URFL_PCNT register provides the number of packets aborted by the EMAC module because of packets underflow error.

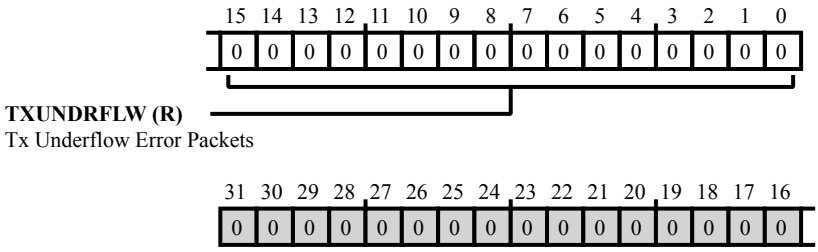

Figure 30-322: EMAC_TX_URFL_PCNT Register Diagram

Table 30-377: EMAC_TX_URFL_PCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	TXUNDRFLW	Tx Underflow Error Packets. The EMAC_TX_URFL_PCNT.TXUNDRFLW field indicates the number of packets aborted because of packets underflow error.

Transmit Unicast Packets Good Bad Counter Register

The EMAC_TX_UCST_PCNT_GB register provides the number of good and bad unicast packets transmitted by the EMAC module.

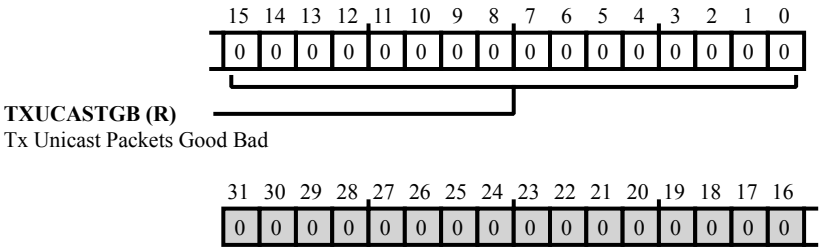

Figure 30-323: EMAC_TX_UCST_PCNT_GB Register Diagram

Table 30-378: EMAC_TX_UCST_PCNT_GB Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	TXUCASTGB	Tx Unicast Packets Good Bad. The EMAC_TX_UCST_PCNT_GB.TXUCASTGB field indicates the number of good and bad unicast packets transmitted.

Transmit VLAN Packets Good Counter Register

The EMAC_TX_VLAN_PCNT_G register provides the number of good VLAN packets transmitted by the EMAC module.

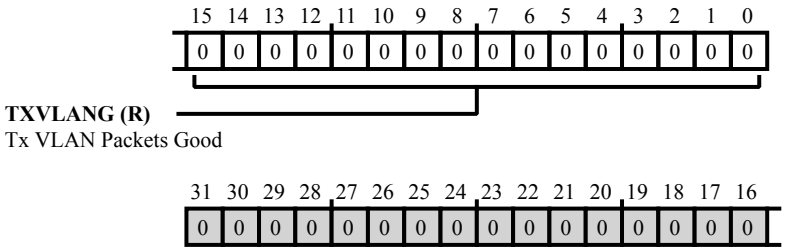

Figure 30-324: EMAC_TX_VLAN_PCNT_G Register Diagram

Table 30-379: EMAC_TX_VLAN_PCNT_G Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	TXVLANG	Tx VLAN Packets Good. The EMAC_TX_VLAN_PCNT_G.TXVLANG field provides the number of good VLAN packets transmitted.

31 Digital Audio Interface (DAI)

The Digital Audio Interfaces (DAIn) are comprised of groups of identical peripherals and their respective Signal Routing Units (SRUn). The SRU connects inputs and outputs of the DAI peripherals with each other and to the external pins. This configuration allows peripherals to be interconnected to accommodate a wide variety of systems without making external pin connections.

In a typical processor, static (multiplexed) pins are assigned to specific peripherals. When certain peripherals are not required for an application, these pins are unnecessary and expensive. The pins may need to be defined as high or low to prevent any illegal conditions. The signal routing units on the SHARC processors addresses this situation by controlling a number of general-purpose pins which can be assigned flexibly (a virtual connectivity between peripherals) depending on system requirements. This virtual connectivity includes pin buffers and routing logic (multiplexer). It also allows the SHARC processors to include an arbitrary number and variety of peripherals while retaining high levels of compatibility without increasing pin count.

SRU Features

The SRU has the following features and capabilities.

- Flexible connections can be made through software and during run time; no hard wiring is required.
- At reset, a default routing scheme is already programmed.
- Connectivity can be made internally between peripherals, externally between pin buffers, or a mix of both.
- Status of the pin buffers can be programmed for conditional execution or interrupts.
- Some pin buffers allow control of signal polarity changes.
- No fan-out limitation, a peripheral or pin buffer output that can be routed to multiple peripheral or pin buffer inputs.

NOTE: The 400-ball HPC BGA package has 2 x 20 DAI pins bonded off-chip (DAIx_PIN01 through DAIx_PIN20).

Functional Description

The fundamental timing clock of the DAI modules is SCLK0.

The DAI Block Diagram shows how the DAI pin buffers are connected through the SRUn. This configuration allows for flexible signal routing.

The DAI units are comprised of four primary blocks:

- Peripherals (A/B/C) associated with DAIn
- Signal Routing Units (SRUn)
- DAIn I/O pin buffers
- Miscellaneous buffers

The peripherals shown in DAI Block Diagram can have up to three connections (if requester or completer capable); one acts as a signal input, one as a signal output and the third as an output enable. The SRUs are based on a group of multiplexers which are controlled by registers to establish the desired interconnections. The DAI pin buffers have three signals which are used for input and output to or from off-chip and the third for output enable.

The miscellaneous buffers have an input and an output and are used for group interconnection.

The figures are a simplified representation of a DAI system. In a real representation, the SRU and DAI would show several types of data being routed from several sources including the following:

- Serial ports (SPORT)
- Precision clock generators (PCG)
- Asynchronous sample rate converters (SRC)
- S/PDIF transmitter
- S/PDIF receiver
- DAI interrupts (miscellaneous)
- PDM interface

ADSP-SC59x DAI Register List

The Digital Audio Interfaces (DAIn) contain groups of identical peripherals which can be connected internally between peripherals, externally between pin buffers, or a mix of both. This module contains the following registers.

Table 31-1: ADSP-SC59x DAI Register List

Name	Description
DAI_CLK0	Clock Routing Control Register 0
DAI_CLK1	Clock Routing Control Register 1
DAI_CLK2	Clock Routing Control Register 2
DAI_CLK3	Clock Routing Control Register 3
DAI_CLK4	Clock Routing Control Register 4

Table 31-1: ADSP-SC59x DAI Register List (Continued)

Name	Description
DAI_CLK5	Clock Routing Control Register 5
DAI_DAT0	Serial Data Routing Control Register 0
DAI_DAT1	Serial Data Routing Control Register 1
DAI_DAT2	Serial Data Routing Control Register 2
DAI_DAT3	Serial Data Routing Control Register 3
DAI_DAT4	Serial Data Routing Control Register 4

DAI Block Diagram

The ***DAI Functional Block Diagram*** and the ***Digital Audio Interconnect Unit*** figures show the functional blocks within the DAI and the unit connections to the peripherals.

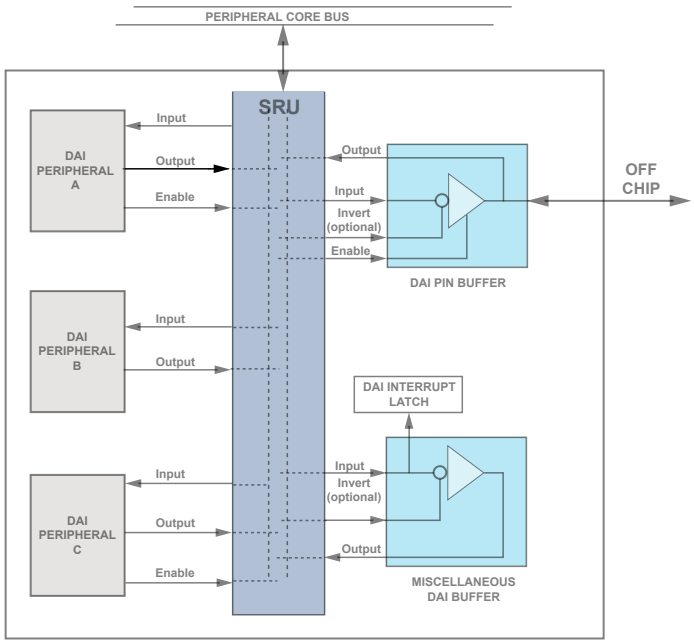

Figure 31-1: DAI Functional Block Diagram

DAI Signal Naming Conventions

The peripherals associated with the DAI do not have any dedicated I/O pins for off-chip communication. Instead, the I/O pin is only accessible in the chip internally and is known as an *internal node*. Every internal node of a DAI peripheral (input or output) is given a unique mnemonic. The convention is to begin the name with an identifier for the peripheral that the signal is coming to or from, followed by the function of the signal.

A number is included if the DAI contains more than one peripheral type (for example, serial ports), or if the peripheral has more than one signal that performs this function (for example, serial ports). The mnemonic always ends with *_I* if the signal is an input, or with *_O* if the signal is an output. An example is shown in the ***Example DAI Mnemonics*** figure.

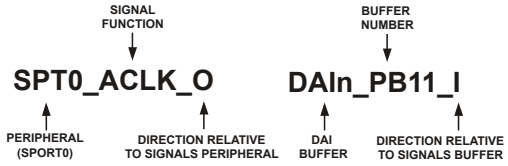

Figure 31-2: Example DAI Mnemonics

I/O Pin Buffers

Within the context of the SRU, physical connections to the DAI pins are replaced by a logical interface known as a *pin buffer*. This three terminal active device is capable of sourcing or sinking output current when its driver is enabled, and passing external input signals when disabled. Each pin has an input, an output, and an enable as shown in the ***Pin Buffer Example*** figure. The inputs and the outputs are defined with respect to the pin, like a peripheral device. This naming convention is consistent with the SRU naming convention.

Pin Buffer Signals

The pin buffer is based on three signals shown in the ***Pin Buffer Example*** figure and described in the following sections.

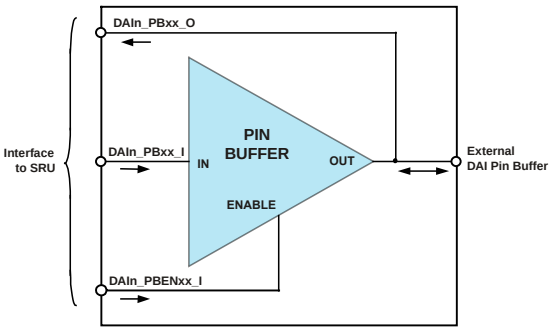

Figure 31-3: Pin Buffer Example

Pin Buffer Input Signal

A pin buffer input (`DAIn_PBxx_I`) is driven as an output from the processor when the pin buffer enable is set (=1). Each physical pin (connected to a bonded pad) can be connected through the SRU to any of the outputs of the DAI peripherals, based on the bit field values. The SRU can also be used to route signals that control the pins in other ways. Many signals can be configured for use as control signals.

Pin Buffer Enable Signal

When a pin buffer enable (`DAIn_PBENxx_I`) is set (=1), the signal present at the corresponding pin buffer input (`DAIn_PBxx_I`) is driven off-chip as an output. When a pin buffer enable is cleared (=0), the signal present at the corresponding pin buffer input is ignored. The pin enable control registers activate the drive buffer for each of the DAI pins. When the pins are not enabled (driven), they can be used as inputs. There are two options to control the pin buffer enable signal; setting the level high for a static solution or connecting the dedicated peripheral's pin buffer output enable signal to its pin buffer, which automatically enables the pin buffer.

Loopback Pin Buffers

Loopback pin buffers provide the ability to route DAI clock signals output from the processor back into the DAI block. There are four loopback pin buffers per DAI block (3/4/5/6) that connect to the external DAI pins with corresponding numbers. The input to a loopback buffer is the same as the input to the DAI pin buffer it corresponds to. Configuring a DAI pin buffer as the output causes the mux output to be from the loopback pin buffer rather than the DAI pin buffer.

For example, when the SPORT0A clock is an output that transmits from DAI Pin 4, then SPORT0A transmits the clock and receives data. In this case, the received data is sampled with respect to the transmit clock that is routed back to the SPORT0A through the loopback pin buffer.

NOTE: For the loopback pin buffers to be applicable, configure the DAI pins when the clock is output and FS/data are inputs.

The *Loopback Pin Buffer* figure shows the connections for the loopback pin buffers in the DAI sub-system.

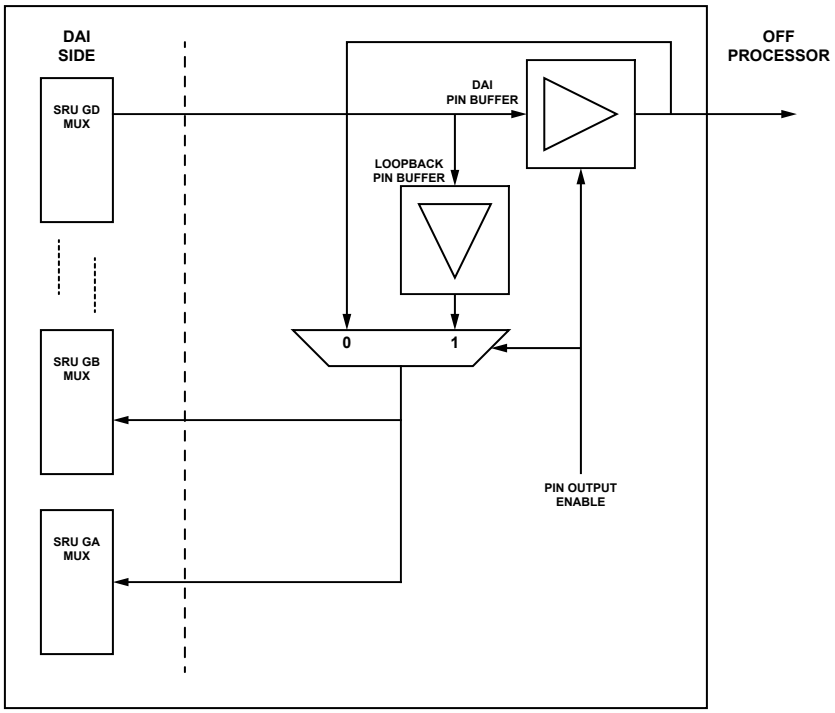

Figure 31-4: Loopback Pin Buffer

Pin Buffer Functions

Pin buffers can be configured as inputs or outputs as described in the following sections.

Pin Buffers as Signal Input

When the DAI pin is used only as an input, connect the corresponding pin buffer enable to logic low as shown in the ***Pin Buffer as Input*** figure. This configuration disables the buffer amplifier and allows an off-chip source to drive the value present on the DAI pin and at the pin buffer output. When the pin buffer enable (for example,

DAI_PBEN0.PB01) is cleared (= 0), the pin buffer output (DAIn_PBxx_O) is the signal driven onto the DAI pin by an external source, and the pin buffer input signal (DAIn_PBxx_I) is not used.

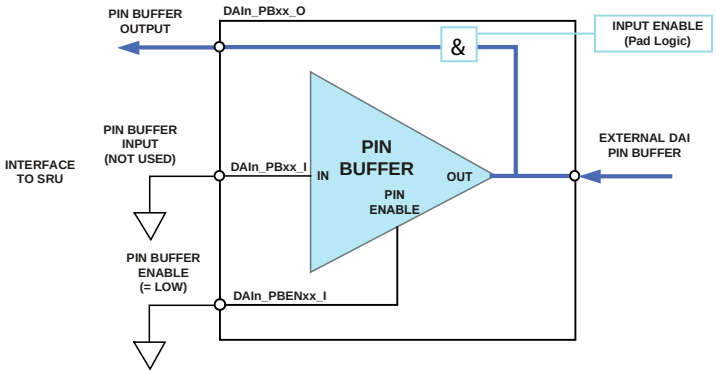

Figure 31-5: Pin Buffer as Input

NOTE: Whether programmed as input or output, a DAI buffer input always routes the same signal to an output internally. DAI pins have programmable internal pull-up resistors. For more information, see the General-Purpose Ports (PORT) chapter for details.

Pin Buffers As Signal Output

In a typical embedded system, most pins are designated as either inputs or outputs when the circuit is designed, even though they can be used in either direction. Each of the DAI pins can be used as either an output or an input. Although the direction of a DAI pin is set simply by writing to a memory-mapped register, most often the direction of the pin is dictated by the designated use of that pin.

When the DAI pin is used only as an output, connect the corresponding pin buffer enable to logic high as shown in the ***Pin Buffer as Output*** figure. This configuration enables the buffer amplifier to operate as a current source and to drive the value present at the pin buffer input onto the DAI pin and off-chip. When the pin buffer enable bits are set (in the DAIn_PBxx_I registers) (=1), the pin buffer output (DAIn_PBxx_O) is the same signal as the pin buffer input (DAIn_PBxx_I), and this signal is driven as an output.

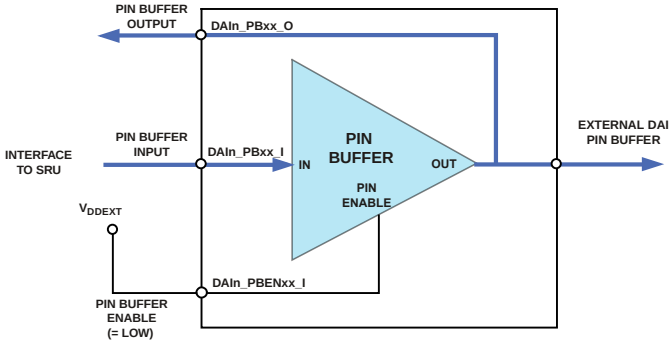

Figure 31-6: Pin Buffer as Output

DAI Pin Buffer Status

The signal levels on the DAI pins can be read with the DAI_PIN_STAT registers.

DAIn Peripherals

There are two categories of peripherals associated with the DAI units. These are described in the following sections.

Output Signals With Pin Buffer Enable Control

Many peripherals within the DAIn that have bidirectional pins generate a corresponding pin enable signal. Typically, the settings within the control registers of a peripheral determine if a bidirectional pin is an input or an output. The pin is then driven accordingly.

Though most peripherals acan operate bidirectionally, it is not required that all of the `_I` and `_O` signals of a peripheral be connected to the pin buffer. When the system design only uses a signal in one direction, it is simpler to connect the pin buffer accordingly.

NOTE: All available pin buffer output enables must be routed to their pin buffer input enable signals in cases where data streaming connections are used. This arrangement guarantees timing requirements.

NOTE: In some cases, it is necessary to use a peripheral's dedicated pin buffer enable signal instead of static levels. For example, SPORT TDM mode requires the SPORT's dedicated data pin buffer enable signal to be used for the SPORT's data pin to three-state the data pins on inactive channels.

Output Signals Without Pin Buffer Enable Control

Some peripherals have signal outputs without an automated pin buffer control enable signal. The operation of these peripherals is simplified. The routing to a DAIn pin buffer enable input requires a static high from the SRUn. To disable the pin buffer output, software must clear the pin buffer enable input.

Signal Routing Units (SRUs)

The following sections provide details specific to the SRUs.

Signal Routing Matrix by Groups

The SRU is similar to a set of patch bays, which contain a bank of inputs and a bank of outputs. For each input (destination), there is a set of permissible output (source) options. Outputs can feed to any number of inputs in parallel, but every input must be patched to exactly one valid output source. Together, the set of inputs and outputs are called a group. The signal's inputs and outputs that comprise each group all serve similar purposes. They are compatible such that almost any output-to-input patch makes functional sense. With the grouping, the multiplexing scheme becomes highly efficient since it does not make sense (for example) to route a frame sync signal to a data signal.

The SRU for the DAI contains six groups named A through F. Each group routes a unique set of signals with a specific purpose:

- Group A routes clock signals
- Group B routes serial data signals
- Group C routes frame sync signals

- Group D routes pin signals
- Group E routes miscellaneous signals
- Group F routes pin output enable signals

Together, the six groups of the SRU include all of the inputs and outputs of the DAI peripherals, a number of additional signals from the core, and all of the connections to the DAI pins.

NOTE: It is not possible to connect a signal in one group directly to a signal in a different group (analogous to wiring from one patch bay to another). However, group D (DAI) is largely devoted to routing in this vein.

DAI Group Routing

Each group has a unique encoding for its associated output signals and a set of configuration registers. For example, DAI group A is used to route clock signals. The memory-mapped group A registers, `DAI_CLK0` through `DAI_CLK5`, contain bit fields corresponding to the clock inputs of various peripherals. The values written to these bit fields specify a signal source that is an output from another peripheral. All of the possible encodings represent sources that are clock signals (or at least could be clock signals in some systems). The ***Example DAI Group A Multiplexing (DAI_CLKx)*** diagrams the input signals that are controlled by the group A registers. All bit fields in the SRU configuration registers correspond to inputs. The value written to the bit field specifies the signal source. This value is also an output from some other component within the SRU.

The SRU is similar to a set of patch bays. Each bay routes a distinct set of outputs to compatible inputs. These connections are implemented as a set of memory-mapped registers with a bit field for each input. The outputs are implemented as a set of bit encodings. Conceptually, a patch cord is used to connect an output to an input. In the SRU, a bit pattern that is associated with a signal output (shown in the ***Example DAI Group A Multiplexing (DAI_CLKx)*** figure) is written to a bit field corresponding to a signal input.

The same encoding can be written to any number of bit fields in the same group. It is not possible to run out of patch points for an output signal.

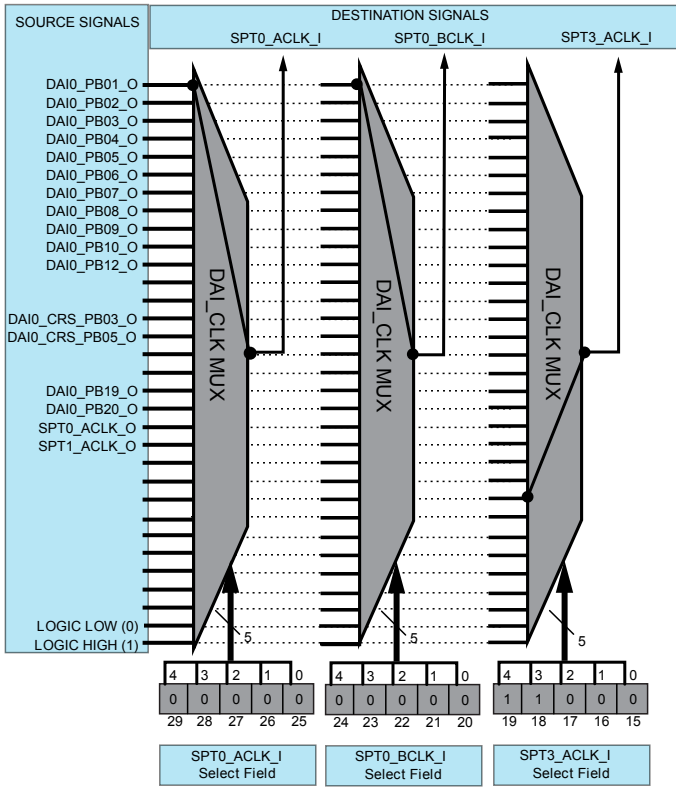

Figure 31-7: Example DAI Group A Multiplexing (DAIn_CLKx)

Just as group A routes clock signals, each of the other groups route a collection of compatible signals. Group B routes serial data streams while group C routes frame sync signals. All of the groups have an encoding that allow a signal to flow from a pin output to the input being specified by the bit field.

Group D routes signals to pins so that they may be driven off-chip (required to route a signal to the pin input). Group F routes signals to the pin enables, and the value of these signals determines if a DAI pin is used as an output or an input. The input of one pin can be patched to the output of another pin, allowing board-level routing under software control.

Rules for SRU Connections

There are two rules which apply to all routing:

1. One source (output node) can drive different destinations (input nodes).
2. One destination (input node) can only be assigned to one source (output node).

As an example from the ***Example DAI Group A Multiplexing (DAI_CLKx)*** figure:

- `DAI0_PIN02_O` is routed to `SPT0_BCLK_I`
- `SPT2_ACLK_O` is routed to `SPT3_ACLK_I`

NOTE: Inputs may only be connected to outputs.

Miscellaneous Buffers and Functions

The SRU group E provides miscellaneous buffers used for group interconnect.

DAI group E connections are slightly different from the others in that the inputs and outputs being routed vary considerably in function. This group routes control signals and provides a means of connecting signals between groups.

In the ***DAI MISCAx SRU Signal Connections*** table, the `DAIn_MISCAx_I` signals appear as inputs in group E (also connected to the DAI interrupt logic), but do not directly feed any peripheral. Rather, the `MISCAx_O` signals reappear as outputs in group F.

Table 31-5: DAI MISCAx SRU Signal Connections

MISCA Source	DAI Connection	MISCA Destination
	Group E	DAIn_MISCA5-0_I
DAIn_MISCA5-0_O	Group F	

Additional connections among groups provide a great amount of utility. Since the output groups F (DAI) dictate pin direction, these few signal paths enable a number of possible uses and connections for the DAI pins. Other examples include:

- A pin input can be patched to another pin's enable, allowing an off-chip signal to gate an output from the processor.
- Any of the DAI pins can be used as interrupt sources or general-purpose I/O (GPIO) signals.

In summary, the SRU enables many possible functional changes, both within the processor as well as externally. Used creatively, it allows system designers to radically change functionality at run time, and to potentially reuse circuit boards across many products.

DAI Routing Unit (DRU)

The DAI routing unit provides all possible connections across DAIs by interconnecting two DAI units through a multiplexer.

- For every input signal of an SRU, there is a control bit that selects either the original signal from the native DAI or its corresponding signal from the other DAI. For example, either SP0_ACLK_O from DAI0 or SP0_ACLK_O from DAI1 is selected and routed to the SP0_ACLK_O input of the SRU of DAI0 based on the programmed control bit.
- By default, all native signals are connected to their respective SRU (for example, SP0_ACLK_O from DAI0 is connected to SP0_ACLK_O input of the SRU of DAI0.

As a part of fully cross-connected DAI Routing unit, following source signals are added to the existing SRU's source group.

- All the source signals of Group A/B/C/D/E/F from the other DAI are added as source signals to the native group A/B/C/D/E/F's respectively.

The *DAI Routing Unit System* figure depicts the block level view of the DAI Routing Unit connecting DAI0 and DAI1 through a multiplexer.

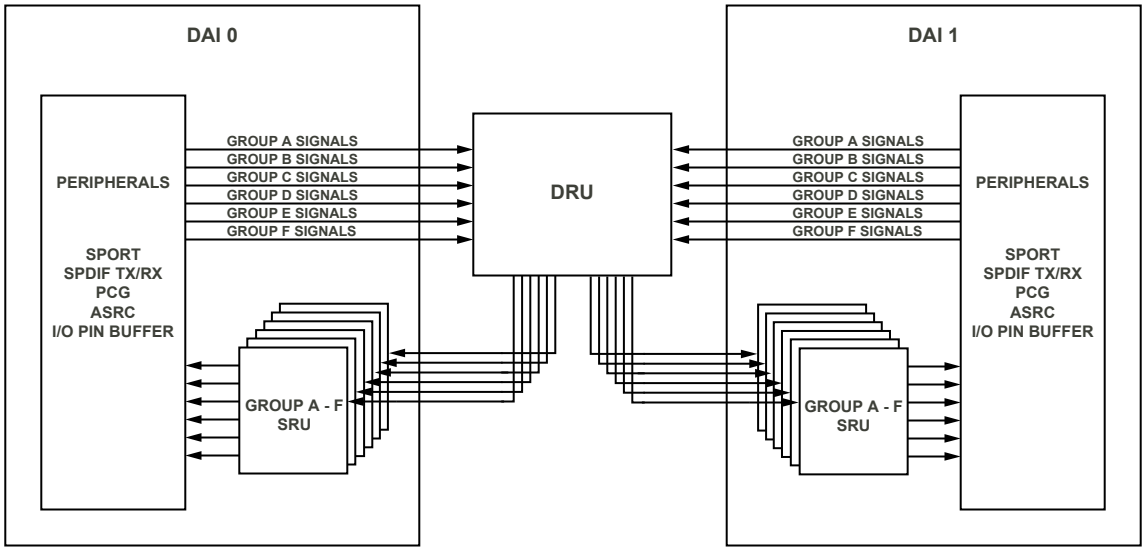

Figure 31-8: DAI Routing Unit System

DAI Routing Capabilities

This section describes the routing options to aid in designing a system using the DAI units. The DAI Default Routing section provides diagrams that show how that DAIs connect at default. The DAI Group tables provide the source signals and selections codes. Finally, the xxx provides information about configuring destinations.

The ***DAI Routing Capabilities*** tables provide an overview of the different routing capabilities for the DAI unit. For information on an individual peripherals routing, see the “SRU Programming” section of the specific peripheral chapter.

DAI Default Routing

When the processor comes out of reset, the SPORT junctions are bidirectional to the DAI pin buffers. This configuration allows systems to use the SPORTs as either requester or completer (without changing the routing scheme). Therefore, programs only need to use the SPORT control register settings to configure requester or completer operations. Note that all DAI inputs which are not routed by default are tied to signal low.

NOTE: All DAI input buffers which are not routed by default are driven low and all DAI pin buffer enable signals are driven low.

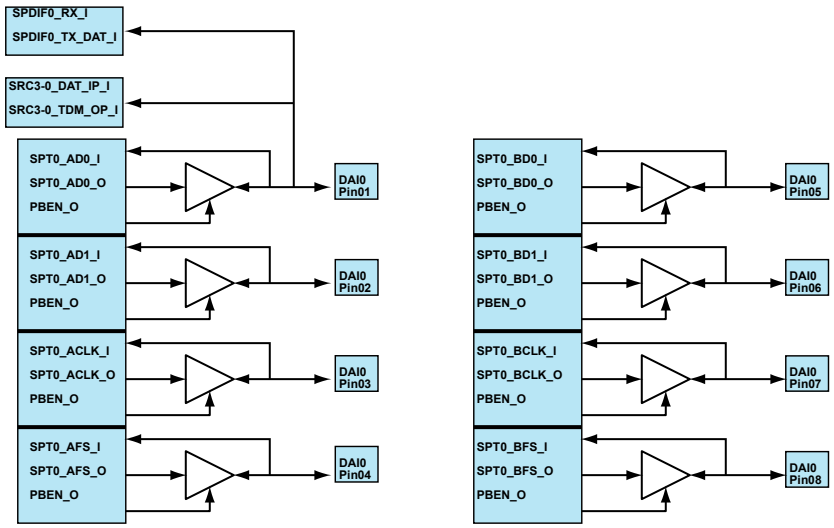

Figure 31-9: DAI0 Default Routing Pins 01-08

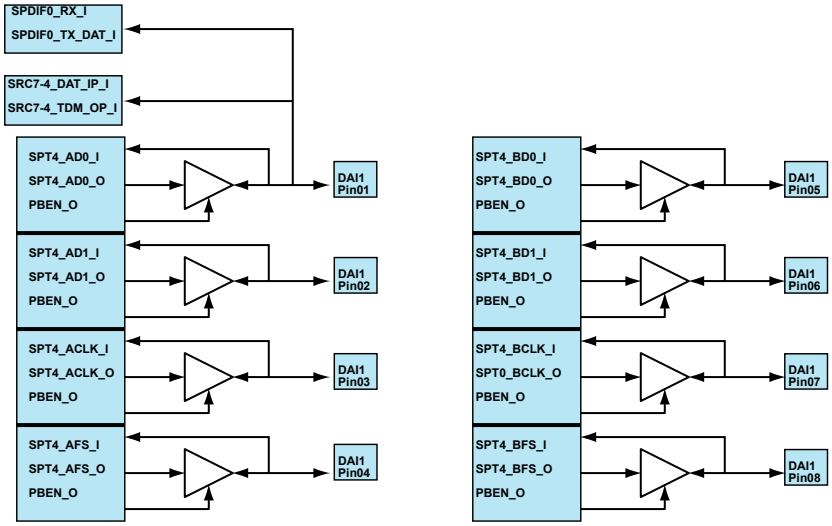

Figure 31-10: DAI1 Default Routing Pins 01-08

Unused DAI Connections

The SRUs have a default general-purpose routing scheme which can be modified to accommodate any number of different system designs. Regardless of the system design, it is good practice to tie all unused inputs to a high or low level to reduce dynamic power consumption.

DAI Operating Modes

Some buffers allow polarity changes, described as follows.

DAI Pin Buffer Polarity

As shown in the ***Pin Buffer Polarity*** figure, the DAI pin buffer 20-19 can change the polarity of the input signal if the corresponding control bits (`DAI_PIN4.INV20`, `DAI_PIN4.INV19`) are set. These bits can be set during run time and the buffer should not loopback to itself.

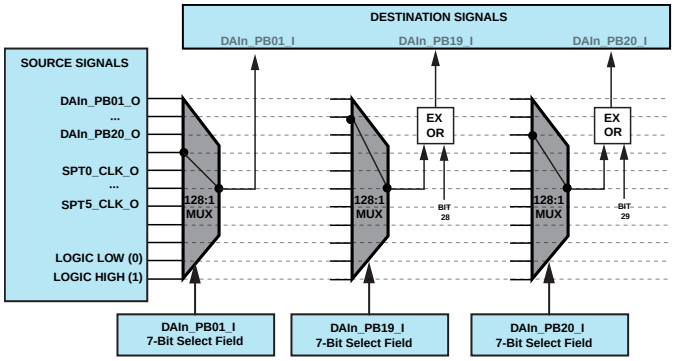

Figure 31-11: Pin Buffer Polarity

DAI Miscellaneous Buffer Polarity

As shown in the ***Pin Buffer Polarity*** figure, the A5-4 miscellaneous buffers can change the polarity of the input signal if the corresponding control bits (`DAI_MISC1.IN5`, `DAI_MISC1.IN4`) are set. Both buffers are not connected to the DAI interrupt latch register. These bits can be set during run time.

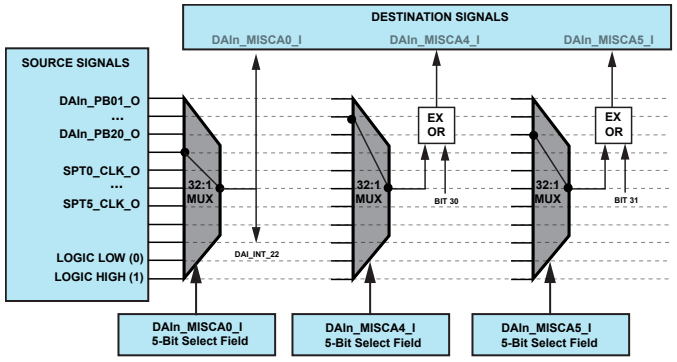

Figure 31-12: Miscellaneous Buffer Polarity

DAI System Interrupt Controller (SIC)

The DAI module incorporates a system interrupt controller (SIC) which is connected to the SEC as seen in the ***DAI System Interrupt Controller*** figure.

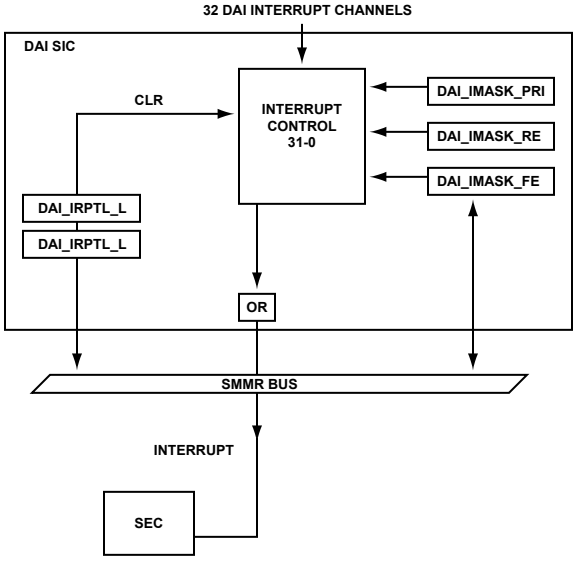

Figure 31-13: DAI System Interrupt Controller

The DAI has its own system interrupt controllers that indicate to the core when DAI audio peripheral-related events have occurred. Since audio events occur infrequently relative to the SHARC core, the DAI interrupt controller reduces all of its interrupts onto two interrupt signals within the core's primary interrupt systems. One interrupt is mapped with DAI low priority. The second interrupt is mapped with DAI high priority. This configuration allows programs to broadly indicate priority. In this way, the DAI SIC provides 32 independently configurable sources or

channels. The output bus interrupt signals are logically OR'ed into one interrupt line and fed to the interrupt controller logic of the core.

Three registers are used to configure the DAI interrupt controller. Each of the 32 interrupt sources can be independently configured to trigger on a rising edge, falling edge, both edges, or neither edge of an incoming signal. All DAI interrupt control registers are memory-mapped registers and are accessed through the peripheral bus.

Interrupt Sources

The DAI's five peripheral sources are multiplexed into 32 interrupt sources and are labeled DAI_INT31-0 (***DAI Interrupt Sources*** table).

NOTE: There are two naming conventions. The DAI interrupt controller register bits are labeled DAI_31-0_INT. Their corresponding SRU routing signals are labeled DAI_INT_31-0_I.

Table 31-8: DAI Interrupt Sources

Interrupt Source	Description	Signal Response
DAI_INT2–0, DAI_INT4	S/PDIF RX, 4 channels	Event
DAI_INT2–0, DAI_INT4	S/PDIF RX, 4 channels	Waveform
DAI_INT21–18	ASRC, 4 channels	
DAI_INT31–22	Miscellaneous, S/PDIF TX, 9 channels	

Interrupt Latch Priority Option

The `DAI_IMSK_PRI` register specifies the priority for the DAI interrupt channels. DAI system interrupt controller has a pair of interrupt latch registers, `DAI_IRPTL_H` and `DAI_IRPTL_L`. The configuration of the `DAI_IMSK_PRI` register also determines the interrupt latch mapping for a particular DAI interrupt. When a DAI interrupt is configured as low priority (`DAI_IMSK_PRI` bit cleared, default setting), interrupts are mapped to the DAI_INTR_IRQL signal and when an interrupt occurs, the corresponding bit of the `DAI_IRPTL_L` register is set. When a DAI interrupt is configured as high priority (`DAI_IMSK_PRI` bit set), interrupts are mapped to the DAI_INTR_IRQH signal and the interrupt is latched to the `DAI_IRPTL_H` register. The low priority DAI interrupt (INTR_DAI_IRQL) and high priority DAI interrupt (INTR_DAI_IRQH) are connected to the SEC .

Interrupt Mask for Waveforms

The `DAI_IMSK_RE` and `DAI_IMSK_FE` registers allow programs to mask or unmask interrupts for specific edges of a signal mapped to the channel. It can be configured for rising edges, falling edges, both rising and falling edges, or neither rising nor falling edges by masking them separately. Signals from the SRU can be used to generate interrupts. For example, when the `DAI_IMSK_FE.MISCINT9` bit is set to one, any falling edge signals from the external channel generate an interrupt and the interrupt latch is set.

Interrupt Mask for Events

The system interrupt controller needs information about a peripheral's interrupt sources that correspond to event signals (see the ***DAI Interrupt Sources*** table). As a result, the rising edge is used as an interrupt source only. For DAI peripherals marked as events, programs may unmask an interrupt source on the rising edge only.

Shadow Interrupt Register

The DAI interrupt controller has shadow registers to simplify debug activities since these registers do not manipulate status control. Any read of the shadow registers (`DAI_IRPTL_HS`, `DAI_IRPTL_LS`), provides the same data as a read of the `DAI_IRPTL_H` and `DAI_IRPTL_L` registers. However, reads of the DAI shadow registers do not change the interrupt acknowledge status to the core interrupt controller.

Interrupt Service

The interrupt acknowledge operates differently when multiple channels are multiplexed into one interrupt output signal. When an interrupt from the DAI must be serviced, any of the two interrupt service routines (INTR_DAI_IRQL, INTR_DAI_IRQH) must query the SIC to determine the source(s). Sources can be any one or more of the DAI channels (DAI_INT31-0).

- When the `DAI_IRPTL_H` register is read, the high priority latched interrupts are cleared.
- When the `DAI_IRPTL_L` register is read, the low priority latched interrupts are cleared.

If an interrupt occurs in the same cycle as a latch register is cleared, the clear mechanism has lower priority and the new interrupt is registered.

Signal Routing Unit Effect Latency

After the DAIy registers are configured the effect latency is 2 *SCLK0* cycles minimum and 3 *SCLK0* cycles maximum.

DAI Programming Model

As discussed in the previous sections, the signal routing unit is controlled by writing values that provide a plug-in tool in CCES so that configuring the SRU is done graphically. Analog Devices offers macros that are included with the CrossCore or VisualDSP++ tools, greatly easing code development in the SRU.

There is a macro that has been created to connect peripherals used in a DAI configuration. This code can be used in both assembly and C code. See the INCLUDE file SRU.H. In practice the macro is provided and forms the style `SRU(source_O, destination_I)` for DAI0. Example appears as: `SRU(DAI0_PB12_O, SPT0_ACLK_I);`

Debug Features

The following section describes the feature that can be used to help in debugging the DAI.

Loopback Routing

The SPORT serial peripheral supports an internal loopback mode. If the loopback bit for each peripheral is enabled, it connects the transmitter with the receiver block internally (does not signal off-chip). The SRU can be used for this purpose. The ***Loopback Routing*** table describes the different possible routings based on the peripheral.

NOTE: The peripheral's loopback mode for debug is independent from both signal routing units.

Table 31-9: Loopback Routing

Peripheral	Loopback Mode	SRU1–0 Internal Routing for Loopback	SRU1–0 External Routing for Loopback
SPORT	Yes	SPTx_xx_O → SPTx_xx_I	SPTx_xx_O → DAIn_PBxx_I DAIn_PBxx_O → SPTx_xx_I
S/PDIF Tx/Rx	No	SPDIFn_TX_O → SPDIFn_RX_I	SPDIFn_TX_O → DAI_PBxx_I DAI_PBxx_O → SPDIFn_RX_I
SRC	No	SRCx_DAT_OP_O → SRCx_DAT_IP_I	SRCx_DAT_OP_O → DAI_PBxx_I DAI_PBxx_O → SRCx_DAT_IP_I

DAI Sources Overview

The following tables provide information of the various DAI sources sorted by group.

Group A – Clock Routing Signals

The group A clock routing sources are listed in the following table.

Table 31-10: Group A – Clock Routing Sources

Extended Selection Code [1:0]		Selection Code [4:0]	Source Signal	Description (Source Selection)
Bit 1	Bit 0			
0	0	00000 (0x0)	DAI0_PB01_O	Pin Buffer 1
0	0	00001 (0x1)	DAI0_PB02_O	Pin Buffer 2
0	0	00010 (0x2)	DAI0_PB03_O	Pin Buffer 3
0	0	00011 (0x3)	DAI0_PB04_O	Pin Buffer 4
0	0	00100 (0x4)	DAI0_PB05_O	Pin Buffer 5
0	0	00101 (0x5)	DAI0_PB06_O	Pin Buffer 6
0	0	00110 (0x6)	DAI0_PB07_O	Pin Buffer 7
0	0	00111 (0x7)	DAI0_PB08_O	Pin Buffer 8
0	0	01000 (0x8)	DAI0_PB09_O	Pin Buffer 9
0	0	01001 (0x9)	DAI0_PB10_O	Pin Buffer 10
0	0	01010 (0xA)	DAI0_PB11_O	Pin Buffer 11
0	0	01011 (0xB)	DAI0_PB12_O	Pin Buffer 12
0	0	01100 (0xC)	DAI0_PB13_O	Pin Buffer 13
0	0	01101 (0xD)	DAI0_PB14_O	Pin Buffer 14
0	0	01110 (0xE)	DAI0_PB15_O	Pin Buffer 15
0	0	01111 (0xF)	DAI0_PB16_O	Pin Buffer 16
0	0	10000 (0x10)	DAI0_PB17_O	Pin Buffer 17
0	0	10001 (0x11)	DAI0_PB18_O	Pin Buffer 18
0	0	10010 (0x12)	DAI0_PB19_O	Pin Buffer 19
0	0	10011 (0x13)	DAI0_PB20_O	Pin Buffer 20
0	0	10100 (0x14)	SPT0_ACLK_O	SPORT 0 Clock A
0	0	10101 (0x15)	SPT0_BCLK_O	SPORT 0 Clock B
0	0	10110 (0x16)	SPT1_ACLK_O	SPORT 1 Clock A
0	0	10111 (0x17)	SPT1_BCLK_O	SPORT 1 Clock B
0	0	11000 (0x18)	SPT2_ACLK_O	SPORT 2 Clock A
0	0	11001 (0x19)	SPT2_BCLK_O	SPORT 2 Clock B

Table 31-10: Group A – Clock Routing Sources (Continued)

Extended Selection Code [1:0]		Selection Code [4:0]	Source Signal	Description (Source Selection)
Bit 1	**Bit 0**			
0	0	11010 (0x1A)	SPDIF0_RX_CLK_O	SPDIF 0 Receive Clock Output
0	0	11011 (0x1B)	SPDIF0_RX_TDMCLK_O	SPDIF 0 Receive TDM Clock Output
0	0	11100 (0x1C)	PCG_CLKA_O	Precision Clock A Output
0	0	11101 (0x1D)	PCG_CLKB_O	Precision Clock B Output
0	0	11110 (0x1E)	LOW	Logic Level Low (0)
0	0	11111 (0x1F)	HIGH	Logic Level High (1)
0	1	00000 (0x0)	SPT3_ACLK_O	SPORT 3 clock A
0	1	00001 (0x1)	SPT3_BCLK_O	SPORT 3 clock B
0	1	00010 (0x2)	PCG_CLKE_O	Precision Clock E output
0	1	00011 (0x3)	PCG_CLKF_O	Precision Clock F output
0	1	00100 (0x4)	PCG_CLKA_INV_O	Inverted Precision Clock A output
0	1	00101 (0x5)	PCG_CLKB_INV_O	Inverted Precision Clock B output
0	1	00110 (0x6)	PCG_CLKE_INV_O	Inverted Precision Clock E output
0	1	00111 (0x7)	PCG_CLKF_INV_O	Inverted Precision Clock F output
0	1	01000 (0x8)	PDM0_CLK0_O	PDM0 Clock0 output
0	1	01001 (0x9) -11111 (0x1F)	Reserved	
1	0	00000 (0x0)	DAI1_PB01_O	Pin Buffer 1 (from other DAI)
1	0	00001(0x1)	DAI1_PB02_O	Pin Buffer 2 (from other DAI)
1	0	00010 (0x2)	DAI1_PB03_O	Pin Buffer 3 (from other DAI). This pin buffer is used for sharing clocks between DAI modules. DAI0_PIN03 and DAI1_PIN03 can be used to share clock signal across DAI. When DAI0_PIN03 is configured as input clock pin then this clock signal is available in Group A of both DAIs. This source signal is DAI0_CRS_PB03_O in group A of DAI 0 and DAI1_CRS_PB03_O in group A of DAI1.
1	0	00011 (0x3)	DAI1_PB04_O	Pin Buffer 4 (from other DAI)

Table 31-10: Group A – Clock Routing Sources (Continued)

Extended Selection Code [1:0]		Selection Code [4:0]	Source Signal	Description (Source Selection)
Bit 1	Bit 0			
1	0	00100 (0x4)	DAI1_PB05_O	Pin Buffer 5 (from other DAI). This pin buffer is used for sharing clocks between DAI modules. DAI0_PIN05 and DAI1_PIN05 can be used to share clock signal across DAI. When DAI0_PIN05 is configured as input clock pin then this clock signal is available in Group A of both DAIs. This source signal is DAI0_CRS_PB05_O in group A of DAI 0 and DAI1_CRS_PB05_O in group A of DAI1.
1	0	00101 (0x5)	DAI1_PB06_O	Pin Buffer 6 (from other DAI)
1	0	00110 (0x6)	DAI1_PB07_O	Pin Buffer 7 (from other DAI)
1	0	00111 (0x7)	DAI1_PB08_O	Pin Buffer 8 (from other DAI)
1	0	01000 (0x8)	DAI1_PB09_O	Pin Buffer 9 (from other DAI)
1	0	01001 (0x9)	DAI1_PB10_O	Pin Buffer 10 (from other DAI)

DAI Destination Registers Overview

The tables in the DAI Routing Capabilities section provide high level descriptions that illustrate source (output) connections to destinations (inputs) depending on the routing groups A through F. These tables list the various input fields (INx), which are described in detail in the register descriptions section.

Table 31-16: Clock Destination Registers (Group A)

DAI Register	Bit Field Name	DAI0 Mapping	DAI1 Mapping	Description
DAI_CLK0	IN0	SPT0_ACLK_I	SPT4_ACLK_I	SPORT0A or SPORT4A Clock
	IN1	SPT0_BCLK_I	SPT4_BCLK_I	SPORT0B or SPORT4B Clock
	IN2	SPT1_ACLK_I	SPT5_ACLK_I	SPORT1A or SPORT5A Clock

Table 31-16: Clock Destination Registers (Group A) (Continued)

DAI Register	Bit Field Name	DAI0 Mapping	DAI1 Mapping	Description
	IN3	SPT1_BCLK_I	SPT5_BCLK_I	SPORT1B or SPORT5B Clock
	IN4	SPT2_ACLK_I	SPT6_ACLK_I	SPORT2A or SPORT6A Clock
	IN5	SPT2_BCLK_I	SPT6_BCLK_I	SPORT2B or SPORT6B Clock
DAI_CLK1	IN0	SRC0_CLK_IP_I	SRC4_CLK_IP_I	SRC0 or SRC4 Clock Input
	IN1	SRC0_CLK_OP_I	SRC4_CLK_OP_I	SRC0 or SRC4 Clock Output
	IN2	SRC1_CLK_IP_I	SRC5_CLK_IP_I	SRC1 or SRC5 Clock Input
	IN3	SRC1_CLK_OP_I	SRC5_CLK_OP_I	SRC1 or SRC5 Clock Output
	IN4	SRC2_CLK_IP_I	SRC6_CLK_IP_I	SRC2 or SRC6 Clock Input
	IN5	SRC2_CLK_OP_I	SRC6_CLK_OP_I	SRC2 or SRC6 Clock Output
DAI_CLK2	IN0	SRC3_CLK_IP_I	SRC7_CLK_IP_I	SRC3 or SRC7 Clock Input
	IN1	SRC3_CLK_OP_I	SRC7_CLK_OP_I	SRC3 or SRC7 Clock Output
	IN2	SPDIF0_TX_CLK_I	SPDIF1_TX_CLK_I	SPDIF0 or SPDIF1 TX Clock
	IN3	PDM0_CLK0_I	PDM1_CLK0_I	PDM0 or PDM1 Clock0 Input
	IN4	PDM0_BCLK_I	PDM1_BCLK_I	PDM0 or PDM1 Bit Clock Input
DAI_CLK3	IN5	SPDIF0_TX_HFCLK_I	SPDIF1_TX_HFCLK_I	SPDIF0 or SPDIF1 TX HF Clock
DAI_CLK4	IN0	PCG0_EXTCLKA_I	PCG0_EXTCLKC_I	PCG0 External Clock A or C
	IN1	PCG0_EXTCLKB_I	PCG0_EXTCLKD_I	PCG0 External Clock B or D
	IN3	SPDIF0_TX_EXT_SYNC_I	SPDIF1_TX_EXT_SYNC_I	SPDIF0 or SPDIF1 TX External Sync
	IN4	PCG0_SYNC_CLKA_I	PCG0_SYNC_CLKC_I	PCG0 Sync Clock A or C
	IN5	PCG0_SYNC_CLKB_I	PCG0_SYNC_CLKD_I	PCG0 Sync Clock B or D
DAI_CLK5	IN0	SPT3_ACLK_I	SPT7_ACLK_I	SPORT3A or SPORT 7A Clock
	IN1	SPT3_BCLK_I	SPT7_BCLK_I	SPORT3B or SPORT 7B Clock
	IN2	PCG0_SYNC_CLKE_I	PCG0_SYNC_CLKG_I	PCG0 Sync Clock E or G
	IN3	PCG0_SYNC_CLKF_I	PCG0_SYNC_CLKH_I	PCG0 Sync Clock F or H
	IN4	PCG0_EXTCLKE_I	PCG0_EXTCLKG_I	PCG0 External Clock E or G
	IN5	PCG0_EXTCLKF_I	PCG0_EXTCLKH_I	PCG0 External Clock F or H

Table 31-17: Data Destination Registers (Group B)

DAI Register	Bit Field Name	DAI0 Mapping	DAI1 Mapping	Description
DAI_DAT0	IN0	SPT0_AD0_I	SPT4_AD0_I	SPORT0A or SPORT4A Primary Data
	IN1	SPT0_AD1_I	SPT4_AD1_I	SPORT0A or SPORT4A Secondary Data
	IN2	SPT0_BD0_I	SPT4_BD0_I	SPORT0B or SPORT4B Primary Data
	IN3	SPT0_BD1_I	SPT4_BD1_I	SPORT0B or SPORT4B Secondary Data
	IN4	SPT1_AD0_I	SPT5_AD0_I	SPORT1A or SPORT5A Primary Data
DAI_DAT1	IN0	SPT1_AD1_I	SPT5_AD1_I	SPORT1A or SPORT5A Secondary Data
	IN1	SPT1_BD0_I	SPT5_BD0_I	SPORT1B or SPORT5B Primary Data
	IN2	SPT1_BD1_I	SPT5_BD1_I	SPORT1B or SPORT5B Secondary Data
	IN3	SPT2_AD0_I	SPT6_AD0_I	SPORT2A or SPORT6A Primary Data
	IN4	SPT2_AD1_I	SPT6_AD1_I	SPORT2A or SPORT6A Secondary Data
DAI_DAT2	IN0	SPT2_BD0_I	SPT6_BD0_I	SPORT2B or SPORT6B Primary Data
	IN1	SPT2_BD1_I	SPT6_BD1_I	SPORT2B or SPORT6B Secondary Data
	IN2	SRC0_DAT_IP_I	SRC4_DAT_IP_I	SRC0 or SRC4 Data
	IN3	SRC1_DAT_IP_I	SRC5_DAT_IP_I	SRC1 or SRC5 Data
	IN4	SRC2_DAT_IP_I	SRC6_DAT_IP_I	SRC2 or SRC6 Data
DAI_DAT3	IN0	SRC3_DAT_IP_I	SRC7_DAT_IP_I	SRC3 or SRC7 Data
	IN1	SRC0_DAT_TDM_OP_I	SRC4_DAT_TDM_OP_I	SRC0 or SRC4 TDM output port
	IN2	SRC1_DAT_TDM_OP_I	SRC5_DAT_TDM_OP_I	SRC1 or SRC5 TDM Output port Data
	IN3	SRC2_DAT_TDM_OP_I	SRC6_DAT_TDM_OP_I	SRC2 or SRC6 TDM Output port Data
	IN4	SRC3_DAT_TDM_OP_I	SRC7_DAT_TDM_OP_I	SRC3 or SRC7 TDM Output port Data
DAI_DAT4	IN0	SPDIF0_TX_DAT_I	SPDIF1_TX_DAT_I	SPDIF0 or SPDIF1 serial transmitter Data
	IN1	PDM0_DAT0_I	PDM1_DAT0_I	PDM0 or PDM1 Data0 Input
	IN2	PDM0_DAT1_I	PDM1_DAT1_I	PDM0 or PDM1 Data1 Input

Table 31-17: Data Destination Registers (Group B) (Continued)

DAI Register	Bit Field Name	DAI0 Mapping	DAI1 Mapping	Description
DAI_DAT5	IN4	SPDIF0_RX_I	SPDIF1_RX_I	SPDIF0 or SPDIF1 receiver bi-phase Data
DAI_DAT6	IN0	SPT3_AD0_I	SPT7_AD0_I	SPORT3A or SPORT7A Primary Data
	IN1	SPT3_AD1_I	SPT7_AD1_I	SPORT3A or SPORT7A Secondary Data
	IN2	SPT3_BD0_I	SPT7_BD0_I	SPORT3B or SPORT7B Primary Data
	IN3	SPT3_BD1_I	SPT7_BD1_I	SPORT3B or SPORT7B Secondary Data
	IN4	Reserved	Reserved	

Table 31-18: Frame Sync Destination Registers (Group C)

DAI Register	Bit Field Name	DAI0 Mapping	DAI1 Mapping	Description
DAI_FS0	IN0	SPT0_AFS_I	SPT4_AFS_I	SPORT0A or SPORT4A Frame Sync
	IN1	SPT0_BFS_I	SPT4_BFS_I	SPORT0B or SPORT4B Frame Sync
	IN2	SPT1_AFS_I	SPT5_AFS_I	SPORT1A or SPORT5A Frame Sync
	IN3	SPT1_BFS_I	SPT5_BFS_I	SPORT1B or SPORT5B Frame Sync
	IN4	SPT2_AFS_I	SPT6_AFS_I	SPORT2A or SPORT6A Frame Sync
	IN5	SPT2_BFS_I	SPT6_BFS_I	SPORT2B or SPORT6B Frame Sync
DAI_FS1	IN0	SRC0_FS_IP_I	SRC4_FS_IP_I	SRC0 or SRC4 Frame Sync Input
	IN1	SRC0_FS_OP_I	SRC4_FS_OP_I	SRC0 or SRC4 Frame Sync Output
	IN2	SRC1_FS_IP_I	SRC5_FS_IP_I	SRC1 or SRC5 Frame Sync Input
	IN3	SRC1_FS_OP_I	SRC5_FS_OP_I	SRC1 or SRC5 Frame Sync Output
	IN4	SRC2_FS_IP_I	SRC6_FS_IP_I	SRC2 or SRC6 Frame Sync Input
	IN5	SRC2_FS_OP_I	SRC6_FS_OP_I	SRC2 or SRC6 Frame Sync Output
DAI_FS2	IN0	SRC3_FS_IP_I	SRC7_FS_IP_I	SRC3 or SRC7 Frame Sync Input
	IN1	SRC3_FS_OP_I	SRC7_FS_OP_I	SRC3 or SRC7 Frame Sync Output
	IN2	SPDIF0_TX_FS_I	SPDIF1_TX_FS_I	SPDIF0 or SPDIF1 Transmit Frame Sync

Table 31-18: Frame Sync Destination Registers (Group C) (Continued)

DAI Register	Bit Field Name	DAI0 Mapping	DAI1 Mapping	Description
DAI_FS4	IN0	SPT3_AFS_I	SPT7_AFS_I	SPORT3A or SPORT7A Frame Sync
	IN1	SPT3_BFS_I	SPT7_BFS_I	SPORT3B or SPORT7B Frame Sync
	IN2	TM0_ACI14_I	TM0_ACI15_I	ACI 14 or ACI 15 Timer Input
	IN3	PDM0_LRCLK_I	PDM1_LRCLK_I	PDM0 or PDM1 Left/Right Clock or Frame Sync Input

Table 31-19: Pin Buffer Assignment Destination Registers (Group D)

DAI Register	Bit Field Name	DAI0 Mapping	DAI1 Mapping	Description
DAI_PIN0	IN0	DAI0_PB01_I	DAI1_PB01_I	Pin Buffer 1
	IN1	DAI0_PB02_I	DAI1_PB02_I	Pin Buffer 2
	IN2	DAI0_PB03_I	DAI1_PB03_I	Pin Buffer 3
	IN3	DAI0_PB04_I	DAI1_PB04_I	Pin Buffer 4
DAI_PIN1	IN0	DAI0_PB05_I	DAI1_PB05_I	Pin Buffer 5
	IN1	DAI0_PB06_I	DAI1_PB06_I	Pin Buffer 6
	IN2	DAI0_PB07_I	DAI1_PB07_I	Pin Buffer 7
	IN3	DAI0_PB08_I	DAI1_PB08_I	Pin Buffer 8
DAI_PIN2	IN0	DAI0_PB09_I	DAI1_PB09_I	Pin Buffer 9
	IN1	DAI0_PB10_I	DAI1_PB10_I	Pin Buffer 10
	IN2	DAI0_PB11_I	DAI1_PB11_I	Pin Buffer 11
	IN3	DAI0_PB12_I	DAI1_PB12_I	Pin Buffer 12
DAI_PIN3	IN0	DAI0_PB13_I	DAI1_PB13_I	Pin Buffer 13
	IN1	DAI0_PB14_I	DAI1_PB14_I	Pin Buffer 14
	IN2	DAI0_PB15_I	DAI1_PB15_I	Pin Buffer 15
	IN3	DAI0_PB16_I	DAI1_PB16_I	Pin Buffer 16
DAI_PIN4	IN0	DAI0_PB17_I	DAI1_PB17_I	Pin Buffer 17
	IN1	DAI0_PB18_I	DAI1_PB18_I	Pin Buffer 18
	IN2	DAI0_PB19_I	DAI1_PB19_I	Pin Buffer 19
	IN3	DAI0_PB20_I	DAI1_PB20_I	Pin Buffer 20
	IN4	INV_DAI0_PB19_I	INV_DAI1_PB19_I	Inverted Pin Buffer 19
	IN5	INV_DAI0_PB20_I	INV_DAI1_PB20_I	Inverted Pin Buffer 20

In #c_dai_RegisterDescriptions_NotYoda_2156x/MiscControlDestinationRegistersGroupE , DAI_MISCAx_I is an alias name for DAI_INT_x_I.

Table 31-20: Miscellaneous Control Destination Registers (Group E)

DAI Register	Bit Field Name	DAI0 Mapping	DAI1 Mapping	Description
DAI_MISC0	IN6	DAI0_MISCA0_I/ DAI0_INT_6_I	DAI1_MISCA0_I/ DAI1_INT_6_I	DAIx miscellaneous A0 input, or DAIx interrupt 28
	IN7	DAI0_MISCA1_I/ DAI0_INT_7_I	DAI1_MISCA1_I/ DAI1_INT_7_I	DAIx miscellaneous A1 input, or DAIx interrupt 29
	IN8	DAI0_MISCA2_I/ DAI0_INT_8_I	DAI1_MISCA2_I/ DAI1_INT_8_I	DAIx miscellaneous A2 input, or DAIx interrupt 30
	IN9	DAI0_MISCA3_I/ DAI0_INT_9_I	DAI1_MISCA3_I/ DAI1_INT_9_I	DAIx miscellaneous A3 input, or DAIx interrupt 31
	IN10	DAI0_MISCA4_I	DAI1_MISCA4_I	DAIx miscellaneous A4 input
	IN11	DAI0_MISCA5_I	DAI1_MISCA5_I	DAIx miscellaneous A5 input
	IN10	DAI0_INV_MISCA4_I	DAI1_INV_MISCA4_I	DAIx inverted miscellaneous A4 input
	IN11	DAI0_INV_MISCA4_I	DAI1_INV_MISCA5_I	DAIx inverted miscellaneous A5 input
DAI_MISC1	IN0	DAI0_INT_0	DAI1_INT_0	DAIx interrupt 22
	IN1	DAI0_INT_1	DAI1_INT_1	DAIx interrupt 23
	IN2	DAI0_INT_2	DAI1_INT_2	DAIx interrupt 24
	IN3	DAI0_INT_3	DAI1_INT_3	DAIx interrupt 25
	IN4	DAI0_INT_4	DAI1_INT_4	DAIx interrupt 26
	IN5	DAI0_INT_5	DAI1_INT_5	DAIx interrupt 27
DAI_MISC2	IN0	PCG_HWA_TRIG_I	PCG_HWC_TRIG_I	PCG hardware trigger input A or C
	IN1	PCG_HWB_TRIG_I	PCG_HWD_TRIG_I	PCG hardware trigger input B or D
	IN2	PCG_HWE_TRIG_I	PCG_HWG_TRIG_I	PCG hardware trigger input E or G
	IN3	PCG_HWF_TRIG_I	PCG_HWH_TRIG_I	PCG hardware trigger input A or C

Table 31-21: Pin Buffer Enable Destination Registers (Group F)

DAI Register	Bit Field Name	DAI0 Mapping	DAI1 Mapping	Description
DAI_PBEN0	IN0	DAI0_PBEN01_I	DAI1_PBEN01_I	Pin Buffer 1 Enable
	IN1	DAI0_PBEN02_I	DAI1_PBEN02_I	Pin Buffer 2 Enable
	IN2	DAI0_PBEN03_I	DAI1_PBEN03_I	Pin Buffer 3 Enable
	IN3	DAI0_PBEN04_I	DAI1_PBEN04_I	Pin Buffer 4 Enable
	IN4	DAI0_PBEN05_I	DAI1_PBEN05_I	Pin Buffer 5 Enable
DAI_PBEN1	IN0	DAI0_PBEN06_I	DAI1_PBEN06_I	Pin Buffer 6 Enable
	IN1	DAI0_PBEN07_I	DAI1_PBEN07_I	Pin Buffer 7 Enable
	IN2	DAI0_PBEN08_I	DAI1_PBEN08_I	Pin Buffer 8 Enable
	IN3	DAI0_PBEN09_I	DAI1_PBEN09_I	Pin Buffer 9 Enable
	IN4	DAI0_PBEN10_I	DAI1_PBEN10_I	Pin Buffer 10 Enable
DAI_PBEN2	IN0	DAI0_PBEN11_I	DAI1_PBEN11_I	Pin Buffer 11 Enable
	IN1	DAI0_PBEN12_I	DAI1_PBEN12_I	Pin Buffer 12 Enable
	IN2	DAI0_PBEN13_I	DAI1_PBEN13_I	Pin Buffer 13 Enable
	IN3	DAI0_PBEN14_I	DAI1_PBEN14_I	Pin Buffer 14 Enable
	IN4	DAI0_PBEN15_I	DAI1_PBEN15_I	Pin Buffer 15 Enable
DAI_PBEN3	IN0	DAI0_PBEN16_I	DAI1_PBEN16_I	Pin Buffer 16 Enable
	IN1	DAI0_PBEN17_I	DAI1_PBEN17_I	Pin Buffer 17 Enable
	IN2	DAI0_PBEN18_I	DAI1_PBEN18_I	Pin Buffer 18 Enable
	IN3	DAI0_PBEN19_I	DAI1_PBEN19_I	Pin Buffer 19 Enable
	IN4	DAI0_PBEN20_I	DAI1_PBEN20_I	Pin Buffer 20 Enable

The ***Interrupt Events*** table presents the information for the following registers.

- DAI_IMSK_PRI (Core Interrupt Priority Assignment) register
- DAI_IMSK_FE (Falling-Edge Interrupt Mask) and DAI_IMSK_RE (Rising-Edge Interrupt Mask) registers
- DAI_IRPTL_H (High-Priority Interrupt Latch) and DAI_IRPTL_L (Low-Priority Interrupt Latch) registers
- DAI_IRPTL_HS (Shadow High Interrupt Latch) and DAI_IRPTL_LS (Shadow Low Interrupt Latch) registers

Table 31-22: Interrupt Events

Bit Field Name	DAI0 Mapping	DAI1 Mapping	Description
RXVALID	SPDIF0_RXVALID_INT	SPDIF1_RXVALID_INT	SPDIF0 or SPDIF1 RX Valid interrupt

Table 31-22: Interrupt Events (Continued)

Bit Field Name	DAI0 Mapping	DAI1 Mapping	Description
RXLOCK	SPDIF0_RXLOCK_INT	SPDIF1_RXLOCK_INT	SPDIF0 or SPDIF1 RX Lock interrupt
RXLOSSOFLOCK	SPDIF0_RXLOSSOFLOCK_INT	SPDIF1_RXLOSSOFLOCK_INT	SPDIF0 or SPDIF1 RX Loss of Lock interrupt
RXNONAUDIO	SPDIF0_RXNONAUDIO_INT	SPDIF1_RXNONAUDIO_INT	SPDIF0 or SPDIF1 RX Non-audio interrupt
SRC0MUTE	SRC0_MUTE_INT	SRC4_MUTE_INT	DAI0 or DAI1 ASRC0 Mute interrupt
SRC1MUTE	SRC1_MUTE_INT	SRC5_MUTE_INT	DAI0 or DAI1 ASRC1 Mute interrupt
SRC2MUTE	SRC2_MUTE_INT	SRC6_MUTE_INT	DAI0 or DAI1 ASRC2 Mute interrupt
SRC3MUTE	SRC3_MUTE_INT	SRC7_MUTE_INT	DAI0 or DAI1 ASRC3 Mute interrupt
MISCINT0	DAI0_INT_00	DAI1_INT_00	DAI0 or DAI1 Miscellaneous Interrupt 0
MISCINT1	DAI0_INT_01	DAI1_INT_01	DAI0 or DAI1 Miscellaneous Interrupt 1
MISCINT2	DAI0_INT_02	DAI1_INT_02	DAI0 or DAI1 Miscellaneous Interrupt 2
MISCINT3	DAI0_INT_03	DAI1_INT_03	DAI0 or DAI1 Miscellaneous Interrupt 3
MISCINT4	DAI0_INT_04	DAI1_INT_04	DAI0 or DAI1 Miscellaneous Interrupt 4
MISCINT5	DAI0_INT_05	DAI1_INT_05	DAI0 or DAI1 Miscellaneous Interrupt 5
MISCINT6	DAI0_EXTMISCA0_INT/ DAI0_INT_06	DAI1_EXTMISCA0_INT/ DAI1_INT_06	DAI0 or DAI1 Miscellaneous Interrupt 6 / External Miscellaneous A0 Interrupt
MISCINT7	DAI0_EXTMISCA1_INT/ DAI0_INT_07	DAI1_EXTMISCA1_INT/ DAI1_INT_07	DAI0 or DAI1 Miscellaneous Interrupt 7 / External Miscellaneous A1 Interrupt
MISCINT8	DAI0_EXTMISCA2_INT/ DAI0_INT_08	DAI1_EXTMISCA2_INT/ DAI1_INT_08	DAI0 or DAI1 Miscellaneous Interrupt 8 / External Miscellaneous A2 Interrupt
MISCINT9	DAI0_EXTMISCA3_INT/ DAI0_INT_09	DAI1_EXTMISCA3_INT/ DAI1_INT_09	DAI0 or DAI1 Miscellaneous Interrupt 9 / External Miscellaneous A3 Interrupt

SPORT Grouping with DAI

DAI supports two registers DAI_GBL_SP_EN and DAI_GBL_INT_EN to group enabling/disabling and interrupt/trigger generation/reception for multiple SPORTs.

For more information about this, refer to the Grouping of SPORTs section.

Global PCG Enable

The DAI module includes the DAI_GBL_PCG_EN register that enables and disables multiple PCGs globally at the same time. For more information, see Global PCG Enable section in the PCG chapter.

ADSP-SC59x DAI Register Descriptions

The Digital Audio Interface (DAIn) registers are used to configure DAI destinations for the DAI sources shown in the Group A - F Routing tables. (DAI) contains the following registers.

Table 31-23: ADSP-SC59x DAI Register List

Name	Description
DAI_CLK0	Clock Routing Control Register 0
DAI_CLK1	Clock Routing Control Register 1
DAI_CLK2	Clock Routing Control Register 2
DAI_CLK3	Clock Routing Control Register 3
DAI_CLK4	Clock Routing Control Register 4
DAI_CLK5	Clock Routing Control Register 5
DAI_DAT0	Serial Data Routing Control Register 0
DAI_DAT1	Serial Data Routing Control Register 1
DAI_DAT2	Serial Data Routing Control Register 2
DAI_DAT3	Serial Data Routing Control Register 3
DAI_DAT4	Serial Data Routing Control Register 4
DAI_DAT5	Serial Data Routing Control Register 5
DAI_DAT6	Serial Data Routing Control Register 6
DAI_EXTD_CLK0	Extended Clock Routing Control Register 0
DAI_EXTD_CLK1	Extended Clock Routing Control Register 1
DAI_EXTD_CLK2	Extended Clock Routing Control Register 2
DAI_EXTD_CLK3	Extended Clock Routing Control Register 3
DAI_EXTD_CLK4	Extended Clock Routing Control Register 4

Table 31-23: ADSP-SC59x DAI Register List (Continued)

Name	Description
DAI_EXTD_CLK5	Extended Clock Routing Control Register 5
DAI_EXTD_DAT0	Extended Serial Data Routing Control Register 0
DAI_EXTD_DAT1	Extended Serial Data Routing Control Register 1
DAI_EXTD_DAT2	Extended Serial Data Routing Control Register 2
DAI_EXTD_DAT3	Extended Serial Data Routing Control Register 3
DAI_EXTD_DAT4	Extended Serial Data Routing Control Register 4
DAI_EXTD_DAT5	Extended Serial Data Routing Control Register 5
DAI_EXTD_DAT6	Extended Serial Data Routing Control Register 6
DAI_EXTD_FS0	Extended Frame Sync Routing Control Register 0
DAI_EXTD_FS1	Extended Frame Sync Routing Control Register 1
DAI_EXTD_FS2	Extended Frame Sync Routing Control Register 2
DAI_EXTD_FS4	Extended Frame Sync Routing Control Register 4
DAI_EXTD_MISC0	Extended Miscellaneous Control Register 0
DAI_EXTD_MISC1	Extended Miscellaneous Control Register 1
DAI_EXTD_MISC2	Extended Miscellaneous Control Register 2
DAI_EXTD_PBEN0	Extended Pin Buffer Enable Register 0
DAI_EXTD_PBEN1	Extended Pin Buffer Enable Register 1
DAI_EXTD_PBEN2	Extended Pin Buffer Enable Register 2
DAI_EXTD_PBEN3	Extended Pin Buffer Enable Register 3
DAI_EXTD_PIN0	Extended Pin Buffer Assignment Register 0
DAI_EXTD_PIN1	Extended Pin Buffer Assignment Register 1
DAI_EXTD_PIN2	Extended Pin Buffer Assignment Register 2
DAI_EXTD_PIN3	Extended Pin Buffer Assignment Register 3
DAI_EXTD_PIN4	Extended Pin Buffer Assignment Register 4
DAI_FS0	Frame Sync Routing Control Register 0
DAI_FS1	Frame Sync Routing Control Register 1
DAI_FS2	Frame Sync Routing Control Register 2
DAI_FS4	Frame Sync Routing Control Register 4
DAI_GBL_INT_EN	Global SPORT Interrupt Grouping Register
DAI_GBL_PCG_EN	Global PCG Enable Control Register
DAI_GBL_SP_EN	Global SPORT Enable Register

Table 31-23: ADSP-SC59x DAI Register List (Continued)

Name	Description
DAI_IMSK_FE	Falling-Edge Interrupt Mask Register
DAI_IMSK_PRI	Core Interrupt Priority Assignment Register
DAI_IMSK_RE	Rising-Edge Interrupt Mask Register
DAI_IRPTL_H	High Priority Interrupt Latch Register
DAI_IRPTL_HS	Shadow High Priority Interrupt Latch Register
DAI_IRPTL_L	Low Priority Interrupt Latch Register
DAI_IRPTL_LS	Shadow Low Priority Interrupt Latch Register
DAI_MISC0	Miscellaneous Control Register 0
DAI_MISC1	Miscellaneous Control Register 1
DAI_MISC2	Miscellaneous Control Register 1
DAI_PBEN0	Pin Buffer Enable Register 0
DAI_PBEN1	Pin Buffer Enable Register 1
DAI_PBEN2	Pin Buffer Enable Register 2
DAI_PBEN3	Pin Buffer Enable Register 3
DAI_PIN0	Pin Buffer Assignment Register 0
DAI_PIN1	Pin Buffer Assignment Register 1
DAI_PIN2	Pin Buffer Assignment Register 2
DAI_PIN3	Pin Buffer Assignment Register 3
DAI_PIN4	Pin Buffer Assignment Register 4
DAI_PIN_STAT	Pin Status Register

Clock Routing Control Register 0

The DAI_CLK0 register provides clock routing connections for the serial ports (SPORTs).

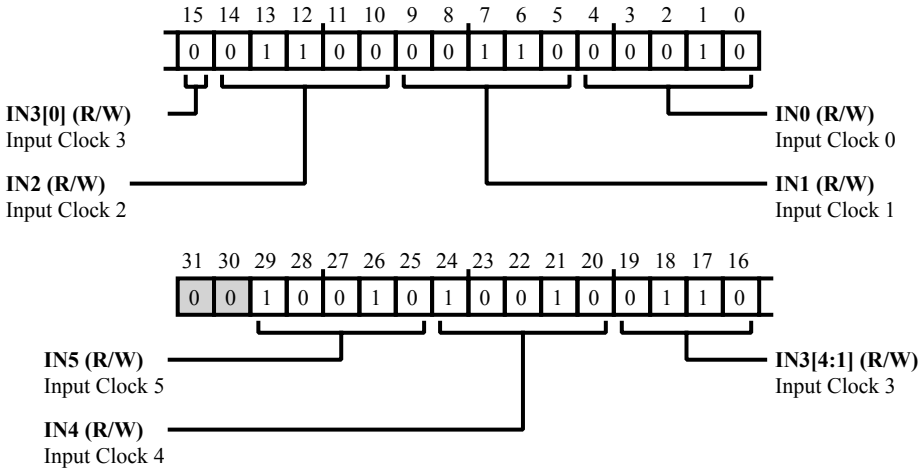

Figure 31-14: DAI_CLK0 Register Diagram

Table 31-24: DAI_CLK0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:25 (R/W)	IN5	Input Clock 5. DAI_CLK0.IN5 holds the Source signal assignment that will be routed to the DAI_CLK0.IN5 Destination. Refer to the Group A Signals table for Source and Destination mappings
24:20 (R/W)	IN4	Input Clock 4. DAI_CLK0.IN4 holds the Source signal assignment that will be routed to the DAI_CLK0.IN4 Destination. Refer to the Group A Signals table for Source and Destination mappings
19:15 (R/W)	IN3	Input Clock 3. DAI_CLK0.IN3 holds the Source signal assignment that will be routed to the DAI_CLK0.IN3 Destination. Refer to the Group A Signals table for Source and Destination mappings
14:10 (R/W)	IN2	Input Clock 2. DAI_CLK0.IN2 holds the Source signal assignment that will be routed to the DAI_CLK0.IN2 Destination. Refer to the Group A Signals table for Source and Destination mappings
9:5 (R/W)	IN1	Input Clock 1. DAI_CLK0.IN1 holds the Source signal assignment that will be routed to the DAI_CLK0.IN1 Destination. Refer to the Group A Signals table for Source and Destination mappings

Table 31-24: DAI_CLK0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
4:0 (R/W)	IN0	Input Clock 0. `DAI_CLK0.IN0` holds the Source signal assignment that will be routed to the `DAI_CLK0.IN0` Destination. Refer to the Group A Signals table for Source and Destination mappings

Clock Routing Control Register 1

The DAI_CLK1 register provides clock routing connections for the asynchronous sample rate converters (ASRC).

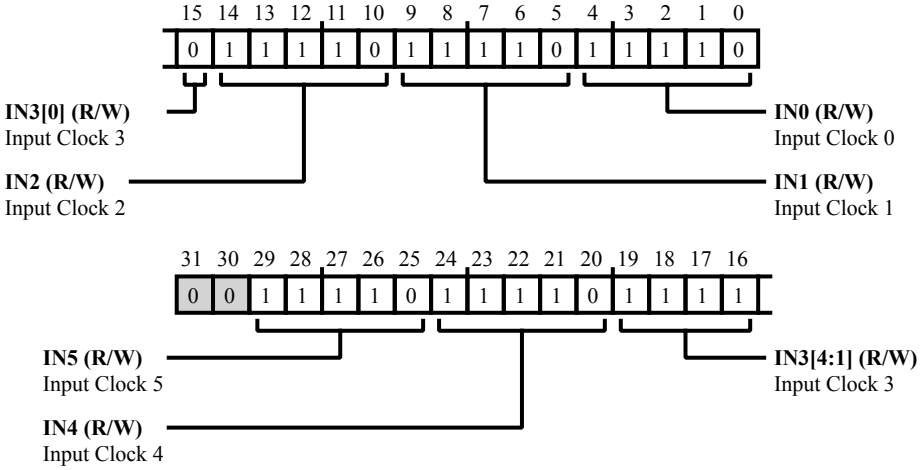

Figure 31-15: DAI_CLK1 Register Diagram

Table 31-25: DAI_CLK1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:25 (R/W)	IN5	Input Clock 5. DAI_CLK1.IN5 holds the Source signal assignment that will be routed to the DAI_CLK1.IN5 Destination. Refer to the Group A Signals table for Source and Destination mappings
24:20 (R/W)	IN4	Input Clock 4. DAI_CLK1.IN4 holds the Source signal assignment that will be routed to the DAI_CLK1.IN4 Destination. Refer to the Group A Signals table for Source and Destination mappings
19:15 (R/W)	IN3	Input Clock 3. DAI_CLK1.IN3 holds the Source signal assignment that will be routed to the DAI_CLK1.IN3 Destination. Refer to the Group A Signals table for Source and Destination mappings
14:10 (R/W)	IN2	Input Clock 2. DAI_CLK1.IN2 holds the Source signal assignment that will be routed to the DAI_CLK1.IN2 Destination. Refer to the Group A Signals table for Source and Destination mappings
9:5 (R/W)	IN1	Input Clock 1. DAI_CLK1.IN1 holds the Source signal assignment that will be routed to the DAI_CLK1.IN1 Destination. Refer to the Group A Signals table for Source and Destination mappings.

Table 31-25: DAI_CLK1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
4:0 (R/W)	IN0	Input Clock 0. `DAI_CLK1.IN0` holds the Source signal assignment that will be routed to the `DAI_CLK1.IN0` Destination. Refer to the Group A Signals table for Source and Destination mappings.

Clock Routing Control Register 2

The DAI_CLK2 register provides clock routing connections for the S/PDIF and ASRC.

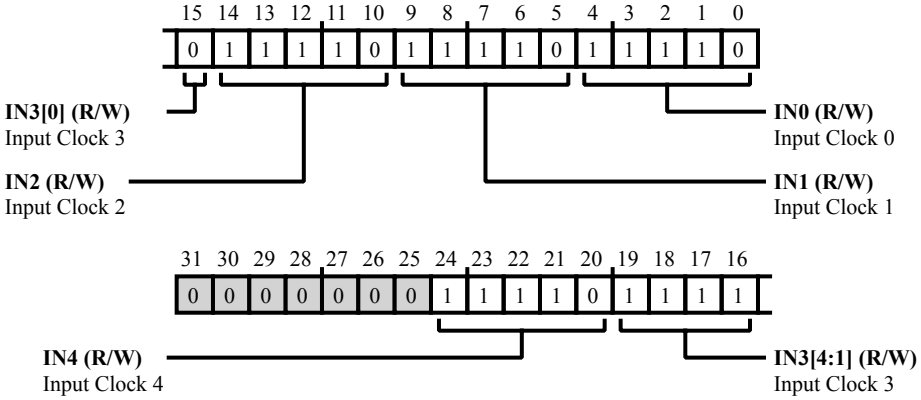

Figure 31-16: DAI_CLK2 Register Diagram

Table 31-26: DAI_CLK2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
24:20 (R/W)	IN4	Input Clock 4. DAI_CLK2.IN4 holds the Source signal assignment that will be routed to the DAI_CLK2.IN4 Destination. Refer to the Group A Signals table for Source and Destination mappings.
19:15 (R/W)	IN3	Input Clock 3. DAI_CLK2.IN3 holds the Source signal assignment that will be routed to the DAI_CLK2.IN3 Destination. Refer to the Group A Signals table for Source and Destination mappings.
14:10 (R/W)	IN2	Input Clock 2. DAI_CLK2.IN2 holds the Source signal assignment that will be routed to the DAI_CLK2.IN2 Destination. Refer to the Group A Signals table for Source and Destination mappings.
9:5 (R/W)	IN1	Input Clock 1. DAI_CLK2.IN1 holds the Source signal assignment that will be routed to the DAI_CLK2.IN1 Destination. Refer to the Group A Signals table for Source and Destination mappings.
4:0 (R/W)	IN0	Input Clock 0. DAI_CLK2.IN0 holds the Source signal assignment that will be routed to the DAI_CLK2.IN0 Destination. Refer to the Group A Signals table for Source and Destination mappings.

Clock Routing Control Register 3

The DAI_CLK3 register provides clock routing connections for the S/PDIF.

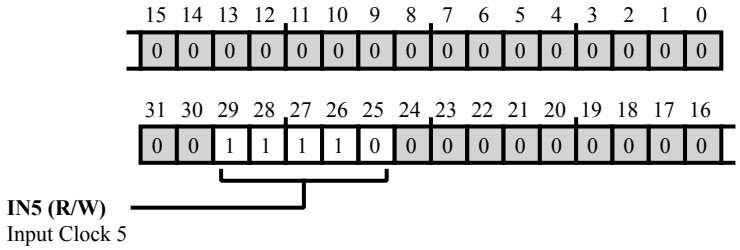

Figure 31-17: DAI_CLK3 Register Diagram

Table 31-27: DAI_CLK3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:25 (R/W)	IN5	Input Clock 5. The DAI_CLK3.IN5 bit field provides the S/PDIF oversampling clock.

Clock Routing Control Register 4

The DAI_CLK4 register provides clock routing connections for the precision clock generators (PCGs).

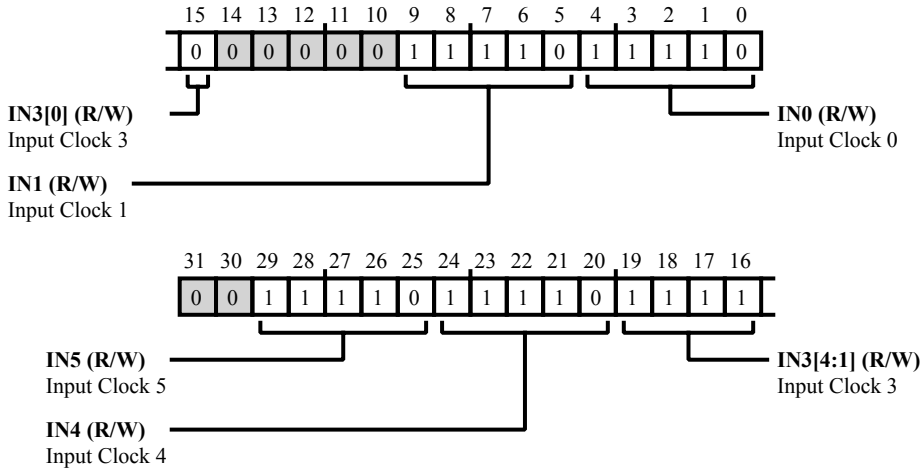

Figure 31-18: DAI_CLK4 Register Diagram

Table 31-28: DAI_CLK4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:25 (R/W)	IN5	Input Clock 5. DAI_CLK4.IN5 holds the Source signal assignment that will be routed to the DAI_CLK4.IN5 Destination. Refer to the Group A Signals table for Source and Destination mappings.
24:20 (R/W)	IN4	Input Clock 4. DAI_CLK4.IN4 holds the Source signal assignment that will be routed to the DAI_CLK4.IN4 Destination. Refer to the Group A Signals table for Source and Destination mappings.
19:15 (R/W)	IN3	Input Clock 3. DAI_CLK4.IN3 holds the Source signal assignment that will be routed to the DAI_CLK4.IN3 Destination. Refer to the Group A Signals table for Source and Destination mappings.
9:5 (R/W)	IN1	Input Clock 1. DAI_CLK4.IN1 holds the Source signal assignment that will be routed to the DAI_CLK4.IN1 Destination. Refer to the Group A Signals table for Source and Destination mappings.
4:0 (R/W)	IN0	Input Clock 0. DAI_CLK4.IN0 holds the Source signal assignment that will be routed to the DAI_CLK4.IN0 Destination. Refer to the Group A Signals table for Source and Destination mappings.

Clock Routing Control Register 5

The DAI_CLK5 register provides clock routing connections for the serial ports.

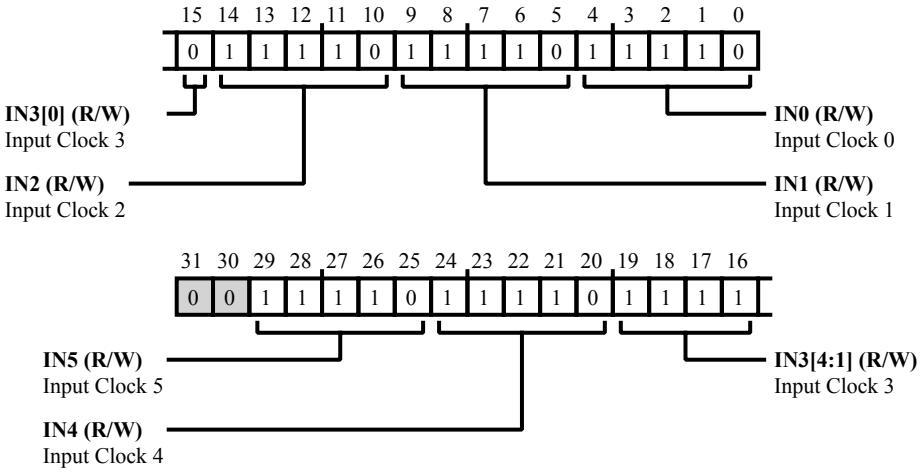

Figure 31-19: DAI_CLK5 Register Diagram

Table 31-29: DAI_CLK5 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:25 (R/W)	IN5	Input Clock 5. DAI_CLK5.IN5 holds the Source signal assignment that will be routed to the DAI_CLK5.IN5 Destination. Refer to the Group A Signals table for Source and Destination mappings.
24:20 (R/W)	IN4	Input Clock 4. DAI_CLK5.IN4 holds the Source signal assignment that will be routed to the DAI_CLK5.IN4 Destination. Refer to the Group A Signals table for Source and Destination mappings.
19:15 (R/W)	IN3	Input Clock 3. DAI_CLK5.IN3 holds the Source signal assignment that will be routed to the DAI_CLK5.IN3 Destination. Refer to the Group A Signals table for Source and Destination mappings.
14:10 (R/W)	IN2	Input Clock 2. DAI_CLK5.IN2 holds the Source signal assignment that will be routed to the DAI_CLK5.IN2 Destination. Refer to the Group A Signals table for Source and Destination mappings.
9:5 (R/W)	IN1	Input Clock 1. DAI_CLK5.IN1 holds the Source signal assignment that will be routed to the DAI_CLK5.IN1 Destination. Refer to the Group A Signals table for Source and Destination mappings.

Table 31-29: DAI_CLK5 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
4:0 (R/W)	IN0	Input Clock 0. `DAI_CLK5.IN0` holds the Source signal assignment that will be routed to the `DAI_CLK5.IN0` Destination. Refer to the Group A Signals table for Source and Destination mappings.

Serial Data Routing Control Register 0

The DAI_DAT0 register routes serial data to the serial ports.

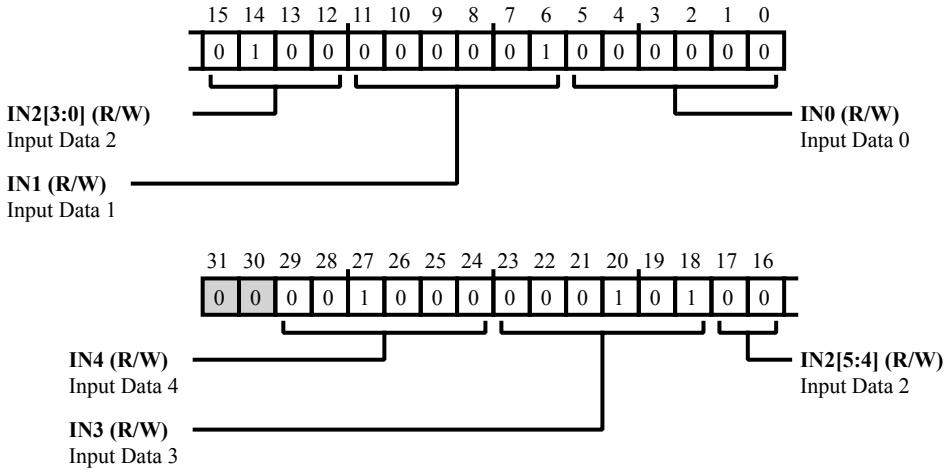

Figure 31-20: DAI_DAT0 Register Diagram

Table 31-30: DAI_DAT0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:24 (R/W)	IN4	Input Data 4. DAI_DAT0.IN4 holds the Source signal assignment that will be routed to the DAI_DAT0.IN4 Destination. Refer to the Group B Signals table for Source and Destination mappings.
23:18 (R/W)	IN3	Input Data 3. DAI_DAT0.IN3 holds the Source signal assignment that will be routed to the DAI_DAT0.IN3 Destination. Refer to the Group B Signals table for Source and Destination mappings.
17:12 (R/W)	IN2	Input Data 2. DAI_DAT0.IN2 holds the Source signal assignment that will be routed to the DAI_DAT0.IN2 Destination. Refer to the Group B Signals table for Source and Destination mappings.
11:6 (R/W)	IN1	Input Data 1. DAI_DAT0.IN1 holds the Source signal assignment that will be routed to the DAI_DAT0.IN1 Destination. Refer to the Group B Signals table for Source and Destination mappings.
5:0 (R/W)	IN0	Input Data 0. DAI_DAT0.IN0 holds the Source signal assignment that will be routed to the DAI_DAT0.IN0 Destination. Refer to the Group B Signals table for Source and Destination mappings.

Serial Data Routing Control Register 1

The DAI_DAT1 register routes serial data to the serial ports.

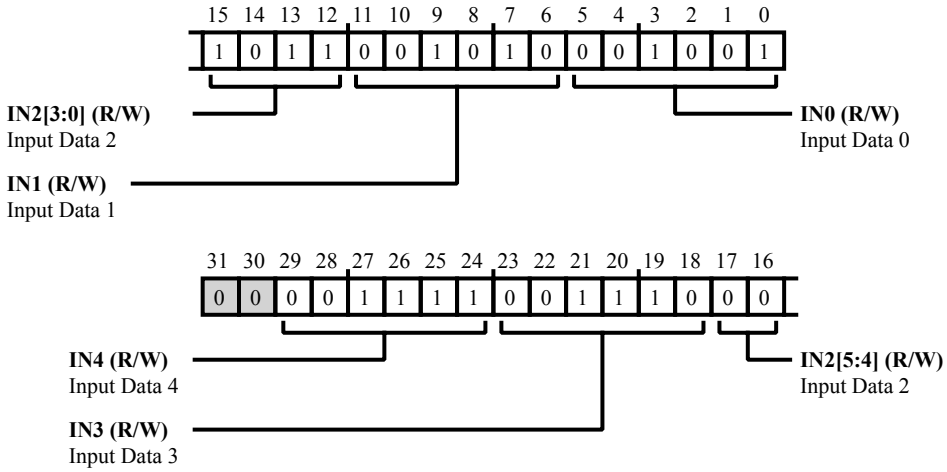

Figure 31-21: DAI_DAT1 Register Diagram

Table 31-31: DAI_DAT1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:24 (R/W)	IN4	Input Data 4. DAI_DAT1.IN4 holds the Source signal assignment that will be routed to the DAI_DAT1.IN4 Destination. Refer to the Group B Signals table for Source and Destination mappings.
23:18 (R/W)	IN3	Input Data 3. DAI_DAT1.IN3 holds the Source signal assignment that will be routed to the DAI_DAT1.IN3 Destination. Refer to the Group B Signals table for Source and Destination mappings.
17:12 (R/W)	IN2	Input Data 2. DAI_DAT1.IN2 holds the Source signal assignment that will be routed to the DAI_DAT1.IN2 Destination. Refer to the Group B Signals table for Source and Destination mappings.
11:6 (R/W)	IN1	Input Data 1. DAI_DAT1.IN1 holds the Source signal assignment that will be routed to the DAI_DAT1.IN1 Destination. Refer to the Group B Signals table for Source and Destination mappings.
5:0 (R/W)	IN0	Input Data 0. DAI_DAT1.IN0 holds the Source signal assignment that will be routed to the DAI_DAT1.IN0 Destination. Refer to the Group B Signals table for Source and Destination mappings.

Serial Data Routing Control Register 2

The DAI_DAT2 register routes serial data to the serial ports and the asynchronous sample rate converter (ASRC).

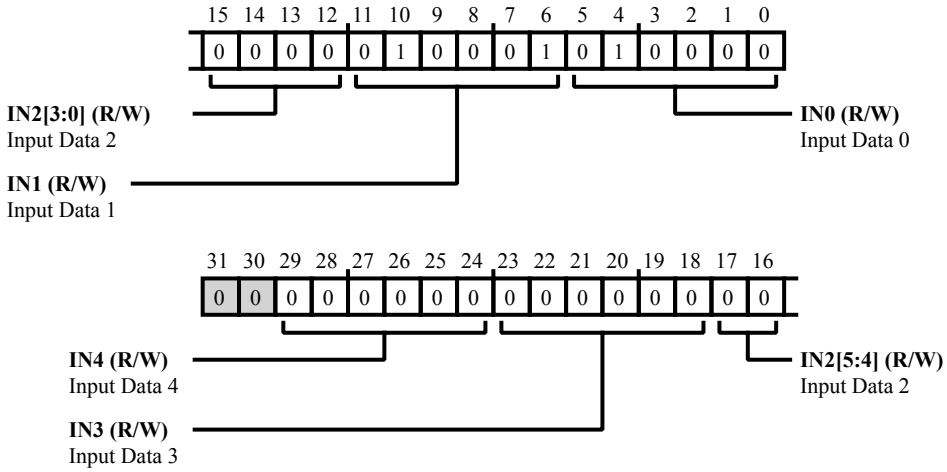

Figure 31-22: DAI_DAT2 Register Diagram

Table 31-32: DAI_DAT2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:24 (R/W)	IN4	Input Data 4. DAI_DAT2.IN4 holds the Source signal assignment that will be routed to the DAI_DAT2.IN4 Destination. Refer to the Group B Signals table for Source and Destination mappings.
23:18 (R/W)	IN3	Input Data 3. DAI_DAT2.IN3 holds the Source signal assignment that will be routed to the DAI_DAT2.IN3 Destination. Refer to the Group B Signals table for Source and Destination mappings.
17:12 (R/W)	IN2	Input Data 2. DAI_DAT2.IN2 holds the Source signal assignment that will be routed to the DAI_DAT2.IN2 Destination. Refer to the Group B Signals table for Source and Destination mappings.
11:6 (R/W)	IN1	Input Data 1. DAI_DAT2.IN1 holds the Source signal assignment that will be routed to the DAI_DAT2.IN1 Destination. Refer to the Group B Signals table for Source and Destination mappings.
5:0 (R/W)	IN0	Input Data 0. DAI_DAT2.IN0 holds the Source signal assignment that will be routed to the DAI_DAT2.IN0 Destination. Refer to the Group B Signals table for Source and Destination mappings.

Serial Data Routing Control Register 3

The DAI_DAT3 register routes serial data to the asynchronous sample rate converter (ASRC).

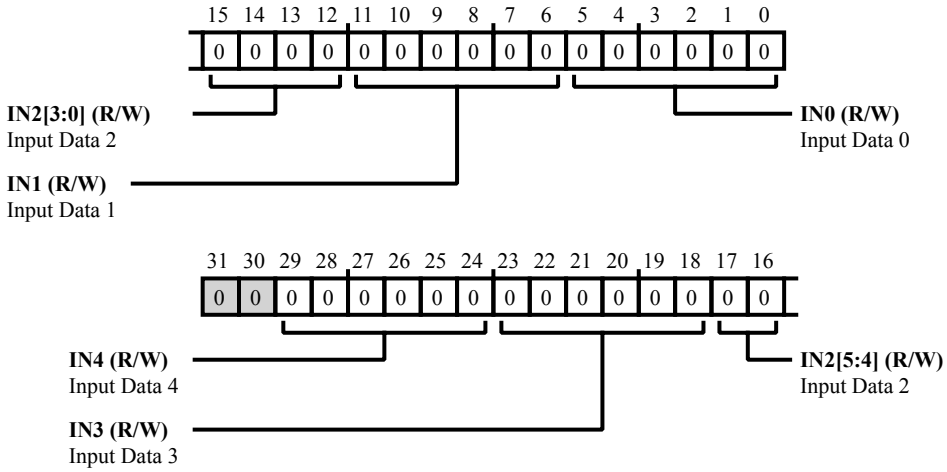

Figure 31-23: DAI_DAT3 Register Diagram

Table 31-33: DAI_DAT3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:24 (R/W)	IN4	Input Data 4. DAI_DAT3.IN4 holds the Source signal assignment that will be routed to the DAI_DAT3.IN4 Destination. Refer to the Group B Signals table for Source and Destination mappings.
23:18 (R/W)	IN3	Input Data 3. DAI_DAT3.IN3 holds the Source signal assignment that will be routed to the DAI_DAT3.IN3 Destination. Refer to the Group B Signals table for Source and Destination mappings.
17:12 (R/W)	IN2	Input Data 2. DAI_DAT3.IN2 holds the Source signal assignment that will be routed to the DAI_DAT3.IN2 Destination. Refer to the Group B Signals table for Source and Destination mappings.
11:6 (R/W)	IN1	Input Data 1. DAI_DAT3.IN1 holds the Source signal assignment that will be routed to the DAI_DAT3.IN1 Destination. Refer to the Group B Signals table for Source and Destination mappings.
5:0 (R/W)	IN0	Input Data 0. DAI_DAT3.IN0 holds the Source signal assignment that will be routed to the DAI_DAT3.IN0 Destination. Refer to the Group B Signals table for Source and Destination mappings.

Serial Data Routing Control Register 4

The DAI_DAT4 register routes serial data to the S/PDIF.

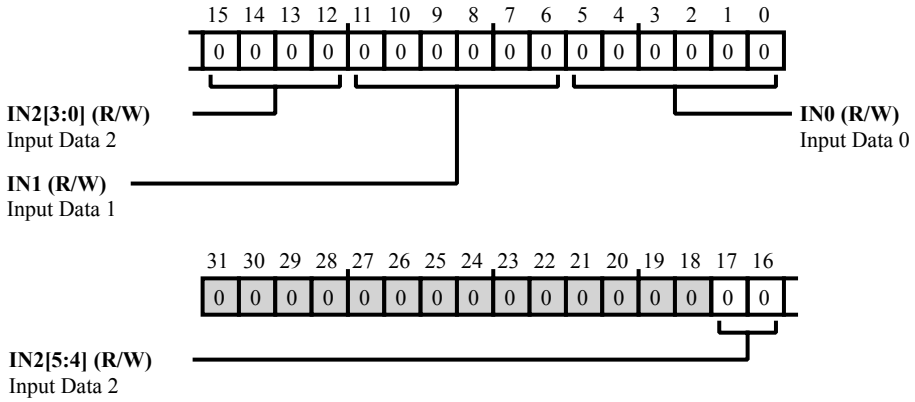

Figure 31-24: DAI_DAT4 Register Diagram

Table 31-34: DAI_DAT4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
17:12 (R/W)	IN2	Input Data 2. DAI_DAT4.IN2 holds the Source signal assignment that will be routed to the DAI_DAT4.IN2 Destination. Refer to the Group B Signals table for Source and Destination mappings.
11:6 (R/W)	IN1	Input Data 1. DAI_DAT4.IN1 holds the Source signal assignment that will be routed to the DAI_DAT4.IN1 Destination. Refer to the Group B Signals table for Source and Destination mappings.
5:0 (R/W)	IN0	Input Data 0. DAI_DAT4.IN0 holds the Source signal assignment that will be routed to the DAI_DAT4.IN0 Destination. Refer to the Group B Signals table for Source and Destination mappings.

Serial Data Routing Control Register 5

The DAI_DAT5 register routes serial data to the S/PDIF.

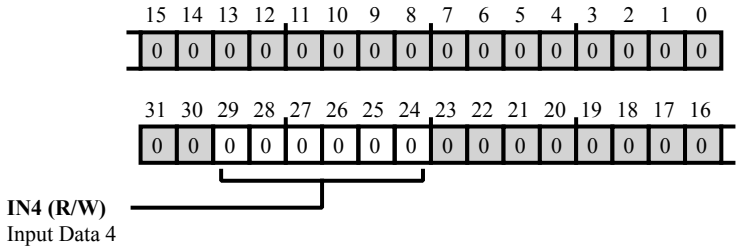

Figure 31-25: DAI_DAT5 Register Diagram

Table 31-35: DAI_DAT5 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:24 (R/W)	IN4	Input Data 4. The DAI_DAT5.IN4 bit field routes input data to the S/PDIF Biphase receiver stream.

Serial Data Routing Control Register 6

The DAI_DAT6 register routes serial data to the serial ports.

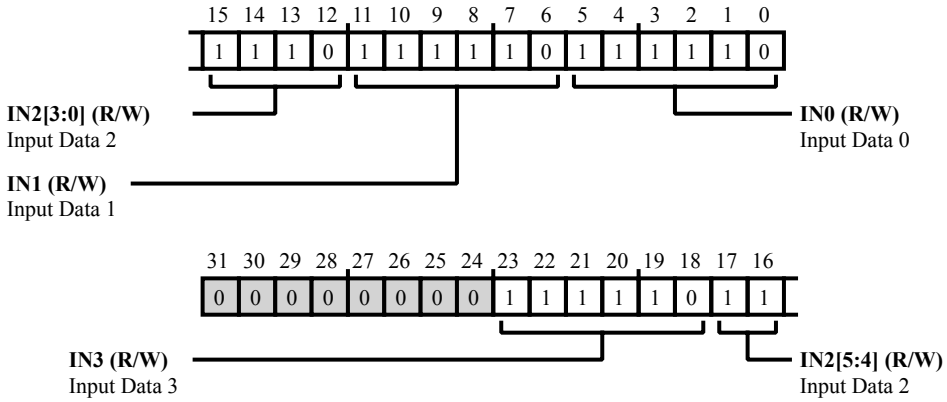

Figure 31-26: DAI_DAT6 Register Diagram

Table 31-36: DAI_DAT6 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
23:18 (R/W)	IN3	Input Data 3. DAI_DAT6.IN3 holds the Source signal assignment that will be routed to the DAI_DAT6.IN3 Destination. Refer to the Group B Signals table for Source and Destination mappings.
17:12 (R/W)	IN2	Input Data 2. DAI_DAT6.IN2 holds the Source signal assignment that will be routed to the DAI_DAT6.IN2 Destination. Refer to the Group B Signals table for Source and Destination mappings.
11:6 (R/W)	IN1	Input Data 1. DAI_DAT6.IN1 holds the Source signal assignment that will be routed to the DAI_DAT6.IN1 Destination. Refer to the Group B Signals table for Source and Destination mappings.
5:0 (R/W)	IN0	Input Data 0. DAI_DAT6.IN0 holds the Source signal assignment that will be routed to the DAI_DAT6.IN0 Destination. Refer to the Group B Signals table for Source and Destination mappings.

Extended Clock Routing Control Register 0

The DAI_EXTD_CLK0 and DAI_CLK0 registers together provides the extended clock routing connections for the serial ports (SPORTs).

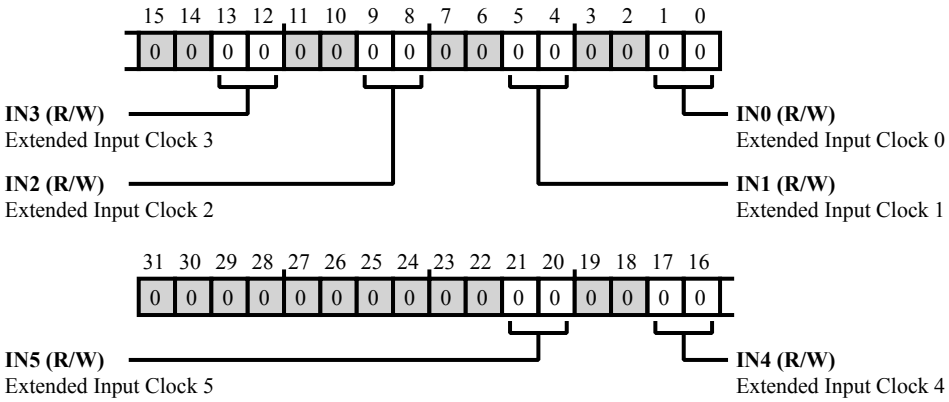

Figure 31-27: DAI_EXTD_CLK0 Register Diagram

Table 31-37: DAI_EXTD_CLK0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
21:20 (R/W)	IN5	Extended Input Clock 5. DAI_EXTD_CLK0.IN5 and DAI_CLK0.IN5 together holds the Extended Source signal assignment that will be routed to the DAI_CLK0.IN5 Destination. Refer to the Group A Signals table for Source and Destination mappings
17:16 (R/W)	IN4	Extended Input Clock 4. DAI_EXTD_CLK0.IN4 and DAI_CLK0.IN4 together holds the Extended Source signal assignment that will be routed to the DAI_CLK0.IN4 Destination. Refer to the Group A Signals table for Source and Destination mappings
13:12 (R/W)	IN3	Extended Input Clock 3. DAI_EXTD_CLK0.IN3 and DAI_CLK0.IN3 together holds the Extended Source signal assignment that will be routed to the DAI_CLK0.IN3 Destination. Refer to the Group A Signals table for Source and Destination mappings
9:8 (R/W)	IN2	Extended Input Clock 2. DAI_EXTD_CLK0.IN2 and DAI_CLK0.IN2 together holds the Extended Source signal assignment that will be routed to the DAI_CLK0.IN2 Destination. Refer to the Group A Signals table for Source and Destination mappings
5:4 (R/W)	IN1	Extended Input Clock 1. DAI_EXTD_CLK0.IN1 and DAI_CLK0.IN1 together holds the Extended Source signal assignment that will be routed to the DAI_CLK0.IN1 Destination. Refer to the Group A Signals table for Source and Destination mappings

Table 31-37: DAI_EXTD_CLK0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
1:0 (R/W)	IN0	Extended Input Clock 0. `DAI_EXTD_CLK0.IN0` and DAI_CLK0.IN0 together holds the Extended Source signal assignment that will be routed to the DAI_CLK0.IN0 Destination. Refer to the Group A Signals table for Source and Destination mappings

Extended Clock Routing Control Register 1

The DAI_EXTD_CLK1 and DAI_CLK1 registers together provides the extended clock routing connections for the serial ports (SPORTs).

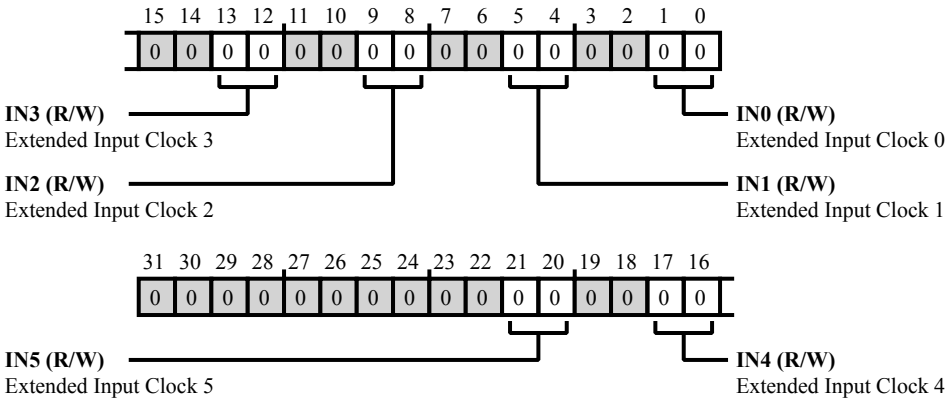

Figure 31-28: DAI_EXTD_CLK1 Register Diagram

Table 31-38: DAI_EXTD_CLK1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
21:20 (R/W)	IN5	Extended Input Clock 5. DAI_EXTD_CLK1.IN5 and DAI_CLK1.IN5 together holds the Extended Source signal assignment that will be routed to the DAI_CLK1.IN5 Destination. Refer to the Group A Signals table for Source and Destination mappings
17:16 (R/W)	IN4	Extended Input Clock 4. DAI_EXTD_CLK1.IN4 and DAI_CLK1.IN4 together holds the Extended Source signal assignment that will be routed to the DAI_CLK1.IN4 Destination. Refer to the Group A Signals table for Source and Destination mappings
13:12 (R/W)	IN3	Extended Input Clock 3. DAI_EXTD_CLK1.IN3 and DAI_CLK1.IN3 together holds the Extended Source signal assignment that will be routed to the DAI_CLK1.IN3 Destination. Refer to the Group A Signals table for Source and Destination mappings
9:8 (R/W)	IN2	Extended Input Clock 2. DAI_EXTD_CLK1.IN2 and DAI_CLK1.IN2 together holds the Extended Source signal assignment that will be routed to the DAI_CLK1.IN2 Destination. Refer to the Group A Signals table for Source and Destination mappings
5:4 (R/W)	IN1	Extended Input Clock 1. DAI_EXTD_CLK1.IN1 and DAI_CLK1.IN1 together holds the Extended Source signal assignment that will be routed to the DAI_CLK1.IN1 Destination. Refer to the Group A Signals table for Source and Destination mappings

Table 31-38: DAI_EXTD_CLK1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
1:0 (R/W)	IN0	Extended Input Clock 0. `DAI_EXTD_CLK1.IN0` and DAI_CLK1.IN0 together holds the Extended Source signal assignment that will be routed to the DAI_CLK1.IN0 Destination. Refer to the Group A Signals table for Source and Destination mappings

Extended Clock Routing Control Register 2

The DAI_EXTD_CLK2 and DAI_CLK2 registers together provides the extended clock routing connections for the serial ports (SPORTs).

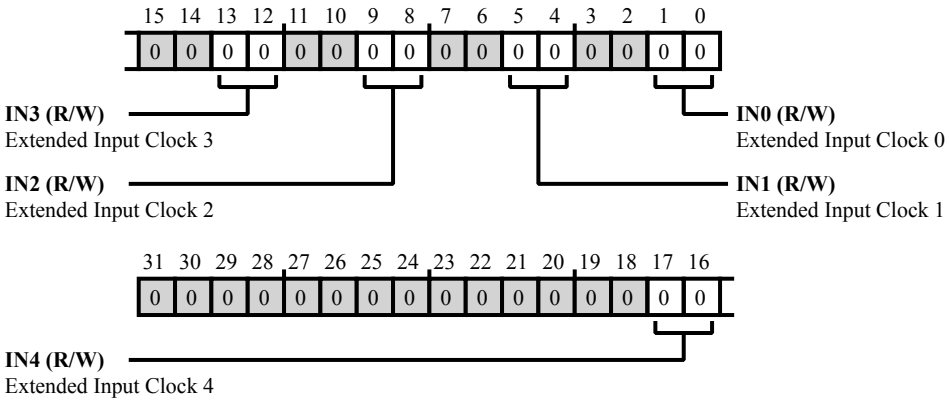

Figure 31-29: DAI_EXTD_CLK2 Register Diagram

Table 31-39: DAI_EXTD_CLK2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
17:16 (R/W)	IN4	Extended Input Clock 4. DAI_EXTD_CLK2.IN4 and DAI_CLK2.IN4 together holds the Extended Source signal assignment that will be routed to the DAI_CLK2.IN4 Destination. Refer to the Group A Signals table for Source and Destination mappings
13:12 (R/W)	IN3	Extended Input Clock 3. DAI_EXTD_CLK2.IN3 and DAI_CLK2.IN3 together holds the Extended Source signal assignment that will be routed to the DAI_CLK2.IN3 Destination. Refer to the Group A Signals table for Source and Destination mappings
9:8 (R/W)	IN2	Extended Input Clock 2. DAI_EXTD_CLK2.IN2 and DAI_CLK2.IN2 together holds the Extended Source signal assignment that will be routed to the DAI_CLK2.IN2 Destination. Refer to the Group A Signals table for Source and Destination mappings
5:4 (R/W)	IN1	Extended Input Clock 1. DAI_EXTD_CLK2.IN1 and DAI_CLK2.IN1 together holds the Extended Source signal assignment that will be routed to the DAI_CLK2.IN1 Destination. Refer to the Group A Signals table for Source and Destination mappings
1:0 (R/W)	IN0	Extended Input Clock 0. DAI_EXTD_CLK2.IN0 and DAI_CLK2.IN0 together holds the Extended Source signal assignment that will be routed to the DAI_CLK2.IN0 Destination. Refer to the Group A Signals table for Source and Destination mappings

Extended Clock Routing Control Register 3

The DAI_EXTD_CLK3 and DAI_CLK3 registers together provides the extended clock routing connections for the serial ports (SPORTs).

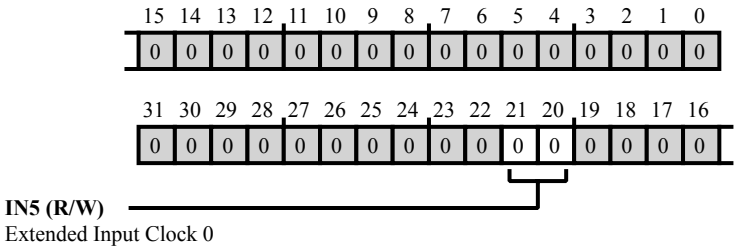

Figure 31-30: DAI_EXTD_CLK3 Register Diagram

Table 31-40: DAI_EXTD_CLK3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
21:20 (R/W)	IN5	Extended Input Clock 0. DAI_EXTD_CLK3.IN5 and DAI_CLK3.IN0 together holds the Extended Source signal assignment that will be routed to the DAI_CLK3.IN0 Destination. Refer to the Group A Signals table for Source and Destination mappings

Extended Clock Routing Control Register 4

The DAI_EXTD_CLK4 and DAI_CLK4 registers together provides the extended clock routing connections for the serial ports (SPORTs).

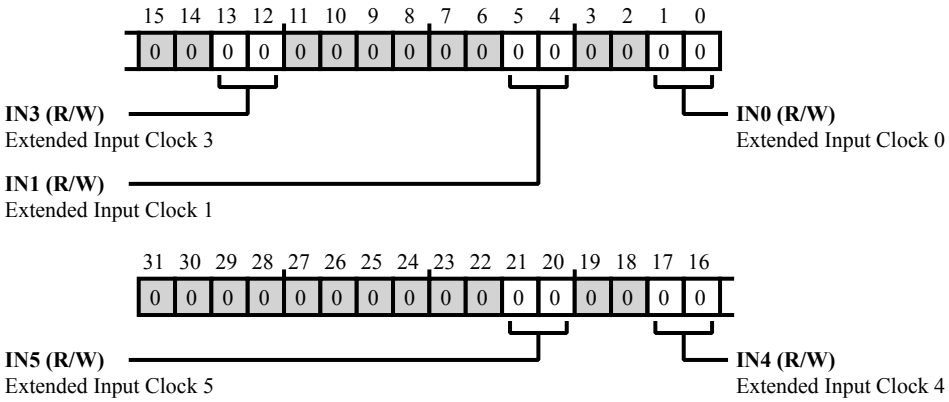

Figure 31-31: DAI_EXTD_CLK4 Register Diagram

Table 31-41: DAI_EXTD_CLK4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
21:20 (R/W)	IN5	Extended Input Clock 5. DAI_EXTD_CLK4.IN5 and DAI_CLK4.IN5 together holds the Extended Source signal assignment that will be routed to the DAI_CLK4.IN5 Destination. Refer to the Group A Signals table for Source and Destination mappings
17:16 (R/W)	IN4	Extended Input Clock 4. DAI_EXTD_CLK4.IN4 and DAI_CLK4.IN4 together holds the Extended Source signal assignment that will be routed to the DAI_CLK4.IN4 Destination. Refer to the Group A Signals table for Source and Destination mappings
13:12 (R/W)	IN3	Extended Input Clock 3. DAI_EXTD_CLK4.IN3 and DAI_CLK4.IN3 together holds the Extended Source signal assignment that will be routed to the DAI_CLK4.IN3 Destination. Refer to the Group A Signals table for Source and Destination mappings
5:4 (R/W)	IN1	Extended Input Clock 1. DAI_EXTD_CLK4.IN1 and DAI_CLK4.IN1 together holds the Extended Source signal assignment that will be routed to the DAI_CLK4.IN1 Destination. Refer to the Group A Signals table for Source and Destination mappings
1:0 (R/W)	IN0	Extended Input Clock 0. DAI_EXTD_CLK4.IN0 and DAI_CLK4.IN0 together holds the Extended Source signal assignment that will be routed to the DAI_CLK4.IN0 Destination. Refer to the Group A Signals table for Source and Destination mappings

Extended Clock Routing Control Register 5

The DAI_EXTD_CLK5 and DAI_CLK5 registers together provides the extended clock routing connections for the serial ports (SPORTs).

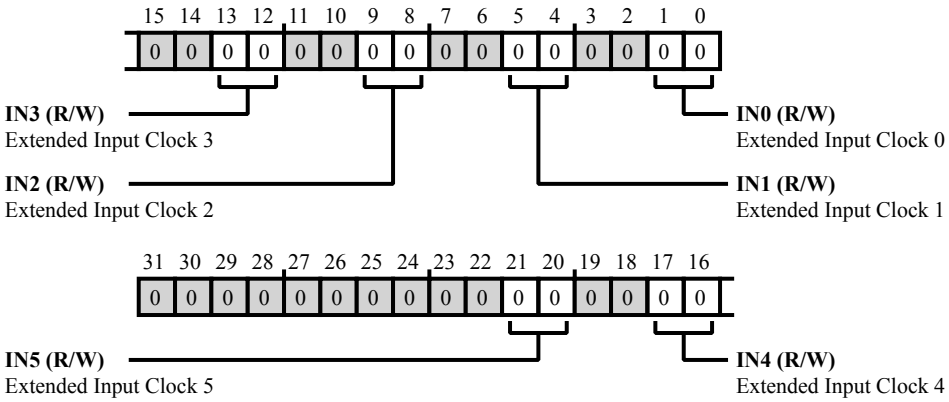

Figure 31-32: DAI_EXTD_CLK5 Register Diagram

Table 31-42: DAI_EXTD_CLK5 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
21:20 (R/W)	IN5	Extended Input Clock 5. DAI_EXTD_CLK5.IN5 and DAI_CLK5.IN5 together holds the Extended Source signal assignment that will be routed to the DAI_CLK5.IN5 Destination. Refer to the Group A Signals table for Source and Destination mappings
17:16 (R/W)	IN4	Extended Input Clock 4. DAI_EXTD_CLK5.IN4 and DAI_CLK5.IN4 together holds the Extended Source signal assignment that will be routed to the DAI_CLK5.IN4 Destination. Refer to the Group A Signals table for Source and Destination mappings
13:12 (R/W)	IN3	Extended Input Clock 3. DAI_EXTD_CLK5.IN3 and DAI_CLK5.IN3 together holds the Extended Source signal assignment that will be routed to the DAI_CLK5.IN3 Destination. Refer to the Group A Signals table for Source and Destination mappings
9:8 (R/W)	IN2	Extended Input Clock 2. DAI_EXTD_CLK5.IN2 and DAI_CLK5.IN2 together holds the Extended Source signal assignment that will be routed to the DAI_CLK5.IN2 Destination. Refer to the Group A Signals table for Source and Destination mappings
5:4 (R/W)	IN1	Extended Input Clock 1. DAI_EXTD_CLK5.IN1 and DAI_CLK5.IN1 together holds the Extended Source signal assignment that will be routed to the DAI_CLK5.IN1 Destination. Refer to the Group A Signals table for Source and Destination mappings

Table 31-42: DAI_EXTD_CLK5 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
1:0 (R/W)	IN0	Extended Input Clock 0. `DAI_EXTD_CLK5.IN0` and DAI_CLK5.IN0 together holds the Extended Source signal assignment that will be routed to the DAI_CLK5.IN0 Destination. Refer to the Group A Signals table for Source and Destination mappings

Extended Serial Data Routing Control Register 0

The DAI_EXTD_DAT0 and DAI_DAT0 together provides the extended data routing connections to the serial data of serial ports.

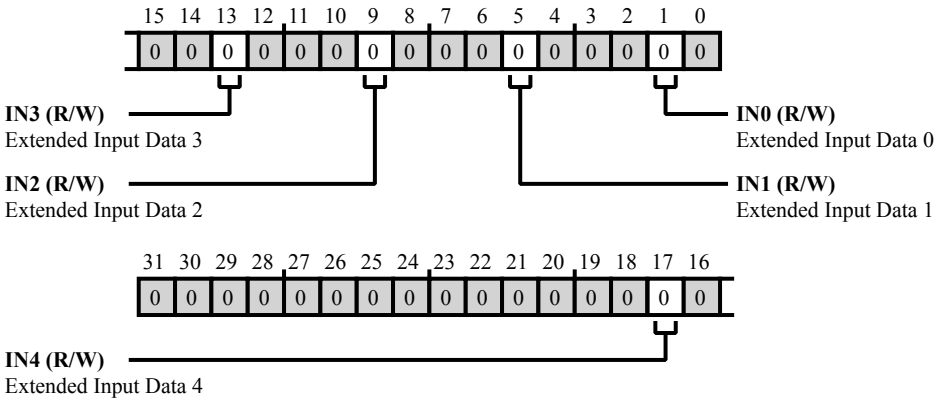

Figure 31-33: DAI_EXTD_DAT0 Register Diagram

Table 31-43: DAI_EXTD_DAT0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
17 (R/W)	IN4	Extended Input Data 4. DAI_EXTD_DAT0.IN4 and DAI_DAT0.IN4 together holds the Source signal assignment that will be routed to the DAI_DAT0.IN4 Destination. Refer to the Group B Signals table for Source and Destination mappings.
13 (R/W)	IN3	Extended Input Data 3. DAI_EXTD_DAT0.IN3 and DAI_DAT0.IN3 together holds the Source signal assignment that will be routed to the DAI_DAT0.IN3 Destination. Refer to the Group B Signals table for Source and Destination mappings.
9 (R/W)	IN2	Extended Input Data 2. DAI_EXTD_DAT0.IN2 and DAI_DAT0.IN2 together holds the Source signal assignment that will be routed to the DAI_DAT0.IN2 Destination. Refer to the Group B Signals table for Source and Destination mappings.
5 (R/W)	IN1	Extended Input Data 1. DAI_EXTD_DAT0.IN1 and DAI_DAT0.IN1 together holds the Source signal assignment that will be routed to the DAI_DAT0.IN1 Destination. Refer to the Group B Signals table for Source and Destination mappings.
1 (R/W)	IN0	Extended Input Data 0. DAI_EXTD_DAT0.IN0 and DAI_DAT0.IN0 together holds the Source signal assignment that will be routed to the DAI_DAT0.IN0 Destination. Refer to the Group B Signals table for Source and Destination mappings.

Extended Serial Data Routing Control Register 1

The DAI_EXTD_DAT1 and DAI_DAT1 together provides the extended data routing connections to the serial data of serial ports.

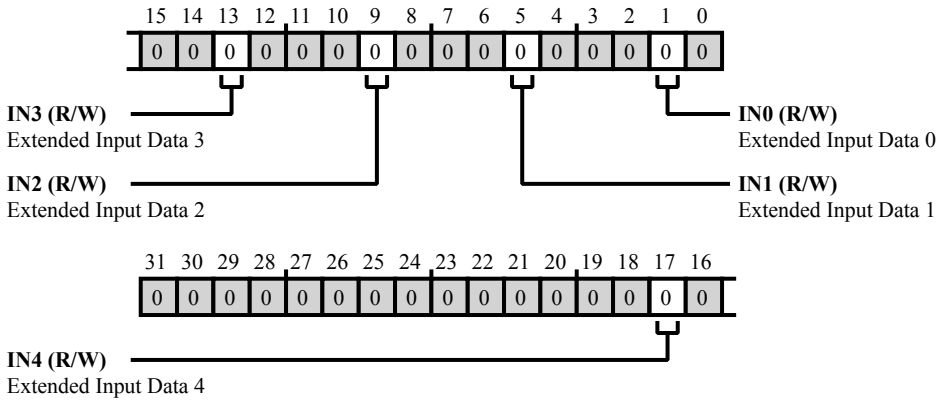

Figure 31-34: DAI_EXTD_DAT1 Register Diagram

Table 31-44: DAI_EXTD_DAT1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
17 (R/W)	IN4	Extended Input Data 4. DAI_EXTD_DAT1.IN4 and DAI_DAT1.IN4 together holds the Source signal assignment that will be routed to the DAI_DAT1.IN4 Destination. Refer to the Group B Signals table for Source and Destination mappings.
13 (R/W)	IN3	Extended Input Data 3. DAI_EXTD_DAT1.IN3 and DAI_DAT1.IN3 together holds the Source signal assignment that will be routed to the DAI_DAT1.IN3 Destination. Refer to the Group B Signals table for Source and Destination mappings.
9 (R/W)	IN2	Extended Input Data 2. DAI_EXTD_DAT1.IN2 and DAI_DAT1.IN2 together holds the Source signal assignment that will be routed to the DAI_DAT1.IN2 Destination. Refer to the Group B Signals table for Source and Destination mappings.
5 (R/W)	IN1	Extended Input Data 1. DAI_EXTD_DAT1.IN1 and DAI_DAT1.IN1 together holds the Source signal assignment that will be routed to the DAI_DAT1.IN1 Destination. Refer to the Group B Signals table for Source and Destination mappings.
1 (R/W)	IN0	Extended Input Data 0. DAI_EXTD_DAT1.IN0 and DAI_DAT1.IN0 together holds the Source signal assignment that will be routed to the DAI_DAT1.IN0 Destination. Refer to the Group B Signals table for Source and Destination mappings.

Extended Serial Data Routing Control Register 2

The DAI_EXTD_DAT2 and DAI_DAT2 together provides the extended data routing connections to the serial data of serial ports.

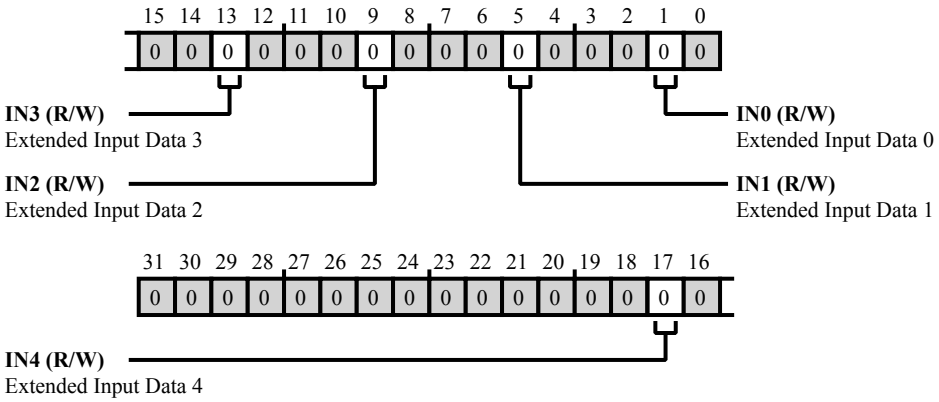

Figure 31-35: DAI_EXTD_DAT2 Register Diagram

Table 31-45: DAI_EXTD_DAT2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
17 (R/W)	IN4	Extended Input Data 4. DAI_EXTD_DAT2.IN4 and DAI_DAT2.IN4 together holds the Source signal assignment that will be routed to the DAI_DAT2.IN4 Destination. Refer to the Group B Signals table for Source and Destination mappings.
13 (R/W)	IN3	Extended Input Data 3. DAI_EXTD_DAT2.IN3 and DAI_DAT2.IN3 together holds the Source signal assignment that will be routed to the DAI_DAT2.IN3 Destination. Refer to the Group B Signals table for Source and Destination mappings.
9 (R/W)	IN2	Extended Input Data 2. DAI_EXTD_DAT2.IN2 and DAI_DAT2.IN2 together holds the Source signal assignment that will be routed to the DAI_DAT2.IN2 Destination. Refer to the Group B Signals table for Source and Destination mappings.
5 (R/W)	IN1	Extended Input Data 1. DAI_EXTD_DAT2.IN1 and DAI_DAT2.IN1 together holds the Source signal assignment that will be routed to the DAI_DAT2.IN1 Destination. Refer to the Group B Signals table for Source and Destination mappings.
1 (R/W)	IN0	Extended Input Data 0. DAI_EXTD_DAT2.IN0 and DAI_DAT2.IN0 together holds the Source signal assignment that will be routed to the DAI_DAT2.IN0 Destination. Refer to the Group B Signals table for Source and Destination mappings.

Extended Serial Data Routing Control Register 3

The DAI_EXTD_DAT3 and DAI_DAT3 together provides the extended data routing connections to the serial data of serial ports.

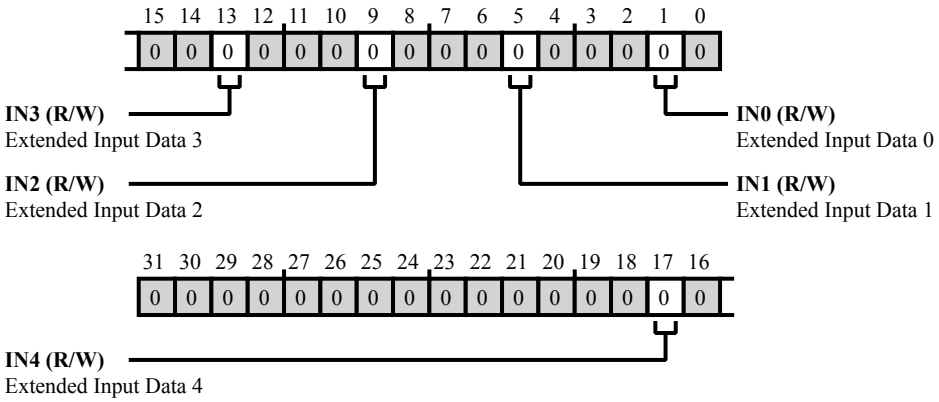

Figure 31-36: DAI_EXTD_DAT3 Register Diagram

Table 31-46: DAI_EXTD_DAT3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
17 (R/W)	IN4	Extended Input Data 4. DAI_EXTD_DAT3.IN4 and DAI_DAT3.IN4 together holds the Source signal assignment that will be routed to the DAI_DAT3.IN4 Destination. Refer to the Group B Signals table for Source and Destination mappings.
13 (R/W)	IN3	Extended Input Data 3. DAI_EXTD_DAT3.IN3 and DAI_DAT3.IN3 together holds the Source signal assignment that will be routed to the DAI_DAT3.IN3 Destination. Refer to the Group B Signals table for Source and Destination mappings.
9 (R/W)	IN2	Extended Input Data 2. DAI_EXTD_DAT3.IN2 and DAI_DAT3.IN2 together holds the Source signal assignment that will be routed to the DAI_DAT3.IN2 Destination. Refer to the Group B Signals table for Source and Destination mappings.
5 (R/W)	IN1	Extended Input Data 1. DAI_EXTD_DAT3.IN1 and DAI_DAT3.IN1 together holds the Source signal assignment that will be routed to the DAI_DAT3.IN1 Destination. Refer to the Group B Signals table for Source and Destination mappings.
1 (R/W)	IN0	Extended Input Data 0. DAI_EXTD_DAT3.IN0 and DAI_DAT3.IN0 together holds the Source signal assignment that will be routed to the DAI_DAT3.IN0 Destination. Refer to the Group B Signals table for Source and Destination mappings.

Extended Serial Data Routing Control Register 4

The DAI_EXTD_DAT4 and DAI_DAT4 together provides the extended data routing connections to the serial data of serial ports.

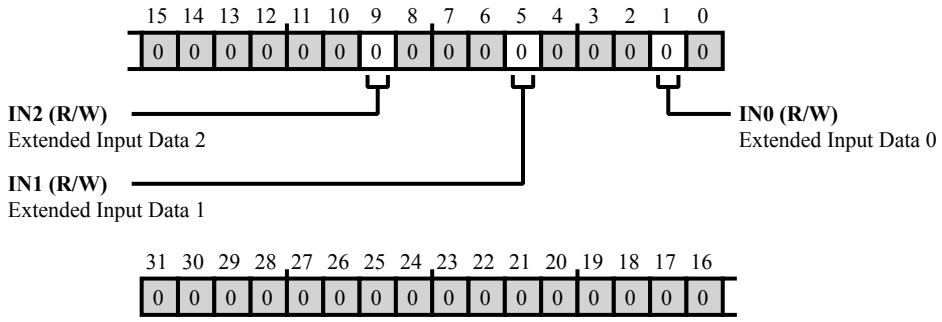

Figure 31-37: DAI_EXTD_DAT4 Register Diagram

Table 31-47: DAI_EXTD_DAT4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
9 (R/W)	IN2	Extended Input Data 2. DAI_EXTD_DAT4.IN2 and DAI_DAT4.IN2 together holds the Source signal assignment that will be routed to the DAI_DAT4.IN2 Destination. Refer to the Group B Signals table for Source and Destination mappings.
5 (R/W)	IN1	Extended Input Data 1. DAI_EXTD_DAT4.IN1 and DAI_DAT4.IN2 together holds the Source signal assignment that will be routed to the DAI_DAT4.IN1 Destination. Refer to the Group B Signals table for Source and Destination mappings.
1 (R/W)	IN0	Extended Input Data 0. DAI_EXTD_DAT4.IN0 and DAI_DAT4.IN0 together holds the Source signal assignment that will be routed to the DAI_DAT4.IN0 Destination. Refer to the Group B Signals table for Source and Destination mappings.

Extended Serial Data Routing Control Register 5

The DAI_EXTD_DAT5 and DAI_DAT5 together provides the extended data routing connections to the serial data of serial ports.

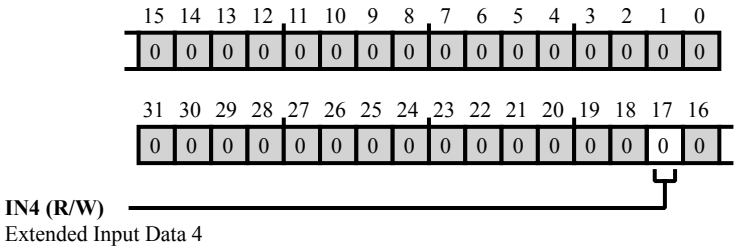

Figure 31-38: DAI_EXTD_DAT5 Register Diagram

Table 31-48: DAI_EXTD_DAT5 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
17 (R/W)	IN4	Extended Input Data 4. DAI_EXTD_DAT5.IN4 and DAI_DAT5.IN4 together holds the Source signal assignment that will be routed to the DAI_DAT5.IN4 Destination. Refer to the Group B Signals table for Source and Destination mappings.

Extended Serial Data Routing Control Register 6

The DAI_EXTD_DAT6 and DAI_DAT6 together provides the extended data routing connections to the serial data of serial ports.

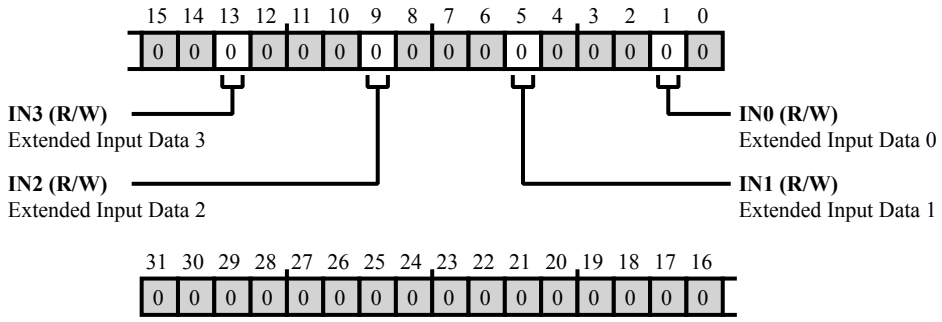

Figure 31-39: DAI_EXTD_DAT6 Register Diagram

Table 31-49: DAI_EXTD_DAT6 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
13 (R/W)	IN3	Extended Input Data 3. DAI_EXTD_DAT6.IN3 and DAI_DAT6.IN3 together holds the Source signal assignment that will be routed to the DAI_DAT6.IN3 Destination. Refer to the Group B Signals table for Source and Destination mappings.
9 (R/W)	IN2	Extended Input Data 2. DAI_EXTD_DAT6.IN2 and DAI_DAT6.IN2 together holds the Source signal assignment that will be routed to the DAI_DAT6.IN2 Destination. Refer to the Group B Signals table for Source and Destination mappings.
5 (R/W)	IN1	Extended Input Data 1. DAI_EXTD_DAT6.IN1 and DAI_DAT6.IN1 together holds the Source signal assignment that will be routed to the DAI_DAT6.IN1 Destination. Refer to the Group B Signals table for Source and Destination mappings.
1 (R/W)	IN0	Extended Input Data 0. DAI_EXTD_DAT6.IN0 and DAI_DAT6.IN0 together holds the Source signal assignment that will be routed to the DAI_DAT6.IN0 Destination. Refer to the Group B Signals table for Source and Destination mappings.

Extended Frame Sync Routing Control Register 0

The DAI_EXTD_FS0 and DAI_FS0 together provides the extended frame sync routing connections to the frame syncs of serial ports.

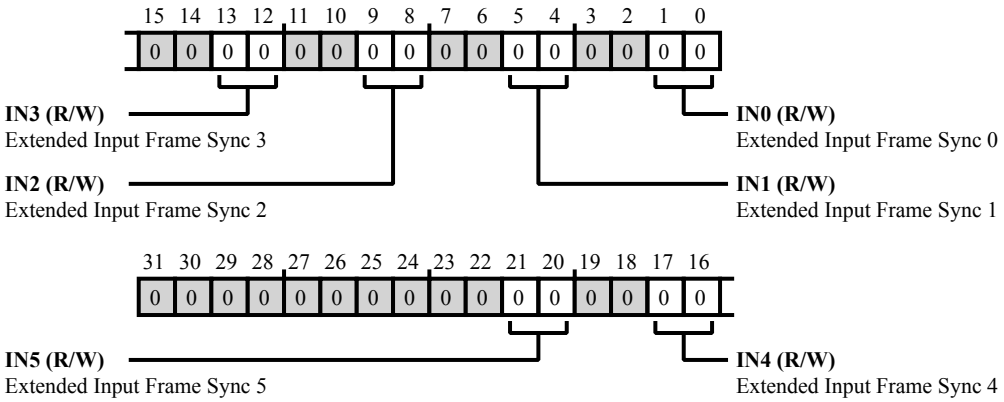

Figure 31-40: DAI_EXTD_FS0 Register Diagram

Table 31-50: DAI_EXTD_FS0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
21:20 (R/W)	IN5	Extended Input Frame Sync 5. DAI_EXTD_FS0.IN5 and DAI_FS0.IN5 together holds the Source signal assignment that will be routed to the DAI_FS0.IN5 Destination. Refer to the Group C Signals table for Source and Destination mappings.
17:16 (R/W)	IN4	Extended Input Frame Sync 4. DAI_EXTD_FS0.IN4 and DAI_FS0.IN4 together holds the Source signal assignment that will be routed to the DAI_FS0.IN4 Destination. Refer to the Group C Signals table for Source and Destination mappings.
13:12 (R/W)	IN3	Extended Input Frame Sync 3. DAI_EXTD_FS0.IN3 and DAI_FS0.IN3 together holds the Source signal assignment that will be routed to the DAI_FS0.IN3 Destination. Refer to the Group C Signals table for Source and Destination mappings.
9:8 (R/W)	IN2	Extended Input Frame Sync 2. DAI_EXTD_FS0.IN2 and DAI_FS0.IN2 together holds the Source signal assignment that will be routed to the DAI_FS0.IN2 Destination. Refer to the Group C Signals table for Source and Destination mappings.
5:4 (R/W)	IN1	Extended Input Frame Sync 1. DAI_EXTD_FS0.IN1 and DAI_FS0.IN1 together holds the Source signal assignment that will be routed to the DAI_FS0.IN1 Destination. Refer to the Group C Signals table for Source and Destination mappings.

Table 31-50: DAI_EXTD_FS0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
1:0 (R/W)	IN0	Extended Input Frame Sync 0. `DAI_EXTD_FS0.IN0` and DAI_FS0.IN0 together holds the Source signal assignment that will be routed to the DAI_FS0.IN0 Destination. Refer to the Group C Signals table for Source and Destination mappings.

Extended Frame Sync Routing Control Register 1

The DAI_EXTD_FS1 and DAI_FS1 together provides the extended frame sync routing connections to the frame syncs of serial ports.

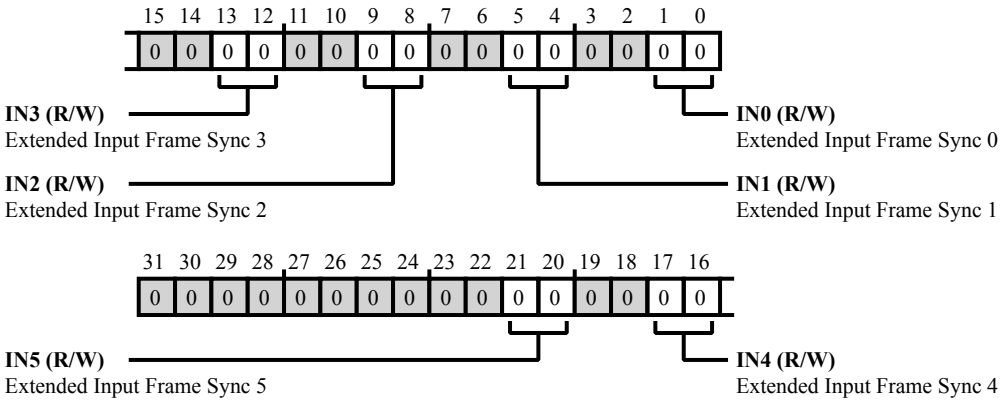

Figure 31-41: DAI_EXTD_FS1 Register Diagram

Table 31-51: DAI_EXTD_FS1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
21:20 (R/W)	IN5	Extended Input Frame Sync 5. DAI_EXTD_FS1.IN5 and DAI_FS1.IN5 together holds the Source signal assignment that will be routed to the DAI_FS1.IN5 Destination. Refer to the Group C Signals table for Source and Destination mappings.
17:16 (R/W)	IN4	Extended Input Frame Sync 4. DAI_EXTD_FS1.IN4 and DAI_FS1.IN4 together holds the Source signal assignment that will be routed to the DAI_FS1.IN4 Destination. Refer to the Group C Signals table for Source and Destination mappings.
13:12 (R/W)	IN3	Extended Input Frame Sync 3. DAI_EXTD_FS1.IN3 and DAI_FS1.IN3 together holds the Source signal assignment that will be routed to the DAI_FS1.IN3 Destination. Refer to the Group C Signals table for Source and Destination mappings.
9:8 (R/W)	IN2	Extended Input Frame Sync 2. DAI_EXTD_FS1.IN2 and DAI_FS1.IN2 together holds the Source signal assignment that will be routed to the DAI_FS1.IN2 Destination. Refer to the Group C Signals table for Source and Destination mappings.
5:4 (R/W)	IN1	Extended Input Frame Sync 1. DAI_EXTD_FS1.IN1 and DAI_FS1.IN1 together holds the Source signal assignment that will be routed to the DAI_FS1.IN1 Destination. Refer to the Group C Signals table for Source and Destination mappings.

Table 31-51: DAI_EXTD_FS1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
1:0 (R/W)	IN0	Extended Input Frame Sync 0. `DAI_EXTD_FS1.IN0` and DAI_FS1.IN0 together holds the Source signal assignment that will be routed to the DAI_FS1.IN0 Destination. Refer to the Group C Signals table for Source and Destination mappings.

Extended Frame Sync Routing Control Register 2

The DAI_EXTD_FS2 and DAI_FS2 together provides the extended frame sync routing connections to the frame syncs of serial ports.

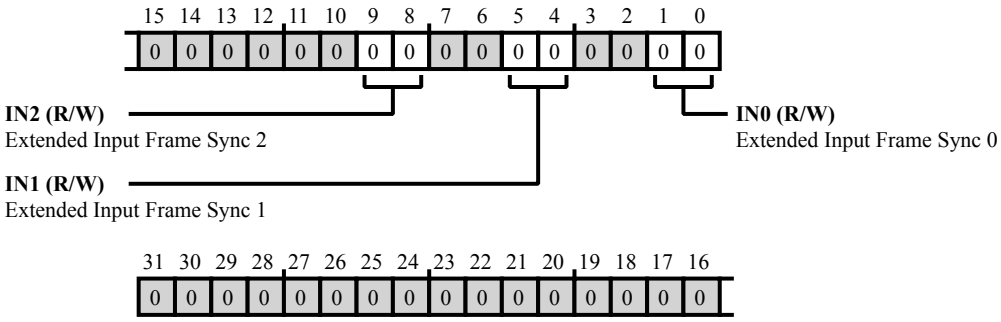

Figure 31-42: DAI_EXTD_FS2 Register Diagram

Table 31-52: DAI_EXTD_FS2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
9:8 (R/W)	IN2	Extended Input Frame Sync 2. DAI_EXTD_FS2.IN2 and DAI_FS2.IN2 together holds the Source signal assignment that will be routed to the DAI_FS2.IN2 Destination. Refer to the Group C Signals table for Source and Destination mappings.
5:4 (R/W)	IN1	Extended Input Frame Sync 1. DAI_EXTD_FS2.IN1 and DAI_FS2.IN1 together holds the Source signal assignment that will be routed to the DAI_FS2.IN1 Destination. Refer to the Group C Signals table for Source and Destination mappings.
1:0 (R/W)	IN0	Extended Input Frame Sync 0. DAI_EXTD_FS2.IN0 and DAI_FS2.IN0 together holds the Source signal assignment that will be routed to the DAI_FS2.IN0 Destination. Refer to the Group C Signals table for Source and Destination mappings.

Extended Frame Sync Routing Control Register 4

The DAI_EXTD_FS4 and DAI_FS4 together provides the extended frame sync routing connections to the frame syncs of serial ports.

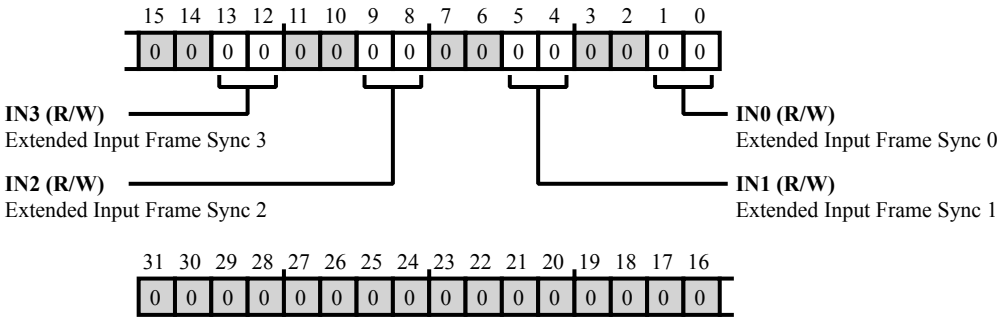

Figure 31-43: DAI_EXTD_FS4 Register Diagram

Table 31-53: DAI_EXTD_FS4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
13:12 (R/W)	IN3	Extended Input Frame Sync 3. DAI_EXTD_FS4.IN3 and DAI_FS4.IN3 together holds the Source signal assignment that will be routed to the DAI_FS4.IN3 Destination. This register is used to map the frame sync to the Timer ACI inputs. Refer to the Group C Signals table for Source and Destination mappings.
9:8 (R/W)	IN2	Extended Input Frame Sync 2. DAI_EXTD_FS4.IN2 and DAI_FS4.IN2 together holds the Source signal assignment that will be routed to the DAI_FS4.IN2 Destination. This register is used to map the frame sync to the Timer ACI inputs. Refer to the Group C Signals table for Source and Destination mappings.
5:4 (R/W)	IN1	Extended Input Frame Sync 1. DAI_EXTD_FS4.IN1 and DAI_FS4.IN1 together holds the Source signal assignment that will be routed to the DAI_FS4.IN1 Destination. Refer to the Group C Signals table for Source and Destination mappings.
1:0 (R/W)	IN0	Extended Input Frame Sync 0. DAI_EXTD_FS4.IN0 and DAI_FS4.IN0 together holds the Source signal assignment that will be routed to the DAI_FS4.IN0 Destination. Refer to the Group C Signals table for Source and Destination mappings.

Extended Miscellaneous Control Register 0

The DAI_EXTD_MISC0 and DAI_MISC0 register together allows programs to route to the DAI interrupt latch, PBEN input routing, or input signal inversion. This register belongs to group E which routes control signals and provides a means of connecting signals between groups.

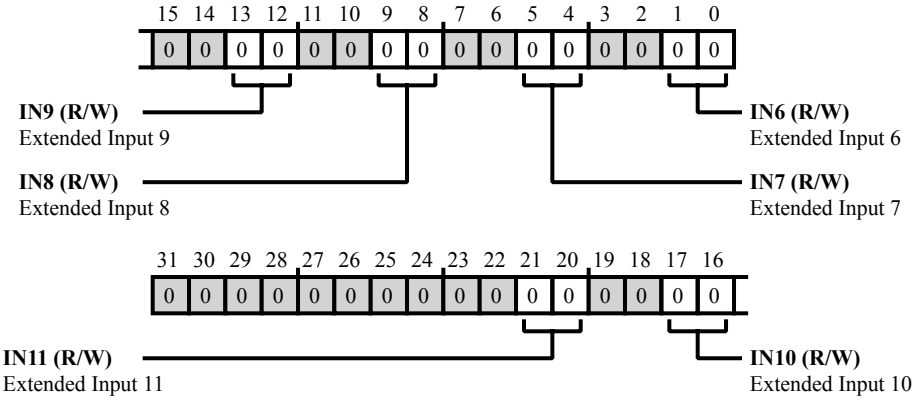

Figure 31-44: DAI_EXTD_MISC0 Register Diagram

Table 31-54: DAI_EXTD_MISC0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
21:20 (R/W)	IN11	Extended Input 11. The DAI_EXTD_MISC0.IN11 bit field and DAI_MISC0.IN11 bit field together holds the source signal assignment for miscellaneous A5 input.
17:16 (R/W)	IN10	Extended Input 10. The DAI_EXTD_MISC0.IN10 bit field and DAI_MISC0.IN10 bit field together holds the source signal assignment for miscellaneous A4 input.
13:12 (R/W)	IN9	Extended Input 9. The DAI_EXTD_MISC0.IN9 bit field and DAI_MISC0.IN9 bit field together holds the source signal assignment for miscellaneous A3 input/miscellaneous Interrupt 9(DAI interrupt 31).
9:8 (R/W)	IN8	Extended Input 8. The DAI_EXTD_MISC0.IN8 bit field and DAI_MISC0.IN8 bit field together holds the source signal assignment for miscellaneous A2 input/miscellaneous Interrupt 8(DAI interrupt 30).
5:4 (R/W)	IN7	Extended Input 7. The DAI_EXTD_MISC0.IN7 bit field and DAI_MISC0.IN7 bit field together holds the source signal assignment for miscellaneous A1 input/miscellaneous Interrupt 7(DAI interrupt 29).

Table 31-54: DAI_EXTD_MISC0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
1:0 (R/W)	IN6	Extended Input 6. The `DAI_EXTD_MISC0.IN6` and DAI_MISC0.IN6 bit field together holds the source signal assignment for miscellaneous A0 input/miscellaneous Interrupt 6(DAI interrupt 28).

Extended Miscellaneous Control Register 1

The DAI_EXTD_MISC1 and DAI_MISC1 register together allows programs to route to the DAI interrupt latch, PBEN input routing, or input signal inversion. This register belongs to group E which routes control signals and provides a means of connecting signals between groups.

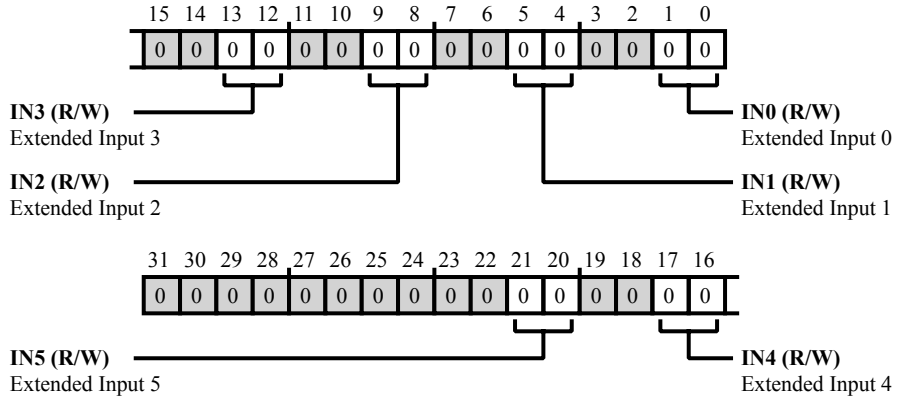

Figure 31-45: DAI_EXTD_MISC1 Register Diagram

Table 31-55: DAI_EXTD_MISC1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
21:20 (R/W)	IN5	Extended Input 5. The DAI_EXTD_MISC1.IN5 bit field and DAI_MISC1.IN5 bit field together holds the source signal assignment for miscellaneous Interrupt 5(DAI interrupt 27).
17:16 (R/W)	IN4	Extended Input 4. The DAI_EXTD_MISC1.IN4 bit field and DAI_MISC1.IN4 bit field together holds the source signal assignment for miscellaneous Interrupt 4(DAI interrupt 26).
13:12 (R/W)	IN3	Extended Input 3. The DAI_EXTD_MISC1.IN3 bit field and DAI_MISC1.IN3 bit field together holds the source signal assignment for miscellaneous Interrupt 3(DAI interrupt 25).
9:8 (R/W)	IN2	Extended Input 2. The DAI_EXTD_MISC1.IN2 bit field and DAI_MISC1.IN2 bit field together holds the source signal assignment for miscellaneous Interrupt 2(DAI interrupt 24).
5:4 (R/W)	IN1	Extended Input 1. The DAI_EXTD_MISC1.IN1 bit field and DAI_MISC1.IN1 bit field together holds the source signal assignment for miscellaneous Interrupt 1(DAI interrupt 23).
1:0 (R/W)	IN0	Extended Input 0. The DAI_EXTD_MISC1.IN0 bit field and DAI_MISC1.IN0 bit field together holds the source signal assignment for miscellaneous Interrupt 0(DAI interrupt 22).

Extended Miscellaneous Control Register 2

The DAI_EXTD_MISC2 and DAI_MISC2 register together allows programs to route to the DAI interrupt latch, PCGs hardware completer trigger, PBEN input routing, or input signal inversion. This register belongs to group E which routes control signals and provides a means of connecting signals between groups.

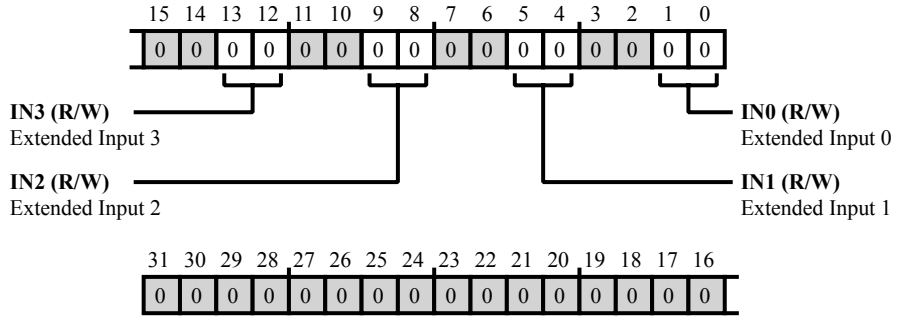

Figure 31-46: DAI_EXTD_MISC2 Register Diagram

Table 31-56: DAI_EXTD_MISC2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
13:12 (R/W)	IN3	Extended Input 3. The DAI_EXTD_MISC2.IN3 bit field and DAI_MISC1.IN3 bit field together holds the source signal assignment for PCG-F's hardware completer trigger input.
9:8 (R/W)	IN2	Extended Input 2. The DAI_EXTD_MISC2.IN2 bit field and DAI_MISC2.IN2 bit field together holds the source signal assignment for PCG-E's hardware completer trigger input.
5:4 (R/W)	IN1	Extended Input 1. The DAI_EXTD_MISC2.IN1 bit field and DAI_MISC2.IN1 bit field together holds the source signal assignment for PCG-B's hardware completer trigger input.
1:0 (R/W)	IN0	Extended Input 0. The DAI_EXTD_MISC2.IN0 bit field and DAI_MISC2.IN0 bit field together holds the source signal assignment for PCG-A's hardware completer trigger input.

Extended Pin Buffer Enable Register 0

The DAI_EXTD_PBEN0 and DAI_PBEN0 register together routes extended signals to the pin enables, and the value of these signals determines if a DAI pin is used as an output or an input.

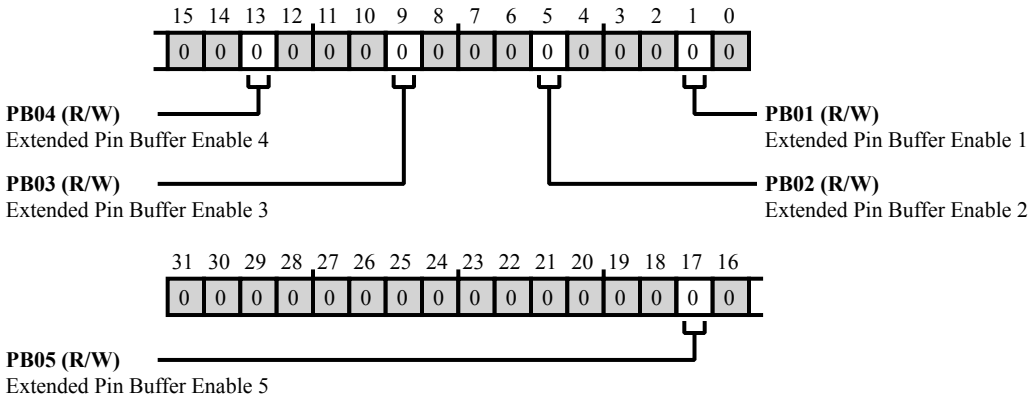

Figure 31-47: DAI_EXTD_PBEN0 Register Diagram

Table 31-57: DAI_EXTD_PBEN0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
17 (R/W)	PB05	Extended Pin Buffer Enable 5. The DAI_EXTD_PBEN0.PB05 bit field and DAI_PBEN0.PB05 bit field together holds the extended source signal assignment that will be routed to the pin buffer enable of DAI port 5.
13 (R/W)	PB04	Extended Pin Buffer Enable 4. The DAI_EXTD_PBEN0.PB04 bit field and DAI_PBEN0.PB04 bit field together holds the extended source signal assignment that will be routed to the pin buffer enable of DAI port 4.
9 (R/W)	PB03	Extended Pin Buffer Enable 3. The DAI_EXTD_PBEN0.PB03 bit field and DAI_PBEN0.PB03 bit field together holds the extended source signal assignment that will be routed to the pin buffer enable of DAI port 3.
5 (R/W)	PB02	Extended Pin Buffer Enable 2. The DAI_EXTD_PBEN0.PB02 bit field and DAI_PBEN0.PB02 bit field together holds the extended source signal assignment that will be routed to the pin buffer enable of DAI port 2.
1 (R/W)	PB01	Extended Pin Buffer Enable 1. The DAI_EXTD_PBEN0.PB01 bit field and DAI_PBEN0.PB01 bit field together holds the extended source signal assignment that will be routed to the pin buffer enable of DAI port 1.

Extended Pin Buffer Enable Register 1

The DAI_EXTD_PBEN1 and DAI_PBEN1 register together routes extended signals to the pin enables, and the value of these signals determines if a DAI pin is used as an output or an input.

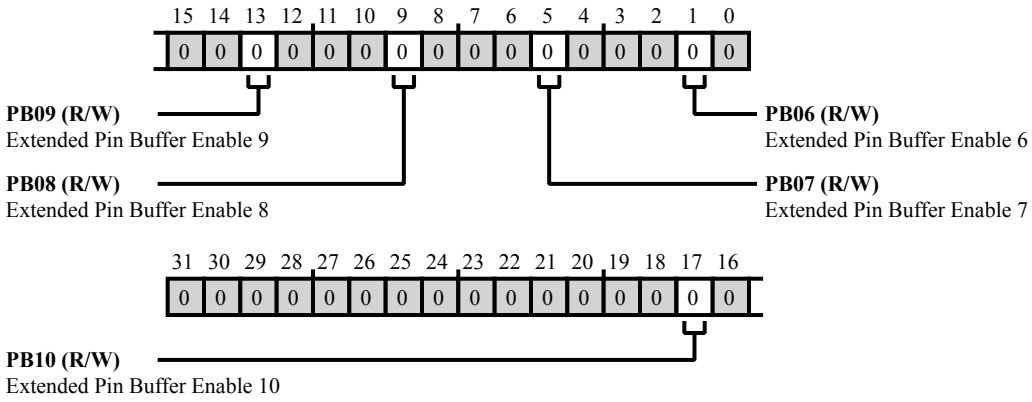

Figure 31-48: DAI_EXTD_PBEN1 Register Diagram

Table 31-58: DAI_EXTD_PBEN1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
17 (R/W)	PB10	Extended Pin Buffer Enable 10. The DAI_EXTD_PBEN1.PB10 bit field and DAI_PBEN0.PB10 bit field together holds the extended source signal assignment which will be routed to the pin buffer enable of DAI port 10.
13 (R/W)	PB09	Extended Pin Buffer Enable 9. The DAI_EXTD_PBEN1.PB09 bit field and DAI_PBEN0.PB09 bit field together holds the extended source signal assignment which will be routed to the pin buffer enable of DAI port 9.
9 (R/W)	PB08	Extended Pin Buffer Enable 8. The DAI_EXTD_PBEN1.PB08 bit field and DAI_PBEN0.PB08 bit field together holds the extended source signal assignment which will be routed to the pin buffer enable of DAI port 8.
5 (R/W)	PB07	Extended Pin Buffer Enable 7. The DAI_EXTD_PBEN1.PB07 bit field and DAI_PBEN0.PB07 bit field together holds the extended source signal assignment which will be routed to the pin buffer enable of DAI port 7.
1 (R/W)	PB06	Extended Pin Buffer Enable 6. The DAI_EXTD_PBEN1.PB06 bit field and DAI_PBEN0.PB06 bit field together holds the extended source signal assignment which will be routed to the pin buffer enable of DAI port 6.

Extended Pin Buffer Enable Register 2

The DAI_EXTD_PBEN2 and DAI_PBEN2 register together routes extended signals to the pin enables, and the value of these signals determines if a DAI pin is used as an output or an input.

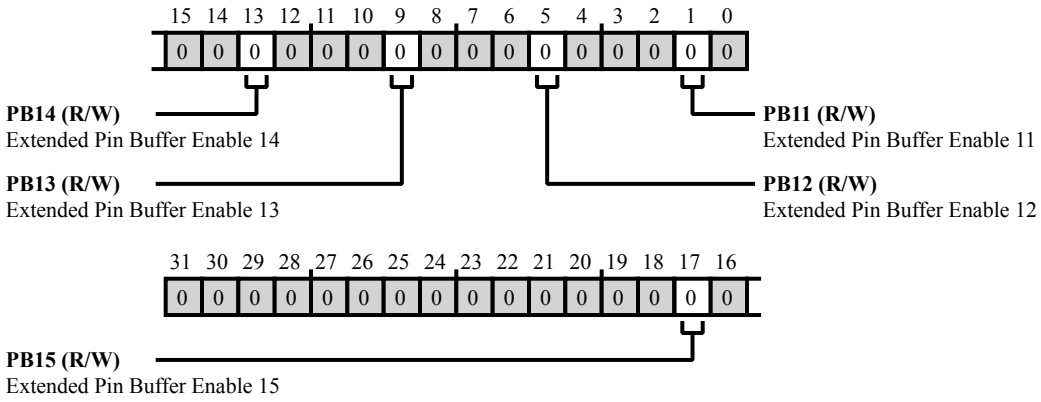

Figure 31-49: DAI_EXTD_PBEN2 Register Diagram

Table 31-59: DAI_EXTD_PBEN2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
17 (R/W)	PB15	Extended Pin Buffer Enable 15. The DAI_EXTD_PBEN2.PB15 bit field and DAI_PBEN0.PB15 bit field together holds the extended source signal assignment which will be routed to the pin buffer enable of DAI port 15.
13 (R/W)	PB14	Extended Pin Buffer Enable 14. The DAI_EXTD_PBEN2.PB14 bit field and DAI_PBEN0.PB14 bit field together holds the extended source signal assignment which will be routed to the pin buffer enable of DAI port 14.
9 (R/W)	PB13	Extended Pin Buffer Enable 13. The DAI_EXTD_PBEN2.PB13 bit field and DAI_PBEN0.PB13 bit field together holds the extended source signal assignment which will be routed to the pin buffer enable of DAI port 13.
5 (R/W)	PB12	Extended Pin Buffer Enable 12. The DAI_EXTD_PBEN2.PB12 bit field and DAI_PBEN0.PB12 bit field together holds the extended source signal assignment which will be routed to the pin buffer enable of DAI port 12.
1 (R/W)	PB11	Extended Pin Buffer Enable 11. The DAI_EXTD_PBEN2.PB11 bit field and DAI_PBEN0.PB11 bit field together holds the extended source signal assignment which will be routed to the pin buffer enable of DAI port 11.

Extended Pin Buffer Enable Register 3

The DAI_EXTD_PBEN3 and DAI_PBEN3 register together routes extended signals to the pin enables, and the value of these signals determines if a DAI pin is used as an output or an input.

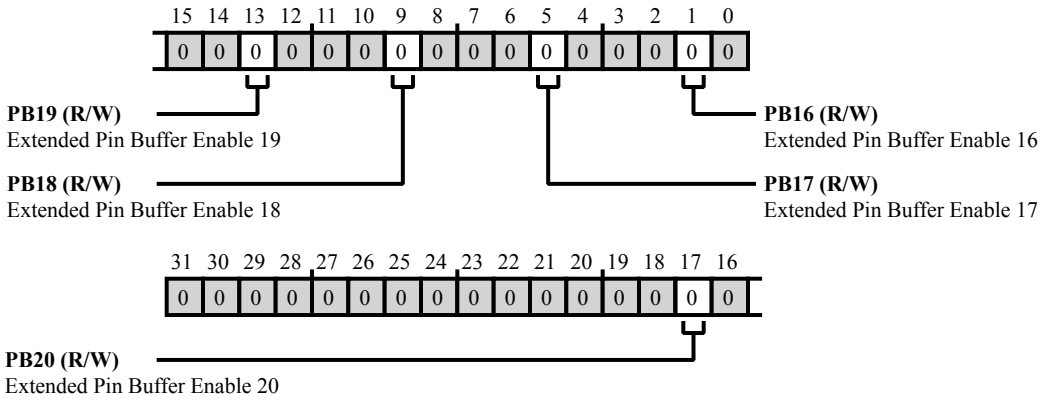

Figure 31-50: DAI_EXTD_PBEN3 Register Diagram

Table 31-60: DAI_EXTD_PBEN3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
17 (R/W)	PB20	Extended Pin Buffer Enable 20. The DAI_EXTD_PBEN3.PB20 bit field and DAI_PBEN0.PB20 bit field together holds the extended source signal assignment which will be routed to the pin buffer enable of DAI port 20.
13 (R/W)	PB19	Extended Pin Buffer Enable 19. The DAI_EXTD_PBEN3.PB19 bit field and DAI_PBEN0.PB19 bit field together holds the extended source signal assignment which will be routed to the pin buffer enable of DAI port 19.
9 (R/W)	PB18	Extended Pin Buffer Enable 18. The DAI_EXTD_PBEN3.PB18 bit field and DAI_PBEN0.PB18 bit field together holds the extended source signal assignment which will be routed to the pin buffer enable of DAI port 18.
5 (R/W)	PB17	Extended Pin Buffer Enable 17. The DAI_EXTD_PBEN3.PB17 bit field and DAI_PBEN0.PB17 bit field together holds the extended source signal assignment which will be routed to the pin buffer enable of DAI port 17.
1 (R/W)	PB16	Extended Pin Buffer Enable 16. The DAI_EXTD_PBEN3.PB16 bit field and DAI_PBEN0.PB16 bit field together holds the extended source signal assignment which will be routed to the pin buffer enable of DAI port 16.

Extended Pin Buffer Assignment Register 0

The DAI_EXTD_PIN0 and DAI_PIN0 register routes extended physical pins that are connected to a bonded pad.

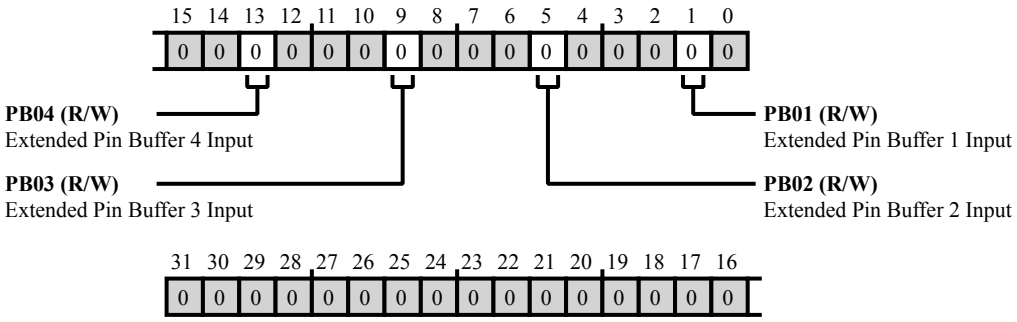

Figure 31-51: DAI_EXTD_PIN0 Register Diagram

Table 31-61: DAI_EXTD_PIN0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
13 (R/W)	PB04	Extended Pin Buffer 4 Input. DAI_EXTD_PIN0.PB04 and DAI_PIN0.PB04 together holds the Source signal assignment that will be routed to the DAI_PIN0.PB04 Destination. Refer to the Group D Signals table for Source and Destination mappings.
9 (R/W)	PB03	Extended Pin Buffer 3 Input. DAI_EXTD_PIN0.PB03 and DAI_PIN.PB03 together holds the Source signal assignment that will be routed to the DAI_PIN0.PB03 Destination. Refer to the Group D Signals table for Source and Destination mappings.
5 (R/W)	PB02	Extended Pin Buffer 2 Input. DAI_EXTD_PIN0.PB02 and DAI_PIN0.PB02 together holds the Source signal assignment that will be routed to the DAI_PIN0.PB02 Destination. Refer to the Group D Signals table for Source and Destination mappings.
1 (R/W)	PB01	Extended Pin Buffer 1 Input. DAI_EXTD_PIN0.PB01 and DAI_PIN0.PB01 together holds the Source signal assignment that will be routed to the DAI_PIN0.PB01 Destination. Refer to the Group D Signals table for Source and Destination mappings.

Extended Pin Buffer Assignment Register 1

The DAI_EXTD_PIN1 and DAI_PIN1 register routes extended physical pins that are connected to a bonded pad.

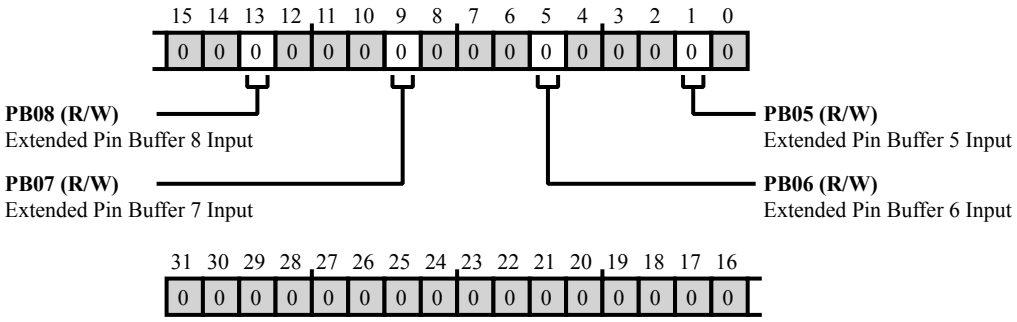

Figure 31-52: DAI_EXTD_PIN1 Register Diagram

Table 31-62: DAI_EXTD_PIN1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
13 (R/W)	PB08	Extended Pin Buffer 8 Input. DAI_EXTD_PIN1.PB08 and DAI_PIN1.PB08 together holds the Source signal assignment that will be routed to the DAI_PIN1.PB08 Destination. Refer to the Group D Signals table for Source and Destination mappings.
9 (R/W)	PB07	Extended Pin Buffer 7 Input. DAI_EXTD_PIN1.PB07 and DAI_PIN1.PB07 together holds the Source signal assignment that will be routed to the DAI_PIN1.PB07 Destination. Refer to the Group D Signals table for Source and Destination mappings.
5 (R/W)	PB06	Extended Pin Buffer 6 Input. DAI_EXTD_PIN1.PB06 and DAI_PIN1.PB06 together the Source signal assignment that will be routed to the DAI_PIN1.PB06 Destination. Refer to the Group D Signals table for Source and Destination mappings.
1 (R/W)	PB05	Extended Pin Buffer 5 Input. DAI_EXTD_PIN1.PB05 and DAI_PIN1.PB05 together holds the Source signal assignment that will be routed to the DAI_PIN1.PB05 Destination. Refer to the Group D Signals table for Source and Destination mappings.

Extended Pin Buffer Assignment Register 2

The DAI_EXTD_PIN2 and DAI_PIN2 register routes extended physical pins that are connected to a bonded pad.

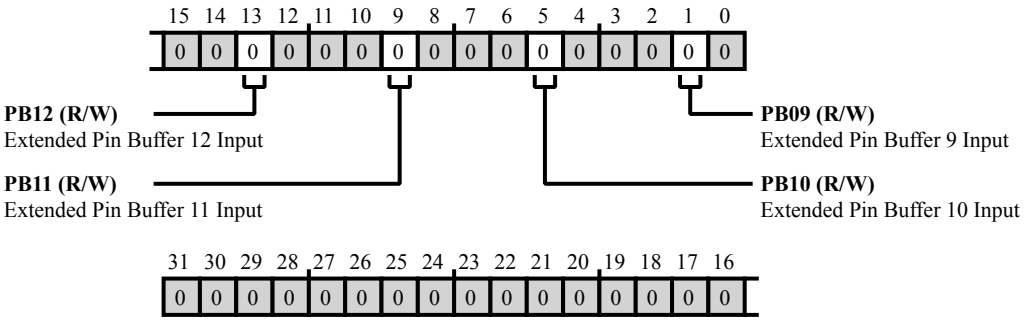

Figure 31-53: DAI_EXTD_PIN2 Register Diagram

Table 31-63: DAI_EXTD_PIN2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
13 (R/W)	PB12	Extended Pin Buffer 12 Input. DAI_EXTD_PIN2.PB12 and DAI_PIN2.PB12 together holds the Source signal assignment that will be routed to the DAI_PIN2.PB12 Destination. Refer to the Group D Signals table for Source and Destination mappings.
9 (R/W)	PB11	Extended Pin Buffer 11 Input. DAI_EXTD_PIN2.PB11 and DAI_PIN2.PB11 together holds the Source signal assignment that will be routed to the DAI_PIN2.PB11 Destination. Refer to the Group D Signals table for Source and Destination mappings.
5 (R/W)	PB10	Extended Pin Buffer 10 Input. DAI_EXTD_PIN2.PB10 and DAI_PIN2.PB10 together holds the Source signal assignment that will be routed to the DAI_PIN2.PB10 Destination. Refer to the Group D Signals table for Source and Destination mappings.
1 (R/W)	PB09	Extended Pin Buffer 9 Input. DAI_EXTD_PIN2.PB09 and DAI_PIN2.PB09 together holds the Source signal assignment that will be routed to the DAI_PIN2.PB09 Destination. Refer to the Group D Signals table for Source and Destination mappings.

Extended Pin Buffer Assignment Register 3

The DAI_EXTD_PIN3 and DAI_PIN3 register routes extended physical pins that are connected to a bonded pad.

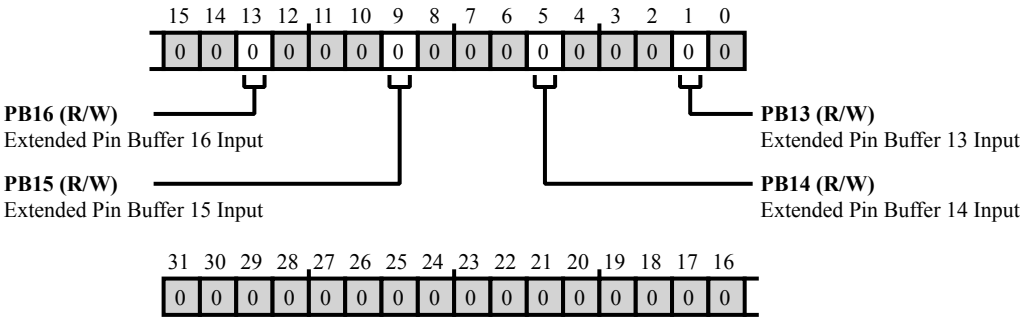

Figure 31-54: DAI_EXTD_PIN3 Register Diagram

Table 31-64: DAI_EXTD_PIN3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
13 (R/W)	PB16	Extended Pin Buffer 16 Input. DAI_EXTD_PIN3.PB16 and DAI_PIN3.PB16 together holds the Source signal assignment that will be routed to the DAI_PIN3.PB16 Destination. Refer to the Group D Signals table for Source and Destination mappings.
9 (R/W)	PB15	Extended Pin Buffer 15 Input. DAI_EXTD_PIN3.PB15 and DAI_PIN3.PB15 together holds the Source signal assignment that will be routed to the DAI_PIN3.PB15 Destination. Refer to the Group D Signals table for Source and Destination mappings.
5 (R/W)	PB14	Extended Pin Buffer 14 Input. DAI_EXTD_PIN3.PB14 and DAI_PIN3.PB14 together holds the Source signal assignment that will be routed to the DAI_PIN3.PB14 Destination. Refer to the Group D Signals table for Source and Destination mappings.
1 (R/W)	PB13	Extended Pin Buffer 13 Input. DAI_EXTD_PIN3.PB13 and DAI_PIN3.PB13 together holds the Source signal assignment that will be routed to the DAI_PIN3.PB13 Destination. Refer to the Group D Signals table for Source and Destination mappings.

Extended Pin Buffer Assignment Register 4

The DAI_EXTD_PIN4 and DAI_PIN4 register routes extended physical pins that are connected to a bonded pad.

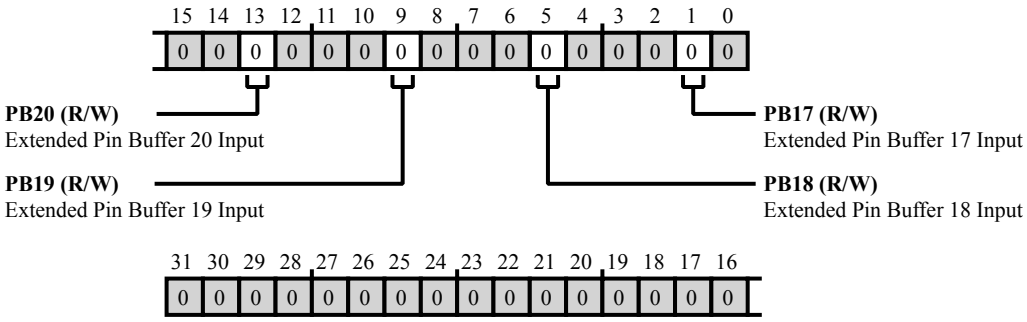

Figure 31-55: DAI_EXTD_PIN4 Register Diagram

Table 31-65: DAI_EXTD_PIN4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
13 (R/W)	PB20	Extended Pin Buffer 20 Input. DAI_EXTD_PIN4.PB20 and DAI_PIN4.PB20 together holds the Source signal assignment that will be routed to the DAI_PIN4.PB20 Destination. Refer to the Group D Signals table for Source and Destination mappings.
9 (R/W)	PB19	Extended Pin Buffer 19 Input. DAI_EXTD_PIN4.PB19 and DAI_PIN4.PB19 together holds the Source signal assignment that will be routed to the DAI_PIN4.PB19 Destination. Refer to the Group D Signals table for Source and Destination mappings.
5 (R/W)	PB18	Extended Pin Buffer 18 Input. DAI_EXTD_PIN4.PB18 an DAI_PIN4.PB18 together holds the Source signal assignment that will be routed to the DAI_PIN4.PB18 Destination. Refer to the Group D Signals table for Source and Destination mappings.
1 (R/W)	PB17	Extended Pin Buffer 17 Input. DAI_EXTD_PIN4.PB17 and DAI_PIN4.PB17 together holds the Source signal assignment that will be routed to the DAI_PIN4.PB17 Destination. Refer to the Group D Signals table for Source and Destination mappings.

Frame Sync Routing Control Register 0

The DAI_FS0 register routes frame syncs to the serial ports.

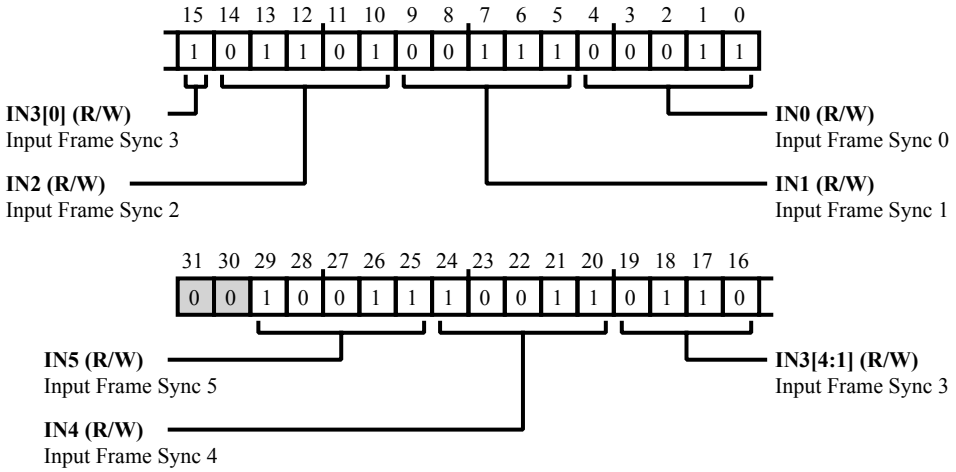

Figure 31-56: DAI_FS0 Register Diagram

Table 31-66: DAI_FS0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:25 (R/W)	IN5	Input Frame Sync 5. DAI_FS0.IN5 holds the Source signal assignment that will be routed to the DAI_FS0.IN5 Destination. Refer to the Group C Signals table for Source and Destination mappings.
24:20 (R/W)	IN4	Input Frame Sync 4. DAI_FS0.IN4 holds the Source signal assignment that will be routed to the DAI_FS0.IN4 Destination. Refer to the Group C Signals table for Source and Destination mappings.
19:15 (R/W)	IN3	Input Frame Sync 3. DAI_FS0.IN3 holds the Source signal assignment that will be routed to the DAI_FS0.IN3 Destination. Refer to the Group C Signals table for Source and Destination mappings.
14:10 (R/W)	IN2	Input Frame Sync 2. DAI_FS0.IN2 holds the Source signal assignment that will be routed to the DAI_FS0.IN2 Destination. Refer to the Group C Signals table for Source and Destination mappings.
9:5 (R/W)	IN1	Input Frame Sync 1. DAI_FS0.IN1 holds the Source signal assignment that will be routed to the DAI_FS0.IN1 Destination. Refer to the Group C Signals table for Source and Destination mappings.

Table 31-66: DAI_FS0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
4:0 (R/W)	IN0	Input Frame Sync 0. `DAI_FS0.IN0` holds the Source signal assignment that will be routed to the `DAI_FS0.IN0` Destination. Refer to the Group C Signals table for Source and Destination mappings.

Frame Sync Routing Control Register 1

The DAI_FS1 register routes frame syncs to the asynchronous sample rate converter (ASRC).

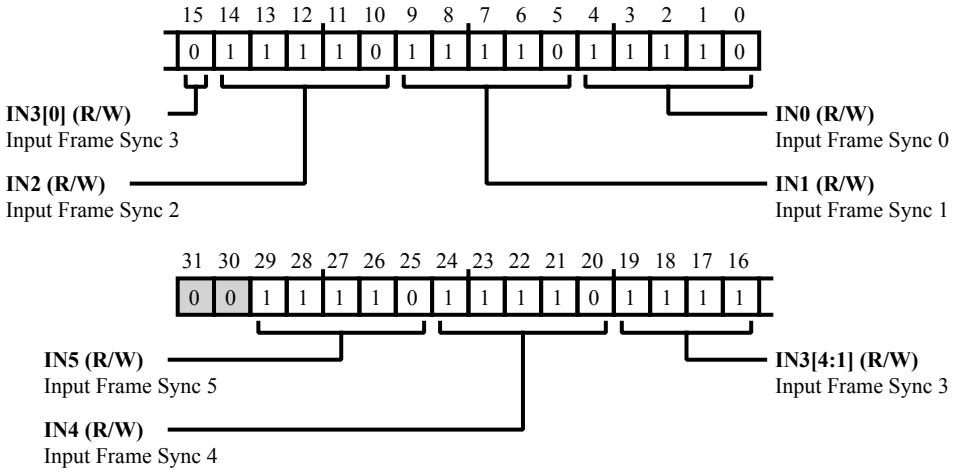

Figure 31-57: DAI_FS1 Register Diagram

Table 31-67: DAI_FS1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:25 (R/W)	IN5	Input Frame Sync 5. DAI_FS1.IN5 holds the Source signal assignment that will be routed to the DAI_FS1.IN5 Destination. Refer to the Group C Signals table for Source and Destination mappings.
24:20 (R/W)	IN4	Input Frame Sync 4. DAI_FS1.IN4 holds the Source signal assignment that will be routed to the DAI_FS1.IN4 Destination. Refer to the Group C Signals table for Source and Destination mappings.
19:15 (R/W)	IN3	Input Frame Sync 3. DAI_FS1.IN3 holds the Source signal assignment that will be routed to the DAI_FS1.IN3 Destination. Refer to the Group C Signals table for Source and Destination mappings.
14:10 (R/W)	IN2	Input Frame Sync 2. DAI_FS1.IN2 holds the Source signal assignment that will be routed to the DAI_FS1.IN2 Destination. Refer to the Group C Signals table for Source and Destination mappings.
9:5 (R/W)	IN1	Input Frame Sync 1. DAI_FS1.IN1 holds the Source signal assignment that will be routed to the DAI_FS1.IN1 Destination. Refer to the Group C Signals table for Source and Destination mappings.

Table 31-67: DAI_FS1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
4:0 (R/W)	IN0	Input Frame Sync 0. `DAI_FS1.IN0` holds the Source signal assignment that will be routed to the `DAI_FS1.IN0` Destination. Refer to the Group C Signals table for Source and Destination mappings.

Frame Sync Routing Control Register 2

The DAI_FS2 register routes frame syncs to the asynchronous sample rate converter (ASRC).

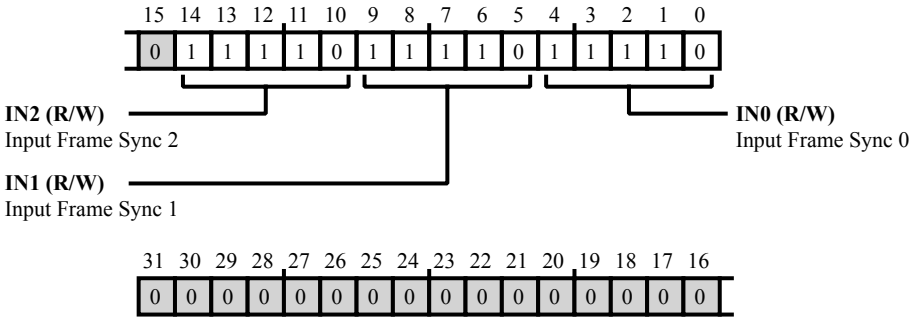

Figure 31-58: DAI_FS2 Register Diagram

Table 31-68: DAI_FS2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
14:10 (R/W)	IN2	Input Frame Sync 2. DAI_FS2.IN2 holds the Source signal assignment that will be routed to the DAI_FS2.IN2 Destination. Refer to the Group C Signals table for Source and Destination mappings.
9:5 (R/W)	IN1	Input Frame Sync 1. The DAI_FS2.IN1 bit field routes the frame sync output to the ASRC3 frame sync input port.
4:0 (R/W)	IN0	Input Frame Sync 0. DAI_FS2.IN0 holds the Source signal assignment that will be routed to the DAI_FS2.IN0 Destination. Refer to the Group C Signals table for Source and Destination mappings.

Frame Sync Routing Control Register 4

The DAI_FS4 register routes frame syncs to the asynchronous sample rate converter (ASRC).

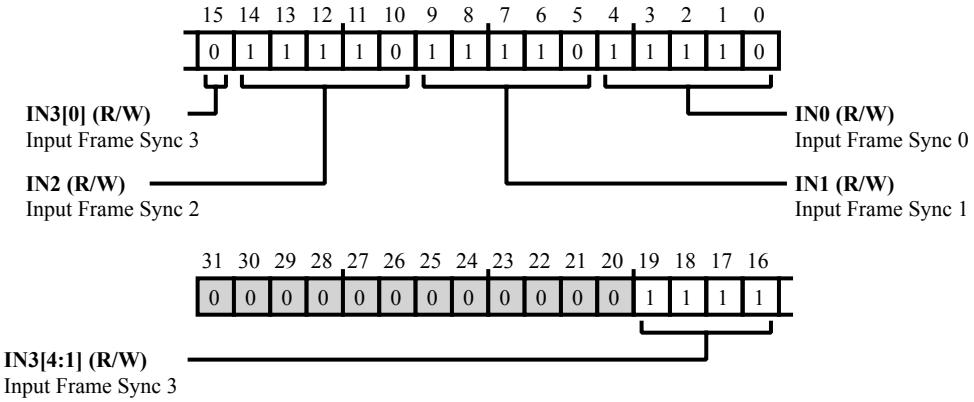

Figure 31-59: DAI_FS4 Register Diagram

Table 31-69: DAI_FS4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
19:15 (R/W)	IN3	Input Frame Sync 3. DAI_FS4.IN3 holds the Source signal assignment that will be routed to the DAI_FS4.IN3 Destination. This register is used to map the frame sync to the Timer ACI inputs. Refer to the Group C Signals table for Source and Destination mappings.
14:10 (R/W)	IN2	Input Frame Sync 2. DAI_FS4.IN2 holds the Source signal assignment that will be routed to the DAI_FS4.IN2 Destination. This register is used to map the frame sync to the Timer ACI inputs. Refer to the Group C Signals table for Source and Destination mappings.
9:5 (R/W)	IN1	Input Frame Sync 1. DAI_FS4.IN1 holds the Source signal assignment that will be routed to the DAI_FS4.IN1 Destination. Refer to the Group C Signals table for Source and Destination mappings.
4:0 (R/W)	IN0	Input Frame Sync 0. DAI_FS4.IN0 holds the Source signal assignment that will be routed to the DAI_FS4.IN0 Destination. Refer to the Group C Signals table for Source and Destination mappings.

Global SPORT Interrupt Grouping Register

The DAI_GBL_INT_EN register contains bits to configure the group interrupts and triggers of the SPORTs when using the SPORT global enable feature.

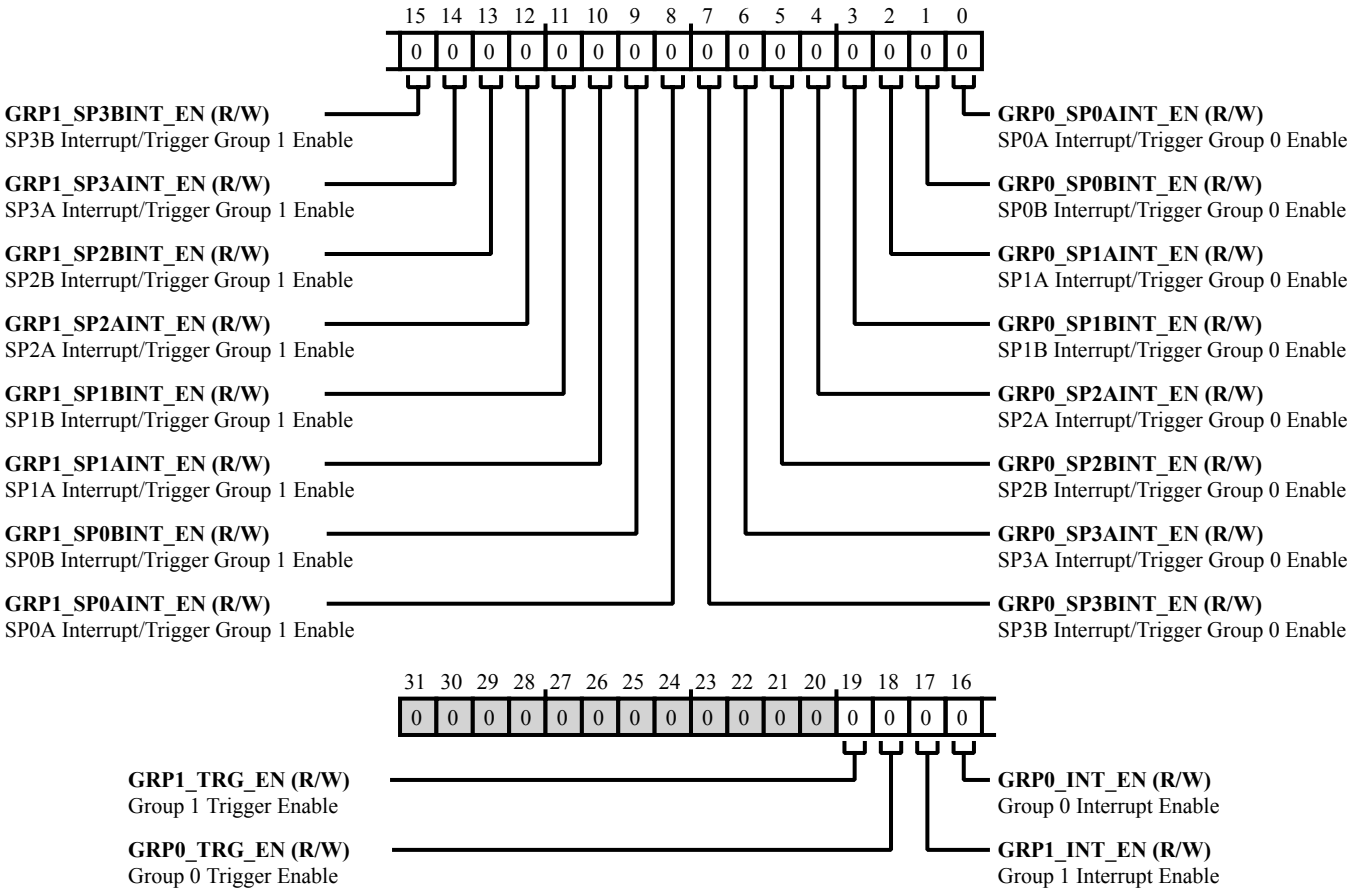

Figure 31-60: DAI_GBL_INT_EN Register Diagram

Table 31-70: DAI_GBL_INT_EN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
19 (R/W)	GRP1_TRG_EN	Group 1 Trigger Enable. The DAI_GBL_INT_EN.GRP1_TRG_EN bit enables the trigger-out for group 1.
18 (R/W)	GRP0_TRG_EN	Group 0 Trigger Enable. The DAI_GBL_INT_EN.GRP0_TRG_EN bit enables the trigger-out for group 0.
17 (R/W)	GRP1_INT_EN	Group 1 Interrupt Enable. The DAI_GBL_INT_EN.GRP1_INT_EN bit enables the interrupt for group 1.

Table 31-70: DAI_GBL_INT_EN Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
16 (R/W)	GRP0_INT_EN	Group 0 Interrupt Enable. The DAI_GBL_INT_EN.GRP0_INT_EN bit enables the interrupt for group 0.
15 (R/W)	GRP1_SP3BINT_EN	SP3B Interrupt/Trigger Group 1 Enable. The DAI_GBL_INT_EN.GRP1_SP3BINT_EN bit enables the interrupt or trigger-out for SPORT3 B when it is part of group 1.
14 (R/W)	GRP1_SP3AINT_EN	SP3A Interrupt/Trigger Group 1 Enable. The DAI_GBL_INT_EN.GRP1_SP3AINT_EN bit enables the interrupt or trigger-out for SPORT3 A when it is part of group 1.
13 (R/W)	GRP1_SP2BINT_EN	SP2B Interrupt/Trigger Group 1 Enable. The DAI_GBL_INT_EN.GRP1_SP2BINT_EN bit enables the interrupt or trigger-out for SPORT2 B when it is part of group 1.
12 (R/W)	GRP1_SP2AINT_EN	SP2A Interrupt/Trigger Group 1 Enable. The DAI_GBL_INT_EN.GRP1_SP2AINT_EN bit enables the interrupt or trigger-out for SPORT2 A when it is part of group 1.
11 (R/W)	GRP1_SP1BINT_EN	SP1B Interrupt/Trigger Group 1 Enable. The DAI_GBL_INT_EN.GRP1_SP1BINT_EN bit enables the interrupt or trigger-out for SPORT1 B when it is part of group 1.
10 (R/W)	GRP1_SP1AINT_EN	SP1A Interrupt/Trigger Group 1 Enable. The DAI_GBL_INT_EN.GRP1_SP1AINT_EN bit enables the interrupt or trigger-out for SPORT1 A when it is part of group 1.
9 (R/W)	GRP1_SP0BINT_EN	SP0B Interrupt/Trigger Group 1 Enable. The DAI_GBL_INT_EN.GRP1_SP0BINT_EN bit enables the interrupt or trigger-out for SPORT0 B when it is part of group 1.
8 (R/W)	GRP1_SP0AINT_EN	SP0A Interrupt/Trigger Group 1 Enable. The DAI_GBL_INT_EN.GRP1_SP0AINT_EN bit enables the interrupt or trigger-out for SPORT0 A when it is part of group 1.
7 (R/W)	GRP0_SP3BINT_EN	SP3B Interrupt/Trigger Group 0 Enable. The DAI_GBL_INT_EN.GRP0_SP3BINT_EN bit enables the interrupt or trigger-out for SPORT3 B when it is part of group 0.
6 (R/W)	GRP0_SP3AINT_EN	SP3A Interrupt/Trigger Group 0 Enable. The DAI_GBL_INT_EN.GRP0_SP3AINT_EN bit enables the interrupt or trigger-out for SPORT3 A when it is part of group 0.
5 (R/W)	GRP0_SP2BINT_EN	SP2B Interrupt/Trigger Group 0 Enable. The DAI_GBL_INT_EN.GRP0_SP2BINT_EN bit enables the interrupt or trigger-out for SPORT2 B when it is part of group 0.

Table 31-70: DAI_GBL_INT_EN Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
4 (R/W)	GRP0_SP2AINT_EN	SP2A Interrupt/Trigger Group 0 Enable. The `DAI_GBL_INT_EN.GRP0_SP2AINT_EN` bit enables the interrupt or trigger-out for SPORT2 A when it is part of group 0.
3 (R/W)	GRP0_SP1BINT_EN	SP1B Interrupt/Trigger Group 0 Enable. The `DAI_GBL_INT_EN.GRP0_SP1BINT_EN` bit enables the interrupt or trigger-out for SPORT1 B when it is part of group 0.
2 (R/W)	GRP0_SP1AINT_EN	SP1A Interrupt/Trigger Group 0 Enable. The `DAI_GBL_INT_EN.GRP0_SP1AINT_EN` bit enables the interrupt or trigger-out for SPORT1 A when it is part of group 0.
1 (R/W)	GRP0_SP0BINT_EN	SP0B Interrupt/Trigger Group 0 Enable. The `DAI_GBL_INT_EN.GRP0_SP0BINT_EN` bit enables the interrupt or trigger-out for SPORT0 B when it is part of group 0.
0 (R/W)	GRP0_SP0AINT_EN	SP0A Interrupt/Trigger Group 0 Enable. The `DAI_GBL_INT_EN.GRP0_SP0AINT_EN` bit enables the interrupt or trigger-out for SPORT0 A when it is part of group 0.

Global PCG Enable Control Register

The DAI_GBL_PCG_EN register bits indicate the status (signal high or low) for each pin. The individual bit reads 1 if the signal to this pin is high and reads 0 if signal to this pin is low.

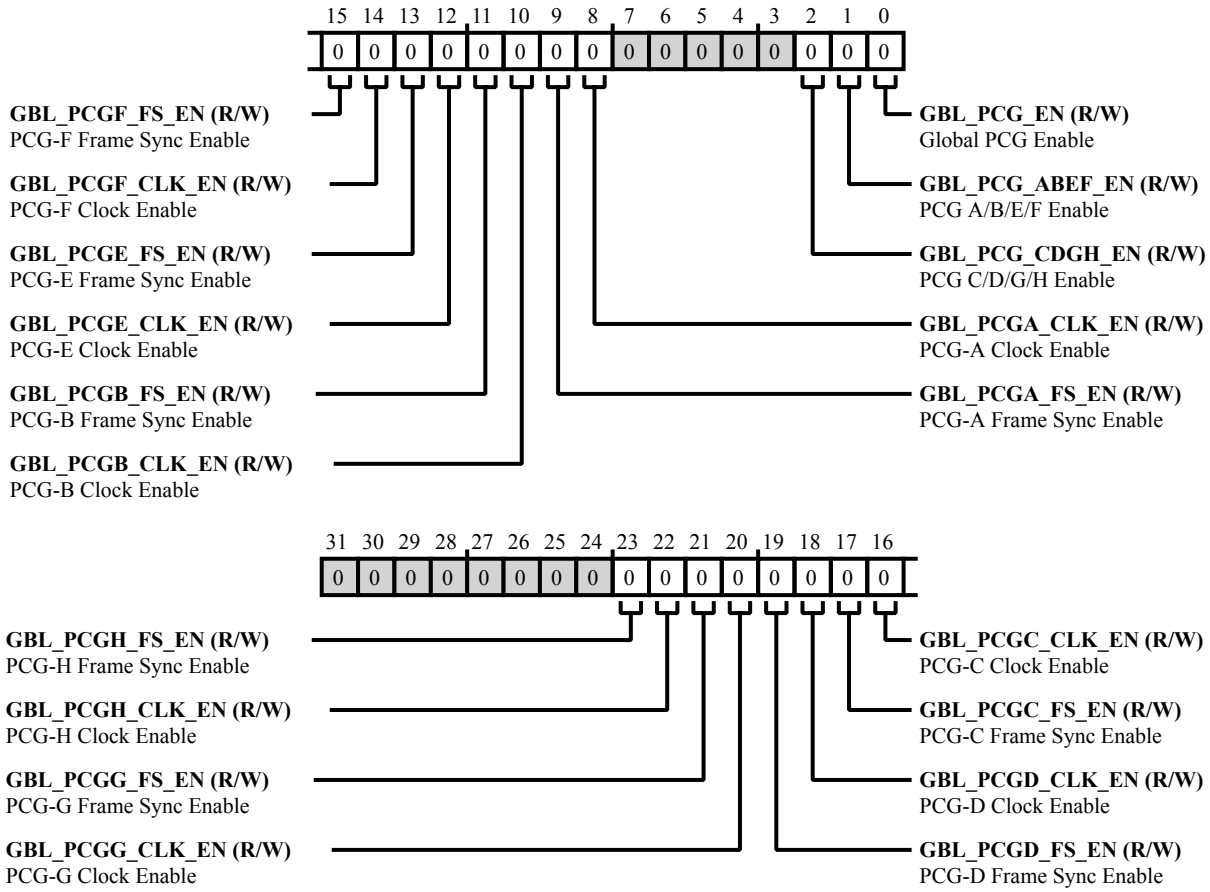

Figure 31-61: DAI_GBL_PCG_EN Register Diagram

Table 31-71: DAI_GBL_PCG_EN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
23 (R/W)	GBL_PCGH_FS_EN	PCG-H Frame Sync Enable. This bit when set to 1 enables the frame sync generation and when set to 0 disables the frame sync generation.
22 (R/W)	GBL_PCGH_CLK_EN	PCG-H Clock Enable. This bit when set to 1 enables the clock generation and when set to 0 disables the clock generation.

Table 31-71: DAI_GBL_PCG_EN Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
21 (R/W)	GBL_PCGG_FS_EN	PCG-G Frame Sync Enable. This bit when set to 1 enables the frame sync generation and when set to 0 disables the frame sync generation.
20 (R/W)	GBL_PCGG_CLK_EN	PCG-G Clock Enable. This bit when set to 1 enables the clock generation and when set to 0 disables the clock generation.
19 (R/W)	GBL_PCGD_FS_EN	PCG-D Frame Sync Enable. This bit when set to 1 enables the frame sync generation and when set to 0 disables the frame sync generation.
18 (R/W)	GBL_PCGD_CLK_EN	PCG-D Clock Enable. This bit when set to 1 enables the clock generation and when set to 0 disables the clock generation.
17 (R/W)	GBL_PCGC_FS_EN	PCG-C Frame Sync Enable. This bit when set to 1 enables the frame sync generation and when set to 0 disables the frame sync generation.
16 (R/W)	GBL_PCGC_CLK_EN	PCG-C Clock Enable. This bit when set to 1 enables the clock generation and when set to 0 disables the clock generation.
15 (R/W)	GBL_PCGF_FS_EN	PCG-F Frame Sync Enable. This bit when set to 1 enables the frame sync generation and when set to 0 disables the frame sync generation.
14 (R/W)	GBL_PCGF_CLK_EN	PCG-F Clock Enable. This bit when set to 1 enables the clock generation and when set to 0 disables the clock generation.
13 (R/W)	GBL_PCGE_FS_EN	PCG-E Frame Sync Enable. This bit when set to 1 enables the frame sync generation and when set to 0 disables the frame sync generation.
12 (R/W)	GBL_PCGE_CLK_EN	PCG-E Clock Enable. This bit when set to 1 enables the clock generation and when set to 0 disables the clock generation.
11 (R/W)	GBL_PCGB_FS_EN	PCG-B Frame Sync Enable. This bit when set to 1 enables the frame sync generation and when set to 0 disables the frame sync generation.
10 (R/W)	GBL_PCGB_CLK_EN	PCG-B Clock Enable. This bit when set to 1 enables the clock generation and when set to 0 disables the clock generation.

Table 31-71: DAI_GBL_PCG_EN Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
9 (R/W)	GBL_PCGA_FS_EN	PCG-A Frame Sync Enable. This bit when set to 1 enables the frame sync generation and when set to 0 disables the frame sync generation.
8 (R/W)	GBL_PCGA_CLK_EN	PCG-A Clock Enable. This bit when set to 1 enables the clock generation and when set to 0 disables the clock generation.
2 (R/W)	GBL_PCG_CDGH_EN	PCG C/D/G/H Enable. This bit when set to 1 along with bits [23:16] of the same register enables the respective PCGs within a DAI1. This bit when set to 0 disables the PCGs within DAI1.
1 (R/W)	GBL_PCG_ABEF_EN	PCG A/B/E/F Enable. This bit when set to 1 along with bits [15:8] of the same register enables the respective PCGs within a DAI0. This bit when set to 0 disables the PCGs within DAI0.
0 (R/W)	GBL_PCG_EN	Global PCG Enable. This bit Globally enables the PCGs across DAI0 and DAI1. This bit when set to 1 along with bit [2:1] and [23:8] enables all the PCGs across DAI0 and DAI1. This bit when set to 0 disables all the PCGs across DAI0 and DAI1.

Global SPORT Enable Register

The DAI_GBL_SP_EN register indicate the status (signal high or low) for each pin. The individual bit reads 1 if the signal to this pin is high and reads 0 if signal to this pin is low.

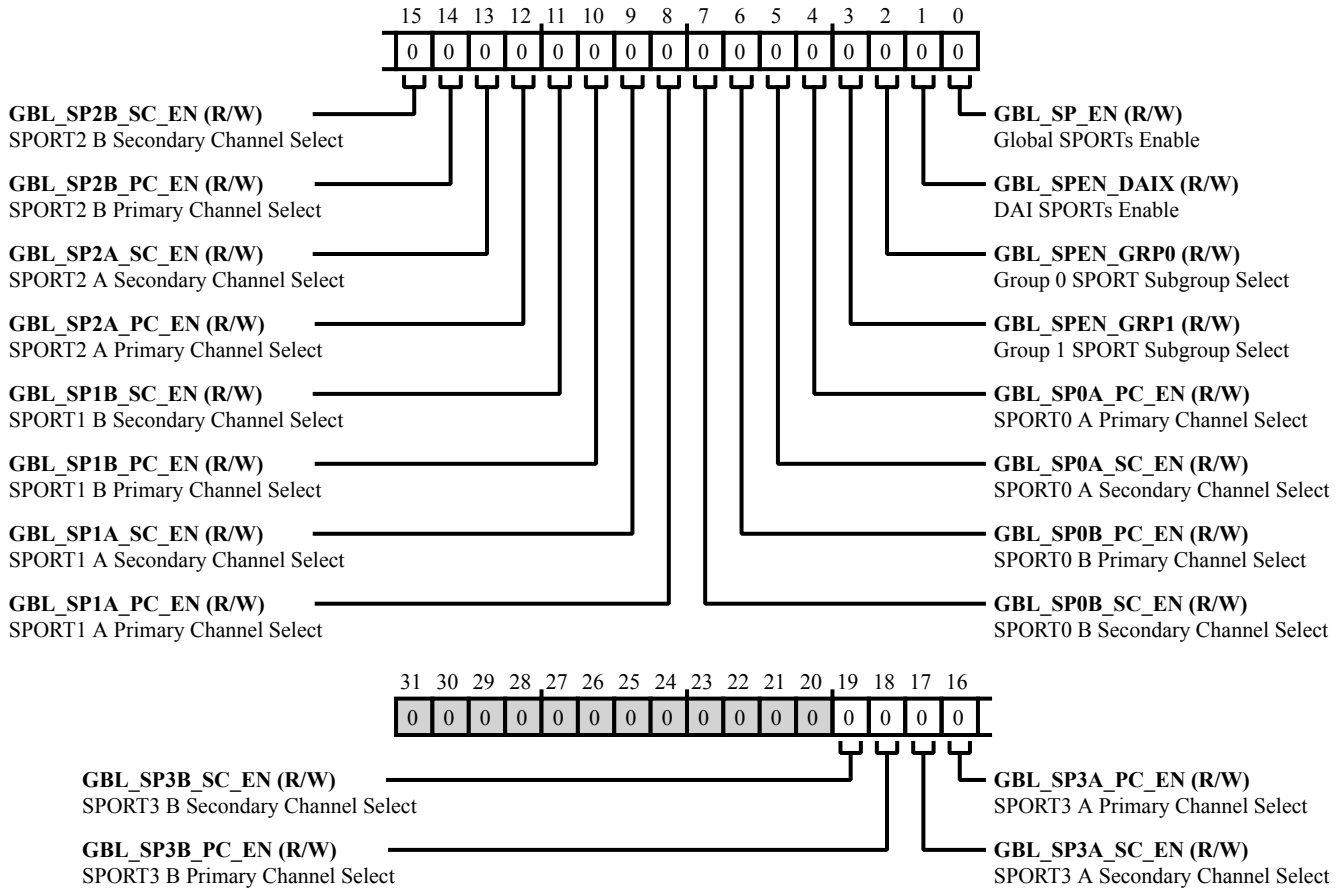

Figure 31-62: DAI_GBL_SP_EN Register Diagram

Table 31-72: DAI_GBL_SP_EN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
19 (R/W)	GBL_SP3B_SC_EN	SPORT3 B Secondary Channel Select. The DAI_GBL_SP_EN.GBL_SP3B_SC_EN bit selects SPORT3 B as the secondary channel for global enable.
18 (R/W)	GBL_SP3B_PC_EN	SPORT3 B Primary Channel Select. The DAI_GBL_SP_EN.GBL_SP3B_PC_EN bit selects SPORT3 B as the primary channel for global enable.

Table 31-72: DAI_GBL_SP_EN Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
17 (R/W)	GBL_SP3A_SC_EN	SPORT3 A Secondary Channel Select. The `DAI_GBL_SP_EN.GBL_SP3A_SC_EN` bit selects SPORT3 A as the secondary channel for global enable.
16 (R/W)	GBL_SP3A_PC_EN	SPORT3 A Primary Channel Select. The `DAI_GBL_SP_EN.GBL_SP3A_PC_EN` bit selects SPORT3 A as the primary channel for global enable.
15 (R/W)	GBL_SP2B_SC_EN	SPORT2 B Secondary Channel Select. The `DAI_GBL_SP_EN.GBL_SP2B_SC_EN` bit selects SPORT2 B as the secondary channel for global enable.
14 (R/W)	GBL_SP2B_PC_EN	SPORT2 B Primary Channel Select. The `DAI_GBL_SP_EN.GBL_SP2B_PC_EN` bit selects SPORT2 B as the primary channel for global enable.
13 (R/W)	GBL_SP2A_SC_EN	SPORT2 A Secondary Channel Select. The `DAI_GBL_SP_EN.GBL_SP2A_SC_EN` bit selects SPORT2 A as the secondary channel for global enable.
12 (R/W)	GBL_SP2A_PC_EN	SPORT2 A Primary Channel Select. The `DAI_GBL_SP_EN.GBL_SP2A_PC_EN` bit selects SPORT2 A as the primary channel for global enable.
11 (R/W)	GBL_SP1B_SC_EN	SPORT1 B Secondary Channel Select. The `DAI_GBL_SP_EN.GBL_SP1B_SC_EN` bit selects SPORT1 B as the secondary channel for global enable.
10 (R/W)	GBL_SP1B_PC_EN	SPORT1 B Primary Channel Select. The `DAI_GBL_SP_EN.GBL_SP1B_PC_EN` bit selects SPORT1 B as the primary channel for global enable.
9 (R/W)	GBL_SP1A_SC_EN	SPORT1 A Secondary Channel Select. The `DAI_GBL_SP_EN.GBL_SP1A_SC_EN` bit selects SPORT1 A as the secondary channel for global enable.
8 (R/W)	GBL_SP1A_PC_EN	SPORT1 A Primary Channel Select. The `DAI_GBL_SP_EN.GBL_SP1A_PC_EN` bit selects SPORT1 A as the primary channel for global enable.
7 (R/W)	GBL_SP0B_SC_EN	SPORT0 B Secondary Channel Select. The `DAI_GBL_SP_EN.GBL_SP0B_SC_EN` bit selects SPORT0 B as the secondary channel for global enable.
6 (R/W)	GBL_SP0B_PC_EN	SPORT0 B Primary Channel Select. Selects SPORT0 B primary channel for global enable.

Table 31-72: DAI_GBL_SP_EN Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
5 (R/W)	GBL_SP0A_SC_EN	SPORT0 A Secondary Channel Select. The `DAI_GBL_SP_EN.GBL_SP0A_SC_EN` bit selects SPORT0 A as the secondary channel for global enable.
4 (R/W)	GBL_SP0A_PC_EN	SPORT0 A Primary Channel Select. The `DAI_GBL_SP_EN.GBL_SP0A_PC_EN` bit selects SPORT0 A as the primary channel for global enable.
3 (R/W)	GBL_SPEN_GRP1	Group 1 SPORT Subgroup Select. The `DAI_GBL_SP_EN.GBL_SPEN_GRP1` bit creates a subgroup of selected SPORTs.
2 (R/W)	GBL_SPEN_GRP0	Group 0 SPORT Subgroup Select. The `DAI_GBL_SP_EN.GBL_SPEN_GRP0` bit creates a subgroup of selected SPORTs.
1 (R/W)	GBL_SPEN_DAIX	DAI SPORTs Enable. The `DAI_GBL_SP_EN.GBL_SPEN_DAIX` bit enables the SPORTs selected within a DAI.
0 (R/W)	GBL_SP_EN	Global SPORTs Enable. The `DAI_GBL_SP_EN.GBL_SP_EN` bit enables the selected SPORTs.

Falling-Edge Interrupt Mask Register

The DAI_IMSK_FE register masks and unmasks interrupts generated on the falling edge of a waveform. Note that any of the Group E signals can be mapped to any of the Miscellaneous interrupts (9-0).

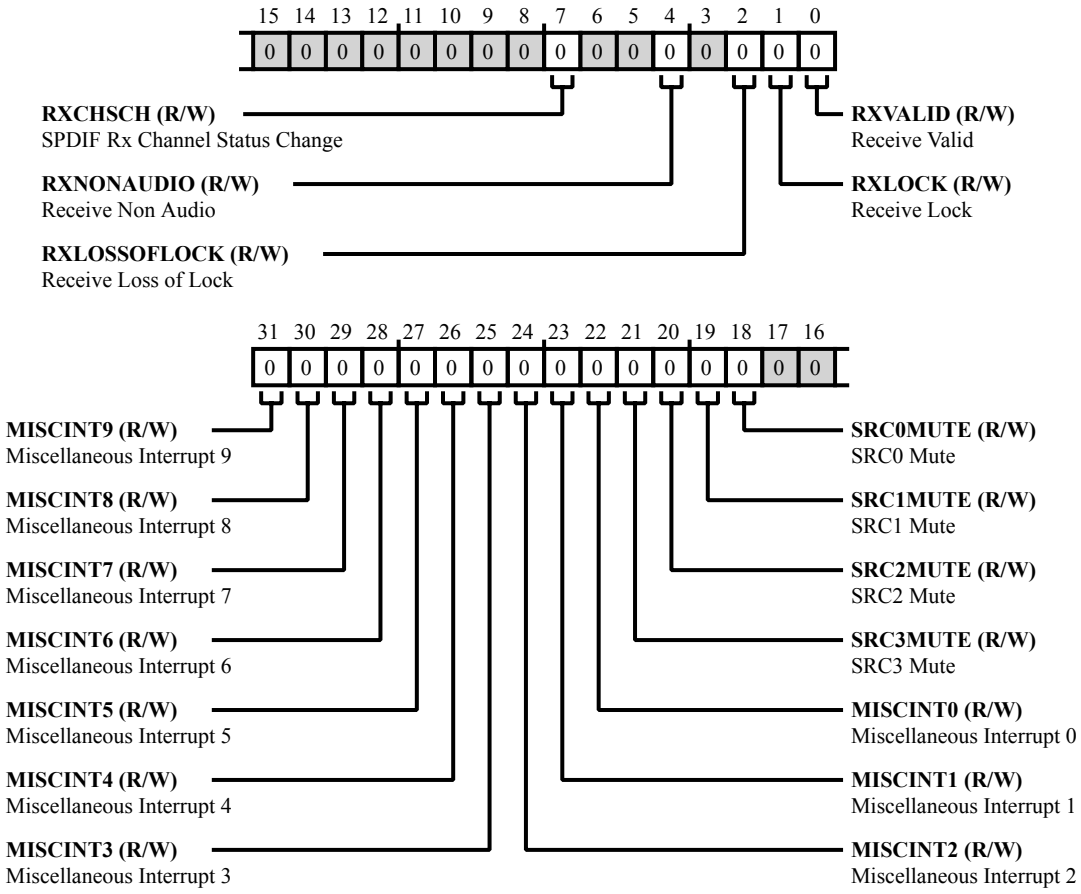

Figure 31-63: DAI_IMSK_FE Register Diagram

Table 31-73: DAI_IMSK_FE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	MISCINT9	Miscellaneous Interrupt 9. Setting the DAI_IMSK_FE.MISCINT9 bit unmasks the interrupt for the falling edge of the routed signal.
30 (R/W)	MISCINT8	Miscellaneous Interrupt 8. Setting the DAI_IMSK_FE.MISCINT8 bit unmasks the interrupt for the falling edge of the routed signal.

Table 31-73: DAI_IMSK_FE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
29 (R/W)	MISCINT7	Miscellaneous Interrupt 7. Setting the DAI_IMSK_FE.MISCINT7 bit unmasks the interrupt for the falling edge of the routed signal.
28 (R/W)	MISCINT6	Miscellaneous Interrupt 6. Setting the DAI_IMSK_FE.MISCINT6 bit unmasks the interrupt for the falling edge of the routed signal.
27 (R/W)	MISCINT5	Miscellaneous Interrupt 5. Setting the DAI_IMSK_FE.MISCINT5 bit unmasks the interrupt for the falling edge of the routed signal.
26 (R/W)	MISCINT4	Miscellaneous Interrupt 4. Setting the DAI_IMSK_FE.MISCINT4 bit unmasks the interrupt for the falling edge of the routed signal.
25 (R/W)	MISCINT3	Miscellaneous Interrupt 3. Setting the DAI_IMSK_FE.MISCINT3 bit unmasks the interrupt for the falling edge of the routed signal.
24 (R/W)	MISCINT2	Miscellaneous Interrupt 2. Setting the DAI_IMSK_FE.MISCINT2 bit unmasks the interrupt for the falling edge of the routed signal.
23 (R/W)	MISCINT1	Miscellaneous Interrupt 1. Setting the DAI_IMSK_FE.MISCINT1 bit unmasks the interrupt for the falling edge of the routed signal.
22 (R/W)	MISCINT0	Miscellaneous Interrupt 0. Setting the DAI_IMSK_FE.MISCINT0 bit unmasks the interrupt for the falling edge of the routed signal.
21 (R/W)	SRC3MUTE	SRC3 Mute. The DAI_IMSK_FE.SRC3MUTE bit masks or unmasks the corresponding SRC mute out interrupt for the falling edge of this interrupt. This interrupt can be generated either entering mute, exiting muting or both.
20 (R/W)	SRC2MUTE	SRC2 Mute. The DAI_IMSK_FE.SRC2MUTE bit masks or unmasks the corresponding SRC mute out interrupt for the falling edge of this interrupt. This interrupt can be generated either entering mute, exiting muting or both.
19 (R/W)	SRC1MUTE	SRC1 Mute. The DAI_IMSK_FE.SRC1MUTE bit masks or unmasks the corresponding SRC mute out interrupt for the falling edge of this interrupt. This interrupt can be generated either entering mute, exiting muting or both.

Table 31-73: DAI_IMSK_FE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
18 (R/W)	SRC0MUTE	SRC0 Mute. The DAI_IMSK_FE.SRC0MUTE bit masks or unmasks the corresponding SRC mute out interrupt for the falling edge of this interrupt. This interrupt can be generated either entering mute, exiting muting or both.
7 (R/W)	RXCHSCH	SPDIF Rx Channel Status Change. The DAI_IMSK_FE.RXCHSCH bit masks or unmasks RXCHSCH interrupt for the falling edge of this interrupt. This interrupt is set if there is a change in the SPDIF Rx channel status bits (SPDIF_RX_STAT0/1_A/B).
4 (R/W)	RXNONAUDIO	Receive Non Audio. The DAI_IMSK_FE.RXNONAUDIO bit masks or unmasks the non audio frame mode interrupt for the falling edge of this interrupt. If the channel status indicates non-PCM audio, the NONAUDIO bit flag is set.
2 (R/W)	RXLOSSOFLOCK	Receive Loss of Lock. The DAI_IMSK_FE.RXLOSSOFLOCK bit masks or unmasks the emphasis loss of lock interrupt for the falling edge of this interrupt. The loss of lock status is set by the S/PDIF receiver if receiver loses the lock of biphase stream.
1 (R/W)	RXLOCK	Receive Lock. The DAI_IMSK_FE.RXLOCK bit masks or unmasks the S/PDIF receiver lock for the falling edge of this interrupt. This interrupt occurs when the S/PDIF receiver locks to the S/PDIF stream.
0 (R/W)	RXVALID	Receive Valid. Setting the DAI_IMSK_FE.RXVALID bit unmasks the interrupt for the falling edge of the routed signal. This interrupt is set based on whether data received by the S/PDIF is linear PCM or non-linear audio data.

Core Interrupt Priority Assignment Register

The DAI_IMSK_PRI register masks interrupts for DAI high or DAI low interrupt priority.

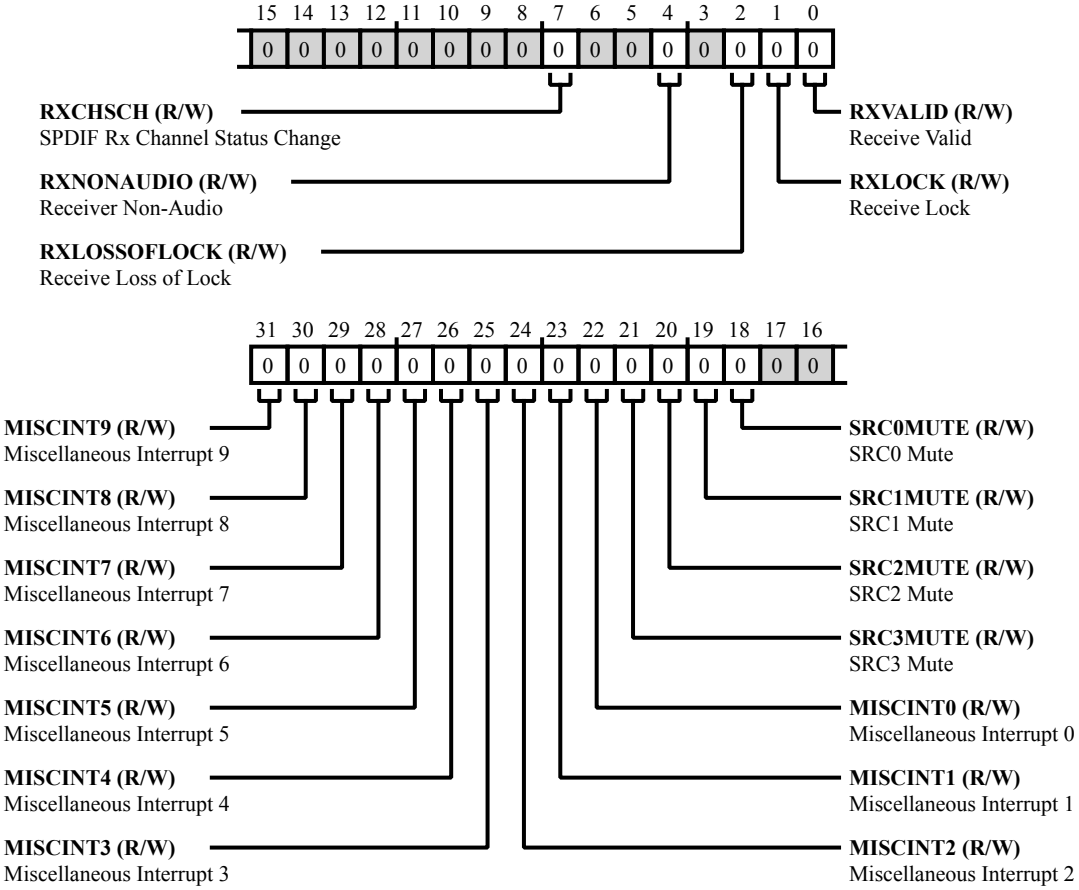

Figure 31-64: DAI_IMSK_PRI Register Diagram

Table 31-74: DAI_IMSK_PRI Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	MISCINT9	Miscellaneous Interrupt 9. If the DAI_IMSK_PRI.MISCINT9 bit is cleared (=0), the interrupt is mapped to INTR_DAI_IRQL signal from the SEC. If the DAI_IMSK_PRI.MISCINT9 bit is set (=1) the interrupt is mapped to INTR_DAI_IRQH signal from the SEC.
30 (R/W)	MISCINT8	Miscellaneous Interrupt 8. If the DAI_IMSK_PRI.MISCINT8 bit is cleared (=0), the interrupt is mapped to INTR_DAI_IRQL signal from the SEC. If the DAI_IMSK_PRI.MISCINT8 bit is set (=1) the interrupt is mapped to INTR_DAI_IRQH signal from the SEC.

Table 31-74: DAI_IMSK_PRI Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
29 (R/W)	MISCINT7	Miscellaneous Interrupt 7. If the DAI_IMSK_PRI.MISCINT7 bit is cleared (=0), the interrupt is mapped to INTR_DAI_IRQL signal from the SEC. If the DAI_IMSK_PRI.MISCINT7 bit is set (=1) the interrupt is mapped to INTR_DAI_IRQH signal from the SEC.
28 (R/W)	MISCINT6	Miscellaneous Interrupt 6. If the DAI_IMSK_PRI.MISCINT6 bit is cleared (=0), the interrupt is mapped to INTR_DAI_IRQL signal from the SEC. If the DAI_IMSK_PRI.MISCINT6 bit is set (=1) the interrupt is mapped to INTR_DAI_IRQH signal from the SEC.
27 (R/W)	MISCINT5	Miscellaneous Interrupt 5. If the DAI_IMSK_PRI.MISCINT5 bit is cleared (=0), the interrupt is mapped to INTR_DAI_IRQL signal from the SEC. If the DAI_IMSK_PRI.MISCINT5 bit is set (=1) the interrupt is mapped to INTR_DAI_IRQH signal from the SEC.
26 (R/W)	MISCINT4	Miscellaneous Interrupt 4. If the DAI_IMSK_PRI.MISCINT4 bit is cleared (=0), the interrupt is mapped to INTR_DAI_IRQL signal from the SEC. If the DAI_IMSK_PRI.MISCINT4 bit is set (=1) the interrupt is mapped to INTR_DAI_IRQH signal from the SEC.
25 (R/W)	MISCINT3	Miscellaneous Interrupt 3. If the DAI_IMSK_PRI.MISCINT3 bit is cleared (=0), the interrupt is mapped to INTR_DAI_IRQL signal from the SEC. If the DAI_IMSK_PRI.MISCINT3 bit is set (=1) the interrupt is mapped to INTR_DAI_IRQH signal from the SEC.
24 (R/W)	MISCINT2	Miscellaneous Interrupt 2. If the DAI_IMSK_PRI.MISCINT2 bit is cleared (=0), the interrupt is mapped to INTR_DAI_IRQL signal from the SEC. If the DAI_IMSK_PRI.MISCINT2 bit is set (=1) the interrupt is mapped to INTR_DAI_IRQH signal from the SEC.
23 (R/W)	MISCINT1	Miscellaneous Interrupt 1. If the DAI_IMSK_PRI.MISCINT1 bit is cleared (=0), the interrupt is mapped to INTR_DAI_IRQL signal from the SEC. If the DAI_IMSK_PRI.MISCINT1 bit is set (=1) the interrupt is mapped to INTR_DAI_IRQH signal from the SEC.
22 (R/W)	MISCINT0	Miscellaneous Interrupt 0. If the DAI_IMSK_PRI.MISCINT0 bit is cleared (=0), the interrupt is mapped to INTR_DAI_IRQL signal from the SEC. If the DAI_IMSK_PRI.MISCINT0 bit is set (=1) the interrupt is mapped to INTR_DAI_IRQH signal from the SEC.
21 (R/W)	SRC3MUTE	SRC3 Mute. If the DAI_IMSK_PRI.SRC3MUTE bit is cleared (=0), the interrupt is mapped to INTR_DAI_IRQL signal from the SEC. If the DAI_IMSK_PRI.SRC3MUTE bit is set (=1) the interrupt is mapped to INTR_DAI_IRQH signal from the SEC.

Table 31-74: DAI_IMSK_PRI Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
20 (R/W)	SRC2MUTE	SRC2 Mute. If the DAI_IMSK_PRI.SRC2MUTE bit is cleared (=0), the interrupt is mapped to INTR_DAI_IRQL signal from the SEC. If the DAI_IMSK_PRI.SRC2MUTE bit is set (=1) the interrupt is mapped to INTR_DAI_IRQH signal from the SEC.
19 (R/W)	SRC1MUTE	SRC1 Mute. If the DAI_IMSK_PRI.SRC1MUTE bit is cleared (=0), the interrupt is mapped to INTR_DAI_IRQL signal from the SEC. If the DAI_IMSK_PRI.SRC1MUTE bit is set (=1) the interrupt is mapped to INTR_DAI_IRQH signal from the SEC.
18 (R/W)	SRC0MUTE	SRC0 Mute. If the DAI_IMSK_PRI.SRC0MUTE bit is cleared (=0), the interrupt is mapped to INTR_DAI_IRQL signal from the SEC. If the DAI_IMSK_PRI.SRC0MUTE bit is set (=1) the interrupt is mapped to INTR_DAI_IRQH signal from the SEC.
7 (R/W)	RXCHSCH	SPDIF Rx Channel Status Change. If the DAI_IMSK_PRI.RXCHSCH bit is cleared (=0), the interrupt is mapped to INTR_DAI_IRQL signal from the SEC. If the DAI_IMSK_PRI.RXCHSCH bit is set (=1) the interrupt is mapped to INTR_DAI_IRQH signal from the SEC.
4 (R/W)	RXNONAUDIO	Receiver Non-Audio. If the DAI_IMSK_PRI.RXNONAUDIO bit is cleared (=0), the interrupt is mapped to INTR_DAI_IRQL signal from the SEC. If the DAI_IMSK_PRI.RXNONAUDIO bit is set (=1) the interrupt is mapped to INTR_DAI_IRQH signal from the SEC.
2 (R/W)	RXLOSSOFLOCK	Receive Loss of Lock. The DAI_IMSK_PRI.RXLOSSOFLOCK bit masks or unmasks the emphasis loss of lock interrupt for the falling edge of this interrupt. The loss of lock status is set by the S/PDIF receiver if receiver loses the lock of biphase stream.
1 (R/W)	RXLOCK	Receive Lock. If the DAI_IMSK_PRI.RXLOCK bit is cleared (=0), the interrupt is mapped to INTR_DAI_IRQL signal from the SEC. If the DAI_IMSK_PRI.RXLOCK bit is set (=1) the interrupt is mapped to INTR_DAI_IRQH signal from the SEC.
0 (R/W)	RXVALID	Receive Valid. If the DAI_IMSK_PRI.RXVALID bit is cleared (=0), the interrupt is mapped to the INTR_DAI_IRQL from the SEC. If the DAI_IMSK_PRI.RXVALID bit is set (=1) the interrupt is mapped to INTR_DAI_IRQH signal from the SEC.

Rising-Edge Interrupt Mask Register

The DAI_IMSK_RE register masks and unmasks interrupts generated on the rising edge of a waveform. Note that any of the Group E signals can be mapped to any of the miscellaneous interrupts (9-0).

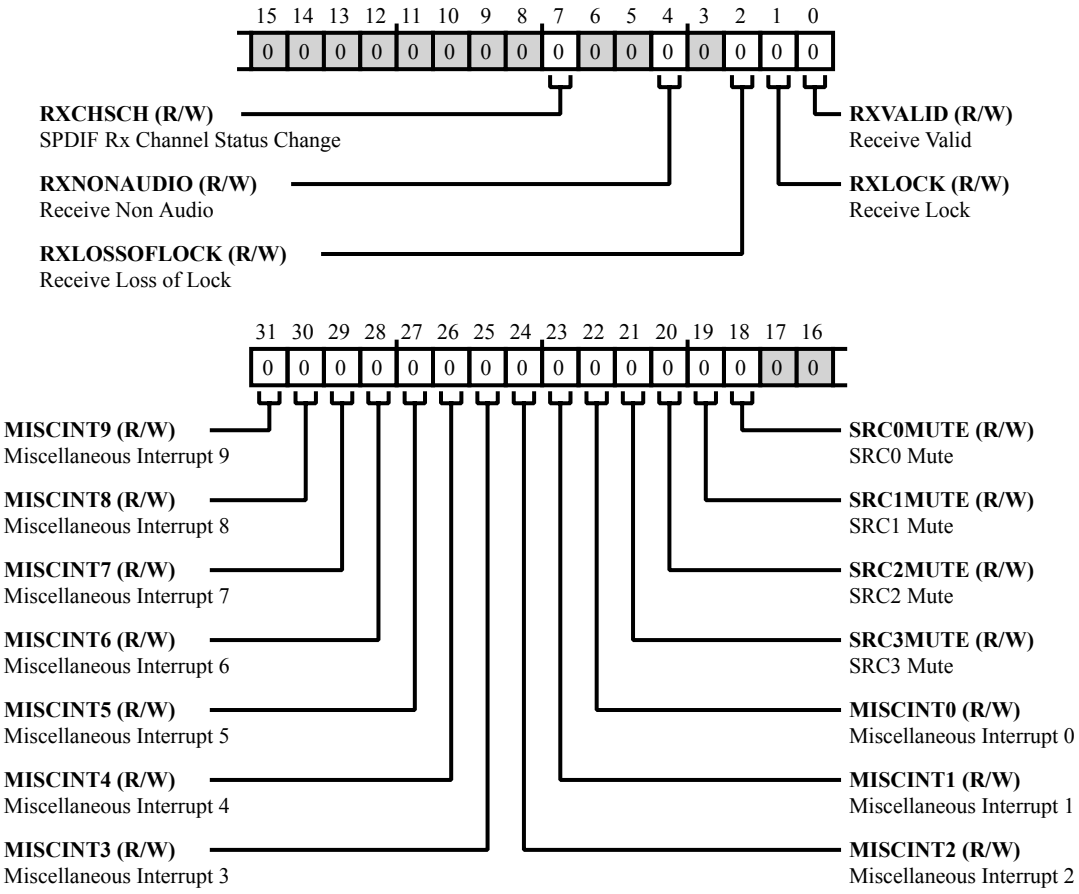

Figure 31-65: DAI_IMSK_RE Register Diagram

Table 31-75: DAI_IMSK_RE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	MISCINT9	Miscellaneous Interrupt 9. Setting the DAI_IMSK_RE.MISCINT9 bit unmasks the interrupt for the rising edge of the routed signal.
30 (R/W)	MISCINT8	Miscellaneous Interrupt 8. Setting the DAI_IMSK_RE.MISCINT8 bit unmasks the interrupt for the rising edge of the routed signal.

Table 31-75: DAI_IMSK_RE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
29 (R/W)	MISCINT7	Miscellaneous Interrupt 7. Setting the DAI_IMSK_RE.MISCINT7 bit unmasks the interrupt for the rising edge of the routed signal.
28 (R/W)	MISCINT6	Miscellaneous Interrupt 6. Setting the DAI_IMSK_RE.MISCINT6 bit unmasks the interrupt for the rising edge of the routed signal.
27 (R/W)	MISCINT5	Miscellaneous Interrupt 5. Setting the DAI_IMSK_RE.MISCINT5 bit unmasks the interrupt for the rising edge of the routed signal.
26 (R/W)	MISCINT4	Miscellaneous Interrupt 4. Setting the DAI_IMSK_RE.MISCINT4 bit unmasks the interrupt for the rising edge of the routed signal.
25 (R/W)	MISCINT3	Miscellaneous Interrupt 3. Setting the DAI_IMSK_RE.MISCINT3 bit unmasks the interrupt for the rising edge of the routed signal.
24 (R/W)	MISCINT2	Miscellaneous Interrupt 2. Setting the DAI_IMSK_RE.MISCINT2 bit unmasks the interrupt for the rising edge of the routed signal.
23 (R/W)	MISCINT1	Miscellaneous Interrupt 1. Setting the DAI_IMSK_RE.MISCINT1 bit unmasks the interrupt for the rising edge of the routed signal.
22 (R/W)	MISCINT0	Miscellaneous Interrupt 0. Setting the DAI_IMSK_RE.MISCINT0 bit unmasks the interrupt for the rising edge of the routed signal.
21 (R/W)	SRC3MUTE	SRC3 Mute. The DAI_IMSK_RE.SRC3MUTE bit masks or unmasks the corresponding SRC mute out interrupt for the rising edge of this interrupt. This interrupt can be generated either entering mute, exiting muting or both.
20 (R/W)	SRC2MUTE	SRC2 Mute. The DAI_IMSK_RE.SRC2MUTE bit masks or unmasks the corresponding SRC mute out interrupt for the rising edge of this interrupt. This interrupt can be generated either entering mute, exiting muting or both.
19 (R/W)	SRC1MUTE	SRC1 Mute. The DAI_IMSK_RE.SRC1MUTE bit masks or unmasks the corresponding SRC mute out interrupt for the rising edge of this interrupt. This interrupt can be generated either entering mute, exiting muting or both.

Table 31-75: DAI_IMSK_RE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
18 (R/W)	SRC0MUTE	SRC0 Mute. The DAI_IMSK_RE.SRC0MUTE bit masks or unmasks the corresponding SRC mute out interrupt for the rising edge of this interrupt. This interrupt can be generated either entering mute, exiting muting or both.
7 (R/W)	RXCHSCH	SPDIF Rx Channel Status Change. The DAI_IMSK_RE.RXCHSCH bit masks or unmasks RXCHSCH (Status Change) interrupt for the rising edge of this interrupt. This interrupt is set if there is a change in the SPDIF Rx channel status bits (SPDIF_RX_STAT0/1_A/B).
4 (R/W)	RXNONAUDIO	Receive Non Audio. The DAI_IMSK_RE.RXNONAUDIO bit masks or unmasks the non audio frame mode interrupt for the rising edge of this interrupt. If the channel status indicates non-PCM audio, the NONAUDIO bit flag is set.
2 (R/W)	RXLOSSOFLOCK	Receive Loss of Lock. The DAI_IMSK_RE.RXLOSSOFLOCK bit masks or unmasks the emphasis loss of lock interrupt for the rising edge of this interrupt. The loss of lock status is set by the S/PDIF receiver if receiver loses the lock of biphase stream.
1 (R/W)	RXLOCK	Receive Lock. The DAI_IMSK_RE.RXLOCK bit masks or unmasks the S/PDIF receiver lock for the rising edge of this interrupt. This interrupt occurs when the S/PDIF receiver locks to the S/PDIF stream.
0 (R/W)	RXVALID	Receive Valid. Setting the DAI_IMSK_RE.RXVALID bit unmasks the interrupt for the rising edge of the routed signal. This interrupt is set based on whether data received by the S/PDIF is linear PCM or non-linear audio data.

High Priority Interrupt Latch Register

The DAI_IRPTL_H register holds the high priority latched interrupt status for interrupt requests that have been unmasked (enabled) by the DAI_IMSK_FE, DAI_IMSK_RE registers and mapped to the INTR_DAI_IRQH signal in the SEC by DAI_IMSK_PRI registers. If a bit in this register is already set and the corresponding interrupt is masked in the DAI_IMSK_FE, DAI_IMSK_RE or DAI_IMSK_PRI registers, the latch holds its old value, leaving the interrupt asserted until its mask registers (DAI_IMSK_FE, DAI_IMSK_RE or DAI_IMSK_PRI) are reset by software with a W1C operation.

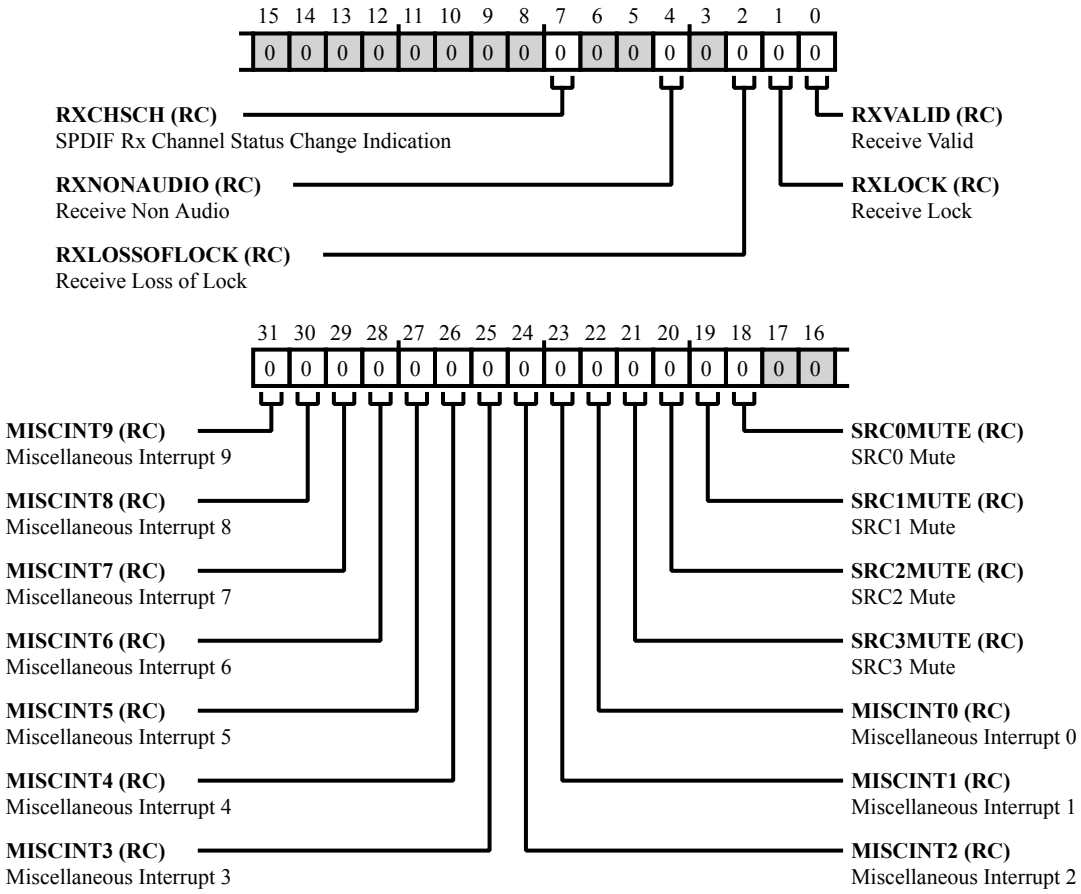

Figure 31-66: DAI_IRPTL_H Register Diagram

Table 31-76: DAI_IRPTL_H Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (RC/NW)	MISCINT9	Miscellaneous Interrupt 9. The DAI_IRPTL_H.MISCINT9 bit is set if the interrupt is mapped to the INTR_DAI_IRQH signal in the SEC using the DAI_IMSK_PRI register.

Table 31-76: DAI_IRPTL_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
30 (RC/NW)	MISCINT8	Miscellaneous Interrupt 8. The DAI_IRPTL_H.MISCINT8 bit is set if the interrupt is mapped to the INTR_DAI_IRQH signal in the SEC using the DAI_IMSK_PRI register.
29 (RC/NW)	MISCINT7	Miscellaneous Interrupt 7. The DAI_IRPTL_H.MISCINT7 bit is set if the interrupt is mapped to the INTR_DAI_IRQH signal in the SEC using the DAI_IMSK_PRI register.
28 (RC/NW)	MISCINT6	Miscellaneous Interrupt 6. The DAI_IRPTL_H.MISCINT6 bit is set if the interrupt is mapped to the INTR_DAI_IRQH signal in the SEC using the DAI_IMSK_PRI register.
27 (RC/NW)	MISCINT5	Miscellaneous Interrupt 5. The DAI_IRPTL_H.MISCINT5 bit is set if the interrupt is mapped to the INTR_DAI_IRQH signal in the SEC using the DAI_IMSK_PRI register.
26 (RC/NW)	MISCINT4	Miscellaneous Interrupt 4. The DAI_IRPTL_H.MISCINT4 bit is set if the interrupt is mapped to the INTR_DAI_IRQH signal in the SEC using the DAI_IMSK_PRI register.
25 (RC/NW)	MISCINT3	Miscellaneous Interrupt 3. The DAI_IRPTL_H.MISCINT3 bit is set if the interrupt is mapped to the INTR_DAI_IRQH signal in the SEC using the DAI_IMSK_PRI register.
24 (RC/NW)	MISCINT2	Miscellaneous Interrupt 2. The DAI_IRPTL_H.MISCINT2 bit is set if the interrupt is mapped to the INTR_DAI_IRQH signal in the SEC using the DAI_IMSK_PRI register.
23 (RC/NW)	MISCINT1	Miscellaneous Interrupt 1. The DAI_IRPTL_H.MISCINT1 bit is set if the interrupt is mapped to the INTR_DAI_IRQH signal in the SEC using the DAI_IMSK_PRI register.
22 (RC/NW)	MISCINT0	Miscellaneous Interrupt 0. The DAI_IRPTL_H.MISCINT0 bit is set if the interrupt is mapped to the INTR_DAI_IRQH signal in the SEC using the DAI_IMSK_PRI register.
21 (RC/NW)	SRC3MUTE	SRC3 Mute. The DAI_IRPTL_H.SRC3MUTE bit is set if the interrupt is mapped to the INTR_DAI_IRQH signal in the SEC using the DAI_IMSK_PRI register.
20 (RC/NW)	SRC2MUTE	SRC2 Mute. The DAI_IRPTL_H.SRC2MUTE bit is set if the interrupt is mapped to the INTR_DAI_IRQH signal in the SEC using the DAI_IMSK_PRI register.

Table 31-76: DAI_IRPTL_H Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
19 (RC/NW)	SRC1MUTE	SRC1 Mute. The DAI_IRPTL_H.SRC1MUTE bit is set if the interrupt is mapped to the INTR_DAI_IRQH signal in the SEC using the DAI_IMSK_PRI register.
18 (RC/NW)	SRC0MUTE	SRC0 Mute. The DAI_IRPTL_H.SRC0MUTE bit is set if the interrupt is mapped to the INTR_DAI_IRQH signal in the SEC using the DAI_IMSK_PRI register.
7 (RC/NW)	RXCHSCH	SPDIF Rx Channel Status Change Indication. The DAI_IRPTL_H.RXCHSCH bit is set if the interrupt is mapped to the INTR_DAI_IRQH signal in the SEC using the DAI_IMSK_PRI register.
4 (RC/NW)	RXNONAUDIO	Receive Non Audio. The DAI_IRPTL_H.RXNONAUDIO bit is set if the interrupt is mapped to the INTR_DAI_IRQH signal in the SEC using the DAI_IMSK_PRI register.
2 (RC/NW)	RXLOSSOFLOCK	Receive Loss of Lock. The DAI_IRPTL_H.RXLOSSOFLOCK bit is set if the interrupt is mapped to the INTR_DAI_IRQH signal in the SEC using the DAI_IMSK_PRI register.
1 (RC/NW)	RXLOCK	Receive Lock. The DAI_IRPTL_H.RXLOCK bit is set if the interrupt is mapped to the INTR_DAI_IRQH signal in the SEC using the DAI_IMSK_PRI register.
0 (RC/NW)	RXVALID	Receive Valid. The DAI_IRPTL_H.RXVALID bit is set if the interrupt is mapped to the INTR_DAI_IRQH signal in the SEC using the DAI_IMSK_PRI register.

Shadow High Priority Interrupt Latch Register

The DAI_IRPTL_HS register is the shadow register of the DAI_IRPTL_H register. Its content is the same as the DAI_IRPTL_H register. Reading the DAI_IRPTL_HS register does not affect its contents while reading the contents of the DAI_IRPTL_H registers clears it.

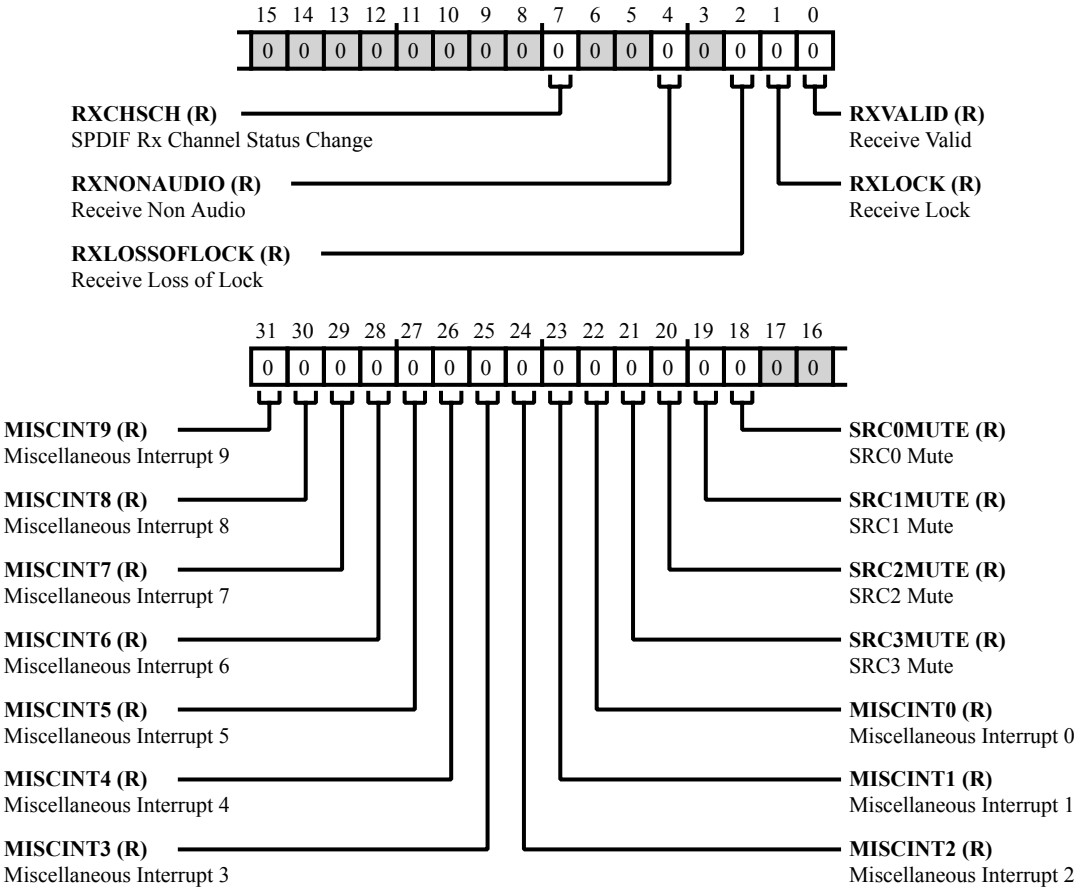

Figure 31-67: DAI_IRPTL_HS Register Diagram

Table 31-77: DAI_IRPTL_HS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/NW)	MISCINT9	Miscellaneous Interrupt 9. The DAI_IRPTL_HS.MISCINT9 bit is the shadow of the DAI_IRPTL_H.MISCINT9 bit and contains the same content. Reading the DAI_IRPTL_HS.MISCINT9 bit does not affect its contents while reading the DAI_IRPTL_H.MISCINT9 bit clears it.

Table 31-77: DAI_IRPTL_HS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
30 (R/NW)	MISCINT8	Miscellaneous Interrupt 8. The DAI_IRPTL_HS.MISCINT8 bit is the shadow of the DAI_IRPTL_H.MISCINT8 bit and contains the same content. Reading the DAI_IRPTL_HS.MISCINT8 bit does not affect its contents while reading the DAI_IRPTL_H.MISCINT8 bit clears it.
29 (R/NW)	MISCINT7	Miscellaneous Interrupt 7. The DAI_IRPTL_HS.MISCINT7 bit is the shadow of the DAI_IRPTL_H.MISCINT7 bit and contains the same content. Reading the DAI_IRPTL_HS.MISCINT7 bit does not affect its contents while reading the DAI_IRPTL_H.MISCINT7 bit clears it.
28 (R/NW)	MISCINT6	Miscellaneous Interrupt 6. The DAI_IRPTL_HS.MISCINT6 bit is the shadow of the DAI_IRPTL_H.MISCINT6 bit and contains the same content. Reading the DAI_IRPTL_HS.MISCINT6 bit does not affect its contents while reading the DAI_IRPTL_H.MISCINT6 bit clears it.
27 (R/NW)	MISCINT5	Miscellaneous Interrupt 5. The DAI_IRPTL_HS.MISCINT5 bit is the shadow of the DAI_IRPTL_H.MISCINT5 bit and contains the same content. Reading the DAI_IRPTL_HS.MISCINT5 bit does not affect its contents while reading the DAI_IRPTL_H.MISCINT5 bit clears it.
26 (R/NW)	MISCINT4	Miscellaneous Interrupt 4. The DAI_IRPTL_HS.MISCINT4 bit is the shadow of the DAI_IRPTL_H.MISCINT4 bit and contains the same content. Reading the DAI_IRPTL_HS.MISCINT4 bit does not affect its contents while reading the DAI_IRPTL_H.MISCINT4 bit clears it.
25 (R/NW)	MISCINT3	Miscellaneous Interrupt 3. The DAI_IRPTL_HS.MISCINT3 bit is the shadow of the DAI_IRPTL_H.MISCINT3 bit and contains the same content. Reading the DAI_IRPTL_HS.MISCINT3 bit does not affect its contents while reading the DAI_IRPTL_H.MISCINT3 bit clears it.
24 (R/NW)	MISCINT2	Miscellaneous Interrupt 2. The DAI_IRPTL_HS.MISCINT2 bit is the shadow of the DAI_IRPTL_H.MISCINT2 bit and contains the same content. Reading the DAI_IRPTL_HS.MISCINT2 bit does not affect its contents while reading the DAI_IRPTL_H.MISCINT2 bit clears it.

Table 31-77: DAI_IRPTL_HS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
23 (R/NW)	MISCINT1	Miscellaneous Interrupt 1. The DAI_IRPTL_HS.MISCINT1 bit is the shadow of the DAI_IRPTL_H.MISCINT1 bit and contains the same content. Reading the DAI_IRPTL_HS.MISCINT1 bit does not affect its contents while reading the DAI_IRPTL_H.MISCINT1 bit clears it.
22 (R/NW)	MISCINT0	Miscellaneous Interrupt 0. The DAI_IRPTL_HS.MISCINT0 bit is the shadow of the DAI_IRPTL_H.MISCINT0 bit and contains the same content. Reading the DAI_IRPTL_HS.MISCINT0 bit does not affect its contents while reading the DAI_IRPTL_H.MISCINT0 bit clears it.
21 (R/NW)	SRC3MUTE	SRC3 Mute. The DAI_IRPTL_HS.SRC3MUTE bit is the shadow of the DAI_IRPTL_H.SRC3MUTE bit and contains the same content. Reading the DAI_IRPTL_HS.SRC3MUTE bit does not affect its contents while reading the DAI_IRPTL_H.SRC3MUTE bit clears it.
20 (R/NW)	SRC2MUTE	SRC2 Mute. The DAI_IRPTL_HS.SRC2MUTE bit is the shadow of the DAI_IRPTL_H.SRC2MUTE bit and contains the same content. Reading the DAI_IRPTL_HS.SRC2MUTE bit does not affect its contents while reading the DAI_IRPTL_H.SRC2MUTE bit clears it.
19 (R/NW)	SRC1MUTE	SRC1 Mute. The DAI_IRPTL_HS.SRC1MUTE bit is the shadow of the DAI_IRPTL_H.SRC1MUTE bit and contains the same content. Reading the DAI_IRPTL_HS.SRC1MUTE bit does not affect its contents while reading the DAI_IRPTL_H.SRC1MUTE bit clears it.
18 (R/NW)	SRC0MUTE	SRC0 Mute. The DAI_IRPTL_HS.SRC0MUTE bit is the shadow of the DAI_IRPTL_H.SRC0MUTE bit and contains the same content. Reading the DAI_IRPTL_HS.SRC0MUTE bit does not affect its contents while reading the DAI_IRPTL_H.SRC0MUTE bit clears it.
7 (R/NW)	RXCHSCH	SPDIF Rx Channel Status Change. The DAI_IRPTL_HS.RXCHSCH bit is the shadow of the DAI_IRPTL_H.RXCHSCH bit and contains the same content. Reading the DAI_IRPTL_HS.RXCHSCH bit does not affect its contents while reading the DAI_IRPTL_H.RXCHSCH bit clears it.

Table 31-77: DAI_IRPTL_HS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
4 (R/NW)	RXNONAUDIO	Receive Non Audio. The `DAI_IRPTL_HS.RXNONAUDIO` bit is the shadow of `DAI_IRPTL_H.RXNONAUDIO` bit and contains the same content. Reading this bit does not affect its content.
2 (R/NW)	RXLOSSOFLOCK	Receive Loss of Lock. The `DAI_IRPTL_HS.RXLOSSOFLOCK` bit is the shadow of `DAI_IRPTL_H.RXLOSSOFLOCK` bit and contains the same content. Reading this bit does not affect its content.
1 (R/NW)	RXLOCK	Receive Lock. The `DAI_IRPTL_HS.RXLOCK` bit is the shadow of `DAI_IRPTL_H.RXLOCK` bit and contains the same content. Reading this bit does not affect its content.
0 (R/NW)	RXVALID	Receive Valid. Setting the `DAI_IRPTL_HS.RXVALID` bit is the shadow of `DAI_IRPTL_H.RXVALID` bit and contains the same content. Reading this bit does not affect its content.

Low Priority Interrupt Latch Register

The DAI_IRPTL_L register holds the low priority latched interrupt status for interrupt requests that have been unmasked (enabled) by the DAI_IMSK_FE, DAI_IMSK_RE or DAI_IMSK_PRI registers. If a bit in DAI_IRPTL_L is already set and the corresponding interrupt is masked in DAI_IMSK_FE, DAI_IMSK_RE or DAI_IMSK_PRI registers, the latch holds its old value, leaving the interrupt asserted until its masked registers (DAI_IMSK_FE, DAI_IMSK_RE or DAI_IMSK_PRI) are reset by software with a W1C operation.

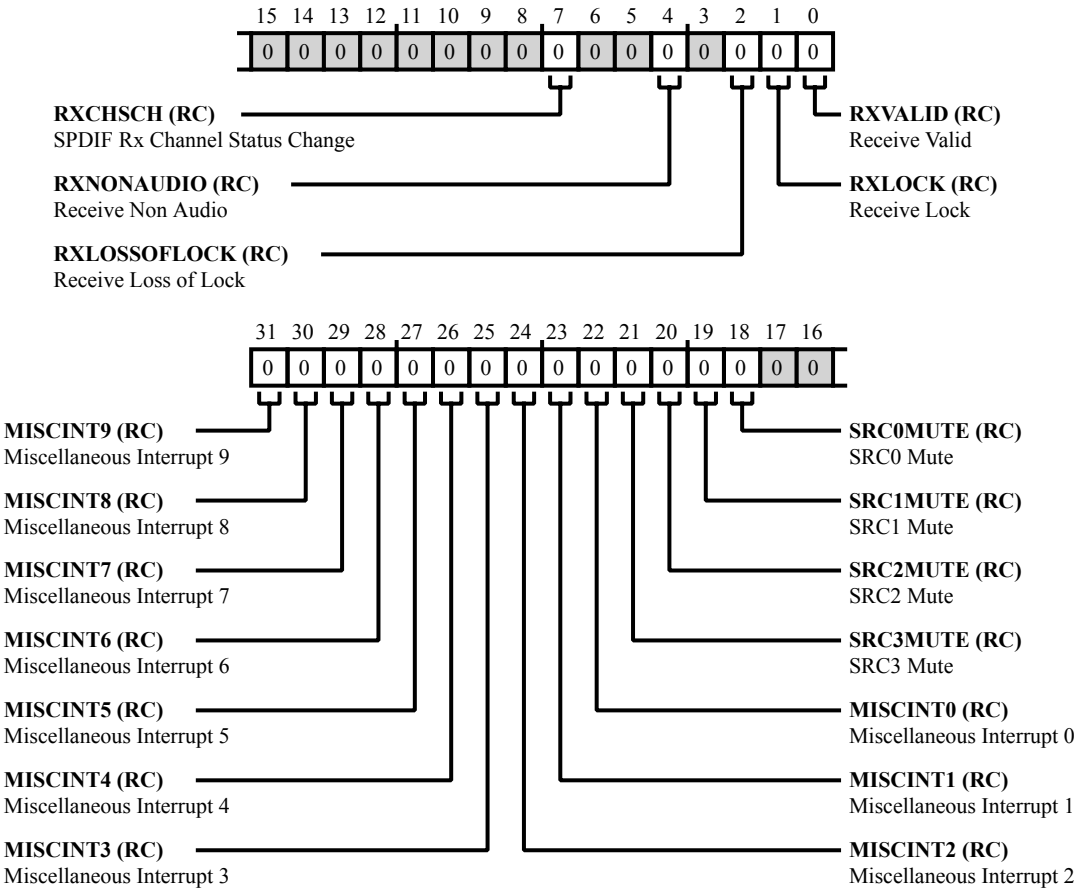

Figure 31-68: DAI_IRPTL_L Register Diagram

Table 31-78: DAI_IRPTL_L Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (RC/NW)	MISCINT9	Miscellaneous Interrupt 9. The DAI_IRPTL_L.MISCINT9 bit is set if the interrupt is mapped to the INTR_DAI_IRQL signal in the SEC using the DAI_IMSK_PRI register.

Table 31-78: DAI_IRPTL_L Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
30 (RC/NW)	MISCINT8	Miscellaneous Interrupt 8. The DAI_IRPTL_L.MISCINT8 bit is set if the interrupt is mapped to the INTR_DAI_IRQL signal in the SEC using the DAI_IMSK_PRI register.
29 (RC/NW)	MISCINT7	Miscellaneous Interrupt 7. The DAI_IRPTL_L.MISCINT7 bit is set if the interrupt is mapped to the INTR_DAI_IRQL signal in the SEC using the DAI_IMSK_PRI register.
28 (RC/NW)	MISCINT6	Miscellaneous Interrupt 6. The DAI_IRPTL_L.MISCINT6 bit is set if the interrupt is mapped to the INTR_DAI_IRQL signal in the SEC using the DAI_IMSK_PRI register.
27 (RC/NW)	MISCINT5	Miscellaneous Interrupt 5. The DAI_IRPTL_L.MISCINT5 bit is set if the interrupt is mapped to the INTR_DAI_IRQL signal in the SEC using the DAI_IMSK_PRI register.
26 (RC/NW)	MISCINT4	Miscellaneous Interrupt 4. The DAI_IRPTL_L.MISCINT4 bit is set if the interrupt is mapped to the INTR_DAI_IRQL signal in the SEC using the DAI_IMSK_PRI register.
25 (RC/NW)	MISCINT3	Miscellaneous Interrupt 3. The DAI_IRPTL_L.MISCINT3 bit is set if the interrupt is mapped to the INTR_DAI_IRQL signal in the SEC using the DAI_IMSK_PRI register.
24 (RC/NW)	MISCINT2	Miscellaneous Interrupt 2. The DAI_IRPTL_L.MISCINT2 bit is set if the interrupt is mapped to the INTR_DAI_IRQL signal in the SEC using the DAI_IMSK_PRI register.
23 (RC/NW)	MISCINT1	Miscellaneous Interrupt 1. The DAI_IRPTL_L.MISCINT1 bit is set if the interrupt is mapped to the INTR_DAI_IRQL signal in the SEC using the DAI_IMSK_PRI register.
22 (RC/NW)	MISCINT0	Miscellaneous Interrupt 0. The DAI_IRPTL_L.MISCINT0 bit is set if the interrupt is mapped to the INTR_DAI_IRQL signal in the SEC using the DAI_IMSK_PRI register.
21 (RC/NW)	SRC3MUTE	SRC3 Mute. The DAI_IRPTL_L.SRC3MUTE bit is set if the interrupt is mapped to the INTR_DAI_IRQL signal in the SEC using the DAI_IMSK_PRI register.
20 (RC/NW)	SRC2MUTE	SRC2 Mute. The DAI_IRPTL_L.SRC2MUTE bit is set if the interrupt is mapped to the INTR_DAI_IRQL signal in the SEC using the DAI_IMSK_PRI register.

Table 31-78: DAI_IRPTL_L Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
19 (RC/NW)	SRC1MUTE	SRC1 Mute. The DAI_IRPTL_L.SRC1MUTE bit is set if the interrupt is mapped to the INTR_DAI_IRQL signal in the SEC using the DAI_IMSK_PRI register.
18 (RC/NW)	SRC0MUTE	SRC0 Mute. The DAI_IRPTL_L.SRC0MUTE bit is set if the interrupt is mapped to the INTR_DAI_IRQL signal in the SEC using the DAI_IMSK_PRI register.
7 (RC/NW)	RXCHSCH	SPDIF Rx Channel Status Change. The DAI_IRPTL_L.RXCHSCH bit is set if the interrupt is mapped to the INTR_DAI_IRQL signal in the SEC using the DAI_IMSK_PRI register.
4 (RC/NW)	RXNONAUDIO	Receive Non Audio. The DAI_IRPTL_L.RXNONAUDIO bit is set if the interrupt is mapped to the INTR_DAI_IRQL signal in the SEC using the DAI_IMSK_PRI register.
2 (RC/NW)	RXLOSSOFLOCK	Receive Loss of Lock. The DAI_IRPTL_L.RXLOSSOFLOCK bit is set if the interrupt is mapped to the INTR_DAI_IRQL signal in the SEC using the DAI_IMSK_PRI register.
1 (RC/NW)	RXLOCK	Receive Lock. The DAI_IRPTL_L.RXLOCK bit is set if the interrupt is mapped to the INTR_DAI_IRQL signal in the SEC using the DAI_IMSK_PRI register.
0 (RC/NW)	RXVALID	Receive Valid. The DAI_IRPTL_L.RXVALID bit is set if the interrupt is mapped to the INTR_DAI_IRQL signal in the SEC using the DAI_IMSK_PRI register.

Shadow Low Priority Interrupt Latch Register

The DAI_IRPTL_LS register is the shadow register of the DAI_IRPTL_L register. Its content is the same as the DAI_IRPTL_L register. Reading the DAI_IRPTL_LS register does not affect its contents while reading the contents of the DAI_IRPTL_L registers clears it.

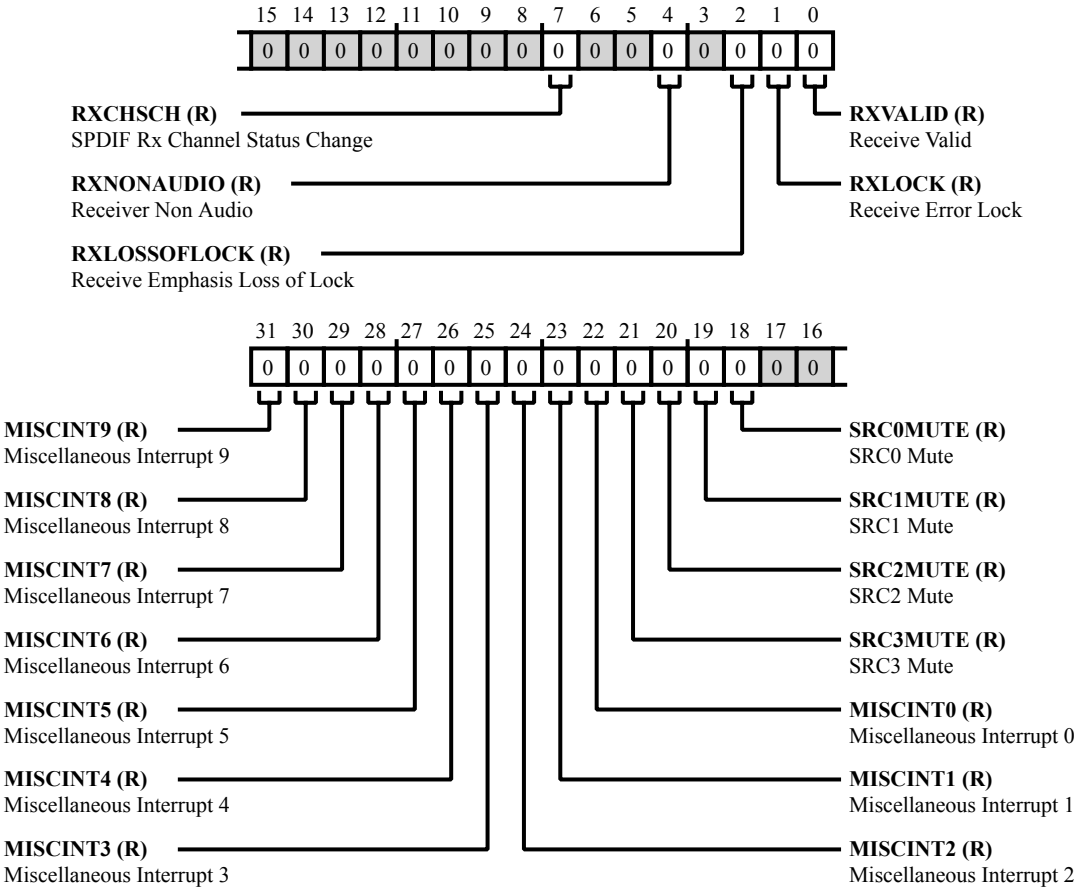

Figure 31-69: DAI_IRPTL_LS Register Diagram

Table 31-79: DAI_IRPTL_LS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/NW)	MISCINT9	Miscellaneous Interrupt 9. The DAI_IRPTL_LS.MISCINT9 bit is the shadow of the DAI_IRPTL_L.MISCINT9 bit and contains the same content. Reading the DAI_IRPTL_LS.MISCINT9 bit does not affect its contents while reading the DAI_IRPTL_L.MISCINT9 bit clears it.

Table 31-79: DAI_IRPTL_LS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
30 (R/NW)	MISCINT8	Miscellaneous Interrupt 8. The DAI_IRPTL_LS.MISCINT8 bit is the shadow of the DAI_IRPTL_L.MISCINT8 bit and contains the same content. Reading the DAI_IRPTL_LS.MISCINT8 bit does not affect its contents while reading the DAI_IRPTL_L.MISCINT8 bit clears it.
29 (R/NW)	MISCINT7	Miscellaneous Interrupt 7. The DAI_IRPTL_LS.MISCINT7 bit is the shadow of the DAI_IRPTL_L.MISCINT7 bit and contains the same content. Reading the DAI_IRPTL_LS.MISCINT7 bit does not affect its contents while reading the DAI_IRPTL_L.MISCINT7 bit clears it.
28 (R/NW)	MISCINT6	Miscellaneous Interrupt 6. The DAI_IRPTL_LS.MISCINT6 bit is the shadow of the DAI_IRPTL_L.MISCINT6 bit and contains the same content. Reading the DAI_IRPTL_LS.MISCINT6 bit does not affect its contents while reading the DAI_IRPTL_L.MISCINT6 bit clears it.
27 (R/NW)	MISCINT5	Miscellaneous Interrupt 5. The DAI_IRPTL_LS.MISCINT5 bit is the shadow of the DAI_IRPTL_L.MISCINT5 bit and contains the same content. Reading the DAI_IRPTL_LS.MISCINT5 bit does not affect its contents while reading the DAI_IRPTL_L.MISCINT5 bit clears it.
26 (R/NW)	MISCINT4	Miscellaneous Interrupt 4. The DAI_IRPTL_LS.MISCINT4 bit is the shadow of the DAI_IRPTL_L.MISCINT4 bit and contains the same content. Reading the DAI_IRPTL_LS.MISCINT4 bit does not affect its contents while reading the DAI_IRPTL_L.MISCINT4 bit clears it.
25 (R/NW)	MISCINT3	Miscellaneous Interrupt 3. The DAI_IRPTL_LS.MISCINT3 bit is the shadow of the DAI_IRPTL_L.MISCINT3 bit and contains the same content. Reading the DAI_IRPTL_LS.MISCINT3 bit does not affect its contents while reading the DAI_IRPTL_L.MISCINT3 bit clears it.
24 (R/NW)	MISCINT2	Miscellaneous Interrupt 2. The DAI_IRPTL_LS.MISCINT2 bit is the shadow of the DAI_IRPTL_L.MISCINT2 bit and contains the same content. Reading the DAI_IRPTL_LS.MISCINT2 bit does not affect its contents while reading the DAI_IRPTL_L.MISCINT2 bit clears it.

Table 31-79: DAI_IRPTL_LS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
23 (R/NW)	MISCINT1	Miscellaneous Interrupt 1. The DAI_IRPTL_LS.MISCINT1 bit is the shadow of the DAI_IRPTL_L.MISCINT1 bit and contains the same content. Reading the DAI_IRPTL_LS.MISCINT1 bit does not affect its contents while reading the DAI_IRPTL_L.MISCINT1 bit clears it.
22 (R/NW)	MISCINT0	Miscellaneous Interrupt 0. The DAI_IRPTL_LS.MISCINT0 bit is the shadow of the DAI_IRPTL_L.MISCINT0 bit and contains the same content. Reading the DAI_IRPTL_LS.MISCINT0 bit does not affect its contents while reading the DAI_IRPTL_L.MISCINT0 bit clears it.
21 (R/NW)	SRC3MUTE	SRC3 Mute. The DAI_IRPTL_LS.SRC3MUTE bit is the shadow of the DAI_IRPTL_L.SRC3MUTE bit and contains the same content. Reading the DAI_IRPTL_LS.SRC3MUTE bit does not affect its contents while reading the DAI_IRPTL_L.SRC3MUTE bit clears it.
20 (R/NW)	SRC2MUTE	SRC2 Mute. The DAI_IRPTL_LS.SRC2MUTE bit is the shadow of the DAI_IRPTL_L.SRC2MUTE bit and contains the same content. Reading the DAI_IRPTL_LS.SRC2MUTE bit does not affect its contents while reading the DAI_IRPTL_L.SRC2MUTE bit clears it.
19 (R/NW)	SRC1MUTE	SRC1 Mute. The DAI_IRPTL_LS.SRC1MUTE bit is the shadow of the DAI_IRPTL_L.SRC1MUTE bit and contains the same content. Reading the DAI_IRPTL_LS.SRC1MUTE bit does not affect its contents while reading the DAI_IRPTL_L.SRC1MUTE bit clears it.
18 (R/NW)	SRC0MUTE	SRC0 Mute. The DAI_IRPTL_LS.SRC0MUTE bit is the shadow of the DAI_IRPTL_L.SRC0MUTE bit and contains the same content. Reading the DAI_IRPTL_LS.SRC0MUTE bit does not affect its contents while reading the DAI_IRPTL_L.SRC0MUTE bit clears it.
7 (R/NW)	RXCHSCH	SPDIF Rx Channel Status Change. The DAI_IRPTL_LS.RXCHSCH bit is the shadow of the DAI_IRPTL_L.RXCHSCH bit and contains the same content. Reading the DAI_IRPTL_LS.RXCHSCH bit does not affect its contents while reading the DAI_IRPTL_L.RXCHSCH bit clears it.

Table 31-79: DAI_IRPTL_LS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
4 (R/NW)	RXNONAUDIO	Receiver Non Audio. The DAI_IRPTL_LS.RXNONAUDIO bit is the shadow of the DAI_IRPTL_L.RXNONAUDIO bit and contains the same content. Reading the DAI_IRPTL_LS.RXNONAUDIO bit does not affect its contents while reading the DAI_IRPTL_L.RXNONAUDIO bit clears it.
2 (R/NW)	RXLOSSOFLOCK	Receive Emphasis Loss of Lock. The DAI_IRPTL_LS.RXLOSSOFLOCK bit is the shadow of DAI_IRPTL_L.RXLOSSOFLOCK bit and contains the same content. Reading this bit does not affect its content. Reading the DAI_IRPTL_L.RXLOSSOFLOCK bit clears it.
1 (R/NW)	RXLOCK	Receive Error Lock. The DAI_IRPTL_LS.RXLOCK bit is the shadow of DAI_IRPTL_L.RXLOCK bit and contains the same content. Reading this bit does not affect its content. Reading the DAI_IRPTL_L.RXLOCK bit clears it.
0 (R/NW)	RXVALID	Receive Valid. The DAI_IRPTL_LS.RXVALID bit is the shadow of DAI_IRPTL_L.RXVALID bit and contains the same content. Reading this bit does not affect its content. Reading the DAI_IRPTL_L.RXVALID bit clears it.

Miscellaneous Control Register 0

The DAI_MISC0 register allows programs to route to the DAI interrupt latch, PBEN input routing, or input signal inversion. This register belongs to group E which routes control signals and provides a means of connecting signals between groups.

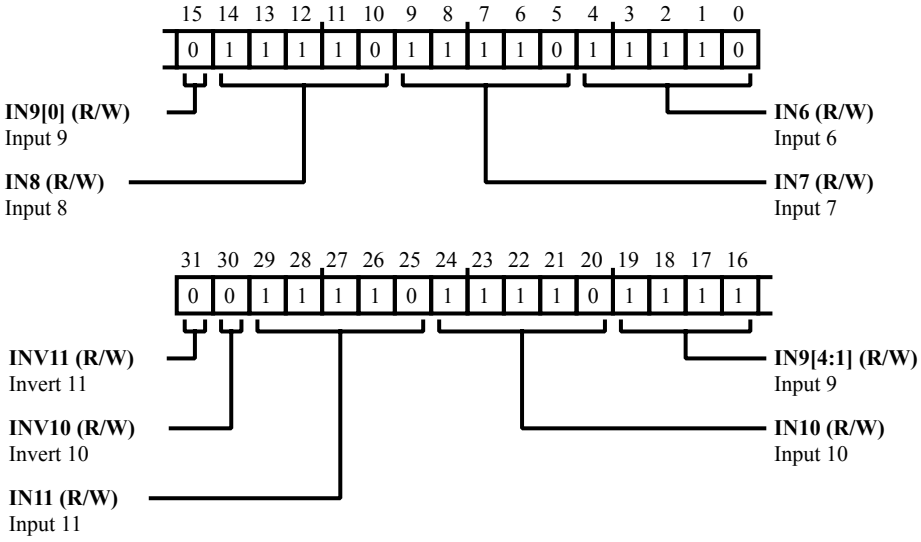

Figure 31-70: DAI_MISC0 Register Diagram

Table 31-80: DAI_MISC0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	INV11	Invert 11. The DAI_MISC0.INV11 bit field inverts miscellaneous A5 input.
30 (R/W)	INV10	Invert 10. The DAI_MISC0.INV10 bit field inverts miscellaneous A4 input.
29:25 (R/W)	IN11	Input 11. The DAI_MISC0.IN11 bit field configures miscellaneous A5 input.
24:20 (R/W)	IN10	Input 10. The DAI_MISC0.IN10 bit field configures miscellaneous A4 input.
19:15 (R/W)	IN9	Input 9. The DAI_MISC0.IN9 bit field configures miscellaneous A3 input/miscellaneous Interrupt 9(DAI interrupt 31).
14:10 (R/W)	IN8	Input 8. The DAI_MISC0.IN8 bit field configures miscellaneous A2 input/miscellaneous Interrupt 8(DAI interrupt 30).

Table 31-80: DAI_MISC0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
9:5 (R/W)	IN7	Input 7. The `DAI_MISC0.IN7` bit field configures miscellaneous A1 input/miscellaneous Interrupt 7(DAI interrupt 29).
4:0 (R/W)	IN6	Input 6. The `DAI_MISC0.IN6` bit field configures miscellaneous A0 input/miscellaneous Interrupt 6(DAI interrupt 28).

Miscellaneous Control Register 1

The DAI_MISC1 register allows programs to route to the DAI interrupt latch, PBEN input routing, or input signal inversion. This register belongs to group E which routes control signals and provides a means of connecting signals between groups.

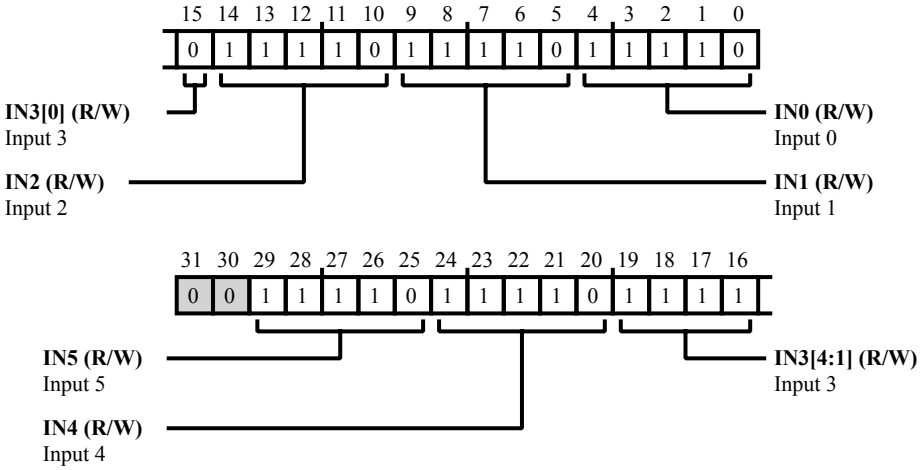

Figure 31-71: DAI_MISC1 Register Diagram

Table 31-81: DAI_MISC1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:25 (R/W)	IN5	Input 5. The DAI_MISC1.IN5 bit field configures miscellaneous Interrupt 5(DAI interrupt 27).
24:20 (R/W)	IN4	Input 4. The DAI_MISC1.IN4 bit field configures miscellaneous Interrupt 4(DAI interrupt 26).
19:15 (R/W)	IN3	Input 3. The DAI_MISC1.IN3 bit field configures miscellaneous Interrupt 3(DAI interrupt 25).
14:10 (R/W)	IN2	Input 2. The DAI_MISC1.IN2 bit field configures miscellaneous Interrupt 2(DAI interrupt 24).
9:5 (R/W)	IN1	Input 1. The DAI_MISC1.IN1 bit field configures miscellaneous Interrupt 1(DAI interrupt 23).

Table 31-81: DAI_MISC1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
4:0 (R/W)	IN0	Input 0. The `DAI_MISC1.IN0` bit field configures miscellaneous Interrupt 0(DAI interrupt 22).

Miscellaneous Control Register 1

The DAI_MISC2 register allows programs to route to the DAI interrupt latch, PBEN input routing, or input signal inversion. This register belongs to group E which routes control signals and provides a means of connecting signals between groups.

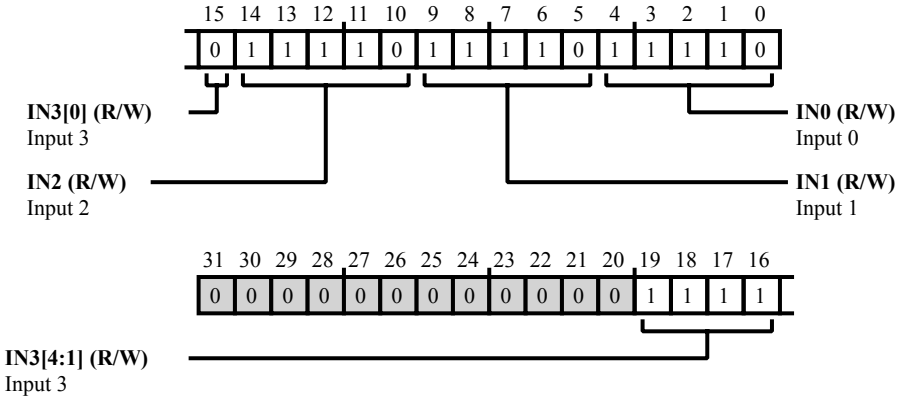

Figure 31-72: DAI_MISC2 Register Diagram

Table 31-82: DAI_MISC2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
19:15 (R/W)	IN3	Input 3. The DAI_MISC2.IN3 bit field configures PCG-F's hardware completer trigger input.
14:10 (R/W)	IN2	Input 2. The DAI_MISC2.IN2 bit field configures PCG-E's hardware completer trigger input.
9:5 (R/W)	IN1	Input 1. The DAI_MISC2.IN1 bit field configures the PCG-B's hardware completer trigger input.
4:0 (R/W)	IN0	Input 0. The DAI_MISC2.IN0 bit field configures the PCG-A's hardware completer trigger input.

Pin Buffer Enable Register 0

The DAI_PBEN0 register routes signals to the pin enables, and the value of these signals determines if a DAI pin is used as an output or an input.

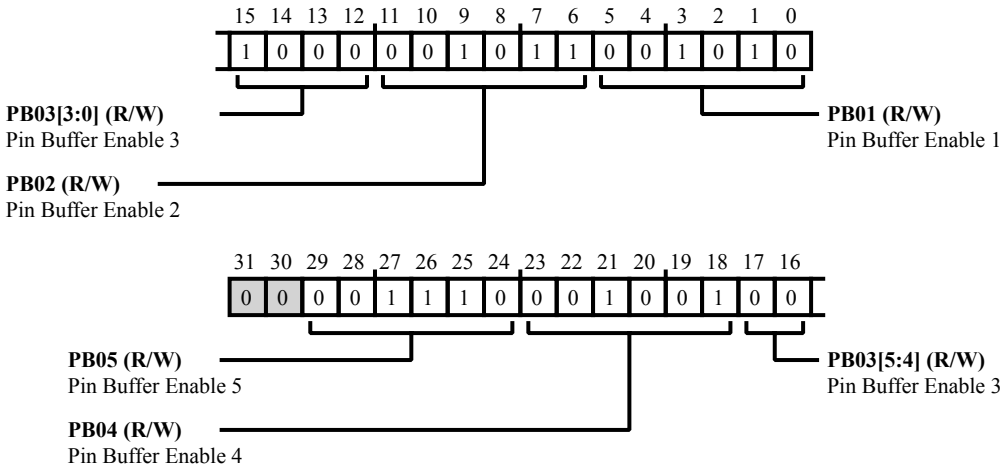

Figure 31-73: DAI_PBEN0 Register Diagram

Table 31-83: DAI_PBEN0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:24 (R/W)	PB05	Pin Buffer Enable 5. The DAI_PBEN0.PB05 bit field is the pin buffer enable for DAI port 5.
23:18 (R/W)	PB04	Pin Buffer Enable 4. The DAI_PBEN0.PB04 bit field is the pin buffer enable for DAI port 4.
17:12 (R/W)	PB03	Pin Buffer Enable 3. The DAI_PBEN0.PB03 bit field is the pin buffer enable for DAI port 3.
11:6 (R/W)	PB02	Pin Buffer Enable 2. The DAI_PBEN0.PB02 bit field is the pin buffer enable for DAI port 2.
5:0 (R/W)	PB01	Pin Buffer Enable 1. The DAI_PBEN0.PB01 bit field is the pin buffer enable for DAI port 1.

Pin Buffer Enable Register 1

The DAI_PBEN1 register routes signals to the pin enables, and the value of these signals determines if a DAI pin is used as an output or an input.

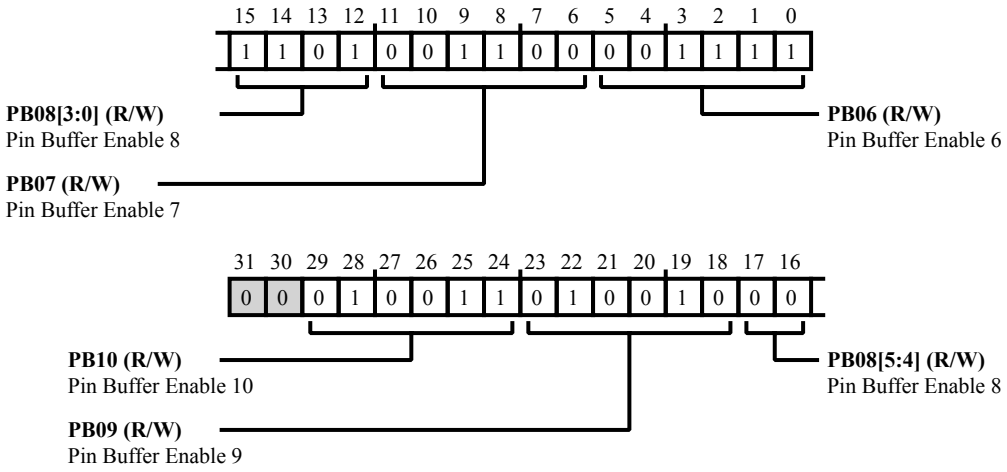

Figure 31-74: DAI_PBEN1 Register Diagram

Table 31-84: DAI_PBEN1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:24 (R/W)	PB10	Pin Buffer Enable 10. The DAI_PBEN1.PB10 bit field is the pin buffer enable for DAI port 10.
23:18 (R/W)	PB09	Pin Buffer Enable 9. The DAI_PBEN1.PB09 bit field is the pin buffer enable for DAI port 9.
17:12 (R/W)	PB08	Pin Buffer Enable 8. The DAI_PBEN1.PB08 bit field is the pin buffer enable for DAI port 8.
11:6 (R/W)	PB07	Pin Buffer Enable 7. The DAI_PBEN1.PB07 bit field is the pin buffer enable for DAI port 7.
5:0 (R/W)	PB06	Pin Buffer Enable 6. The DAI_PBEN1.PB06 bit field is the pin buffer enable for DAI port 6.

Pin Buffer Enable Register 2

The DAI_PBEN2 register routes signals to the pin enables, and the value of these signals determines if a DAI pin is used as an output or an input.

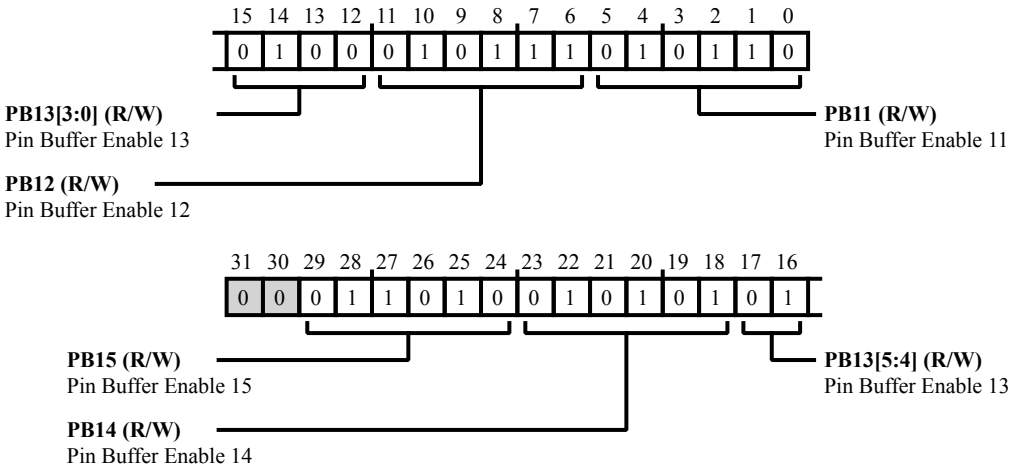

Figure 31-75: DAI_PBEN2 Register Diagram

Table 31-85: DAI_PBEN2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:24 (R/W)	PB15	Pin Buffer Enable 15. The DAI_PBEN2.PB15 bit field is the pin buffer enable for DAI port 15.
23:18 (R/W)	PB14	Pin Buffer Enable 14. The DAI_PBEN2.PB14 bit field is the pin buffer enable for DAI port 14.
17:12 (R/W)	PB13	Pin Buffer Enable 13. The DAI_PBEN2.PB13 bit field is the pin buffer enable for DAI port 13.
11:6 (R/W)	PB12	Pin Buffer Enable 12. The DAI_PBEN2.PB12 bit field is the pin buffer enable for DAI port 12.
5:0 (R/W)	PB11	Pin Buffer Enable 11. The DAI_PBEN2.PB11 bit field is the pin buffer enable for DAI port 11.

Pin Buffer Enable Register 3

The DAI_PBEN3 register routes signals to the pin enables, and the value of these signals determines if a DAI pin is used as an output or an input.

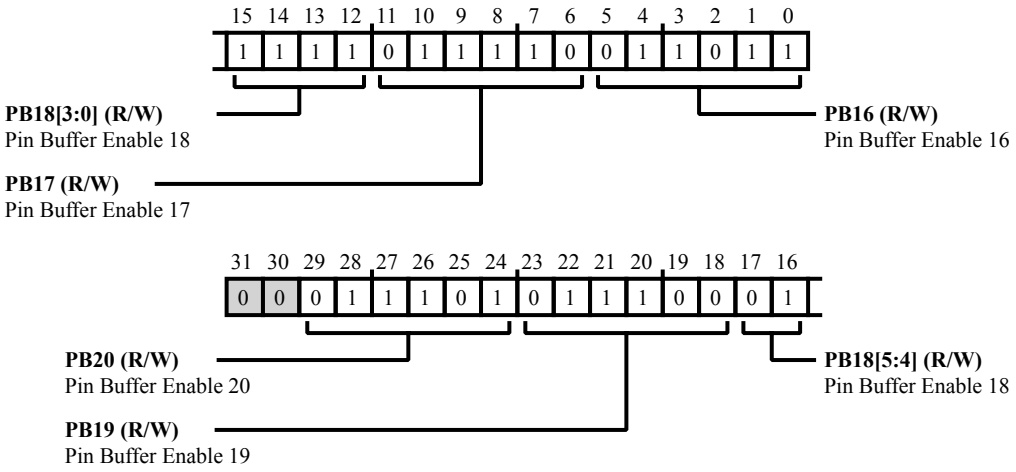

Figure 31-76: DAI_PBEN3 Register Diagram

Table 31-86: DAI_PBEN3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:24 (R/W)	PB20	Pin Buffer Enable 20. The DAI_PBEN3.PB20 bit field is the pin buffer enable for DAI port 20.
23:18 (R/W)	PB19	Pin Buffer Enable 19. The DAI_PBEN3.PB19 bit field is the pin buffer enable for DAI port 19.
17:12 (R/W)	PB18	Pin Buffer Enable 18. The DAI_PBEN3.PB18 bit field is the pin buffer enable for DAI port 18.
11:6 (R/W)	PB17	Pin Buffer Enable 17. The DAI_PBEN3.PB17 bit field is the pin buffer enable for DAI port 17.
5:0 (R/W)	PB16	Pin Buffer Enable 16. The DAI_PBEN3.PB16 bit field is the pin buffer enable for DAI port 16.

Pin Buffer Assignment Register 0

The DAI_PIN0 register routes physical pins that are connected to a bonded pad.

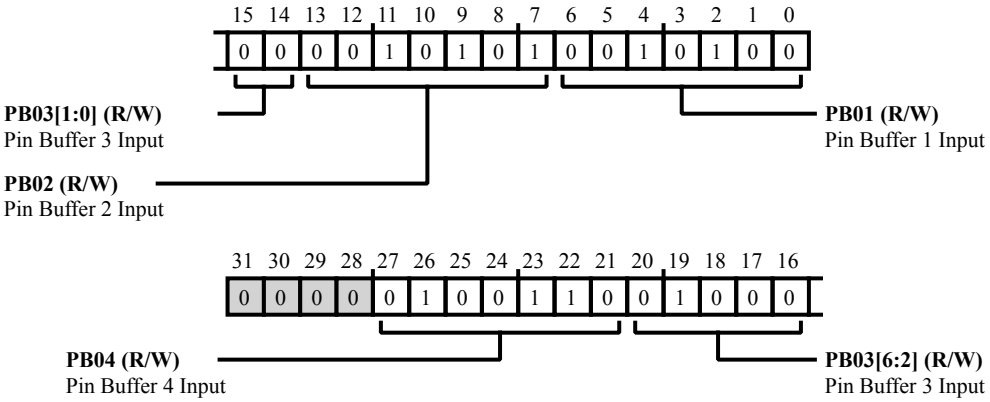

Figure 31-77: DAI_PIN0 Register Diagram

Table 31-87: DAI_PIN0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
27:21 (R/W)	PB04	Pin Buffer 4 Input. DAI_PIN0.PB04 holds the Source signal assignment that will be routed to the DAI_PIN0.PB04 Destination. Refer to the Group D Signals table for Source and Destination mappings.
20:14 (R/W)	PB03	Pin Buffer 3 Input. DAI_PIN0.PB03 holds the Source signal assignment that will be routed to the DAI_PIN0.PB03 Destination. Refer to the Group D Signals table for Source and Destination mappings.
13:7 (R/W)	PB02	Pin Buffer 2 Input. DAI_PIN0.PB02 holds the Source signal assignment that will be routed to the DAI_PIN0.PB02 Destination. Refer to the Group D Signals table for Source and Destination mappings.
6:0 (R/W)	PB01	Pin Buffer 1 Input. DAI_PIN0.PB01 holds the Source signal assignment that will be routed to the DAI_PIN0.PB01 Destination. Refer to the Group D Signals table for Source and Destination mappings.

Pin Buffer Assignment Register 1

The DAI_PIN1 register routes physical pins that are connected to a bonded pad.

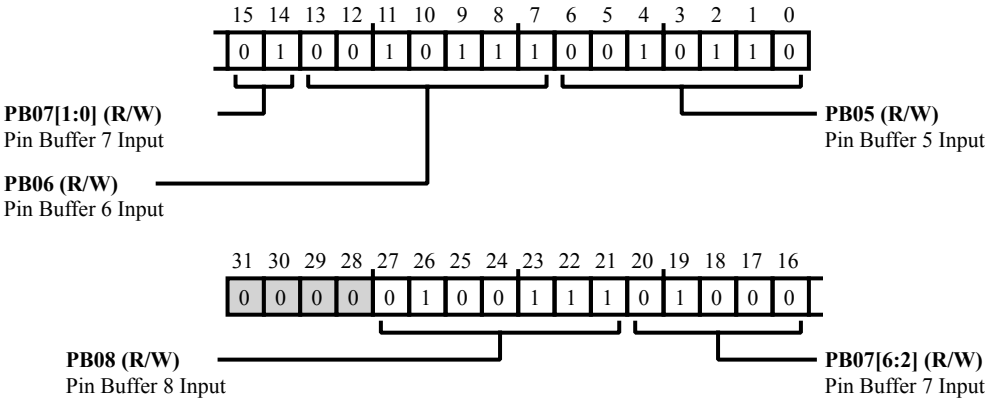

Figure 31-78: DAI_PIN1 Register Diagram

Table 31-88: DAI_PIN1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
27:21 (R/W)	PB08	Pin Buffer 8 Input. DAI_PIN1.PB08 holds the Source signal assignment that will be routed to the DAI_PIN1.PB08 Destination. Refer to the Group D Signals table for Source and Destination mappings.
20:14 (R/W)	PB07	Pin Buffer 7 Input. DAI_PIN1.PB07 holds the Source signal assignment that will be routed to the DAI_PIN1.PB07 Destination. Refer to the Group D Signals table for Source and Destination mappings.
13:7 (R/W)	PB06	Pin Buffer 6 Input. DAI_PIN1.PB06 holds the Source signal assignment that will be routed to the DAI_PIN1.PB06 Destination. Refer to the Group D Signals table for Source and Destination mappings.
6:0 (R/W)	PB05	Pin Buffer 5 Input. DAI_PIN1.PB05 holds the Source signal assignment that will be routed to the DAI_PIN1.PB05 Destination. Refer to the Group D Signals table for Source and Destination mappings.

Pin Buffer Assignment Register 2

The DAI_PIN2 register routes physical pins that are connected to a bonded pad.

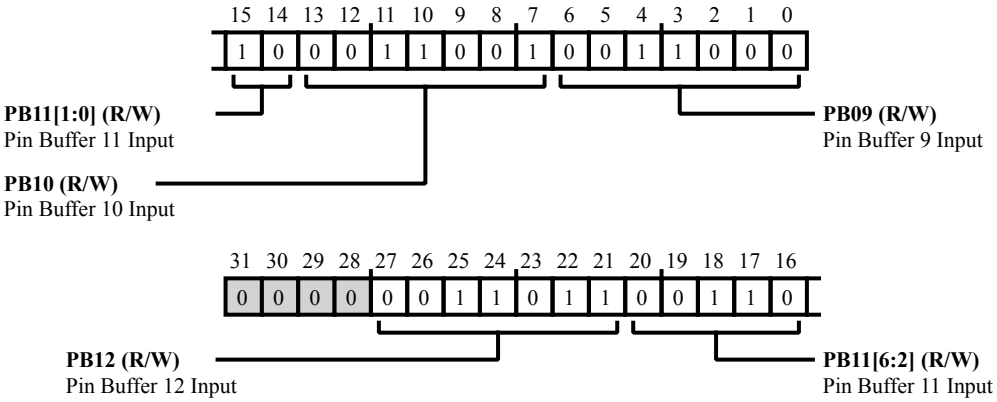

Figure 31-79: DAI_PIN2 Register Diagram

Table 31-89: DAI_PIN2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
27:21 (R/W)	PB12	Pin Buffer 12 Input. DAI_PIN2.PB12 holds the Source signal assignment that will be routed to the DAI_PIN2.PB12 Destination. Refer to the Group D Signals table for Source and Destination mappings.
20:14 (R/W)	PB11	Pin Buffer 11 Input. DAI_PIN2.PB11 holds the Source signal assignment that will be routed to the DAI_PIN2.PB11 Destination. Refer to the Group D Signals table for Source and Destination mappings.
13:7 (R/W)	PB10	Pin Buffer 10 Input. DAI_PIN2.PB10 holds the Source signal assignment that will be routed to the DAI_PIN2.PB10 Destination. Refer to the Group D Signals table for Source and Destination mappings.
6:0 (R/W)	PB09	Pin Buffer 9 Input. DAI_PIN2.PB09 holds the Source signal assignment that will be routed to the DAI_PIN2.PB09 Destination. Refer to the Group D Signals table for Source and Destination mappings.

Pin Buffer Assignment Register 3

The DAI_PIN3 register routes physical pins that are connected to a bonded pad.

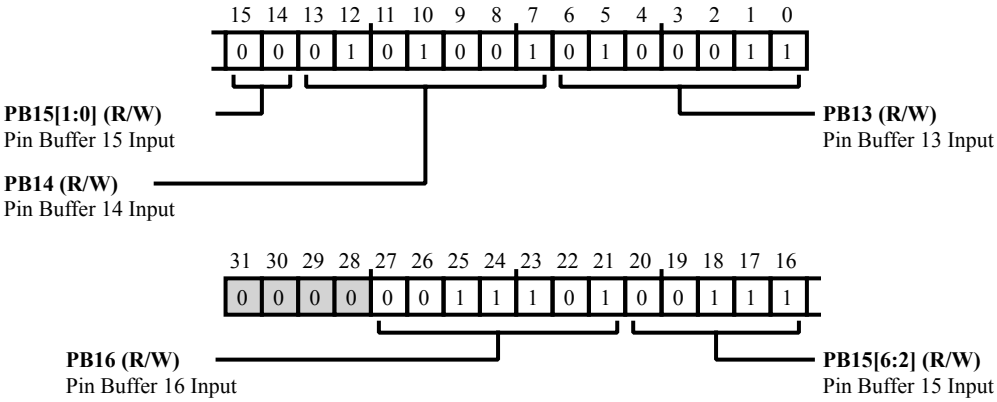

Figure 31-80: DAI_PIN3 Register Diagram

Table 31-90: DAI_PIN3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
27:21 (R/W)	PB16	Pin Buffer 16 Input. The DAI_PIN3.PB16 bit field is the pin buffer 16 input.
20:14 (R/W)	PB15	Pin Buffer 15 Input. DAI_PIN3.PB15 holds the Source signal assignment that will be routed to the DAI_PIN3.PB15 Destination. Refer to the Group D Signals table for Source and Destination mappings.
13:7 (R/W)	PB14	Pin Buffer 14 Input. DAI_PIN3.PB14 holds the Source signal assignment that will be routed to the DAI_PIN3.PB14 Destination. Refer to the Group D Signals table for Source and Destination mappings.
6:0 (R/W)	PB13	Pin Buffer 13 Input. DAI_PIN3.PB13 holds the Source signal assignment that will be routed to the DAI_PIN3.PB13 Destination. Refer to the Group D Signals table for Source and Destination mappings.

Pin Buffer Assignment Register 4

The DAI_PIN4 register routes physical pins that are connected to a bonded pad.

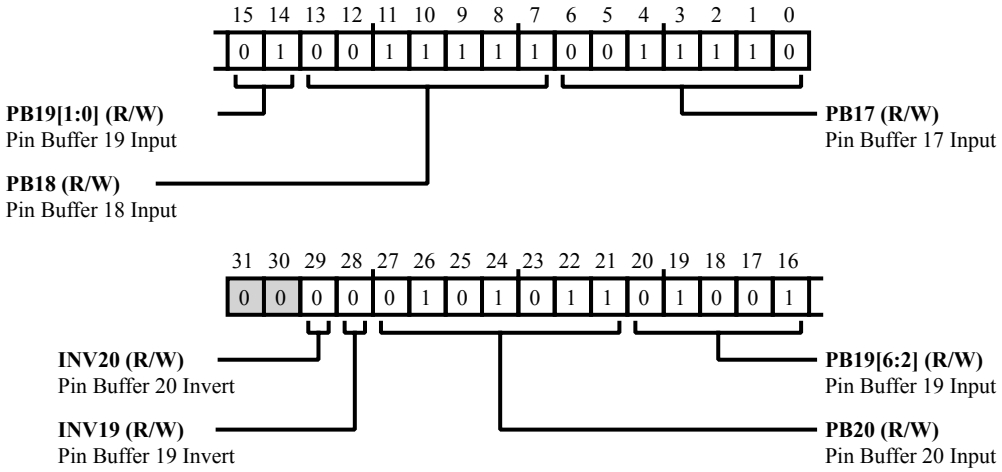

Figure 31-81: DAI_PIN4 Register Diagram

Table 31-91: DAI_PIN4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29 (R/W)	INV20	Pin Buffer 20 Invert. DAI_PIN4.INV20 holds the Source signal assignment that will be routed to the DAI_PIN4.INV20 Destination. Refer to the Group D Signals table for Source and Destination mappings.
28 (R/W)	INV19	Pin Buffer 19 Invert. DAI_PIN4.INV19 holds the Source signal assignment that will be routed to the DAI_PIN4.INV19 Destination. Refer to the Group D Signals table for Source and Destination mappings.
27:21 (R/W)	PB20	Pin Buffer 20 Input. DAI_PIN4.PB20 holds the Source signal assignment that will be routed to the DAI_PIN4.PB20 Destination. Refer to the Group D Signals table for Source and Destination mappings.
20:14 (R/W)	PB19	Pin Buffer 19 Input. DAI_PIN4.PB19 holds the Source signal assignment that will be routed to the DAI_PIN4.PB19 Destination. Refer to the Group D Signals table for Source and Destination mappings.
13:7 (R/W)	PB18	Pin Buffer 18 Input. DAI_PIN4.PB18 holds the Source signal assignment that will be routed to the DAI_PIN4.PB18 Destination. Refer to the Group D Signals table for Source and Destination mappings.

Table 31-91: DAI_PIN4 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
6:0 (R/W)	PB17	Pin Buffer 17 Input. `DAI_PIN4.PB17` holds the Source signal assignment that will be routed to the `DAI_PIN4.PB17` Destination. Refer to the Group D Signals table for Source and Destination mappings.

Pin Status Register

The DAI_PIN_STAT register bits indicate the status (signal high or low) for each pin. The individual bit reads 1 if the signal to this pin is high and reads 0 if signal to this pin is low.

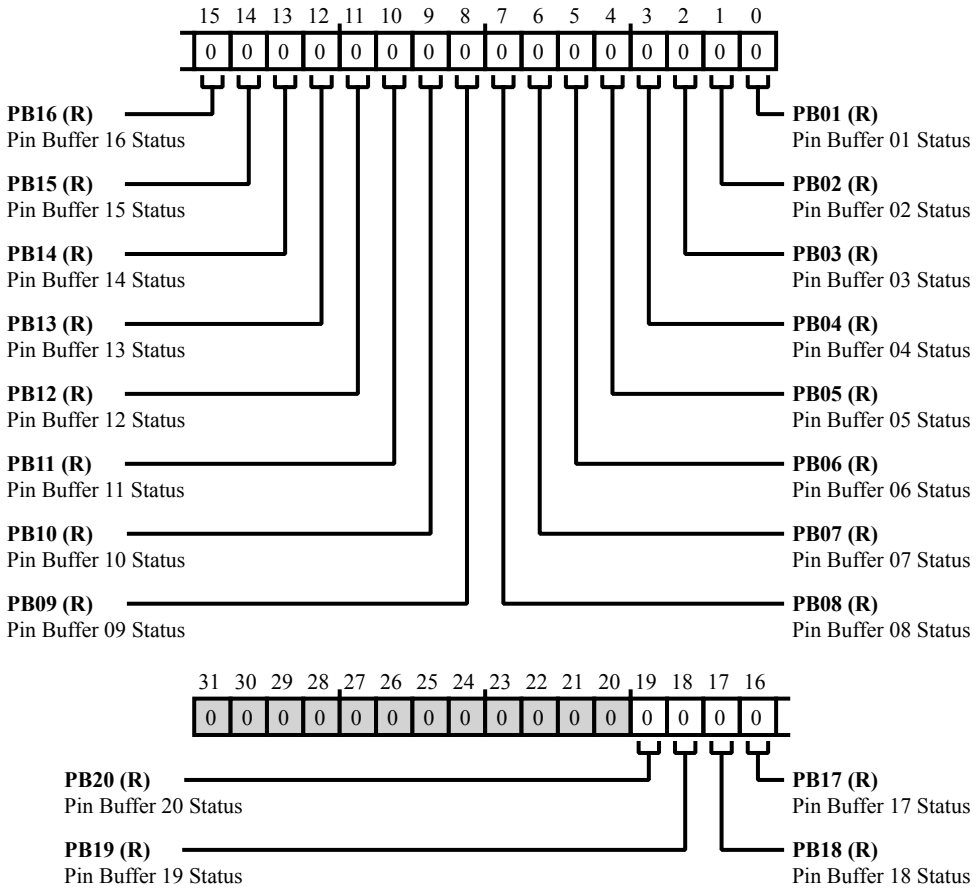

Figure 31-82: DAI_PIN_STAT Register Diagram

Table 31-92: DAI_PIN_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
19 (R/NW)	PB20	Pin Buffer 20 Status. The DAI_PIN_STAT.PB20 bit reads 1 if the signal to this pin is high and reads 0 if signal to this pin is low.
18 (R/NW)	PB19	Pin Buffer 19 Status. The DAI_PIN_STAT.PB19 bit reads 1 if the signal to this pin is high and reads 0 if signal to this pin is low.

Table 31-92: DAI_PIN_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
17 (R/NW)	PB18	Pin Buffer 18 Status. The DAI_PIN_STAT.PB18 bit reads 1 if the signal to this pin is high and reads 0 if signal to this pin is low.
16 (R/NW)	PB17	Pin Buffer 17 Status. The DAI_PIN_STAT.PB17 bit reads 1 if the signal to this pin is high and reads 0 if signal to this pin is low.
15 (R/NW)	PB16	Pin Buffer 16 Status. The DAI_PIN_STAT.PB16 bit reads 1 if the signal to this pin is high and reads 0 if signal to this pin is low.
14 (R/NW)	PB15	Pin Buffer 15 Status. The DAI_PIN_STAT.PB15 bit reads 1 if the signal to this pin is high and reads 0 if signal to this pin is low.
13 (R/NW)	PB14	Pin Buffer 14 Status. The DAI_PIN_STAT.PB14 bit reads 1 if the signal to this pin is high and reads 0 if signal to this pin is low.
12 (R/NW)	PB13	Pin Buffer 13 Status. The DAI_PIN_STAT.PB13 bit reads 1 if the signal to this pin is high and reads 0 if signal to this pin is low.
11 (R/NW)	PB12	Pin Buffer 12 Status. The DAI_PIN_STAT.PB12 bit reads 1 if the signal to this pin is high and reads 0 if signal to this pin is low.
10 (R/NW)	PB11	Pin Buffer 11 Status. The DAI_PIN_STAT.PB11 bit reads 1 if the signal to this pin is high and reads 0 if signal to this pin is low.
9 (R/NW)	PB10	Pin Buffer 10 Status. The DAI_PIN_STAT.PB10 bit reads 1 if the signal to this pin is high and reads 0 if signal to this pin is low.
8 (R/NW)	PB09	Pin Buffer 09 Status. The DAI_PIN_STAT.PB09 bit reads 1 if the signal to this pin is high and reads 0 if signal to this pin is low.
7 (R/NW)	PB08	Pin Buffer 08 Status. The DAI_PIN_STAT.PB08 bit reads 1 if the signal to this pin is high and reads 0 if signal to this pin is low.

Table 31-92: DAI_PIN_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
6 (R/NW)	PB07	Pin Buffer 07 Status. The DAI_PIN_STAT.PB07 bit reads 1 if the signal to this pin is high and reads 0 if signal to this pin is low.
5 (R/NW)	PB06	Pin Buffer 06 Status. The DAI_PIN_STAT.PB06 bit reads 1 if the signal to this pin is high and reads 0 if signal to this pin is low.
4 (R/NW)	PB05	Pin Buffer 05 Status. The DAI_PIN_STAT.PB05 bit reads 1 if the signal to this pin is high and reads 0 if signal to this pin is low.
3 (R/NW)	PB04	Pin Buffer 04 Status. The DAI_PIN_STAT.PB04 bit reads 1 if the signal to this pin is high and reads 0 if signal to this pin is low.
2 (R/NW)	PB03	Pin Buffer 03 Status. The DAI_PIN_STAT.PB03 bit reads 1 if the signal to this pin is high and reads 0 if signal to this pin is low.
1 (R/NW)	PB02	Pin Buffer 02 Status. The DAI_PIN_STAT.PB02 bit reads 1 if the signal to this pin is high and reads 0 if signal to this pin is low.
0 (R/NW)	PB01	Pin Buffer 01 Status. The DAI_PIN_STAT.PB01 bit reads 1 if the signal to this pin is high and reads 0 if signal to this pin is low.

32 Serial Port (SPORT)

The programmable serial ports (SPORTs) support various protocols for serial data communication and provide a glueless hardware interface to many industry-standard data converters and codecs. They have high data rates and dual half-duplex datapaths and are ideal for establishing a direct serial connection among two or more processors in a multiprocessor system, as many processors provide compatible serial interfaces.

The SPORT top module consists of two half SPORTs with identical functionality and programming requirements. Each half SPORT can be independently configured as either a transmitter or receiver and can be coupled with the other half SPORT within the same SPORT top module. Further, each half SPORT provides two synchronous half-duplex data lines to double the total supported throughput. As such, a single SPORT top module can be used to provide up to four unidirctional or up to two full-duplex data streams. Further channels are possible as well, but utilization of multiple SPORT top modules is required, thus requiring external connections to provide a common time base.

Features

An individual SPORT top module consists of two independently configurable SPORT halves with identical functionality. These SPORT halves offer the following features:

- Up to two bidirectional data lines - each half SPORT supports up to two transmit or receive channels, thus allowing two unidirectional streams into or out of each half SPORT and providing greater flexibility for serial communications. If full-duplex functionality is desired, two SPORT halves can be combined to enable dual-stream bidirectional communication.
- Six operating modes:
    1. Standard DSP serial mode
    2. I^2S mode
    3. Left-Justified mode
    4. Right-Justified mode
    5. Multichannel (TDM) mode
    6. Packed mode

- Supports internally or externally generated clock.
- Support for both even and odd SCLK0 to SPORT clock (SPORT_CLK) ratios. If both data lines of a half SPORT are active, the maximum throughput is 2 x SPORT_CLK bps.
- Configurable rising or falling edge of the SPORT_CLK for driving and sampling data and frame syncs.
- Gated clock mode support for internally or externally generated clocks in DSP serial mode and stereo modes (left-justified and I^2S mode).
- Supports frameless operation.
- Supports internally or externally generated frame sync signals.
- Programmable frame sync polarity.
- Programmable frame sync timing (synchronous to data or 1 SPORT clock in advance of it).
- Detection of prematurely received external frame syncs (with optional interrupt request generation).
- Programmable level-/edge-sensitivity for external frame syncs.
- Programmable (4–32-bit) data length, either in most significant bit (MSB) first or in least significant bit (LSB) first format, with optional sign-extension on received data.
- Optional 16-bit to 32-bit word packing (as receiver) and 32-bit to 16-bit word unpacking (as transmitter).
- Support for A-law and μ-law compression/decompression hardware companding, according to the G.711 specification, on transmitted/received words in all operating modes.
- Transmit underrun and receive overflow detection (with optional interrupt request generation).
- TDM mode transfers data on 128 contiguous channels from a stream of up to 1024 total channels (useful for H.100/H.110 and other telephony interfaces as a network communication scheme for multiple processors).
- Performs interrupt-driven, single word core transfers to and from on-chip or off-chip memory.
- Dedicated DMA channel for each SPORT half supporting autobuffer (for a repeated, identical range of transfers) and numerous descriptor-based (individual or repeated ranges of transfers with differing DMA parameters) modes.
- Generator and receiver trigger functionality.
- Unique transfer finish interrupt (TFI) signaling when the last transmit word is fully out of the transmit shift register.
- Multiplexer to internally connect critical timing signals between SPORT halves.
- Support for Global Sport Enable functionality, where enabling multiple SPORTs need to be synchronized so that all of them start and/or end at the same time.
- Support for late reception of SPORT data and frame sync.

Signal Descriptions

Each half SPORT module has five dedicated signals, as described in the ***SPORT Signal Descriptions*** table. The actual pin name varies with different SPORT halves. Individual SPORT halves do not share any of its signals across the pair that comprises the SPORT top module; however, it is possible to connect the clock and frame sync signals between the SPORT half pair, as explained in the Multiplexer Logic section.

All of the SPORT signals are multiplexed on the PORT pins, possibly sharing functionality with other peripherals on the device. By default, the PORT pins are in GPIO mode and must be reconfigured for SPORT functionality by setting the appropriate bits in the PORT_FER and PORT_MUX registers. Consult the processor data sheet for details regarding which ports the SPORT signals are available and to ensure to configure the PORT_MUX register before the PORT_FER register.

Table 32-1: SPORT Signal Descriptions

Internal Node	Direction	Description
SPORTx_CLK	I/O	Transmit or receive serial clock. Data and frame syncs are driven or sampled on this clock's edges. This signal can be either internally or externally generated.
SPORTx_FS	I/O	Transmit or receive frame sync. The frame sync pulse initiates shifting of serial data. This signal is either internally or externally generated.
SPORTx_D0	I/O	Primary transmit or receive data channel. This signal can be configured as an output to transmit serial data or as an input to receive serial data.
SPORTx_D1	I/O	Secondary transmit or receive data channel. This signal can be configured as an output to transmit serial data or as an input to receive serial data.
SPORTx_TDV	O	Multichannel transmit data valid. This signal is only active in multichannel transmit mode and is asserted during enabled slots, as defined by the channel selection registers (SPORT_CS0_A through SPORT_CS3_B).

The data channel signals are transmit signals when the serial port is configured in transmit mode (SPORT_CTL_A.SPTRAN = 1). They are receive signals when the serial port is configured in receive mode (SPORT_CTL_A.SPTRAN = 0). The following sections further describe the SPORT signals.

NOTE: These sections explicitly refer to the registers associated with half SPORT A, but the same concepts also apply to half SPORT B.

Serial Clock

The serial port clock (SPORT_ACLK) is either a receive serial clock or a transmit serial clock, depending on the transfer direction (SPORT_CTL_A.SPTRAN), governing when the data bits are serially shifted into or out of the SPORT and when the frame sync signal is driven (in internal frame sync mode) or sampled (in external frame sync mode). It can be internally generated from the processor's system clock (SCLK) or externally provided. If the half SPORT is configured in internal clock mode (SPORT_CTL_A.ICLK= 1), then the SPORT_DIV_A.CLKDIV field specifies the divisor applied to SCLK to generate the SPORT clock. As it is a 16-bit divisor, a wide range of serial clock rates is possible. Use the following equation to calculate the serial clock frequency:

SPORT_ACLK = [SCLK ÷ (SPORT_DIV_A.CLKDIV + 1)]

From this, the following equation can be used to determine the value of SPORT_DIV_A.CLKDIV, given the SCLK frequency and the desired frequency of the SPORT clock:

SPORT_DIV_A.CLKDIV= [(SCLK ÷ SPORT_ACLK) - 1]

The half SPORT also supports a 1:1 SPORT_ACLK to ratio (per the equations above, program the clock divisor field to zero). In this case, the resulting SPORT clock frequency is equal to SCLK.

NOTE: Be careful not to exceed the maximum SPORT_ACLK frequency specified in the processor data sheet.

In certain operating modes, the SPORT can be configured to generate a gated clock, which is active only during valid data. In some applications, a SPORT uses it to generate a general-purpose clock in the system. In this case, enable the SPORT with the appropriate SPORT_DIV_A.CLKDIV divisor field in internal clock mode.

If a SPORT is configured in external clock mode (SPORT_CTL_A.ICLK= 0), the serial clock is an input signal, thus making the SPORT operate in target mode. In this mode, the SPORT_DIV_A.CLKDIV is irrelevant and is ignored. The optional loopback capability provided by the internal SPORT multiplexer (SPMUX) block allows the target SPORT to use the serial clock from the neighboring SPORT half in the same SPORT top module.

An externally-supplied serial clock does not need to be synchronous with the processor clocks. Further, the external clock can be a gated clock, but it must comply with the requirements described in the Gated Clock Mode section.

Refer to the product data sheet for exact AC timing specifications.

Frame Sync

The SPORT frame sync (SPORT_AFS) signal is either a receive frame sync or a transmit frame sync, depending on the transfer direction (SPORT_CTL_A.SPTRAN), which is used to determine the start of a new word or frame. When this signal goes active, the serial port starts serially shifting data into or out of the SPORT. The frame sync signal can be internally generated based on its serial clock (SPORT_ACLK) or externally provided, as configured by the SPORT_CTL_A.IFS bit.

If the half SPORT is configured to generate frame syncs (SPORT_CTL_A.IFS= 1), then the SPORT_DIV_A.FSDIV field specifies the divisor used to generate the periodic SPORT_AFS signal from the SPORT clock. As this is a 16-bit divisor, a wide range of frame sync rates to initiate periodic transfers is possible. Whether the serial clock is internally or externally generated, this divisor is a count of SPORT clock cycles between frame sync pulses, the formula for which is:

Number of serial clocks between frame syncs = (SPORT_DIV_A.FSDIV + 1)

From this, the following equation can be used to determine the value of SPORT_DIV_A.FSDIV, given the serial clock frequency and the desired frame sync frequency:

SPORT_DIV_A.FSDIV = [(SPORT_ACLK ÷ SPORT_AFS) – 1]

The frame sync is continuously active when SPORT_DIV_A.FSDIV= 0. The value of SPORT_DIV_A.FSDIV cannot be less than the serial word length minus one (the value of the SPORT_CTL_A.SLEN bit field). Failure to

adhere to this guideline can cause an external device to abort the current operation or cause other unpredictable results.

NOTE: After enabling the SPORT, the first internal frame sync appears after a delay of SPORT_DIV_A.FSDIV + 3 SPORT clock cycles.

If a SPORT is configured for external frame syncs (SPORT_CTL_A.IFS = 0), then SPORT_AFS is an input signal and the SPORT_DIV_A.FSDIV field of the SPORT_DIV_A register is irrelevant and ignored. By default, this external signal is level-sensitive, but it can be configured as an edge-sensitive signal by setting the SPORT_CTL_A.FSED bit. The frame sync is expected to be synchronous with the serial clock. If not, it must meet the timing requirements that appear in the data sheet.
